

# Life Science Health System

prepared by T.C. Fry

hosted at [Rawfoodexplained.com](http://Rawfoodexplained.com)

- [Inspiring Quotes](#)
- [About Rawfoodexplained.com](#)
- [Author Credits](#)
- [Links](#)
- [Disclaimer](#)
  
- [Lesson 1 - Introduction To Life Science As A Way Of Life](#)
  - [1. What Is Life Science?](#)
  - [2. An Introduction To Life Science](#)
  - [3. An Inquiry Into The Philosophy, Principles, And Practices Of Life Science](#)
  - [4. Discussion Of The Medical Approach To Health And Disease](#)
  - [5. What Health Really Is](#)
  - [Article #1: The Return To Perfection By Dr. Herbert M. Shelton](#)
  - [Article #2: What is health?](#)
- [Lesson 2 - The Nature And Purpose Of Disease](#)
  - [1. What Is Disease?](#)
  - [2. Purposes Of Disease](#)
  - [3. Toxemia Is The Universal Cause Of Disease](#)
  - [4. Natural Hygiene Or Life Science Care Of The Ailing](#)
  - [5. The Character Of Disease](#)
  - [6. Questions & Answers](#)
  - [Article #1: A True Perspective Of Health And Disease by Dr. Herbert M. Shelton](#)
  - [Article #2: The Nature Of Disease: Its Cause And Purpose by Dr. Hereward Carrington](#)
- [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#)
  - [1. The Essentials Of Life Listed](#)
  - [2. Pure Air](#)
  - [3. Pure Water](#)
  - [4. Questions & Answers](#)
  - [Article #1: The Importance Of Pure Water by John H. Tilden, M.D.](#)
  - [Article #2: Are Humans Drinking Creatures? by Dr. Herbert M. Shelton](#)
  - [Article #3: Ama Says Fresh Air Bad For You by Frances Adelhardt](#)
  - [Article #4: The Breath Of Death by Prof. Hilton Hotema](#)
- [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#)
  - [1. A Survey Of The Lesson](#)
  - [2. Cleanliness Is An Essential Of Life](#)
  - [3. Temperature Maintenance](#)

- [4. Sleep Is An Essential Of Life-The Role Of Sleep In Life](#)
- [5. Food Is An Essential Of Life-The Role Of Food In Health](#)
- [6. Exercise And Activity Are Essential To Well-Being](#)
- [7. Rest And Relaxation Are Essential To Health](#)
- [8. Sunshine Is An Essential To Health](#)
- [9. Recreation And Play Are Health Essentials](#)
- [10. Emotional And Mental Well-Being Are Necessary To Health](#)
- [11. Assurance Of Life And Its Means Is Necessary To Health](#)
- [12. Pleasant Environment Is Necessary To Well-Being](#)
- [13. Creative Useful Work And Its Role In Life](#)
- [14. Self-Mastery Is Necessary To Best Well-Being](#)
- [15. Gregariousness Is An Element Of Health](#)
- [16. Motivation: Having Purposes Or Causes To Serve](#)
- [17. Expression Of Natural Instincts Relative To Health](#)
- [18. Aesthetic Well-Being](#)
- [19. About This Survey Of Life's Essentials](#)
- [20. Questions & Answers](#)
- [Article #1: The Importance Of Body Temperature by Dr. Herbert M. Shelton](#)
- [Article #2: Are You Suited For Health? by Mike Benton](#)
- [Article #3: Mental And Emotional Poise by Lee Bauer](#)
- [Lesson 5 - Introduction To Nutritional Science](#)
  - [1. What Constitutes Nutrition? \(Definitions And Concepts\)](#)
  - [2. Food Is An Element Of Nutrition](#)
  - [3. Physiological Criteria Foods Must Meet](#)
  - [4. Nonfood Nutritional Factors](#)
  - [5. Discussion Of Conventional Nutritional Teachings](#)
  - [6. Discussion Of Human Eating Habits The World Over](#)
  - [7. Negative Nutrition: Harmful Foods And Practices](#)
  - [8. A Survey Of Unconventional Dietetic Schools And Their Fallacies](#)
  - [9. The Physiological Necessity Of Proper Food Combining](#)
  - [10. Nutritional Miscellany](#)
  - [11. Questions & Answers](#)
  - [Article #1: The Paradise Diet by Dr. Herbert M. Shelton](#)
  - [Article #2: The Elements Of Nutrition by Dr. Herbert M. Shelton](#)
  - [Article #3: Nutrition, A Hygienic Perspective by Ralph C. Cinque, D.C.](#)
- [Lesson 6 - The Immense Wisdom And Providence Of The Body](#)
  - [1. What Constitutes Body Wisdom And Providence?](#)
  - [2. Cell And Brain Programming](#)
  - [3. Knowledge, Expertise And Resources For Healing Processes](#)
  - [4. Programming The Intellect For Exuberant Well-Being](#)
  - [5. Questions & Answers](#)
  - [Article #1: The Great Power Within You by T. C. Fry](#)
  - [Article #2: Life's Engineering by Dr. Herbert M. Shelton](#)
- [Lesson 7 - Carbohydrates - Fuel For The Human Body](#)
  - [1. Introduction](#)
  - [2. Classifications Of Carbohydrates](#)
  - [3. The Role Of Carbohydrates In The Body](#)
  - [4. How Carbohydrates Are Digested And Used By The Body](#)

- [5. Sources Of Carbohydrates](#)
- [6. Why Starches Are Less Than Ideal Sources Of Carbohydrates](#)
- [7. Why Fruits Are The Ideal Source Of Carbohydrates](#)
- [8. Amounts And Variety Of Carbohydrates Needed By Humans](#)
- [9. Disease Conditions Related To Carbohydrate Consumption](#)
- [10. Questions & Answers](#)
- [Article #1: Carbohydrates By Dr. Herbert M. Shelton](#)
- [Article #2: Digestion Of Foods By Dr. Herbert M. Shelton](#)
- [Article #3: Starches Are Second-Rate Foods By Marti Fry](#)
- [Article #4: The "Staff Of Life" By Marti Fry](#)
- [Article #5: What's Wrong With Wheat By Marti Fry](#)
- [Article #6: Fruit - The Ideal Food By Dr. Herbert M. Shelton](#)
- [Article #7: Are Humans Starch Eaters? By Dr. Herbert M. Shelton](#)
- [Lesson 8 - Proteins In The Diet](#)
  - [1. Introduction](#)
  - [2. Why We Need Protein](#)
  - [3. How Much Protein Do We Need?](#)
  - [4. What Are Proteins?](#)
  - [5. The Importance Of Amino Acids](#)
  - [6. "Complete Proteins"](#)
  - [7. Protein And The Optimum \(Life Science\) Diet](#)
  - [8. Questions & Answers](#)
  - [Article #1: The Question Of Proteins By Arnold DeVries](#)
  - [Article #2: Protein By Ralph Cinque, D.C.](#)
  - [Article #3: The Superiority Of Plant Foods By Ralph Cinque, D.C.](#)
  - [Article #4: The Question Of Protein By Dr. Ralph Bircher Benner](#)
- [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#)
  - [1. Prologue](#)
  - [2. Introduction](#)
  - [3. A Study Of Each Individual Vitamin](#)
  - [4. Questions & Answers](#)
  - [Article #1: Caution: Megavitamins May Be Dangerous To Your Health By Dr. Alan Immerman, D.C.](#)
  - [Article #2: Vitamins And Disease Causation By Marti Fry](#)
  - [Article #3: Why RDAs Are Too High By T. C. Fry](#)
  - [Article #4: Vitamin B-12 And Your Diet By Dr. Alan Immerman](#)
  - [Article #5: Do We Need To Take Vitamins? By Alan M. Immerman, D.C.](#)
  - [Article #6: Antivitamins And Vitamin Antagonists By Marti Fry](#)
  - [Article #7: What To Do About Vitamin Antagonists By Marti Fry](#)
  - [Article #8: Factors That Lower Vitamin Needs By T. C. Fry](#)
  - [Article #9: Factors That Interfere With Vitamin Utilization And The Applicable Principles By T. C. Fry](#)
- [Lesson 10 - The Role Of Minerals In Human Nutrition](#)
  - [1. Introduction](#)
  - [2. The Minerals In The Body](#)
  - [3. Organic And Inorganic Minerals](#)
  - [4. Mineral Deficiencies](#)
  - [5. Obtaining The Minerals We Need](#)

- [6. Questions & Answers](#)
- [Article #1: The Minerals Of Life By Dr. Herbert M. Shelton](#)
- [Lesson 11 - Fats In The Diet](#)
  - [1. Introduction](#)
  - [2. What Are Fats?](#)
  - [3. Fat Digestion](#)
  - [4. How The Body Uses Fat](#)
  - [5. Harmful Fats](#)
  - [6. The Use Of Fats In A Healthy Diet](#)
  - [7. Questions & Answers](#)
  - [Article #1: A Natural Diet And Sunlight Could Save Your Life By Dr. Zane R. Kime \(M.D.\)](#)
  - [Article #2: Fats In The Diet By Marti Fry](#)
  - [Article #3: Are We Oil And Fat Eaters By T. C. Fry](#)
- [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#)
  - [1. Acid-Base Balance](#)
  - [2. Body Maintenance Of Normal Ph](#)
  - [3. Acid And Alkaline In The Diet](#)
  - [4. Acute Conditions Involving Acid-Alkaline Imbalances](#)
  - [5. Case Histories Of Acid Indigestion Due To Improper Diet](#)
  - [6. The Acid-Alkaline Ratio In The Diet](#)
  - [7. Considerations For Working With pH Imbalances](#)
  - [8. Questions & Answers](#)
  - [Article #1: Alkalinity And Acidity Of Foods In Metabolic Reaction](#)
  - [Article #2: Acid/Alkaline: Clearing Up The Confusion By Marti Fry](#)
- [Lesson 13 - Air, Sunshine, And Natural Light Essential To Health](#)
  - [1. Sunshine And Its Role In Human Health](#)
  - [2. Natural Light Versus Artificial Light](#)
  - [3. Air And Breathing](#)
  - [4. Questions & Answers](#)
  - [Article #1: Sunlight And Air By Otto Carque](#)
- [Lesson 14 - Water Transports Nutrients To All The Body Cells](#)
  - [1. Water Is The Essence Of Life](#)
  - [2. Water's Role In The Body](#)
  - [3. Other Body Uses Of Water](#)
  - [4. Water In Our Diet](#)
  - [5. Water: Is It Fit To Drink?](#)
  - [6. Sources Of Pure Water](#)
  - [7. The Choice Is Yours](#)
  - [8. Questions & Answers](#)
  - [Article #1: The Fountain Of Life By Herbert M. Shelton](#)
- [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#)
  - [1. Introduction](#)
  - [2. What Is Rest?](#)
  - [3. What Is Sleep?](#)
  - [4. What Determines The Quality And Quantity Of Sleep We Need?](#)
  - [5. The Value Of Napping](#)
  - [6. Dreams And Their Role In Sleep](#)

- [7. Establishing Conditions Most Favorable For Sleep](#)
- [8. Sleep Problems In Adults And Their Solutions](#)
- [9. Sleep Problems In Infants And Children With Suggested Solutions](#)
- [10. Nostrums, Medications And Drugs Adminstered For Sleep Problems](#)
- [11. Our Biological Clock And Sleep](#)
- [12. Improving The IQ Through Sleep](#)
- [13. Questions & Answers](#)
- [Article #1: How To Put Yourself To Sleep Easily By A.F. Willat](#)
- [Article #2: Rest: A Much-Neglected Health Factor](#)
- [Article #3: The Need For Rest By Dr. Herbert M. Shelton](#)
- [Article #4: Rest vs. Stimulation By Dr. Herbert M. Shelton](#)
- [Lesson 16 - Nutrition, Mind And The Emotions](#)
  - [1. Introduction](#)
  - [2. How Foods Affect Mental And Emotional Health](#)
  - [3. Emotional Aspects Of Diet And Digestion](#)
  - [4. Methods For Overcoming Negative Emotional Conditioning](#)
  - [5. The Optimum Diet For Mental And Emotional Health](#)
  - [6. Questions & Answers](#)
  - [Article #1: About Emotions And Health By Marti Fry](#)
  - [Article #2: Fruitarianism For Health And Long Life By Dr. O.L.M. Abromowski](#)
  - [Article #3: The Mind-Benders By Kecki R. Sidhwa, N.D., D.O.](#)
- [Lesson 17 - Exercise And Its Beneficial Role In Nutrition And Digestion](#)
  - [1. The Philosophy Of Exercise](#)
  - [2. Effects Of Exercise On The Bodily Systems](#)
  - [3. The Three Major Categories Of Exercise](#)
  - [4. Exercise And Nutrition](#)
  - [5. Questions & Answers](#)
  - [Article #1: Staying In Shape For Life By Richard K. Schmidt](#)
  - [Article #2: Exercise: A Hygienic Perspective By Ralph C. Cinque, D.C.](#)
- [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#)
  - [1. Prologue](#)
  - [2. Necessity Of Different Approaches To Nutritional Science](#)
  - [3. Understanding The Role Of Foods In Nutrition](#)
  - [4. Edibility Of Foods](#)
  - [5. Other Food Qualities](#)
  - [6. Summary Of Criteria Relative To Goodness](#)
  - [7. Ratings Of Generally Available Foods](#)
  - [8. Questions About The Lesson](#)
  - [Article #1: Are We Vegetarians Or Fruitarians?](#)
  - [Article #2: Research Yields Bombshell Of A Surprise!](#)
  - [Article #3: Are We Meat Eaters?](#)
  - [Article #4: Are We Milk Drinkers?](#)
  - [Article #5: Are We Grain Eaters?](#)
- [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#)
  - [1. Humans Developed To Their Hight State Entirely On Fruits](#)
  - [2. Fruits Still Best Meet Our Needs Despite Their Present Lower Quality](#)
  - [3. Some Charges Made Against Fruits And Fruit Eaters](#)
  - [4. Questions & Answers](#)

- [Article #1: Fruit Eating By Dr. Herbert M. Shelton](#)
- [Article #2: Fruit: Best Food Of All By William L. Esser](#)
- [Article #3: Proteins In The Fruitarian Diet By Dr. Herbert M. Shelton](#)
- [Lesson 20 - The Physiology Of Digestion](#)
  - [1. Introduction](#)
  - [2. The Journey Of Food](#)
  - [3. The Physiological Determinants Of The Optimum Diet](#)
  - [4. Questions & Answers](#)
- [Lesson 21 - Symptoms During Dietary Transition](#)
  - [1. Introduction](#)
  - [2. Some Unpleasant Symptoms And Their Causes](#)
  - [3. The Recovery Of Health](#)
  - [4. Questions & Answers](#)
  - [Article #1: What To Expect When You Improve Your Diet By Stanley S. Bass, D.C.](#)
  - [Article #2: The Three Phases Of Metabolism](#)
- [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#)
  - [1. The Basis Of The Food Combining System](#)
  - [2. What Is Food?](#)
  - [3. The Chemistry And Physiology Of Digestion](#)
  - [4. Food Combining Rules-Updating, Exceptions](#)
  - [5. The Crux Of Food Combining](#)
  - [6. Question & Answers](#)
  - [Article #1: Skin problems? Tell me about them! By Richard Hill](#)
  - [Article #2: The Hygienic Diet By Dr. Alec Burton](#)
  - [Article #3: Food Combining By Dr. Herbert M. Shelton](#)
  - [Article #4: Protein-Starch Combinations By Dr. Herbert M. Shelton](#)
  - [Article #5: Basic Considerations In Food Combining By Virginia Vetrano, B.Sc.](#)
- [Lesson 23 - Application Of Food Combining Principles](#)
  - [1. The Food Combining System](#)
  - [2. Planning Meals](#)
  - [3. Daily Menus](#)
  - [4. Mono Meals And Mono Diets](#)
  - [5. Application Of The Food Combining Rules](#)
  - [6. Trying Too Hard](#)
  - [7. Your Social Life](#)
  - [8. Your Family](#)
  - [9. Looking Forward](#)
  - [10. Food Classification Charts](#)
  - [11. Questions & Answers](#)
  - [Article #1: Your Probing Mind By Dr. Virginia Vetrano](#)
  - [Article #2: Proteins In Your Diet! By Dr. Alec Burton](#)
  - [Article #3: Food Combining By Dr. Herbert M. Shelton](#)
  - [Article #4: Chlorophyll And Hemoglobin By Viktoras Kulvinskas](#)
- [Lesson 24 - Selection And Storage Of Most Wholesome Foods, Part I](#)
  - [1. Changing To A Nutritionally Superior Diet](#)
  - [2. Let's Go Shopping](#)
  - [3. Fruits](#)
  - [4. Storage Of Foods](#)

- [5. Storage Of Fresh Fruit](#)
- [6. Storage Of Dried Fruit](#)
- [7. Nuts And Seeds](#)
- [8. Storage Of Nuts And Seeds](#)
- [9. Questions & Answers](#)
- [Article #1: Does Freezing Harm Foods? By Marti Fry](#)
- [Article #2: Your Probing Mind - Queries with answers By Virginia Vetrano, B.S., D.C.](#)
- [Article #3: Figs](#)
- [Article #4: Imagine Avocados-As A Dieter's Delight By Lincoln Kaye](#)
- [Article #5: "Natural" Foods](#)
- [Lesson 25 - Selection And Storage Of Most Wholesome Foods, Part II](#)
  - [1. Vegetables](#)
  - [2. Storage Of Fresh Vegetables](#)
  - [3. Purchasing And Storing Seeds For Sprouting And Ready-To-Eat Sprouts](#)
  - [4. Selection And Storage Of Dried Grains And Legumes](#)
  - [5. Bread-General Information](#)
  - [6. Butter And Oil-General Information](#)
  - [7. Sweeteners](#)
  - [8. Packaged, Frozen And Canned Foods-General Information And Storage](#)
  - [9. Questions & Answers](#)
  - [Article #1: Well! You Wanted To Know By V.V. Vetrano, B.S., D.C.](#)
- [Lesson 26 - Preparing And Serving Foods For Best Nourishment, Part I](#)
  - [1. Evaluation Of The Various Stages And Methods Of Preparation Of Uncooked Foods](#)
  - [2. Priority Of Food Preparation](#)
  - [3. Preparation Of Foods Without Cooking](#)
  - [4. The Sprouting Garden](#)
  - [5. Questions & Answers](#)
  - [Article #1: Well, You Wanted To Know By V.V. Vetrano, B.S., D.C.](#)
  - [Article #2: Some Fundamentals Of Food And Feeding By Ian Fowler](#)
  - [Article #3: Vegetable Salads By Herbert M. Shelton](#)
  - [Article #4: Hypoalkalinity By Herbert M. Shelton](#)
  - [Article #5: Sprouts And Sprouting By H. Jay Dinshah](#)
  - [Article #6: The Marvelous Avocado](#)
- [Lesson 27 - Preparing And Serving Foods For Best Nourishment, Part II](#)
  - [1. Cooked Foods](#)
  - [2. Preparation Of Cooked Foods](#)
  - [3. Miscellaneous Recipes](#)
  - [4. Recipe Conversions](#)
  - [5. Questions & Answers](#)
  - [Article #1: Your Probing Mind](#)
  - [Article #2: Hygienic Considerations In The Selection of Foods By Ralph C. Cinque, D. C.](#)
  - [Article #3: How To Get More Food Value for Your Money By Marti Fry](#)
- [Lesson 28 - The Elixir Of Life: An Exploration Of Food Conditions, Body Conditions, And Eating Conditions That Beget Euphoric Health And Long Life](#)
  - [1. Introduction](#)
  - [2. Achieving Natural Life Potential](#)
  - [3. Food And Short Or Long Life](#)
  - [4. Factors That Shorten Life](#)

- [5. Exercise And Vigorous Purposeful Activity As Life Essentials](#)
- [6. Mental And Emotional Factors In Living A Natural Life Span](#)
- [7. Happiness, Enjoyment And Pleasure As Factors In Realizing Life Potential](#)
- [8. Questions & Answers](#)
- [Lesson 29 - Why Condiments Should Not Be Included In The Diet](#)
  - [1. Condiments, Seasonings and Spices](#)
  - [2. Specific Condiments](#)
  - [3. Condiments In General](#)
  - [4. Question & Answers](#)
  - [Article #1: Are Any Condiments Acceptable In the Hygienic Diet? by T. C. Fry](#)
  - [Article #2: Salt](#)
  - [Article #3: Here Are Some of the Reasons Why You Should Not Use Condiments](#)
  - [Article #4: Using Condiments Is Like Wearing Makeup by Marti Fry](#)
- [Lesson 30 - Sugars And Other Sweeteners May Be Worse Than Bad](#)
  - [1. Introduction](#)
  - [2. Refined Sweeteners](#)
  - [3. Sugar: Where Does It All Come From?](#)
  - [4. The Cousins of Sugar](#)
  - [5. Some Final Thoughts about Sugars](#)
  - [6. Questions About The Lesson](#)
  - [Article #1: Why Honey Is A Harmful Food By T.C. Fry](#)
  - [Article #2: More About Honey By T.C. Fry](#)
  - [Article #3: Blackstrap Molasses: Super Junk Food By T.C. Fry](#)
- [Lesson 31 - Refined And Processed Foods Are Hazardous To Your Health](#)
  - [1. Introduction](#)
  - [2. Questions & Answers](#)
  - [Article #1: Pure Starch Factors by Thomas E. Scown](#)
  - [Article #2: Cereals, Grain, Flour](#)
- [Lesson 32 - Why We Should Not Eat Meat](#)
  - [1. The Principle Hygienic Concern Is Optimal Health](#)
  - [2. The Best Fuel For The Human Body](#)
  - [3. Flesh Foods Cause Degenerative Disease](#)
  - [4. Vegetarianism Receiving More Attention](#)
  - [5. The Evidence Is Mounting](#)

## Inspiring Quotes by Morris Krok

- By attending to the excretion and elimination of unwanted substances is the first step to good health.
- The greatest or most important health step that one can take is to put the body into an extended and deep elimination mode - to eliminate everything that is unwanted and obstructing the functions of the body.
- When the body is thoroughly cleansed and magnetized by the power of breath, the mind becomes calm, insight is enhanced and there is greater harmony in the entire system.
- The body must be cleansed from the filth of civilized food so that the flow of innovation and inspiration is not impeded.
- Man is suffocating, suffering and sinking, in a swampy sea of saturating, silting, sticky, slippery, sloppy slicks of sludgy slime.
- Cleanse the system so that purified mind is forever inspired.
- Miracles are wrought on an empty stomach.
- Good habits last a lifetime, bad habits are short-lived, you won't live long enough to enjoy them.
- He who loves his stomach does not love his life.
- Health is the balance between assimilation and elimination.
- Eyes must sparkle with the laughter of inner cleansing.
- Truth comes in small segments to one who is attuned.
- More murders are enacted in the kitchen than anywhere else.
- In ten minutes you can eat so badly that you will become an invalid for a week.
- Internal purification is best when we drink an abundance of light water for it to create a healing pressure as it flows through the body like a silken thread.
- A mind totally in harmony with a body functioning with rhythmic clocklike efficiency is something that man unknowingly is searching for.
- It has been truly said that magic is wrought on an empty stomach. For if the digestive tract is always stuffed with food, and the bloodstream saturated with food essence, breathing, nerve and blood circulation is impeded.
- To learn the truth listen to the sermon and song of an old and trusty preacher - nature. It is everything that is logical, simple, effective, intelligent and powerful; but it will not be denied by man-made philosophies, religions, commercialism and laboratory produced substances.
- One obtains the best results from food eaten when all the previous meals have been well assimilated and its residues have been eliminated from the body. As it is written in the New Testament do not put new wine into old skins.
- Though not generally accepted, illness is fed by what we imbibe through the air, from the food and liquids we take. Conversely, as illness, including germs and viruses cannot live in a clean environment, the solution is to abstain from food for a while and replace it with large amounts of clean water to purify the entire system.
- In the same way that hunger or thirst cannot be appeased by one meal or one glassful of water during our lifetime, so health and fitness cannot be stored. It has to be earned by rational living

every day of our life.

- When we can breathe deeper and slower, its effect on the mind is so pronounced as it releases life's treasures, not of coins and gems but of effulgent, lucid and clear thinking.
- You can eat enough of the wrong foods in ten minutes to make you an invalid for a week. As one meal takes 24 hours or more to be fully digested and for its residues to be eliminated, the body can feel the harmful effects for that length of period.
- There is no more satisfying way of living than by refraining from food and also drink if we are not hungry or thirsty. With a little discipline in this regard and providing we choose natural food when we do eat, we will become less body conscious as our mind can now function with all the freedom in creative endeavours and our everyday tasks.
- Man will only realize the truth about illness and health, something that has evaded him since the dawn of time and which he still has not accepted, by placing himself on a thorough internal elimination regime. It makes no difference what his illness is called and he can even be a so called healthy person. They will be shocked by the unceasing flow of unwanted toxic and slimy matter that is excreted from every aperture of their body. It is amazing that this truth was understood by the ancient yogis of India and their method the six shatkarmas is perhaps the greatest legacy that the old world has bestowed on contemporary man.
- Life is breath and breath is life. Accordingly it is more a breathing mechanism than anything else. It is certainly the body's most predominating feature.
- Man reaches his full potential when our consciousness is bathed with innovative inspiration delightfully experienced with each breath.
- When you are attuned in this way, and as you grow in awareness of life's infinite range of logical and intelligent segments, truth will be forever your companion. It is out of this never exhausting supply that man has discovered and invented what he has or has streamlined the way he does things.
- Thinking after gathering all the relevant facts, and allowing the subconscious to weave its unique brand of magic, is waiting for that gleam of light to flash on the mind which it usually does unexpectedly.
- The easiest way to achieve success is to find a simple formula, easy to keep uppermost in the mind and perform. In the search for higher health, waiting for natural hunger and thirst, even if we do not imbibe anything for the entire day fits this bill perfectly. When the inner activities of the body do not always have to contend with the intake of food, it can perform its higher duties more efficiently. It is therefore, true that one is more satisfied when this rule is followed as it concurs with the axiom that magic is wrought on an empty stomach.
- Language is magical because it is the only thing that can express or capture consciousness and awareness our most prized possession — the meanderings of the mind, the fleeting and frail ethereal essences called thought and thinking that unceasingly flow in diverse and unexpected ways.
- The mind cannot be forced but it can be fooled.
- A wise man learns from the mistakes of others; a fool doesn't even learn from his own.
- After gathering all the relevant information, thinking is waiting for the subconscious to weave its unique brand of magic by flashing solutions unexpectedly on the mind.
- Outwardly you will be silent, but within your master will speak to you in the voice of a roaring rapid and resounding waterfall.

- Nothing is more detrimental to man's advancement and well-being than an untruth which is given authoritative approval.
- We shall continually chant so that we and our children shall never forget that we are sons of the morning, children of the light.
- Knowledge is light but knowledge from light is most revealing of all.

## About [Rawfoodexplained.com](http://www.rawfoodexplained.com)

The materials on this website are based on the Philosophy, Principles and Practices of Natural Hygiene and were originally published as a course consisting of 106 lessons called *The Life Science Health System* by T.C. Fry.

The *Life Science Health System* is vast compilation of knowledge by [various authors](#) and was intended to prepare the student for a career as a *Natural Hygiene Health Consultant*.

If you want to buy the printed version of the *Life Science Health System*, you can do so at <http://www.rawschool.com/course.htm>

A revised and edited version, including testing and certification, called "Essential Natural Hygiene Course" with 44 Lessons of the *Life Science Health System* is available at the [Transformation Institute](#).

For the principal Discussion Forum on *Natural Hygiene* on the Internet, go to <http://health.groups.yahoo.com/group/Rawschool/>

## About me

I'm 27 years old and changed to a Raw Food Diet about six years ago. This was one of best decisions I have ever made.

After reading the very inspiring book [Survival Into The 21st Century](#) by Viktoras Kulvinskis, I decided to go raw the same day.

I cut out all the cooked, processed and canned foods and ate very simple meals of fresh organic fruits, raw vegetables, nuts & seeds and sprouts. I realized that all those beautiful fruits and vegetables are the divine gifts of nature to humans and animals and that our bodies are designed to thrive on these pure foods.

After about a year, I noticed very positive physical changes like normalized weight, high energy levels, clear skin, fuller hair, no more body odor etc.

What was most astonishing, was the mental/spiritual transformation that had taken place. For the first time in my life, I was able to feel love for myself and my body. I accepted myself as I was. I felt more and more connected to the earth and the people around me and I became very sensitive. I actually had to pay attention not to pick up too much of the thoughts/emotions of other people.

At first, I wasn't consciously aware of it, but after a while it became increasingly apparent that I could ask myself questions and actually get valid answers from within. The connection to my intuition/higher self was greatly enhanced. This has nothing to do with anything "paranormal". I think it's a very natural thing.

Beside the Raw Food Lifestyle, I'm interested in everything related to personal development. I spend a lot of time reading books about Spirituality, Philosophy and Psychology. I'm also practicing Yoga and Meditation.

My other interests include all things related to Lucid Dreaming and Astral Projection. About three years ago, after reading a book on the topic, I had an Out of Body Experience. I'm researching the subject in more depth ever since.

My two major goals in life are to always live consciously and to be able to give unconditional love to all sentient beings of this wonderful world.

For questions or feedback, feel free to contact me per email at rawfoodexplained [at] yahoo [dot] com or use the [contact form](#).

Thank you very much and have a nice day!

Philip

Welcome! It is my privilege to introduce you to the science of health known by the descriptive term "Life Science." It is also known as health science, Natural Hygiene, Hygiene, and other terms.

### 1. What is Life Science?

At the outset it is wise to delineate just what Life Science is—just what grounds it covers.

Life as we know it is possible and became possible because certain favorable conditions are and were present. Some of these conditions include favorable temperature, presence of oxygen and other gases and minerals, presence of water, absence of lethal substances, etc. Life Science is the study of all the conditions which make life possible. Because present-day life seems to be losing touch with those conditions which made life possible, Life Science brings us "back to our roots," so to speak. We should endeavor to meet life's requisites so that we can lead a joyous existence.

Science is not the cold dispassionate pursuit many of us have been led to believe. Rather, it is personal, and relevant to all that we are involved in. When we turn our studies upon ourselves so that we may have a very personal science, we begin to arrive at the essence of Life Science.

Science as represented today is not the warm practical medium we speak of here. Science that we can't use and benefit by is hardly science. Life Science is the exploration and elaboration of those elements and influences we can invoke to exalt our lives and being. Certain truths are applicable to our being. Studying and systemizing these truths so that we can be guided by them is our aim here. That which begets correct results is scientific.

That which begets wrong results is unscientific.

Life Science concerns itself with those principles and truths applicable to human life so that we may observe and avail ourselves of them. We are of the firm conviction that only by scientific living can we realize the loftiest joys *and the destiny* which is our birthright.

Animals in nature are creatures of instinct. Following the guidance of instinct, they are correctly self-directed to meet their needs. Thus they thrive optimally in accord with their environmental possibilities. Inborn guidance is, in effect, Life Science or a science of life for nature's creatures.

Humans have infinitely more potential for happiness and goodness than nature's simpler forms of life. We are endowed with immeasurably more sophisticated faculties.

These superior endowments can keep us in a state of euphoria during a long life.

Life Science must be for humans what inborn direction is for animals. We, too, have instincts, but we are far more than these basic impulses of life. Unfortunately, we not only fail to follow our instincts but we often reject them in our living practices. Our instincts have been vitiated and perverted by unwholesome conditioning in a world that is quite berserk by sane standards. When humans act contrary to instincts *they are being unscientific*. When their practices are in accord with their instincts—with their inherent biological adaptations—*they are living scientifically*. Life Science is as simple as that.

Obedying our natural instincts is part and parcel of Life Science. We believe nature did not err in instilling in us guiding instincts. We contend that humans, with our as yet fledgling intellects, do the erring that begets our sickness and suffering.

Life Science is an intellectual endeavor. We are far enough along that we can determine what is good and what is bad for us. We are profound enough in our knowledge to construct a science of life that will guide us to realize the happiness and the destiny that should be ours.

Life Science is, therefore, a way of life that rightfully concerns itself with every facet of human life and human well-being. Only such a thoroughgoing philosophy and concern can be a true science of life.

[Home](#) > [Lesson 1 - Introduction To Life Science As A Way Of Life](#) > 2. An Introduction To Life Science

## **2. An Introduction To Life Science**

### **2.1 Life Science as a Philosophy of Life**

In introducing Life Science as a true philosophy of life thoroughly in accord with the facts of existence, the question arises as to how its validity was determined. The surest way of assessing the correctness of any system is to put it to the test. Does it work? If it works, it must be deemed valid. If it does not work, then it must be unscientific.

Life Science began with success. From its beginnings as a new, but not yet complete, healing science it developed until today it is a full-blown scientific system touching upon everything that relates to human well-being. That it is valid is beyond doubt—Life Science works perfectly!

To capture the essence of the science of healthful living, I feel it appropriate to quote from a most notable hygienist, Dr. Keki Sidwha. He's been a Hygienic practitioner in Great Britain for almost twenty years.

"In spite of all the great advances in many branches of science, we are still in a period of prehistory, a dark age, in our thinking about health, disease and healing. What the world sorely needs is a new concept of health. A different orientation of thoughts, words and deeds than we have been led to accept for umpteen generations is now urgently called for.

Natural Hygiene, a life science, is that branch of biology which investigates the conditions upon which health depends and the means by which it may be sustained in all its virtue and purity, while we have it, and restored when it has been lost or impaired.

Before physiology developed, the rules of Hygiene were instinctive, traditional, and empirical. Today these rules are based on the growing knowledge of physiology and biology. If we had perfect knowledge of the laws of life and applied them in a perfect system of Hygiene, disease would be impossible and never occur. In this sense Hygiene is the science of intelligent and healthful living.

Natural Hygiene refutes the present-day ideas that disease and ill health are inevitable in people's

lives, depending on chance and circumstances outside their own control and domain. Natural Hygiene is a way of life, a philosophy of living. Health can only be obtained through healthful living; it cannot be bought across the counter of a drugstore, nor can it be found in a physician's office or in a hospital. We contend that healing is a biological process which is continuously going on inside every organism."

This brilliant expression of the Hygienic stand by Dr. Sidwha deserves immortality. His salutary contributions to the science of healthful living will achieve immortality in our annals. Certainly this statement embodies the essence of hygienic philosophy.

The following is a concise statement of the philosophy, principles and practices of Life Science.

## **2.2 Life Science Philosophy, Principles And Practices**

- LIFE SCIENCE holds that life should be meaningful and filled with beauty, goodness and happiness.
- LIFE SCIENCE holds that humans are inherently good, righteous, and virtuous, and that their exalted character will be realized under ideal life conditions.
- LIFE SCIENCE holds that superlative well-being is normal to human existence and necessary to the realization of the highest human ideals.
- LIFE SCIENCE holds that supreme human excellence can be realized only in those who embrace those precepts and practices which are productive of well-being.
- LIFE SCIENCE, which encompasses all that bears upon human well-being, constitutes the only way to realize the highest possible order of human existence.
- LIFE SCIENCE, alone, is in harmony with nature, in accord with the principles of vital organic existence, correct in science, sound in philosophy and ethics, in agreement with common sense, and successful in practice and a blessing to humankind.
- LIFE SCIENCE recognizes that the human body is a fully self-sufficient organism, that it is self-directing, self-constructing, self-preserving and self-healing, and that it is capable of maintaining itself in superb functioning order, *completely free of disease*, if its needs are met. Foremost among these needs are fresh air, pure water, rest and sleep, wholesome foods, cleanliness, comfortable temperature, sunshine, exercise, constructive work, emotional poise, self-mastery, recreation and pleasant environment.
- LIFE SCIENCE recognizes that humans are constitutionally adapted to a diet of fruits, vegetables, nuts, and seeds eaten in compatible combinations while in the fresh raw natural state.
- LIFE SCIENCE recognizes that diseases are caused by improper life practices, especially dietary indiscretions. Illness proceeds from reduced nerve energy and consequent toxemia. Insufficient nerve energy arises from dissipation, stress, overindulgence, *excess or deficiency* of the normal essentials of life, or pollution of the body with substances not normal to it. Accordingly, recovery from sickness can be achieved only by discontinuing its causes and supplying conditions favorable to healing.
- LIFE SCIENCE recognizes that a thoroughgoing rest, which includes fasting, is the most favorable condition under which an ailing body can purify and repair itself.
- LIFE SCIENCE, which teaches that exalted well-being can be attained and maintained only through biologically correct living practices, is not in any sense a healing art or a curing cult. It regards as mistaken and productive of much grief the idea that diseases can be prevented or overcome by agencies abnormal to our natural being. Consequently, LIFE SCIENCE emphatically rejects all drugs, medications, vaccinations and treatments because they undermine health by interfering with or destroying vital body processes and tissues.

Therefore, LIFE SCIENCE regards the body and mind as the Inviolable sanctuary of an individual's being. LIFE SCIENCE holds that everyone has an inalienable right to have a pure and uncontaminated body, to be free of abnormal compulsions and restraints, and to be free to meet his/her needs as a responsible member of society.

### **3. An Inquiry Into The Philosophy, Principles, And Practices Of Life Science**

#### **3.1 The Concept of Innate Individual Worth**

Life Science holds that we are born naturally innocent and naturally good. The first two paragraphs of the concise statement we heretofore printed in exposition of Life Science's philosophy, principles, and practices states this.

Scientific studies of babies and youngsters have pointed to one inescapable conclusion. As gregarious creatures, humans are naturally empathetic, altruistic and moral, i.e., humans are naturally righteous toward one another in keeping with their gregarious instinct.

Humans are woefully perverted by unnatural conditions within the context of civilization. They are made vicious by inhumane influences such as deceptive practices, exploitation, insecurity, and other baneful conditions in a society gone mad.

Individuals usually strive to present the appearance of upright character to others. This bespeaks our innate urge and conviction that we should be righteous. Life Science holds that if a society of assurance exists these innate virtues will assert themselves naturally.

#### **3.2 The Concept of Happiness and Ideal Health as Normal**

Life Science holds that life was developed to be a long joyous event from birth until a natural death. Happiness and health flow from ideal life conditions. Ideal life conditions are normal in the environments of our development. However, such is the human intelligence that it has made almost all environments over the face of the globe inhabitable. Many arts, artifices, and artificial environments have been created to satisfactorily supplant the wonders, beauties, and beneficence of a natural environment in many habitats though, in truth, such artifices are never completely wholesome substitutes.

Life Science holds that humans developed to their high state because they adapted so well to the environment and its possibilities. This means that health is normal and natural when the conditions to which we are adapted are met. Superb excellence in humans flows from ideal life conditions and the superlative health begotten of them.

#### **3.4 The Self-Evident Concept of Self-Government In All Organisms**

Simple observation of the development of complex organisms from the union of sperm and ovum is indicative that the powers of life reside within. Without anything from the outside other than needed raw materials, the organism has the inner direction to fashion itself from a fertilized ovum into a mature adult.

This implies an inherent character that embraces the following capabilities:

- Organisms are self-programmed.
- Organisms are self-directing or self-governing.
- Organisms are self-sufficient when their material requisites are available.
- Organisms are self-constructing in accord with their genetic blueprint.
- Organisms are self-defensive and preservative, defending themselves against all internal and external threats.
- Organisms are self-repairing or self-healing and possess solely and exclusively the faculties and powers to accomplish restoration in event of damage or derangement.

These faculties and powers are self-evident upon the simplest observation of yourself or other organisms. This

concept and its axioms should ever be borne in mind when dealing with clients. The confidence needed in dealing with your own problems should you have any, or with the problems of your clients, can be derived and reinforced by referring to these self-evident truths.

### **3.5 Life Science as a New Concept of Healthful Living**

Life Science may be said to be a reassertion of the conditions best suited to human life. In pristine nature, humans lived what we now call Life Science because of primal urges—on the instinctual level. They lived as gatherers of fruits from vine, stalk, and tree.

With the development of intellect, humans became ever more versatile in dealing with the forces of nature. But this eventually led to human alienation from both nature and our biological heritage. Though most humans observed much of their pristine endowment well into the civilization of the Christian era, the dark ages of medieval times brought on the renunciation of nature and earthly considerations. Humans became poorer in the observation of the elementary needs of life. Human needs on earth were contravened in the name of religion and salvation.

Fortunately, the dark ages did not wipe out humankind. Near the end of the dark ages the unnatural and inhumane conditions under which European civilization lived decimated the population with plagues. Great plagues were not due to any kind of contagion. The only thing contagious in the times of the bubonic and black plagues was widespread modes of death-dealing living practices.

Hygiene or Life Science as a philosophy and outlook survived the dark ages when the twin human scourges of medical and religious superstition saddled most of what we refer to smugly as the civilized world. In many parts of the world our biological mandate was fairly well maintained, notably in tropical cultures of the Far East and in isolated pockets here and there. It was preserved among many traditions and cultures in part.

Well before the Christian era Pythagoras elaborated a rather extensive philosophy of living on all planes of life. Among them was perhaps the best formulated statement of Hygienic living until this time. While the Greeks, of whom Pythagoras was one, were heavy on fruitarianism, they were also heavy into the incipient practices that begot the modern goliath of medicine.

The philosophy of Pythagoras gave rise to Appolonius and the Essenes, an ascetic culture that was vegetarian/fruitarian in practice. Much of Essenian philosophy and practices were preserved in the New Testament and is quoted in the sayings of Christ. The thin thread of Hygienic philosophy survived and received a modern impetus from the greatest universal genius of all times, Leonardo da Vinci, who was a vegetarian/fruitarian.

Though medical beliefs remained relatively unscathed while the areas of religious domination were receding during the Renaissance, some elements of the Hygienic philosophy survived.

I reiterate that our natural heritage was largely unaffected by the medical outlook in many areas of the world, notably in the Far East. But healthful living as a philosophy of life in the Western Culture did not exist as such.

It was not until the time of Dr. Isaac Jennings in 1822 that Hygiene as a formalized philosophy of life had its beginnings. Not until the consummate genius of Drs. Graham, Trail, Dewey, Tilden, and Shelton did the philosophy and science of health become fully ascertained.

Life Science is not new from many perspectives, although it is relatively new to what we call civilization. But it is totally new for most who learn it the first time. Now it is alien to our culture because of its relative rarity. At this time Life Science, even though in accord with our pristine being, is in eclipse because of medical thinking and a commerce that trades upon pathogenic fare.

It is our hope to teach enough dedicated individuals this science of health to assure that humanity thrives in health and enlightenment. In pursuing this course you are asked to be the torchbearers of a way of life whose time has come.

### **3.6 Life Science as a Broad-Based Science of Life**

By no means is Life Science confined to dietary principles as you might gather from association with today's Hygienists. Few Hygienists involve themselves with the expansive aspects of Life Science as a philosophy embracing every facet of human well-being.

Dietary concerns are but one area of Life Science's dominion. It also includes mental and emotional well-being, as well as social and economic well-being. It includes environmental factors or ecology and is coextensive with all factors that touch upon human welfare. While this course is nominally on the specific area of nutrition, nutrition is but a small part of the all-encompassing philosophy of Life Science.

### **3.7 The Concept of Self-Healing or Self-Repair**

Self-healing is the only healing. Throughout nature we see animals with cuts, bruises, broken bones, and other injuries undergo healing. Obviously this healing is effected by internal faculties and powers, for in nature, animals seek out a quiet secluded spot and rest. They undergo almost no activity. They partake of no food.

Instinctively an injured animal will abstain from all indulgences that detract from the full application of the body's energies and faculties to the reparative/restorative process. Likewise, humans when placed under the same conditions in keeping with our nature and disposition undergo healing in a fraction of the time that occurs when regular activities are pursued.

Healing is always and ever a biological process. Our task is but to establish the conditions so that the body may conduct the process more quickly and efficiently. The inherent programming, intelligence, and power that developed a fertilized ovum into a wonderfully and beautifully built creature is all the healing power that is needed. Conditions favorable to the exercise of these powers can be established. As a health practitioner/nutritionist it will be your role to know and apply these conditions.

Much suffering and grief result from the idea that the body can be helped by the application of substances, conditions, and treatments abnormal to the body. It will be your role to rescue the victims from harmful practices as well as set them on a right course for health recovery and maintenance.

### **3.8 The Concept of Individual Sovereignty**

Life Science holds that everyone is an independent entity unto himself or herself within the context of society. Everyone should be entirely free—fettered in no way—within the context of enlightened self-interest—within the context of our symbiotic mandate on earth.

Every man, woman, and child must be regarded as capable of carrying on life's affairs for himself or herself. It is not our role to judge or impose ourselves on others but to help if our aid is sought. We should not impose ourselves on anyone no matter how wise or unwise, or how good or bad such imposition is or would be. We must accord to everyone the prerogative of leading their lives as is their bent and capability so long as their pursuits do not impinge upon the birthright of others. The golden rule should be our rule of conduct.

While it may seem unwise to grant the same privileges and prerogatives to both the genius and the relatively unlettered, nevertheless a society is not free in which either are denied their right to pursue opportunities on an equal footing. The capable are bound to succeed and should offer aid to their biologically crippled or less favored brethren.

For all its drawbacks and advantages we must always respect everyone as supremely sovereign. Whatever they do or decide, however good or bad their acts or decisions, in their own interests, we must pursue a role of non-interference. We may, by example, seek to inspire and motivate. But to impose ourselves and our precepts on others is reprehensible.

## **4. Discussion Of The Medical Approach To Health And Disease**

### **4.1 The Erroneous Notion of "Cure"**

The idea behind medicine is more than 2,500 years old and, like most ideas from behind the dark ages, it's very unscientific. The premise is that the body is like a machine that can be repaired by outside agencies. The machine goes wrong because of invading entities. In ancient times these entities were evil spirits, demons, and devils which had to be exorcised. By and by these evil spirits became known as little beasties called microbes, germs, bacteria, viruses, and yet other appellations.

Medicine today has the concept of "cure," a word that has been perverted from the original of "care." Medicine itself means a curative or healing substance. The idea behind the use of medicine is that the "medicine" acts within the organism, that it seeks out the trouble, routs the invaders and effects in some manner the necessary healing. The medical concept of the modus operandi of drugs which they call medicines is very hazy at best. But medicine is the harmful practices that men do to try to help ailing people.

People go to physicians for medical intervention. They want to get "fixed up." They're ailing. Something must be done lest they suffer grave consequences or death. Medical practitioners take advantage of the clients—they play upon their fears. They applaud their clients for coming to them when they did. They flatter them for this bit of "wisdom" and assure them that, if they do not do something soon, grave dangers will ensue. The medical man always has a course of treatment to suggest, invariably a prescription of drugs and tests.

The idea is that the tests will reveal what is wrong and thereby determine what drugs to prescribe or what steps to take, as in surgery.

That their beliefs and practices are, on the whole, precisely contrary to biological science seems never to enter their minds. We'll treat medical concepts in depth at a later time but here, suffice it to say, there is no healing other than self-healing. All modalities can interfere with healing but none can aid healing.

### **4.2 "Cures" Do Not Deal With Causes**

Can you imagine trying to develop a drug to "cure" drunkenness without going to the root of the whole matter, i.e., the drunkard's drinking habit? How can we deal with drunkenness if the drunkard continues to drink?

This is what happens with the medical approach. They try to remedy effects or symptoms without dealing with causes. In reality they drug, butcher, and purge while almost totally ignoring basic causes of physiological problems. They resort to crippling surgery and treatments running into the thousands of dollars when the problems can be simply and inexpensively solved by a change in life practices.

You'll learn herein that nothing happens without sufficient cause. You'll learn that all affections of the body must be caused and the cause is almost always initiated by the sufferer. You'll learn that unless cause is discontinued the problem will always develop again, ever more serious.

In learning nutritional and health science you're basically learning to do two things: 1. to remove causes of problems and 2. to establish the conditions of health. Since these two steps are so very easy overall, that is one reason we can confidently bestow upon you a degree of Doctor of Philosophy at the end of the lessons. If you've mastered the understanding of cause and effect in nutrition and health—that diseases are suffered because the sufferer has indulged or been subjected to cause and that health results when reasons for health are dominant—you'll be a mountain among a throng of mole hills called health care professionals.

### **4.3 "Cures" Do Not Furnish the Needs of Life**

To be returned to health the body must be provided with its requirements. First, those substances, influences, and practices which beget illnesses and disease must be discontinued. Secondly, it is necessary to bring to the client the essentials of health. Very simply these are pure air, pure water, correct diet, sunshine, exercise or wholesome activity, adequate rest and sleep, emotional poise, security of life and its means and yet other factor elements and influences.

If you reflect upon medical procedures it is obvious they do not try to ascertain causes that are inherent in lifestyle and practices. They do what an auto mechanic does—they try to find out which cylinder is missing and then proceed as if the body can be repaired much in the manner of a vehicle. They rarely advise about practices and beliefs which cause problems. Since most medical men are financially oriented, it is wise that they do not teach correct habits. They'd be out of business if their clients became well.

### **4.4 "Cures" Destroy Body Vitality**

Dr. Herbert M. Shelton must be proclaimed the greatest oracle of Hygienic philosophy, principles, and practices unto this day. He has noted that now we have more medical discoveries than ever before; we have more medical practitioners than ever before; medical men enjoy more respect than ever before (at least until recent years) and yet, for all this, we also have more disease and suffering than ever before.

Why is this so?

Because, very simply, drugs destroy. They never build. It is not within the province of drugs to create cells and replace body tissue. Medical men would be the first to tell you this for they've studied physiology too. But yet they act as if their drugs perform some kind of magic that will effect healing.

What do drugs, when administered, really do?

In truth, drugs do nothing other than form chemical unions with body compounds and fluids. When these chemical unions occur, the body suffers distress. When the character of a substance is determined as harmful by the body, it goes into a frenzy. When it does this, it is stimulated. Sometimes the body has a reaction of depression in which case it is sedated or narcotized. This means function has been inhibited or paralyzed. In both cases the reaction is one of self-protection against an unwelcome intruder, in this case a poison even though it is called a medicine.

In causing an emergency in the body, drugs are harmful. The body must redirect its energies from the healing process which it is conducting. The symptoms for which the drugs or medicines are administered are evidences of the body's self-conducted healing process. When drugs are ingested or injected, the body must leave off partially or wholly the cleansing/healing efforts and attend to a greater threat which the drugs represent. When healing efforts are discontinued the symptoms disappear. Physicians interpret the disappearance of symptoms as a "cure" or a healed condition. They thus mistake drug or poison effects for healing effects. In reality the body has more problems than before. For now it has, additional to its prior problems, the problem of expelling a terrible poison too.

### **4.5 Medical and "Healing Art" Approaches Are Deadly And Deadend**

We readily recognize that drug addicts take illicit drugs and eventually become physiological wrecks as a result. Also the drug addict loses moral values. Thinking ability is lessened and almost totally redirected to acquiring the addictive drugs and to the spell the body casts when they are taken.

What we also recognize is that physician-prescribed drugs have precisely the same actions. What we do not recognize is that the prescriptions, administrations and treatments of all so-called healers have the very same effects whether the medics be called physicians, homeopaths, chiropractors, osteopaths, herbal doctors, acupuncturists, or whatever. Their modalities devitalize while their ignorance of cause likewise continues to devitalize and destroy. Because treatments are more or less deadly and because causes are left intact by those

who treat the diseased, the situation gets progressively worse. Those who get better do not become so because of the treatments. Better health comes from self-healing which occurs despite, not because of, treatments.

Under medical and other care, recovery takes place about 90% of the time. Medical men, just as do herbologists, chiropractors, osteopaths, etc., attribute healing to their intervention. But the unrecognized truth is that witch doctors have a much higher "cure rate" and that Hygienic practitioners have a nearly 100% recovery rate! As a Hygienic practitioner or health professional following the dictates of a true health science, you'll realize a nearly 100% success rate. Healing always takes place to the extent of residual healing potential when causes are discontinued and the conditions of health instituted.

[Home](#) > [Lesson 1 - Introduction To Life Science As A Way Of Life](#) > 5. What Health Really Is

## **5. What Health Really Is**

### **5.1 Delineation and Description of Health**

Can we define health?

Yes, we can. Conventionally, a lack of obvious disease is regarded as a state of health. In actuality about 99% of our peoples are diseased in some manner or other regardless of appearances.

Health may be defined as having fullness of function. Health means complete well-being, inner and outer harmony, vigor, strength, mental acuity, in short, total fitness.

Perhaps no better statement of health has ever been made than that of Dr. Herbert M. Shelton. I'm happy to quote his definition:

Health is a condition of perfect development, a state of wholeness and harmonious development and growth, an adaptation of part to part of the organism, or organ to organ, with no part stunted and no part in excess.

In this state of organic development lies the perfection and symmetry of beauty. Beauty is but the reflection of wholeness, of health. It is easy to demonstrate that the forms and proportions of humans and every animal and plant which are in their highest and most useful state are the most beautiful and therefore the most healthy.

When every bone is of the best form and size for its service in the total organism, there is perfect proportion. When every muscle is fully and proportionally developed, with just enough of fat and the cellular tissues to round out the muscles, we have the highest beauty of form. When the texture of the skin is finest, when the circulation of the blood most vigorous, the blood well-nourished and freed of all waste, there is the glow and charm of the finest complexion.

The highest beauty is the expression of the highest health. Partial beauty, fading beauty or decaying beauty—these are but expressions of partial, fading or decaying health.

When we suffer any impairment or impediment we cannot be said to be in a state of health. We can be in a relatively high state of health but to the extent we do not enjoy perfection of body function, we are not healthy.

We live in a nation where disease is the norm of life rather than a rarity. In taking up a health career it is our duty to make health the norm and disease a relative rarity.

I refer you to text material included in this lesson for a fuller discussion of what health is. Therein appear two articles by the dean of health teachers, Dr. Herbert M. Shelton.

## **5.2 Beauty as Reflecting Health**

Though our standards of beauty are rather low today, they still, nevertheless, take note of the exceptionally beautiful. Beauty, as a reflection of health and well-being, should be the norm, not the exception. How many women have we seen whom are so lovely and beautiful that we are drawn to them as a magnet? How many men are so wholesome, so fit and handsome that they, likewise, are irresistible to their female counterparts? I daresay such men and women constitute less than 1% of our peoples.

The ability to appreciate beauty is highest in humans. And humans would normally be the epitome of beauty if they lived in keeping with their birthright, that is, their biological mandate. We readily recognize beauty in birds, flowers, and other life in nature. But our fellow humans, whether aged or young, whether nice or disagreeable, are, for the most part, in some way repulsive to our aesthetic senses. Forty percent of our population are repulsively overweight. This is but one impact of the ugliness that characterizes an unhealthy population.

I've seen "monsters" transformed as if by magic upon undergoing as little as a month's Hygienic care. Fatness and ugliness both were overcome with the restoration of a relatively high level of health.

One of the "miracles" you can hold forth to your would-be clients is that of handsomeness or beauty. That quality will be tremendously enhanced in those whom you help to achieve a high level of health.

## **5.3 Fullness of Function as a Barometer of Health**

While it is not always true that athletes are superb examples of health, it is true that all in superb health are quite athletic. Suppleness, agility, stamina, strength, and vigor are qualities essential to a state of health.

Physiological function will be ideal in every respect to someone in full health. A sense of euphoria, of joy, and of total well-being is a condition of health. Healthy people usually wear smiles and pleasant countenances. Glumness and a downcast disposition personify inner unhealthfulness. Nothing sabotages beauty, function, happiness, and well-being as a body shot through with the poisons or toxins borne of bad living practices.

## **5.4 The Possibility of Perfect Health for Humans**

Life Science holds that perfect health is the norm of life. We hold that all creatures in nature adapted perfectly to the conditions of life under which they developed. They changed to cope with their environment and their food supplies.

In nature, perfect health is the norm of existence. Animals have no knowledge or concept about healthful living. They live healthfully naturally by doing only what their instincts bid them do.

It would seem that with a technological society at the apex of development human health would have kept pace and be better now than ever. The contrary is true. Humans are probably unhealthier now than at any time except the immediate past, that is, the last ten to twenty centuries. In the Dark Ages and Medieval times health was at an overall low.

Technological progress builds upon itself, and it is a credit to the human heritage that we still have, even though in a degenerated state, sufficient intelligence to develop and husband a highly technological society. Even though affected by physical degeneracy, the brain is always the least affected of organs in famine, disease, starvation, and physical debilitation.

Perfect health is possible if the conditions of health are ideal. With our intelligence and extensive technology we can create the conditions for healthful living practically anywhere in the world where humans live.

## 5.5 Health Is Normal and Natural

Over eons of time, organisms have developed to cope with changed environmental conditions and food supplies that varied environments were capable of producing. Environments range from the ideal to the impossible for every creature on earth, even microbial forms of life. Perfection arises from adaptation—from coping with conditions. Adjustments to every vagary of nature created organisms that functioned perfectly.

In humans and animals we witness what is obvious: health is normal and natural. We see animals in nature being born, living their natural life spans and dying naturally without once suffering the infirmities of sickness. And for all our modern pathogenic practices we see humans more or less well most of the time. In view of my Hygienic experience and by my observation of hundreds of others who remain sickness-free under the Hygienic regime, there is but one inescapable conclusion: health is a normal condition of life. It is our birthright.

Life Science is truly a science of life for it is based soundly and scientifically upon our biological requirements for thriving in perfect health.

This is the outlook which you are studying in this course and being asked to advocate and follow in your professional career.

Let us now explore Life Science's beginnings.

## 5.6 How Life Science Began in Modern Times

Life Science or Natural Hygiene had its awakening in 1822 when Dr. Isaac Jennings, who had a medical practice in Derby, Connecticut, despaired of drugging. In his many years of practice he was distressed to see his patients become worse from the drugging modality. His patients died and many became chronically afflicted. His yearning to help his fellow beings was sincere.

Dr. Jennings noted that as physicians became older they drugged less and less. He did likewise and found his patients were faring better under less drugging. Then he quit prescribing drugs altogether and found that it wrought miracles.

When patients with problems came to Dr. Jennings he would dispense pills of colored flour and vials of tinted waters. He gave strict instructions for their use just as other physicians gave detailed instructions for the ingestion of drugs. But, in Dr. Jennings' case, he made a prescription that was to launch a great health movement and an infant science. In 1822 at age thirty-four Dr. Jennings gave his patients placebos with instructions to take them at specified hours of the day with a glass of water. His prescription was that no food could be taken, or else the pills would not work. His patients were ordered to do this for a number of days and then return for a checkup. Upon return they would be terminated from the regimen or continued on it "a few more days."

Under Dr. Jennings' new modality, his patients invariably became well. While other physicians lost patients by the graveyard full, his thrived. The ailing flocked to him from far and near.

The success of his "no-drugging" system astounded Dr. Jennings as much as it did his patients and colleagues. Wisely, in his initial years, Dr. Jennings did not reveal his "secrets." Instead he sought the rationale for his success. He called his treatments "the leave alone" method while professing to dispense pills of unnamed composition. They came to be regarded as pills with magic curative properties.

From this rather inauspicious start, Dr. Jennings began to develop a few laws relative to his observations and experience. He called the system that flowed from the employment of these laws "orthopathy," or correct affection. He formulated many of the "laws" of life and named some of them as follows:

- The Laws of Action and Repose, i.e., the necessity for activity and rest (sleep).
- The Law of Economy which resulted from his observation of the way in which the body managed its vital energies.
- The Law of Physiological Distribution or the way in which the body supplies all its parts and faculties adequately.

- The Law of Stimulation or how the body accelerates its physiological activities at a frenzied level when a toxic material is introduced therein.
- The Law of Accommodation or how the body adjusts to poisons by decreasing its vital resistance and more effectively quarantining itself from the toxins' baneful influences. The body gradually builds defensive mechanisms much as armies grow to ward off attack as the need becomes greater.
- The Law of Limitation or the conservation of vital energies.
- The Law of Equilibrium or the revitalization of debilitated parts and faculties when normalcy has been restored to an ailing organism.

Dr. Jennings, to his credit, saw disease not as an attack from some malevolent entity but as lowered vital energy or vital energy redirected to other purposes. His new outlook ventured that disease was caused by an ebb of the body's energy supply. In essence he was correct, but his explanations were quite formative for it remained for successors to build upon the foundations he built. Dr. Jennings may rightfully be ascribed as the father of Natural Hygiene or Life Science, for he is the first to attempt a systematic ascertainment of the physiology of health and disease.

The next illustrious forefather of the science of health was Sylvester Graham. He was born six years after Dr. Jennings in 1794. He was a very sickly boy. Becoming healthy was an obsession with him which led him to study health. He became well versed in anatomy and physiology. Before coming onto the health scene, he was a Presbyterian preacher. In 1830 during the temperance movement, he lectured in Philadelphia on the physiological evils of alcohol. As a firebrand orator he was amazingly effective with large audiences. In Philadelphia he expanded his knowledge of physiology and health and became acquainted with the teachings of a "vegetarian" group who abstained from animal foods and products and many modern ways of preparing foods. This group was known as the Bible Christian Church and based its mode of life on Biblical commands.

In the great cholera "epidemic" of 1832 Sylvester Graham rose to fame. He literally took on the whole medical fraternity of New York City and the interests supporting the medical system. While the medical men were advising New Yorkers to abstain from fruit and to cook their food thoroughly, Dr. Graham was advocating eating more fruits in the raw state. He advocated open windows, more light, and fresh air and other healthful measures which were contrary to medical teachings. It is noteworthy that those who followed Dr. Graham's teachings were not affected by the cholera epidemic, whereas those who followed medical bidding died wholesale.

His fame as a health lecturer was well established in 1832 and he, more than anyone else, gave health science a tremendous impetus. He was in demand as a lecturer over the whole Eastern seaboard. He appeared before audiences of several thousand. People flocked to his lectures and listened to them raptly for hours in seeking salvation from disease and suffering.

So effective was Dr. Sylvester Graham in his lectures and writings that books and magazines blossomed presenting the "Graham system." The first health food stores came into existence to sell foods which he advocated. Special eateries and living facilities were established for those who wanted to follow his system. The name of Graham became synonymous with the Hygienic diet and Hygienic living.

Where Dr. Isaac Jennings approached health and healing from the point of view of helping people regain health, Dr. Sylvester Graham was instrumental in teaching the touchstones of healthful living so that people would not become ill in the first place.

During the 1840's, Dr. Jennings and Dr. Graham were joined by perhaps one of the greatest geniuses the movement has produced, Dr. Russell Thacker Trall. His was an inquiring methodical mind that ever sought the rationale and scientific basis for the concepts and findings developed by his predecessors. Thus he brought the Hygienic system to a standard that could thoroughly challenge the medical system. Dr. Trall delivered a lecture in the Smithsonian Institute to some of the nation's highest dignitaries in 1863. The title of the lecture was THE TRUE HEALING ART. It made quite a ripple during the time. Dr. Trall is the originator of the famous challenge which, though oft-repeated, has never been accepted by a single physician unto this day. This challenge is stated below:

1. That the medical system is ENTIRELY FALSE. That it is untrue in philosophy, absurd in science, in opposition to natural principles, contrary to common sense, disastrous in results, and a curse to humanity.
2. That the Hygienic System is TRUE. That it is in harmony with nature, in accord with the principles of vital organic existence, correct in science, sound in philosophy, in agreement with common sense, successful in results, and a blessing to mankind.

The new system of health did not discriminate against women. In fact it encouraged women to participate in the movement on an equal footing with men. Among the notable women in this new movement were such luminaries as Florence Nightingale, Mary Gove, Harriet Austin, Susanna May Dodds, Ellen White (guiding light of the Seventh Day Adventists), and Louisa May Alcott, the famous author whose brother became an M.D. and a Hygienic professional.

In the 1870's the medical profession adopted the Pasteurian germ theory with a passion. People found it much easier to blame their problems on little mysterious beasts rather than on their mode of living. No matter what they did they were absolved of responsibility for their condition. The germ theory made them unfortunate victims of malevolent entities over which they could exercise little control.

With the ushering in of the "germ era" came about the decline of Hygiene. While the philosophy remains alive and still receives a good following, it has been in continual decline relative to our population. In recent years there has been growth in the ranks of those practicing Hygiene in their lives, but there are yet only a few thousand devoted Hygienists.

The revival of Natural Hygiene in the 1920's owed much of its impetus to the efforts of Bernarr McFadden and Dr. Herbert M. Shelton. Though there were some great Hygienists in the early part of this century, notably Hereward Carrington, Otto Carque, John H. Tilden, and Linda Burfield Hazzard, Dr. Shelton became the acknowledged voice of Hygiene with the publication of his immortal book, "Human Life, Its Philosophy And Laws", in 1927. Though Dr. Shelton built upon the shoulders of his predecessors, he produced such a wealth of literature with new findings and thoughts that he added more to the science and art of healthful living than any other person. He had the benefit of new findings, and his fertile mind generated a new body of knowledge based on them.

Today the Hygienic movement still survives though it cannot be said that it thrives. A few thousand Americans practice it conscientiously. A greater multitude pay lip service to it and practice healthier living because of it. But, by and large, Hygiene is almost completely out of the mainstream on the American health scene.

In this lesson we cannot hope to more than summarily deal with Hygiene's history. Books on the history of Hygiene are practically nonexistent. It must be picked up in fragments here and there from books and magazines that make reference to the past. You'll pick up the history of Hygiene throughout your studies. Perhaps, someday, a history will be published.

## 6. Questions & Answers

### What do the words Natural, Unnatural, Normal, and Abnormal really mean?

Natural or normal is that to which we became accustomed while living in a pristine state of nature and that to which our bodies were adapted. That which is contrary to our adaptations, that is, to our biological heritage, is abnormal and unnatural.

### What are biological adaptations?

Biological adaptations is a term to describe the faculties an organism has developed to meet its requirements in the environment in which its growth has occurred. What is natural to an organism depends on its environmental adaptations.

**Would you say carnivores are biologically adapted to meat-eating because of the structure of their teeth and other body structures?**

Yes, I'd say that. Animals that live primarily upon meat have developed the tools or faculties for securing their food supply and best digesting it for their physiological needs. Animals that have claws and fangs are usually carnivores.

**Are we adapting to our present environment?**

Probably, but not perceptibly. A social adaptation or accommodation is not physiological and anatomical adaptation. Biological adaptations are slow and often require hundreds of thousands of years to come about. For example, when humans started eating meat, they did not during all their meat-eating days over a period of several thousand years develop fangs, claws, or the concentrated hydrochloric acid solution that characterizes meat-eating animals. You need but look at Eskimos to see confirmation of this. Animals adapt very slowly to changed conditions. On the other hand if there is a failure to adapt or the change is too quick, the danger of extinction exists.

**In nature there are checks and balances. Isn't something like the black plague a natural check on the population?**

No. In nature there are no such things as checks and balances in that context. In normal circumstances there are periods of famine and periods of feast. When there's famine, death overtakes many of the organisms that are victims of the scarcity. When there's a feast, a rapid multiplication occurs. Organisms in nature live in symbiosis with each other and a balance exists amongst them according to the food chain. For instance, if you study and witness insect hordes, you'll learn that when they are thriving on abundant vegetation there is a corresponding increase in their predators, that is, birds and other animals that feed upon insects. When the insect population is practically wiped out the predators decline in numbers. These are the only kinds of checks and balances that exist in nature. Nothing can exceed its possibilities.

What you call calamities cannot be in any sense referred to as natural. A plague or any sickness or disease is not natural. It happens because an organism has lived contrary to the laws or principles that apply to its life. When we contravene the laws of our existence, we will incur disease. Diseases or plagues are in no sense checks and balances. If humans live in pathogenic perversions they'll develop diseases and die amidst plenteousness.

**What is your opinion of holistic health?**

Those who are striving for something better than the medical system with which they've become disillusioned must be admired for both their perspicacity and their courage in undertaking an independent course. We Hygienists may not agree with the course or courses they've chosen as an alternative, but we hold they have every right to pursue it as is their bent and persuasion. The word "holistic" derives from the word "health" which, again, means "whole," "complete," or possessing fullness of function. The word "holy" also derives from the word whole or healthy, although we have lost sight of this.

What we call "holistic health" in current society is a catchall of all modalities. The term is a tautology. It's like saying "healthy health." But the holistic movement involves M.D.'s, homeopaths, chiropractors, osteopaths, naturopaths, herbologists, acupuncturists, polarity therapists, foot reflexologists, and just about anything else that attaches itself to the movement. The holistic health

movement embraces anyone who wants to join it.

Hygienists who bring their philosophy with them are not accepted in the holistic movement. To be accepted into the movement you must be of a "curing" frame of mind, that is, basically medically oriented. This movement is therapy-oriented rather than health-oriented. However, some of the practitioners in the movement, notably the naturopaths, do recognize that we must remove the causes of disease in order to establish a basis for health. Even some chiropractors are enlightened in this regard. There are, in fact, practitioners in all schools that recognize the real needs of the human organism and advise their clients of these needs.

We call ourselves wholistic. To us this means that we embrace every facet or condition that touches upon human welfare. In the sense that we recognize that health is realized only by the length and breadth of the living regime, we're wholistic. But we do not identify with the current movement that calls itself holistic.

**I think you're wrong about all healing being self-healing. I've personally seen a woman who had a leg ulcer for over a year. Topical application of comfrey poultices healed it in less than ten days. How can you deny that?**

I do not deny that the leg ulcer healed, and I do not deny that the comfrey poultice was the agency that precipitated the healing process of the leg ulcer. But the body is probably worse, not better for the treatment.

What happens physiologically to cause the ulcer in the first place? Why do they sometimes persist only to heal later? What happens when the agency of toxic materials such as in garlic, aloe, comfrey, or in pharmacological preparations are applied and the ulcer is healed?

The comfrey poultice neither caused nor healed the ulcer. The body created the ulcer in the first place just as it creates a boil, fever, pimple, or other so-called infection. The body creates these conditions as outlets for an extraordinary load of toxic materials. As long as the body is burdened with toxicity that it cannot eliminate through normal channels, it will utilize vicarious outlets, i.e., outlets other than normal. As long as the practices introduce into the body toxic materials and the sufferer's habits are such as to cause the body to retain its own metabolic wastes, then the body will protect itself against a death-dealing situation by getting rid of its problems any way it can. An ulcer is created in two ways. First, a lesion can be created by the body through self-autolysis of its tissues. The body causes the self-digestion of a hole to the surface in the case of a boil or pimple. It is the body that forces toxic materials into the hole it has created to the surface. It is the body that creates the tremendous pressure necessary to keep the pus and debris near the surface in the form of a boil until drainage or expulsion occurs.

Just so it is the body that causes the ulcer in one way or another. Probably the leg ulcer was caused by the body's collection and concentration of poisons in a given area until the cells and tissues of the area were totally destroyed. Then the body utilizes the open sore as a drainage outlet much as a teakettle will discharge its steam through a blown hole after the hole is blown. When aloe vera, comfrey, or certain pharmaceutical preparations are applied, they do not solve the body's problems. Herbs and drugs have not the intelligence or power to create cells and new tissue to bridge the chasm or gulf that constitutes the ulcer or lesion.

What happens is that the poultice or drug application applied to an open sore poses a new danger. Absorption of poisons from the outside causes the body to change strategy. Where it had been exuding poisons to keep them low, the body is now absorbing poisons there. To obviate this new threat the body closes up the dumping ground and seals it off from the outside by scarring it over.

Though the body healed the ulcer, it is now worse off than before. It is retaining the toxic material previously expelled through the open sore or ulcer. Either it must now create a new extraordinary outlet or suffer the retention of the toxic materials it previously expelled through the ulcer. Had the ulcer sufferer fasted, the ulcer would have healed more quickly than with the application of a poultice. Moreover, the body would, under the fasting condition, be free of the input of toxic materials and toxigenesis due to enervating habits. Under this condition it can accelerate expulsion of toxic materials through regular channels. Once the level of toxicity has been reduced below a certain tolerance level, the body will promptly proceed to heal the ulcer. Healing takes place much more quickly under the fasting condition than any other. While fasting, the body can concentrate its energies and its material resources to the healing process, thus affecting healing much more speedily.

So, the comfrey poultice did not do anything other than become a source of irritation. The body "closed up shop," so to speak, at the ulcer site and did business elsewhere. Keep in mind that all healing is a body process and never that of drugs. And let us not mistake the drug nature of comfrey. It contains pyrrolizidine and allantoin, two quite toxic alkaloids or glycosides.

**Are you telling us we'd get along better without doctors and healers? Does not nature furnish natural remedies for our problems?**

I just furnished an example of the physiological *modus operandi* of the body under the influence of toxic materials. I had hoped that would suffice to dispel any ideas that healing can be effected by extraneous agencies.

Yes, we would be better off without physicians, miscalled doctors, and so-called healers. We do need teachers to help people see their errors concerning health. We need teachers to get them on the right biological track so they can lead healthy and happy lives. Nature never developed humans or other animals so that remedies are needed in the first place, and it never created remedies in the second place. These interpretations errant humans have ascribed to disease and healing phenomena are based on illusory appearances. The only remedy for any ailment is the capacity of the body to right itself once the assault upon it has been discontinued.

**Aren't diseases caused by germs and viruses? Surely you can't mean that millions of physicians the world over are wrong about this?**

We'll get into the depths of these matters in subsequent lessons. But the answer is no: germs do not cause disease. They can, at worst, complicate them secondarily. Bacteria are our symbiotic partners in life. Partners accommodate each other for mutual benefit. Viruses as an entitative existence are a medical myth. If diseases are caused by uneliminated metabolic debris, which is what so-called viruses are, then the medics have a point. But we Hygienists call that metabolic debris retained wastes, not viruses. "Viruses" are nothing more than the proteinacious debris of spent cells. Their accumulation can precipitate a healing crisis in the body. When this occurs, the body is likely to transport bacteria to the scene to aid it in cleaning up the mess, but the bacteria did not cause the problem. The habits and practices of the sufferer must be looked to as the real culprits. Once these deleterious habits and practices are discontinued, there will be no further toxic accumulations and thus the need for disease or healing crises will cease to exist. Sickness-free health will exist thereafter.

**You say that disease is abnormal. Everyone has been sick at some time or other. Haven't you ever been sick? If everyone gets sick, wouldn't you say getting sick is a rather normal thing?**

Yes, it is undeniable that disease and sickness are normal in our society. That is one reason there's a great need for enlightened Life Scientists to be on the scene. We can put an end to this misery.

Let us not, however, confuse what is normal in nature and what is normal in a vitiated society. Disease is a normal body response to an abnormal toxic condition. But the toxic condition is, let us recognize, abnormal.

### **You talk about Life Science as a cure-all. Aspirin will cure a headache, at least for a while. Can Life Science cure a headache?**

Those practices which, aggregately, we term Life Science, are, indeed, a panacea, a cure-all. Correct diet and health practices build health, not disease. Aspirin does not "cure a headache." The problems remain as before plus the toxic presence of the aspirin itself. Aspirin merely causes our body to paralyze or incapacitate the nervous system. Just because you remove thermometers does not alter the temperature. The fact that the body finally expels the aspirin from its domain and reinstates the processes that give rise to another headache is ample indication that drugs solve no problems. Under the Life Science regime all causes of headaches are removed. Causes of health are instituted. This is the ultimate solution to the problem of disease and suffering. When there are no causes there can be no disease. When only the causes of health are indulged, only health can result.

[Home](#) > [Lesson 1 - Introduction To Life Science As A Way Of Life](#) > Article #1: The Return To Perfection by Dr. Herbert M. Shelton

### **Article #1: The Return To Perfection by Dr. Herbert M. Shelton**

Our word health is derived from the Saxon word for whole. Heal is derived from the same word and means to restore to a state of wholeness, soundness, integrity. Holy comes from the same root and signifies wholeness and purity of mind. Taken in its fullness of meaning, health means completeness and perfection of organization, fitness of life, freedom of action, harmony of functions, vigor and freedom from all stain and corruption—in a phrase, it is "a sound mind in a sound body."

### **Condition of Perfection**

Health is a condition of perfect development, a state of wholeness and harmonious development and growth and adaptation of part to part of the organism, of organ to organ, with no part stunted and no part in excess. In this state of organic development lies the perfection and symmetry of beauty. Beauty is but the reflection of wholeness, of health. It is easy to demonstrate that the forms and proportions of man and of every animal and plant which are in their highest and most useful state are also the most beautiful.

When every bone is of the best form and size for its service in the total organism, there is perfect proportion; when every muscle is fully and proportionately developed, with just enough fat in the cellular tissues to round out the muscles, we have the highest beauty of form; when the texture of the skin is finest and the circulation of the blood most vigorous, the blood well nourished and freed of all waste, there is the glow and charm of the finest complexion. The highest beauty is the expression of the highest health.

### **Beauty Fades with Loss of Health**

Partial beauty, fading beauty, decaying beauty—these are but the expressions of partial, fading or decaying health. They represent unsatisfactory and painful states of existence. Beauty belongs to glowing health and perfection of organization. It is impossible for us to separate these ideals. We cannot picture health in terms of the conventional, for contemporary man is far short of this wholeness of organization and vigor of function that is health.

## **A Picture of Health**

If we try to picture health what do we see? A form of perfect symmetry and proportion; a clean, smooth, semi-transparent skin, with the red blood shining through, especially in the cheeks and ends of the fingers and toes; glossy hair that is full of life; clear, bright eyes that are full of expression and dance with life; rosy lips that smile with the joys of life; pearly white, sound, even teeth; a breath that is as sweet as that of a flower in the springtime; freedom from disagreeable body odors, indeed, where health is perfect, emitting an agreeable aroma; a body that is filled with activity, delighting in work or exercise; and a happy, courageous, mirthful, and hopeful disposition, and a desire to help others.

Such a picture of health can come only from the orderly, regular and perfect performance of the functions of life—from a sound heredity, a congenial environment and conduct that conforms with the constitutional nature of man. Health is the perfect combination of bodily organization, intellectual energy and moral power in harmonious unity. It means perfect organization of brain and nerves that are as finely proportioned as the bones and muscular system. In a healthy person we would expect to see the symmetry and proportion of head of the Cro-Magnon, not the asymmetry and disproportion of head of modern man.

## **A Perfect Instrument Perfect in Every Respect**

As every organ of the body is essential to wholeness and integrity of structure and vigor of function, no organ can be spared. Not merely must the nutritive and drainage systems be perfectly adapted to the requirements of the brain and body, but the smallest and apparently least important parts of the body must be harmoniously and fully developed. As Dr. Nichols so well expressed it: "The smallest instrument out of tune brings discord into the harmony of life."

How is such a high state of health to be attained? How may we assure wholeness and fullness of development; vigor of function and freedom from disease and suffering? How may man be returned to that soundness and integrity of structure and vigor and force of life that he knew in the morning of his existence? If contemporary man is so lacking in health that he is but a puny specimen of manhood, how can he be restored to his pristine power and majesty? In a word: How may man be healed?

## **Living in Accord with Natural Law Produces Perfect Health**

It should not require argument to convince the intelligent man and woman that this can be done only upon a basis of law—natural law—specifically, upon a basis of those laws that operate to make human life possible. All laws operate to make human life possible. All laws essential to the welfare of man are written in his own constitution. Every rule of human conduct, to be valid in promoting human welfare and happiness, must be in harmony with his nature. No law, no social custom (convention), no moral precept can have any reality to man that does not accord with his highest welfare. If it is not intimately related to man's highest fitness—physical, moral and intellectual—it cannot correspond to his highest ideals of truth, duty and enjoyment. The unperverted instincts of wild animals living in their natural homes are the laws of their lives. There seems to be no reason to doubt that man's instincts were once equally perfect guides in his ways of life. But if this was ever true, it certainly is not so today. Man's instincts have been so smothered and buried beneath a layer of cultural baggage that they no longer constitute reliable guides to him in his way of life. They have been "conditioned" until they are misguides.

## **Health-Sapping Perversions Begin Early In Life**

Nonetheless it is true that even now instincts are fairly reliable guides to conduct in the young. But we begin the process of perverting these instincts almost from birth. Instinct does not leave us unwarned when we take our first smoke, but social usage demands that we ignore the warning and suppress the vigorous protests of instinct. We must learn to smoke, even now that we are aware that the end may be death from lung cancer. Today we may get our first smoke second-hand as mere infants. Smoking in the house has become almost universal. Many

babies are sickened and even killed by the unintelligent practice of fathers and mothers filling the house with the poisonous fumes of burning tobacco.

We are not left unwarned by our first effort to develop alcoholism. The first drink of beer is obnoxious. Wine both smells and tastes fermented, and it is. The first drink of brandy or whiskey burns and bites, it smarts and stings as it goes down, there is protest every inch of the way. But we ignore these protests, we disregard these warnings, we are determined to "grow up," and the only way this can be done in our society is to become an addict of one or more kinds.

## **Bad Practices Produce Human Wrecks**

Coffee and tea are reproaches to both our sense of smell and to our sense of taste. They produce a "high" state that should not be mistaken for vigor and well-being; they interfere with sleep, keeping us awake for hours. But we ignore these warnings of the faithful sentinels of life. We suppress the urge to flee from such poisons. We are determined to *belong*. We want to be "one of the gang" even if we have to wreck ourselves in the process.

We have learned to take the miserable fragments of natural-foods with which the food processors and refiners have flooded the market, fragments that lack all appeal to our gustatory sense, and to add sweetening, colorings, flavorings, etc. to them to make them appeal to the senses of sight, smell and taste in spite of their unfitness to serve the needs of human nutrition. We eat them, little thinking that they do not represent true foods or that they may prove to be actually hurtful. We have found ways to get unfit substances by the guards that stand at the entrance to the alvine canal. We have found ways to deceive ourselves and to wreck ourselves without knowing that we are doing it.

## **Disciplined Correct Life Practices Will Restore Pristine Perfection**

For the evils of ignorance the remedy is knowledge—for the evils of false ideas the remedy is truth. For the source of truth and knowledge we have nature—especially human nature. Only when truth and knowledge are universal can we expect men and women to cease injuring and destroying themselves in riotous indulgence in tobacco, alcohol, and foodless food. In the spread of Natural Hygiene lies the hope of the future.

[Home](#) > [Lesson 1 - Introduction To Life Science As A Way Of Life](#) > Article #2: What Is Health?

### **Article #2: What Is Health?**

Health does not consist merely of the absence of symptoms of illness. It is a state of positive well-being that is evidenced by a constant state of euphoria. It is rarely, if ever, experienced by humans today.

### **Various States of Existence**

We could well divide the people we meet into the following categories:

1. People who are definitely sick.
2. People who are on the borderline of sickness.
3. People who are apparently healthy.
4. People who enjoy high-level health.

The first three groups constitute the vast majority of our population. Perhaps only a mere handful of our youth

could fall within the last category. Great vigour and the buoyant feeling of well-being are extremely rare in our populace.

### **Delineating Health**

Health is a state of soundness and integrity of organism; vigour and efficiency of function; and excellence of mental faculties. Much of this well-being springs from antecedent heredity but that is merely the base requisite to building and maintaining health.

Health manifests itself by such a feeling of tone in the entire organism that the body fairly glows with it and bespeaks it at every turn. There is cleanliness and sparkle to the eyes, clearness and fine color to the skin, vigor and activity and bounce to the step, and an evident feeling of joy of living that is infectious.

We witness traces of the pristine vigor and well-being in our youngest children. Rarely do we observe exuberant physiological excellence beyond the age of six. If we really want to see vigor we must watch the young of animals.

This vigor is possible to humans throughout most of their lives.

## Lesson 2 - The Nature And Purpose Of Disease

- [1. What Is Disease?](#)
- [2. Purposes Of Disease](#)
- [3. Toxemia Is The Universal Cause Of Disease](#)
- [4. Natural Hygiene Or Life Science Care Of The Ailing](#)
- [5. The Character Of Disease](#)
- [6. Questions & Answers](#)
- [Article #1: A True Perspective Of Health And Disease by Dr. Herbert M. Shelton](#)
- [Article #2: The Nature Of Disease: Its Cause And Purpose by Dr. Hereward Carrington](#)

Inasmuch as we're having only one lesson specifically on the subject of disease, I bid you to study hard and absorb it well, for nearly all your clientele will suffer disease in one form or another.

In this lesson we will ascertain what disease is, what brings it about, what purposes it serves, and why it ends at all in view of the fact that it is supposed to be an occasion when malevolent microbial entities have gained a destructive foothold in our bodies. We will explore how a body in descendancy (as it is said to be in disease) and microbes in ascendancy reverse these tendencies.

### 1. What is Disease?

- a. Disease, as a word, means very simply not at ease—a person is uncomfortable or suffering difficulties in maintaining energies for the functions he wishes to discharge and in keeping operative those faculties he wishes to exercise.

In physiological terminology, disease means deviation from normal. That means that the body has deviated from regular functions. In a state of disease the body has rechanneled or redirected its energies so that it has less than usual energy for functions normally engaged in.

- b. There are two distinct types of disease. The first type of disease serves a purpose and the second type serves none. Discerning these two types in your clients will be no problem at all. These two types of disease are as follows:
  1. The first type is constructive disease, often called acute disease.
  2. The second type of disease is degenerative. This results from organic impairment in which organs, tissues, bones, or other faculties have undergone destruction, distortion, or irreversible impairment.

Your service to your clients will largely depend on your ability to recognize whether a disease is constructive or degenerative. I repeat: this is not difficult. You will, regardless of these conditions of disease, still proceed by guiding your client into healthful practices, healthful practices being the universal panacea.

If diseases are remediable and reversible as most of them are, it is constructive. When disease can no longer be reversed through body remediable processes, it is degenerative. For instance, an arthritic's bony deposits can usually be autolyzed and restored to near normal. But when ankylosis has occurred due to destruction of bone and cartilage and subsequent fusing, healthful practices will restore health

except for the ankylosis—it is rarely reversible. However, many diseases commonly regarded as degenerative can be corrected by the body, most cases of arthritis being among them.

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > 2. Purposes of Disease

## 2. Purposes of Disease

Disease affects the whole body, not just a part. Disease serves an important body purpose. The body initiates remedial diseases to accomplish a goal. The goal serves the whole body, not just an organ, area, or part. For instance, we can know we have diseased kidneys. But, in actuality, the whole body is diseased. The fact that the symptoms are noticeable only in the kidneys does not mean that the rest of the body is unaffected—it means that the kidneys are the focal point for the eliminative effort, the point at which toxic matters are put out of the body.

Everything that affects any part of the body affects the whole organism. If we have a bad back, the whole body is affected. We are concerned about the welfare of our toes, fingers, ears, legs, eyes, arms—we defend our whole being because our whole body is a single unit. There are no isolated parts about which we are unconcerned, either at the conscious or unconscious level of intelligence. We defend it all at all levels because it is all of us.

We don't have a disease here or a disease there. It's suffered all over. An inflamed appendix has been overloaded with toxic materials because the body is overloaded. Body intelligence puts the overload out through all channels of elimination, but despite this the load is so great the appendix is burdened with more than it can handle. This condition is the same in all remedial diseases where a local organ seems to be the only thing affected.

### 2.1 Disease Is Started by the Body

The body itself institutes the crisis known as disease. Life Scientists call this process a "housecleaning" or healing crisis. Such a procedure by the body is instituted when bodily integrity is compromised or threatened by an accumulation of uneliminated toxic materials. The level of vitality and the extent of the overload determine the type of crisis. Given high vitality as in an infant, a very low level of toxicity is tolerated. In infants, colds are frequent. Given low vitality as in most older people in our society, colds are a rarity. Because so few older people maintain vital bodies, the toxic overload drags them down into chronic diseases, degenerative diseases, and unsuspected pathology that leads to unexpected death or a "sudden onset" of cancer.

The body must be in a toxic state before it will institute a crisis. Neither bacteria nor anything else starts and sustains a crisis. Microorganisms are incapable of unified action; in fact they cannot exist where there is no food (soil) for them, and living cells are not soil for bacteria.

Bacteria are helpless against living cells. An "invasion" by bacteria such as we imagine in contagion never takes place. The bacteria that proliferate in a crisis are with us all the time. We harbor uncounted billions of microorganisms in our intestinal tract, on our skin, in our mouth and nose and other body cavities. Thus, the body is the ONLY actor in the crisis of elimination or cleansing called a disease.

Bacteria and viruses cannot be blamed for disease.

Blaming disease on viruses or bacteria is an easy cop out. It's not good business to tell a client that they have caused their own miseries, so the medical profession has blamed suffering on everything but the individual's own failure in the game of living.

## 2.2 Disease Is an Eliminative Process

The body creates a crisis in response to a body need to free itself of toxic matters and repair damages. Consequently, the body withdraws energy from normal body activities and redirects them to the healing crisis.

*I could tell you that I am suffering a disease at this moment. I'm not at ease with my larynx as you've noticed in my trying to clear my voice. I ate some cabbage for my evening meal. It was very sharp as it had some mustard oil in it, without doubt. Typically any irritant in the throat, esophagus or windpipe will occasion the flow of mucus which encompasses the irritant for the purpose of ejecting it from the body. In my case now, the body has started a mucus flow to clear the passage of what was regarded as toxic or irritating substance. This is a minor disease or unease. But it is disease and the body reacted to maintain its functional integrity.*

The body will reject anything that's irritating. For example, if dust is put into your nose, the body will secrete mucus to surround and eject the dust irritant. Or you may sneeze. In both cases, the body is acting defensively. Thus, all remedial disease is body-defensive action.

Bacteria do not invade organisms for they're always within the organism. Even after we've lost our intestinal flora after fasting, bacteria are still there. Bacteria can in many cases do what bears and many other animals do—hibernate or become dormant. Pasteur was not the father of bacteriology as many people think. Antoine Bechamp was the father of this science. Bechamp was a scientist in the true sense of the word. He took what he called microzyma from the chalk cliffs of France. He found that, upon furnishing water, warmth and other nutrients, the microzyma proliferated. These microorganisms had been entombed for ten million years in a state of dormancy. So bacteria have certain qualities for survival that most are not aware of.

The celebrated Dr. Lewis Thomas who heads the Sloan-Kettering Cancer Institute said, "pity not the man who has caught bacteria; pity the bacteria that was caught by the man." This is to say that humans furnish a very rough environment for bacteria. The body keeps them restricted within certain bounds. The body controls bacteria at all times. The body is master of its domain.

Bacteria do not control the body as medical people have led us to believe.

Following are two paragraphs from a "bible" on Natural Hygiene, Dr. Shelton's first major work, *Human Life: Its Philosophy and Laws*.

"For ages the study of disease has progressed. One by one the various systems and system complexes that are presented by the diseased human body have been studied with painstaking care in both living and dead bodies. The study of pathology has reached a degree of perfection unknown to most of the collateral sciences that form what is called the science of medicine. Knowledge of pathology increased by leaps and bounds after the invention of the microscope, until today pathology is one of the most important studies for the medical student. Physiology, anatomy, histology and biology are all made subservient to pathology.

"The study of disease has fascinated the student for ages. Health has received scant attention. Strange as it may appear, health has been considered of so little importance as to be unworthy of investigation. No schools ever existed for teaching the conditions of health. Medical schools existed to train the student in a knowledge of disease and cures. Even today no school exists that has as its purpose the teaching of the conditions and requirements of health. The conditions of a healthy life are but little understood by the various healing professions and still less so by the general public. Health is not in the professional line of the physician."

The medical world is preoccupied with treating disease with drugs that are currently in fashion. Their seeking out of bacteria and "viruses" as culprits in disease reminds me of a little joke we heard back after the Second World War. It goes like this.

During the Second World War a German civilian worked in a concentration camp. One evening he pushed a wheelbarrow to the exit gate for inspection by a guard. The wheelbarrow was loaded with rags. The guard, very conscientious about his job and the security of the camp and its assets, methodically went through the rags but found nothing. So he waved the worker through the gate.

The very next day the worker came through with a wheelbarrow of newspapers. The guard repeated the previous careful examination. The following day came a wheelbarrow of leaves. Again the same thorough inspection.

The day following this the worker came to the guard pushing a heavy load of dirt. The guard was not going to be fooled. He made the worker dump the dirt and spread it out, then laboriously reload it on the wheelbarrow.

The next workday came another load of newspapers. The guard was very suspicious that the worker was sneaking something out. So, in addition to other procedures, he tapped the handles and other places for concealed material that the worker might be stealing. But nothing was found.

This went on almost every workday for a year. On occasion the guard systematically searched the wheelbarrows but never found anything of value being removed from the camp.

By and by the war was over. A while later the former guard met the former construction worker on the street.

He went up to the worker and stopped him abruptly with this smiling demand:

"Hans, you have to tell me something. I'm no dummy. You were stealing something from the camp. I could never find it. Now that it doesn't matter, why not let me in on it?"

Hans replied, "Why, dummkopf, you saw it with your own eyes. I was stealing wheelbarrows."

Such blindness characterizes the medical profession. The purpose of disease is so evident that the medics can't see it. They are looking for something that doesn't exist, and they have no idea, after countless millions of man hours of chasing microbes and similar deadends, that viruses as living entities do not exist.

So they have gone into the phenomenon of disease elaborately and have chronicled over twenty thousand different diseases. They name them after the area that is most affected. Sometimes they have multiple names because of the number of organs or organ systems or tissues which are affected.

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > 3. Toxemia Is The Universal Cause Of Disease

### **3. Toxemia Is The Universal Cause Of Disease**

Actually, there is only one disease, no matter how it manifests itself. And the disease, which we call constructive disease, is occasioned by the body itself and is known as a crisis of toxemia or healing.

#### **3.1 The Seven Stages of Disease**

There are several stages of disease. The underlying cause of disease in all stages is toxemia. Although

toxemia may arise from many sources, it basically exists because of insufficient nerve energy to sufficiently eliminate exogenous poisons and body wastes. Toxemia is not broad enough a term to cover the whole poisoning process for it means poison in the blood. Actually toxicosis exists. Tissues, cells and interstitial spaces are also toxic-laden. In short, the whole body is toxic.

Diseases present many different aspects because they evolve with the progressing deterioration of the organism that suffers them. Disease has seven distinct stages. These stages correspond to the distinct differences of each stage of evolution.

### **3.1.1. Enervation**

The first stage is not even recognized by physicians as a disease. Life Scientists call it enervation. Most people call it nervous exhaustion. Enervation is a state in which the body is either not generating sufficient nerve energy for the tasks the body must perform, or the tasks the body must perform may be greater than the normal nerve energy supply can cope with. In any event, the body becomes impaired, and an impaired body generates less nerve energy if the conditions of overwork or under-generation persist. Most people know when they are nervously exhausted.

Enervation can be caused by depletion of nerve energy in any of hundreds of ways. Sleep regenerates nerve energy. Obviously, insufficient sleep will not supply us with our needs. It will not fully recharge our batteries. We need sleep to regenerate nerve energy for the brain and nervous system.

Nerve energy is a form of electricity measurable in millivolts. Sleep laboratories have successfully substituted electricity in place of the body's own. When this is accomplished it is called electrosleep. It takes only two hours out of twenty-four to fully restore nerve energy in this manner.

Demonstrating that nerve energy is electrical is easy. If you mashed your finger, a message would immediately go to the brain and back would come a command to remove the finger from that which applied the pressure. Moreover, the brain would command the entire balance of the body to cooperate in the extraction of the finger from the offending pressure. Only electricity is capable of such speedy transmission. No chemical process or circulatory process is capable of this dispatch. It occurs only through a network of nerves with conductive abilities, and electricity is the only form of energy it can conduct. If you take a weak voltage and hook up to it while holding someone else's hand, the other person gets a shock immediately when you touch the live electrical source. I don't think anyone can doubt that we do generate electricity, and that is the form of energy we use to conduct our physical and mental activities. Sensations are transformed into electrical stimuli and forwarded to the brain. The brain interprets these and sends out commands based upon the interpretation. Thus, if you put your finger to a hot object, the finger is commanded in a flash to withdraw from it.

The foregoing is to demonstrate that the body is primarily an organism that works on the amount of electricity it generates and which it has in its reserves. If this supply is depleted or otherwise insufficient to cope with the needs of the body, then body functions become impaired, including the processes of elimination of both endogenous metabolic wastes and exogenous poisons introduced into the body. This impairment begets further impairment including diminishing the body's ability to restore depleted nerve energy. The body starts going downhill. The next stage of this decline is called toxemia.

### **3.1.2. Toxemia or Toxicosis**

When toxic substances from whatever source saturate the blood and tissues, the lymph system and interstitial fluids, then the conditions of toxemia and toxicosis exist.

As functioning organisms, we generate a tremendous amount of toxic by-products. We generate enough carbon dioxide to kill us within a few minutes. If our lungs failed to function, carbon dioxide buildup and lack of oxygenation would overwhelm us quite quickly. We can accommodate only so much carbon dioxide. And this is but one of many waste products. There are trillions of cells in the human body. Tens

of billions of these expire every day. They are replaced by new cells. The old cells are broken down by lysosomes, enzymes that reside in a little organelle within the cell itself. Upon cell death, these enzymes break the cell down into many smaller components for elimination. These components are cell debris. Some of these components such as iron, protein, and amino acids are recycled by the body. Some 95% of the body's iron needs and 70% of its protein needs are met by recycling. Certain other of the body's needs are met by recycling as well. This will give you some idea as to the immense providence and wisdom of the body in meeting its needs. Other components of the decomposed cell are the RNA and DNA. These are toxic while in the system. If they accumulate as they do in most humans in today's society, a condition of intoxication (toxemia and toxicosis) exists. These are what medical people call viruses, and they mistakenly attribute to this dead debris the powers of life and malevolence.

Tissue and blood saturation with toxic materials can be caused by both internally generated wastes and pollutants taken in from the outside which the body has not been able to eject from the vital domain. Intoxication occurs when we overload the body with toxic materials from the outside, or we fail to observe our capacities, and overwork, get insufficient sleep, or are subjected to great stress, or when any number of other factors deplete the body of nerve energy or prevent its sufficient regeneration. For instance, stresses, emotional shocks, or traumatic experiences can drain our bodies of nerve energy very quickly. It's just like shorting out the battery of a car.

At some level of intoxication we begin to experience the next stage of disease which is called irritation.

### **3.1.3. Irritation**

Irritation results from toxic materials being sensed by our nerve network. Most of us pay this stage little mind, and certainly physicians do not pay it heed. When we feel itchy, queasy, jumpy, uneasy, or when we have bothersome but not painful areas, irritation exists. Tickling of the nose is a form of irritation. Collections of mucus along the mucus membranes irritate, although irritation is not painful. It is a gentle prod that moves us to seek comfort, to establish freedom from it. For instance, the urge to urinate or defecate is a form of irritation due to accumulation of wastes greater than the body feels comfortable with. However, the urge is not painful unless it is ignored until it creates too much pressure in its area. Near painful irritation forces us to deal with the problem.

When a person drinks too much alcohol we say that he or she is intoxicated. That's a good example of exogenous intoxication. While all alcohol intake is damaging to the organism, the body can speedily eliminate a small amount before much damage has occurred. Increase the intake, and the elimination is proportionately less and the damage proportionately greater. The first drink of alcohol occasions only irritation which we also call stimulation. But any toxic material, be it salt, caffeine, or condiments will irritate or stimulate. This is a condition wherein the body sets in force its defensive mechanisms and accelerates its internal activities. This might well be likened to an alarm aboard ship where all hands are summoned. A frenzy of activity results in a bout with enemy forces. Unfortunately, this often makes us feel good or hyper or even euphoric. It is distressing to see a euphoric condition arise out of a situation that is damaging to the organism.

If the causes of enervation/intoxication/irritation remain in force and the body can't cope with it the body initiates a responsive crisis called inflammation.

### **3.1.4. Inflammation**

This is usually the stage in which physicians recognize pathology. It is the stage where sufferers are keenly aware of a problem, for it involves pain. As well, it involves bodily redirection of vital energies. The intestinal tract is closed down. Energy that would normally be available for activity there is pre-empted and redirected to the massive effort to cope with a severe condition of intoxication. Lest the integrity of the organism be dealt a mortal blow or crippled, the body musters its all to the emergency.

In inflammation, the toxicants have usually been concentrated in an organ or area for a massive

expulsive effort. The area becomes inflamed due to the constant irritation of the toxic materials. When inflammation exists we are said to have an "itis," appendicitis, tonsillitis, hepatitis, or nephritis for example. Note that the "itises" just cited are all due to overburdening of four different organs of purification and elimination.

The names of "itises" are usually after the organ or tissue area that is inflamed. Thus if we have a cold we have rhinitis. If we have inflammation of the sinus cavities we have sinusitis. If we have inflammation of bronchial tissue we have either bronchitis or asthma. And so it goes. We have these peculiar pathologies because in each case the body elected to eliminate the extraordinary toxic load through the organ affected. For instance, asthma exists because the body has selected the bronchi as an outlet for toxic materials. The condition is chronic because the toxic condition is unceasing. While the sufferer continues to intoxicate himself or herself, the body continues to eliminate the overload through the bronchi or alveolar tissue.

Inflammation or fever is a body crisis response to a life-threatening situation. The body and the body alone creates the fever. It is an evidence or symptom of increased and intense body activities directed at cleansing and repair. The extraordinary energies employed for a fever are at the expense of energies normally involved in digestion, work or play, thinking and seeing, etc. Fever is a healing activity. The idea of suppressing it is equivalent to hitting a drowning man over the head so he'll cease his struggles. For instance, if rhinitis or influenza sufferers are drugged it amounts to hitting the body's healer over the head. Thus, the eliminative effort is suppressed, and the toxicity increases until other organs, usually the lungs, become saturated—not only with the toxicity but the drugs administered as well. When body vitality reasserts itself a condition known as pneumonia is likely to result.

Inflammation is the fourth stage of disease and is the body's most intense effort to cleanse and restore itself. The next stage of disease is destructive and degenerative. It will result if the causes of general body intoxication are continued.

### **3.1.5. Ulceration**

Ulceration means that a staggering amount of cells and tissue structures are, being destroyed. Physiological systems are wiped out due to the body's inability to live in an unceasing toxic media. Where tissue is destroyed there remains a void. An example is a canker sore of the mouth. Lesions or ulcers can occur in other areas of the body also. These conditions are often intensely painful, for there are exposed nerves.

While the body may use an ulcer as an outlet for extraordinary toxic buildup thereby relieving itself, it will heal the ulcer if causes are discontinued, or if the toxicity level is significantly lowered. This process of repairing the damage is like patching up pants with holes in them. This patching up process is called induration.

### **3.1.6. Induration**

Induration is a hardening of tissue or the filling in of tissue vacancy with hard tissue. Scarring is a form of induration. But in this stage of disease, there is direction and purpose in hardening. The space is filled, and the toxic materials that threaten bodily integrity are encapsulated in a sac of hardened tissue. The ulcer and the toxic materials are sealed off by the hardening of the tissue around them. This is a way of quarantining the toxic materials, often called tumor formation. It is this condition that is diagnosed as cancer nineteen times out of twenty when, in fact, no cancer exists.

Induration is the last stage during which the body exerts intelligent control. Should the pathogenic practices which brought matters to this stage be continued, cells and tissue systems go wild. They survive as best they can on their own. Cells become parasitic—living off the nutrients they can obtain from the lymph fluid but contributing nothing to the body economy. They have become disorganized. Their genetic encoding has been altered by the poisons. Thus, they are not capable of intelligent normal

organized action within the context of a vital economy. When cells go wild in this manner, the condition is called cancer.

### **3.1.7. Cancer**

The endpoint of the evolution of disease is cancer. It is the last stage of disease and is usually fatal, especially if the causes that brought it about are continued. Cessation of causes and indulgence of healthful practices may arrest it, for they can so revitalize the body that they may even destroy the cancer cells. It's all relative. Cancer cells live in a hostile environment but still divide and flourish as long as nutrients are available to them. Cancer cells may be regarded as cells that have become independent and have reverted to the status of uncontrolled primitive cells—cells that live entirely on their own as do protozoa.

These stages of disease are quite distinct in their characters, yet the lines are more or less arbitrarily drawn. This often happens in attempts at categorization where one form evolves into another. The dividing lines have no clear-cut delineation.

People sometimes ask when cancer begins. Hygienists or Life Scientists say that it begins with the first cold or rash of childhood. The first crisis a baby endures begins the pathological chain that leads to cancer. This evolutionary chain begins then because the phenomenon of life is one constant violation of the laws of life from beginning to end.

### **3.2. Viruses And Bacteria—Their Role In Disease**

After reviewing the seven stages of disease it should be obvious that bacteria and so-called viruses do not cause diseases. Viruses do cause diseases if you call toxic waste materials of decomposed body cells viruses. Decomposed cell debris is precisely what virologists and physicians are calling viruses. They regard viruses as living entities when, in fact, medics have not in all history observed any quality of life they ascribe to viruses. What is called virus is always dead. It's never been observed to be alive. It doesn't have the first prerequisites of life, that is, metabolic and control mechanisms. Even bacteria have that. I repeat that what is called viruses are nothing more than components of decomposed cells.

Some people insist that syphilis is caused by bacteria, more specifically spirochetes. Though the term spirochetes has given way to viruses called Herpes these days—that's today's fashion—it was easy to demonstrate that spirochetes were never responsible in the first place. When you ask a bacteriologist which comes first, the soil or the bacteria, he will answer that the soil must exist first for bacteria to thrive, for bacteria are presented a deadly environment by living cells. So, bacteria never exist in a proliferating state where there is no food or soil for their propagation. They multiply when there is feast, and they die off when there is famine or adverse environment, hence, bacteria no more create their food supply than flies cause garbage. The garbage must preexist the flies and, on the same order, the garbage or soil on which bacteria thrive in our bodies must preexist their presence and propagation. In other words, they do not cause the condition—they are there because of the condition.

When the body has a highly toxic condition such as inflammation, it will absorb bacteria from the intestinal cavity and transport them to the point where deadly materials have been concentrated. The bacteria then symbiotically assist in breaking up these toxic materials for elimination. Of course, the excreta of bacteria are toxic, too.

Ignorant physicians regard these bacteria not as our symbiotic partners in the process of combating disease, but as the cause of the disease. Koch destroyed Pasteur's original theories by his four postulates. The first two state that if a disease is caused by a certain type of bacterium, then that form of bacteria must always be present when the disease exists. The other says that the disease must always be occasioned by the presence or introduction of the bacteria said to be responsible. Although these cardinal principles are self-evident, so many exceptions existed as to disprove totally the germ theory of disease-causation. Koch laid down his postulates in 1892; the medical profession never has given them

credence. To this day the profession clings to the disproven germ theory except that germs in the form of bacteria are taking a back seat to an even more elusive entity called a virus.

Bacteria exist in a multitude of strains, forms, and metabolic capabilities. Bacteria are versatile and in many cases change forms and lifestyles in keeping with the character of the soil available to them. Round bacteria can become rod shaped and vice versa.

It used to be said that pneumococcus caused pneumonia. But it was noted that this type of bacteria was absent in nearly half the cases. Moreover, administering the bacteria to healthy organisms never occasioned pneumonia. The plain fact that bacteria are in the human body as they are everywhere else is not recognized by the medical profession. Bacteria are symbiotic partners of all creatures in nature. In order to come to exist in nature in the first place, humans had to establish a state of symbiosis with all natural forces.

In the second place, if bacteria invaded organisms and laid them low as they're supposed to do—if the body could be laid low while in a state of health—then the impetus or momentum the bacteria had built up would become more pronounced and overwhelming as the organism receded in disease. It would be a one-way trip the same as vultures picking the bones of a cadaver. If bacteria and viruses cause disease, once they have overwhelmed the body and actually debilitated it, how does the much weakened body regain ascendancy? If you were to inquire into this deeply and pursue it to its logical conclusions, you'd find that, once a body has lost the battle while in a state of health, it's going to lose the war after being disabled.

### **3.3 Disease Complicated by By-Products of Symbiotic Bacteria**

At their strongest, bacteria complicate disease because the byproducts of bacterial fermentation or putrefaction are deadly poison. In fermentation the by-products are lactic acid, acetic acid or vinegar, and alcohol. Putrefaction involves nitrogenous foods or proteins. The by-products of rotting protein are ammonias, indoles, skatoles, purines, etc. They are toxic within organisms, although the body can normally eliminate these poisons. In fact, our feces and urine are loaded with the by-products of protein decomposition, both from our body decomposition and bacterial decomposition.

You've heard of the ideal of living in a germ-free environment. That is an impossibility, of course. Trillions of bacteria are in and on our bodies at all times. If we were free of these minute organisms, we'd soon die. They perform many essential services for us which will be discussed in a later lesson. Suffice it to say that we live symbiotically with bacteria.

Bacteria are wrongfully blamed for our own indiscretions. It's the rare medic who doesn't find a scapegoat for his client and remove responsibility for problems from the shoulders of the sufferer.

Medical logic is not very logical. According to medical thinking, bacteria or viruses invade our bodies and destroy our cells. It would seem that our body defenses permit this by their intimations. It would seem that once these invading entities have a headstart they would not stop destroying the rest of the cells of the organism, especially as the first strike has crippled the organism and lessened its ability to defend itself. By medical logic, the bacteria are there in greater numbers, for they proliferate astronomically when they've found a feast situation. How can the body reverse this situation and recover? '

The medics believe that they administer drugs that kill off the bacteria so that the body can have a chance to recover. Also, they have people believing that medicines are healing agents or that they assist in healing.

When you start asking deep penetrating questions into the causes of disease, the medical theories fall of their own weight. They cannot be sustained in the face of self-evident truths. So we have to find the rational basis for disease causation.

Disease has a sole unitary cause. It is instituted and conducted by the body itself. It is the only organized entity capable of coordinating the various processes of disease. Disease is occasioned when toxic

materials that we have generated within or taken in from without are uneliminated due to the body's inability to cope with them. These debilitate and devitalize the organism until, at a point where it can no longer tolerate the growing toxic load at its mean level of vitality, the body institutes a crisis, redirecting its body energies to the enemy within.

Let's go back to pneumonia. Physicians worry that when a person has a cold or the flu, it will become pneumonia. It occurs so many times among their patients that they make "heroic" efforts to prevent this. They administer drugs galore. Yet, pneumonia occurs so frequently despite the drugging that doctors feel powerless in the face of pneumonia, one of the primary causes of death in our society. The question arises: what causes pneumonia then? Does pneumococcus survive the drug onslaught and cause pneumonia anyway?

If colds are, as we teach, a cleansing process, how does a body that is in crisis get yet worse? If the body is eliminating toxic materials profusely through the respiratory tract as in colds and flu, then how do the lungs also become contaminated?

All cases of colds and flu recover very quickly if the sufferer goes to bed in an airy room with lots of natural daylight. Almost total rest is called for. Total abstention from food but plenty of pure water is needed. Under these conditions debility ceases in from one to three days. But, if the sufferer refuses to rest and continues to eat the same bad food that contributed heavily to the crisis in the first place, the eliminative effort may be less than the continued toxic buildup, in which case pneumonia may be a concomitant. But, if the sufferer goes to a medic and gets drugged in addition, the body turns its attention to eliminating the drugs. It may cease the cold or flu altogether in face of the greater enemy. The continued toxic buildup spreads to the lungs. The drugs and toxic materials may concentrate so strongly in the lungs as to cause death or to set the stage for cancer. Many autopsies reveal people who have had pneumonia or who have smoked or lived in highly polluted air have tumors, indurated sacs of lung tissue which encapsulate toxic substances in the lungs. Many cases of long fasts have been conducted in which pneumonia had been suffered many years before. The drugs that had been given had been noted to make their exit from the lungs during the course of the fast as the body autolyzed the tumors and expelled their contents.

Yet, despite the obvious causes of pneumonia, medical professionals are still saying that pneumococcus causes pneumonia when, in fact, more than 25% of pneumonia cases never have pneumococcus. Now that medics are getting more and more away from the germ theory of disease causation they're invoking viruses as the culprits. This is true only if by viruses we mean uneliminated metabolic wastes. But when you start probing into what viruses are and how they cause disease, you might call this the "evil spirit" theory of disease, for the medics imbue viruses with all the qualities of malevolent spirits.

Such blindness characterizes the medical profession. The purpose of disease is so evident that medics can't see it. Just as with the guard in the concentration camp, they are looking for something that doesn't exist and they overlook that which they see so plainly all the time.

Medical researchers have chronicled over 20,000 different diseases. They name almost every variation. They have multiple names because of the number of organs or tissue systems that exhibit symptoms. All of this is only one disease. And the disease, which we call constructive disease, is occasioned by the body itself and is known as toxemia or toxicosis.

## 4. Natural Hygiene Or Life Science Care Of The Ailing

### 4.1 The Work of Doctors Tilden, Carrington and Shelton

Just as there is one universal cause of disease there is one universal panacea! In mythology Asclepius had two daughters. Both were goddesses. One was the goddess of health and she was called Hygeia. The other daughter was Panacea. She was the goddess of healing. The name itself, in Greek, means all-healing or universal healing.

While these goddesses are mythological, they do represent valid concepts. Panacea can be achieved by a return to natural practices. Fasting is the quickest way to invoke the universal panacea. Just as the universal disease is a toxic-laden body, the universal panacea is establishing the most ideal conditions under which the body can cleanse itself of the toxicity and repair the damages suffered. Fasting is the answer. It works in all cases of constructive disease, that is, disease where organic damage of an irremediable nature has not occurred.

Some great luminaries have long since rediscovered the Grecian panacea. Dr. Jennings first employed it until Dr. John Tilden elaborated on it in his scholarly book, *Toxemia Explained*. Dr. Hereward Carrington wrote a few very illuminating volumes about Natural Hygiene. But Dr. Shelton probed deeper and farther afield than did all those before him. He built upon the shoulders of all who went before him and added a touch of his own genius. In our text section some observations of Dr. Carrington are presented. Here is a quote from Dr. Herbert M. Shelton about the nature of disease:

### 4.2 The Hygienic Definition of Disease

*"The Hygienic system teaches that disease is a remedial effort, a struggle of the vital powers to purify the system and recover the normal state. This effort should be aided, directed, and regulated if need be, but never suppressed. What is this mysterious thing called disease? It is simply an effort to remove obstructing material which we call toxic materials from the organic domain and to repair damages. Disease is a process of purification and repair. It is remedial action. It is a power struggle to overcome obstruction and to keep the channels of circulation free."*

Actually disease is really more than this if we view it in all aspects. Dr. Carrington has simplified Dr. Shelton's presentation somewhat. He says the following:

*"Disease is an attempt of the body to free its cells and circulatory system of clogging and toxic materials. It is a desperate body rallying its remaining resources to the task of purgation and restoration."*

We have many illustrious forebears in the elaboration and creation of what we call Natural Hygiene or Life Science. Most notable among our forebears have been some truly great women. While women were spurned in the medical profession, the Hygienic movement was truly an enlightened and unfettered one. It welcomed women with open arms and, if we leave the renegade M.D.'s aside, their numbers almost equal those of male Hygienic professionals.

How many of you have heard of Louisa May Alcott? Yes, all of you have. But how many of you know that she was a Hygienist? That her father was a Hygienist? That her brother William Alcott was a professional Hygienist and was also a brilliant writer?

I'm sure you've all heard of Florence Nightingale, who gave new dignity and direction to the profession

of nursing. She was a Hygienist.

How many of you have heard of Ellen White? She was a Hygienist who founded the religion we know today as the Seventh Day Adventists.

There are many unsung heroines among women who were Hygienic professionals. Mary Gove, Susan Nichols, Linda Burfield Hazzard and others were a credit to both the profession of Hygiene and to womanhood.

Perhaps the most famous Hygienist of the fair sex was Florence Nightingale. Her daring on the battle fields of eastern Europe still draws our admiration for the courage of her convictions. The British were fighting the Russians and more soldiers were dying behind the battle lines than on them. The physicians and their treatments were killing off the wounded and ailing faster than the Russians.

When Florence Nightingale arrived on the battle scene she really took charge despite the physicians. What she did was a very simple thing: she went to the rooms of the wounded and ailing and opened the windows for fresh air. She would not permit drugs. She gave the patients water which was against medical policy at the time. She rejected heavy feeding and, in fact, for many, any feeding at all. Being confined to a battlefield hospital had been a death sentence before. Now almost all the wounded and sick became well speedily. It's all history and Florence Nightingale became famous because of her tremendous success employing the mere rudiments of Hygienic methods. This is all the more phenomenal when you consider that Ms. Nightingale lived in a medical age and in a man's world. She defied the medics and won. She was truly a pioneer Hygienist. The world, despite its poverty on the health scene, is still richer for her having been amongst our forebears.

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > 5. The Character Of Disease

## **5. The Character Of Disease**

In order to understand disease, we must understand health. Health is the enjoyment of full faculties and functioning power. Disease is not the opposite of health but an expression of healthy vitality while under the burden of toxicosis. Disease is a body-instituted and conducted crisis for the purpose of purifying and repairing itself.

Disease is caused by indulging in practices or being subjected to materials and influences not normal to the human organism: that to which we are not adapted will cause disease.

It is a misconception that we have to fight disease. It will not occur unless it is caused. A huge catalog of materials and influences which are abnormal to the body could be given, but it's not that complicated. We need only to maintain the simple needs of life which build and sustain health. We should consume only pure water as thirst demands and wholesome raw ripe fruits, vegetables, nuts and seeds as genuine hunger dictates. We are frugivores, and it is to a diet of fruits as nature delivers them that we are biologically adapted.

Further, we are adapted to pure air, sunshine, rest and sleep, pleasant environment, emotionally balanced companions - in short we are adapted to a harmonious world. We are so constituted that health results when all our physical, mental, emotional, intellectual, and aesthetic needs are met. Thus diseases other than degenerative ones may be said to be body crises for the purpose of restoring health.

The cause, purpose, and nature of disease have now been delineated. Certain questions will be explained below.

## 5.1 Diseases Are Not Contagious

STUDENT: Is it true that diseases are not contagious in any sense?

INSTRUCTOR: That is correct. Diseases are not contagious in any sense simply because they are body instituted. We cannot transfer our toxic load to someone else. That should be self-evident. A Hygienist can go into a sickroom and not suffer a bit for it. Obviously most physicians and nurses and other people go to the sickrooms, even those housing the most so-called contagious diseases. They never contract the disease or suffer even though on occasion medics claim they do. You cannot transfer your toxic materials to another person unless you have it drawn out of you and injected into the person. The medics do, indeed, do that in transfusions. But the contagion here is medically induced rather than occurring within the realm of natural possibilities.

It is said that colds, flu, leprosy, and a number of other things are contagious. As we learn more, diseases become less and less contagious. Asthma, cancer, psoriasis, meningitis, poliomyelitis and a long list of other diseases have come off the contagious list. Measles, chicken pox, and other affections are still on the list of diseases said to be contagious. The only thing contagious about these diseases is medical ignorance. That is the most contagious of all.

## 5.2 How Plagues and Epidemics Develop

The reason that there seems to be "epidemics" is that the true contagion is an epidemic of similar bad habits. We all eat pretty much the same junk, are subjected to the same seasons, the same type of housing and, in many other ways, indulge the same health-sapping practices. It's no wonder that many of us suffer the same diseases. Like causes beget like effects. Of course this is modified in the human situation by the diathesis of each individual.

Thus we see that, within the context of a given family or group, people have more or less the same bad habits and suffer the same diseases.

This business about incubation periods of germs and viruses is strictly medical mythology. We'll get into the depths of that and study it methodically in later lessons.

To what are plagues and epidemics attributed? Today's epidemics are for the most part invented and publicized in America by the Center for Disease Control in Atlanta, Georgia. It is a federal service that does yeoman service for the medical profession. When the drug companies want to sell lots of flu vaccine, measles vaccine, etc. they get CDC to release the scare propaganda that stampedes the public into the physicians' offices for shots. To entertain the thought that vaccines injected into people makes them immune is an absurdity not worthy of serious consideration—it is a species of voodooism.

Epidemics today result, I reassure you, from mass indulgence of the same bad habits and subjection to the same pathogenic living conditions. It's no accident that almost 90% of the affections labeled generally as colds and influenza occur within a seven-month period of the year.

The reason epidemics occur in winter and not in summer should be obvious. If anything, microbial life is more active in summer just as we are and their functions are depressed in winter. But lo and behold, microbial forms of life are said to be more active and to cause epidemics. That's nonsense of course. In the winter we eat less wholesome food—we eat more junk. We do not exercise as much. We stay indoors and breathe foul air. In the summer we get more sunshine, more exercise, more fresh air, fresh ripe fruits—in short we live more healthfully in summer and less healthfully in winter. Conditions cause us to so live as to generate our diseases. General conditions cause general ill health. It is not contagion of germs but contagion of pathogenic conditions that create what are termed plagues or epidemics.

## 5.3 Drugs are Dangerous to Both Bacteria and Human Cells

Hygienists or Life Scientists deplore the medical practice of feeding the ailing and drugging them too.

When ill, the continuance of feeding alone is enough to thwart the healing forces within. But the addition of drugs so destroys vital powers that the body must often redirect its purification efforts to freeing itself from the more virulent poisons administered. Thus it is seen that medical professionals are death-dealing rather than being life-enhancing.

Yes, drugs kill bacteria. But they're just as deadly to all forms of metabolic life. That which deranges and destroys the metabolic functions of bacteria usually does likewise to the cells of all forms of life. Even physicians will tell you that drugs have no effect on viruses. Of course they don't have any effect on what they call viruses because that is dead cell debris that can't be made any deader.

In conclusion I assure you that disease is not something to fear. That's like being scared of your own body. If you fear anything fear your disposition to indulge in unwholesome foods and unwholesome living conditions.

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > 6. Questions & Answers

## 6. Questions & Answers

### **Are indigestion and acidosis diseases or just passing little crises?**

These are diseases even though usually of short duration. Anything that puts us at unease is disease. While there is no such thing as acidosis because we'd die long before our body fluids reached the acid stage, there is such a thing as hypo-alkalinity. A reduction in alkalinity from a pH of 7.40 to as little as 7.35 is enough to bring on coma and another five to ten points lower may cause death.

Indigestion and what is called acidosis are usually caused by eating foods in incompatible digestive combinations and in eating a predominantly acid-forming diet. These are the primary causes of these complaints.

### **You said that diseases are not contagious. If so how do you explain away venereal disease? That's proven to be contagious.**

I've responded to this in a way before but I'll go over these grounds again. Conventional thinking has it that gonococcus and spirochetes are transferred from one person to another during the sexual act. The "infected" person will then develop either gonorrhea or syphilis. Even the medical profession is deserting this long held belief today in favor of the herpes virus as causing what is called venereal disease.

First, syphilis is a figment of the medical imagination. Most of what is described as syphilis in the books of yesteryear were effects of mercury and sulfa drugs which the profession administered so liberally. What is described as gonorrhea is no more serious than the canker sores of the mouth. Both are eliminative steps by the body. The ulceration and suppuration represent the fifth stage of the evolution of disease. The so-called contagious factors, bacteria, are there because of the disease, not the cause of it. In fact something like 20% of those who suffer venereal diseases have neither gonococcus nor spirochetes. Saying that a pimple, ulcer or pustule in the sexual area is caused by either bacteria or viruses is like saying boils are caused by the same when it is generally agreed that boils are a result of filth in the body. Both are the same processes but occur in different areas of the body. Besides it must be recognized that the autolysis of tissue and the creation of inflammations and boils

are body actions, not bacterial or viral actions.

It is not true that venereal diseases are contagious. The U.S. Navy conducted experiments wherein it was shown that so-called infected persons could not infect healthy persons. When I was with a vice squad in Japan we had cases of so-called infected prostitutes who had been with dozens of GI's, none of whom contracted the disease. On the other hand there are many who have infections in the sexual area who have not been in contact with anyone, especially in small children who do sometimes have infections in the sexual area.

The concept of contagion is unproven despite appearances. It is a medical scareword that stampedes customers into the offices of medical practitioners. It's much like insurance companies who like to see fires and pay off for that makes it all the easier to sell insurance.

**It seems rather impudent of you to say millions of scientists, doctors, researchers and teachers of medical science are all wrong. Isn't it just possible that you're wrong about disease being body action instead of bacterial or viral action? Isn't it just possible that the medical people who've been around so long are really right?**

Old myths die hard, don't they? The older and more revered the myth, the harder it is to dispel. Your question would have done well nearly five hundred years ago when Copernicus presented his heliocentric theory of the solar system. It's just difficult to believe that everyone can be wrong. But I insist that the whole profession operates on a wrong premise. The fact that fasting will enable an organism to heal quickly in injury or illness and drugging will defer or prevent healing altogether is some indication of the error of the medical school of thought. The very word medicine is a misnomer. The word means healing agent or substance. There is not such an agent or substance. Healing is always the sole prerogative of the affected organism. There's not enough intelligence and know how in the collective knowledge of the world to effect the knitting of a bone within an organism. Healing is, I repeat, entirely a body process.

The impudence lies not with me but with those who deny the obvious and plainly evident truth. Age does not make beliefs true, and truth never changes with age. The belief that the world was flat was accepted by millions over nearly two thousand years but that did not flatten the world. Likewise if the masses of our people do not accept obvious truths, truths that account for everything in health and disease and are demonstrable when put to the test, then it is those who deny the obvious that are impudent. Should I repeat an old refrain: "I'd rather be right with a persecuted few than wrong with many."

**I know about the swine flu hoax but is the measles vaccination really a hoax too? If children are exposed to the measles they get it; but if they have been vaccinated they don't get it, right?**

It's general knowledge that the swine flu vaccination was a hoax. It is only a question of time before people will learn of the tetanus hoax, the rabies hoax, the whooping cough hoax, the measles hoax and other medical hoaxes.

If children are exposed to others who have the measles they don't "catch" it. It is not something that is contagious. What is "contagious" are the food habits, that cause it (any unhealthful living habits, wrong food combinations, stress, etc.). But children usually do not have measles if their system is too drugged and devitalized. And that's what happens when they're vaccinated. They cannot conduct the simple eliminative crisis called measles. If they cannot have measles they'll sooner or later have something worse—like cancer! Measles is a body instituted and conducted crisis to get rid of toxic accumulations. Vaccinal interference destroys the vitality necessary to have measles.

Measles is helpful, not hurtful. The body creates the measles and keeps the process in force until body cleansing has been completed. Contrary to medical myth, the body will not harm itself by conducting this or any other crisis. This is more than can be said for the vaccines, which are poisonous in themselves.

The harm said to be derived from measles is actually from the "heroic" drugging and treatment administered by the medical profession. Measles and other acute diseases are helpful body functions; the body is grappling with an overload of toxic materials. Vaccinations and drugging add to these toxic materials. They are never a "preventive" or an antidote. They can make matters worse but they have no intelligence or ability to help under any circumstances.

**If vaccinations don't give us immunity, how about the antibodies vaccinated organisms produce? Don't antibodies really defend against a virus as in the case of measles?**

This reminds me of a joke that goes like this: An Air Force Colonel who commanded a fighter wing was inspecting his pilots one Saturday morning. He stopped by a Captain and Lieutenant who piloted and co-piloted a plane. He asked the Captain: "What would you do, Captain, if your plane caught on fire and you couldn't open the overhead canopy?" The Captain replied: "Sir, I'd eject through the canopy." The Colonel rejoined with "You idiot, you'd be squashed to death in the process." Then he turned to the Lieutenant and asked him what he'd do. The Lieutenant meekly said, "Sir, I'd go through the hole the Captain made." Of such substance is this question. The truth is that the body does not create new defensive faculties in responses to a poison. Rather it has its defensive faculties destroyed. Putting a question that way is like saying that the body creates antibodies to defend against tar and nicotine in cigarette smoking because the body can tolerate ever greater quantities without the same ill effects as with the first cigarette of life. The body can't tolerate smoke any better after a thousand smokes than after one. The body no longer defends against the pathogenic poisons of cigarette smoke simply because its defenses have been destroyed, not built up.

Medical researchers will tell you that "antibodies" are merely presumed and not something actually demonstrable in the laboratory as a new body faculty. They are presumed because, when vaccines are administered, most recipients no longer get the disease. This is because the body's defensive faculties are destroyed, not enhanced. The body's ability to conduct the simple cleansing crisis known as measles is so debilitated by the vaccinal poison that it retains what would normally be expelled. It's no accident that cancer is now the number one killer of our children. When simple cleansing cannot occur, the body all the more quickly evolves to the next and succeeding stages of disease.

Antibodies are, I repeat, a medical myth, a figment of the medical imagination.

**Well, you've just admitted that vaccines lower the incidence of measles. Isn't that a good thing since measles can cause brain damage?**

How can I get this across that measles are not a bane but a boon. If the body is filthy inside, a cleansing is a good thing. Measles are a cleansing process. The body conducts the crisis called measles and it is doing so to help itself, not hurt itself. The body never injures itself except where injury is necessary as the lesser of two evils. Brain damage does not occur from a cleansing crisis. Rather, it is the drugs that are administered in such a crisis that are responsible for the damage. Physicians damage many people with their drugs and conveniently place all blame on the body's noble reparative efforts rather than take responsibility.

**How can you prove that a sickness is caused by toxicity rather than germs? Do you base your statement on laboratory proof or on empirical observations?**

Were germs the cause of disease there would be no remission. If they had the power to successfully attack living tissue and proliferate enough to lay a person low as is commonly supposed, then the results would be like the effects of rotten apples amidst good ones—they'd all soon be bad. Humans simply would not survive the ordeal and there would be no human race.

Should we fast people who were laid low with a germ-caused disease the fasting would not kill off the germs. Just as a rotten apple can spoil the good ones so, too, the germ proliferation would continue whether we are eating or fasting. Actually people who fast recover health rapidly whereas, if they continue to eat and take drugs, they recover slowly if at all.

Actually there have been fasts conducted under laboratory conditions in many hospitals and university medical centers with controls. It has been proven beyond doubt that the body cleanses itself under the condition of fasting and heals two or three times speedier when fasting than in alimentation and/or drug therapy. Medical experimentation with fasting has been conducted at the University of Illinois in Chicago and the University of Pennsylvania in Philadelphia. You won't have to delve much into the literature on fasting to come up with the results observed. All medical research has proven the truth of the toxemia causation of disease regardless of the misinterpretations of the researchers. Researchers usually interpret their data to suit those who are paying for the experimentation, usually drug companies or drug beneficiaries. If the experiments are too contrary to the ends sought they are usually buried quietly. Both laboratory evidence and empirical observations substantiate that disease is a body reaction to intoxication rather than germs.

**How can we convince our clientele that they're responsible for their diseases and that it is not just a bit of bad luck that has befallen them?**

Fortunately, you don't have to lay the load of responsibility on your clients' shoulders. Your clients will at first be "cure-minded" and want a way out of the dilemma. You can point out the positive way back to health without getting into culpability. You can have them fill out an extensive questionnaire which we've developed and the answers to which are advance weighted so that you can suggest changes in the customer's living regime. You can make the process one of adventure and exploration by holding forth the benefits to be obtained by doing this and this and not doing that and that anymore.

Dr. Jennings had people fasting under a deception. He gave them bread and sugar pills, what we'd call placebos, and instructed the taking of water with them four or five times daily. With that he advised bed rest, fresh air, etc. He cautioned against taking anything with the pills other than water, otherwise they would not work. The results his clients realized were nothing short of miraculous. His patients were recovering 100% while his medical colleagues who were into heroic drugging lost patients in epidemic numbers.

You can impute health magic to certain foods or limited diets, even a distilled water diet. But you can assure a healthful outcome only within certain parameters. Hence the client will likely go along with you in the matter of his welfare just as he or she goes along with every charlatan in the medical or other fields of the so-called healing arts.

I reiterate that you can make a game of this, i.e., make it an interesting adventure rather than an onerous chore. The education and whyfore can follow the results. People are interested in

results and you are there to show them how. People believe in the magic of nutrition and we're going to teach it to you as it really is. We'll teach it to you so that you can guide your clients back to health most speedily, not only in matters of diet but diet within the context of a thoroughgoing health regimen. You can always give instructions that are completely appropriate and straightforward that will enable the client to quickly regain health. Yet you can do it in such a manner as to make it exciting enterprise. You'll cultivate this confident manner of knowing just what is called for by sympathetic and empathic consideration of your client's problems as related to you through questionnaire and verbal complaint.

**I find no fault with the toxemia explanation of disease but it seems too utterly simple to be for real. Do you think our clients will go for this?**

I must repeat that your clients aren't interested in theories or explanations. They're looking for results, a magic carpet from a state of disease to a state of health. Just wave the magic wand of nutritional salvation before them within the context of a thoroughgoing health regime and they'll usually follow it religiously. Your expertise will awe them and once word of mouth has gotten around about the miraculous results your guidance makes possible, clients will flock to you.

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > Article #1: A True Perspective Of Health And Disease by Dr. Herbert M. Shelton

### **Article #1: A True Perspective Of Health And Disease by Dr. Herbert M. Shelton**

We live in a day of sensational discoveries and "miracle medicines." Remarkable new cures and near-panaceas are frequently announced. Snake venom, artificial fever, frozen sleep, the sulfonamides, penicillin, streptothricin, blood plasma, powerful X-rays and ever more comes before us almost daily—these compete with sports, movies, politics, crime and other publicity for free newspaper space. So much is claimed for this parade of "miracle cures" and so many new discoveries are made relatively that the public is kept constantly keyed up with open-mouthed and wild-eyed expectancy. Perfect health via the medical promises seems always just around the corner.

At long last, "science" is staging a powerful and winning Blitz-Krieg against our ancient and most implacable foe—*disease*. With remarkable and sensational discoveries crowding so closely one upon the heels of another, the time is surely not far distant when universal health will prevail and disease will have disappeared from the human scene.

Not only is ours an age of remarkable "cures," it is also a time of equally remarkable preventatives. We now have so much "successful" vaccines and serums that there is no longer any need for anyone ever to suffer from many of the "diseases" that were previously so common. New serums are frequently discovered. We may look forward hopefully to the time when all "disease" will be conquered.

Surgery, too, has made rapid strides. It has grown much more daring. Today it invades physiological precepts which only a few years ago it would not have touched. With the newer advances in surgery added to the new "cures" and the new serums and vaccines, we have an almost ideal combination for the "conquest of disease." What these three groups of anti-disease weapons lack in power and effectiveness is completely compensated for by the many glandular products (hormones), and by vitamin and mineral combinations that are claimed to do so much for the sick. Surely, there is no reason to doubt that the *Golden Age* has arrived.

The intelligent and informed reader, however, will notice one very important defect in all these methods of "cure" and "prevention." He or she will quickly detect a deficiency for which no amount of shouting can compensate. It is this:

*None of these methods of "cure" or "prevention" are designed to affect or even touch the basic causes of disease.*

Drugs may suspend vital activity such that symptoms disappear but they do not remove cause. They may kill germs but they also kill off patients. They do not clear up the systemic condition that permits bacteria to thrive and grow in parts of the body where they are not normal. "Frozen sleep" may temporarily check the growth of a tumor or cancer, but it does not and cannot remove the causes of cancer. Powerful X-rays may destroy a cancerous growth but they also destroy healthy tissue and cause further cancer while leaving intact the causes of disease. It cannot be emphasized too much that:

*If a modality does not remove causes, it does not "cure".*

Serums and vaccines are admittedly capable of doing much harm, but they do not remove the causes of disease. Therefore, they do not enable us to "avoid" diseases, even those for which they are administered. We need to know that:

*If they do not enable us to avoid the causes of disease, they cannot prevent disease.*

Surgeons may pull a tooth, extract the tonsils, cut out the gall-bladder, excise the appendix, sever and remove the ovaries and seminal vesicles, drain the sinuses, etc. but they do not thereby remove the causes of disease. Mopping up the water from a leaky faucet does not remove the causes of the leak. Removing effects of cause likewise does not remove the cause. It is time for us to understand the following:

*If surgery does not remove the causes of disease, it cannot "cure" the disease. There is no "cure" short of removal of causes.*

Cutting out an organ, suppressing a symptom with a drug (medicine), destroying a growth, removing a stone—these processes touch effects only. They fail to restore health for three very vital reasons:

1. They do not remove the causes of ill health.
2. They are not the factors out of which good health is built.
3. They produce positive injury to the body.

We must look to constructive natural agencies, forces, and methods for "prevention" of disease and recovery of health. We must cease relying on destructive, unnatural or anti-natural measures, forces, agents and processes. Agents such as drugs that produce disease in the well cannot possibly produce health in the sick. Disease-producing agents and measures are not health-preserving. The popular methods of "prevention" and "cure" neither prevent nor restore health. Witness the ever-growing army of sick and suffering in spite of the ever-increasing size of our army of physicians, nurses and hospitals, and the ever-growing list of "cures" and "miracle drugs."

*To be healthy, do not indulge the causes of disease. Only madness can lead us to attempt to be free of disease by submitting to means which cause yet more disease.*

*To "cure" disease, remove the causes of disease. It is the worst kind of folly to attempt to cure disease by ignoring its causes and employing modalities which are in themselves causes of disease.*

*To build health, employ the causes of health. It is absurd to attempt to build health by employing means and measures that are known to impair and wreck health.*

For over forty years this writer has helped the sick and suffering back to health and has taught them how to remain well. I have employed a system called NATURAL HYGIENE. For over forty years my health

school has been host to over 40,000 people. Dr. Shelton's Health School has been employing the health-building system of NATURAL HYGIENE with only successful results. At the Health School we have received a great preponderance of people who have suffered for years and "have tried everything" without avail. Our success in building good health in the great majority of these sufferers has been remarkable.

At the Health School we have no "cure" at all. We recognize that only nature (normal forces and processes of life) restores health. We accord to nature the conditions and the opportunity to restore health. We recognize that in nature and nature only exists the power of healing. The forces and powers of nature constitute the true panacea. Ours is a plan of living and a program of education that restores our guests to harmonious living with nature. If this plan of care seems too simple, too easy or not heroic enough, just think this over:

*If this plan were ineffectual we would not have succeeded where all others had failed.*

I implore you to intelligently consider the preceding statements. Lay aside your previous conditioning and prepossessions. Do some real honest-to-goodness thinking. Then, when you thoroughly understand NATURAL HYGIENE, give it a fair and honest test. Heed the ancient admonition: "Prove (test) all things, hold fast that which is good (true)."

An old adage has it that "the proof of the pudding is in the eating thereof." The proof of the truth of the principles presented in NATURAL HYGIENE and of the value of the practices built thereon is in making use of it. "The wise will understand."

[Home](#) > [Lesson 2 - The Nature And Purpose Of Disease](#) > Article #2: The Nature Of Disease: Its Cause And Purpose by Dr. Hereward Carrington

## **Article #2: The Nature Of Disease: Its Cause And Purpose by Dr. Hereward Carrington**

Primitive peoples, as we know, believe disease represents the entry into the patient's body of some evil spirit or entity—which was caused to enter it by some malevolent voodoo man or witch doctor. The unfortunate victim remains so afflicted until he rights a wrong, appeases the witch doctor, or secures the services of another whose "magic" is more powerful than that of the original spell-caster. When once this "evil spirit" has been removed, he is well and strong again; if he fails in this, he dies!

Strange as it may seem, a modified form of this same belief underlies public thinking and constitutes a basic belief of many physicians. True, we no longer believe that an "evil spirit" has entered into the body of a sick person, but it survives in the form of thinking that disease is an "entity" of some sort which is caught and which can be driven out or expelled by suitable medicines— something in a bottle! When this entity has been expelled, the patient is "cured." Such is the popular conception...

### **Disease: A Phase of the Healing Process**

As opposed to this, the Hygienist believes that so-called "diseases" represent merely the bodily states or conditions, nearly always self-caused which are manifested in a series of symptoms, but which are in themselves the very processes of "cure." As Dr. Emmet Densmore stated, in his book *How Nature Cures*:

*The hygienic system teaches that disease is a remedial effort, a struggle of the vital powers to purify the system and recover the normal state. This effort should be aided, directed and regulated, if need be, but never suppressed... What is this mysterious thing called disease?*

*Simply an effort to remove obstructing material from the organic domain, and to repair damages. Disease is a process of purification. It is a remedial action. It is a vital struggle to overcome obstructions and to keep the channels of circulation free...*

Precisely the same idea was expressed by Miss Florence Nightingale, in her *Notes on Nursing*, when she said:

*Shall we begin by taking it as a general principle that all disease, at some period or other of its course, is more or less a reparative process, not necessarily accompanied by suffering; an effort of nature to remedy a process of poisoning or decay, which has taken place weeks, months, sometimes years beforehand, unnoticed—the termination of the disease being then determined?*

So-called disease is, therefore, in the vast majority of cases, merely a *curative* effort on the part of Nature; *it is the process of cure itself*—manifested in a set of symptoms. Attempting to "cure" a disease, in the ordinary sense of the word, leads us to a ridiculous paradox: viz., an attempt to "cure" a "curing" process! The disease IS the "cure." The outward manifestations, the symptoms we notice, represent merely the outward and visible signs of this curative process in action. Any attempt to deal with or smother these symptoms merely retards the process of cure to that extent. Instead of treating symptoms, we should aim at the disease itself—or rather at the causes of the so-called disease. These are really the dangerous factors involved, and those which have brought about the abnormal conditions noted. Once we have removed these causes, the disease (so-called) disappears, and the symptoms vanish. The patient is then restored to health.

Viewed in this light, everything becomes simple! Toxins and waste material of all kinds accumulate in the body, over a period of weeks, months or years—finally reaching the point when they must be expelled or deterioration sets in. This violent expulsive effort on the part of nature produces a series of characteristic symptoms. The body attempts in every way possible to expel these poisonous substances — through the bowels, the kidneys, the skin, the lungs, etc.—with the result that these organs are overtaxed and break down under the load. Clogging and toxemia then set in more seriously than ever, and the patient is really ill. Obviously, the only way to relieve this condition is to stop adding to the waste material the body must eliminate, and assist it in every way possible to dispose of what is already there. Once the body is given a chance to "catch up," so to say, and cleanse itself to some extent, the violence of the internal upheaval will subside, and as this becomes more normal, the external symptoms will lessen and the patient is then said to be "convalescent." If this process continues, he ultimately becomes "cured."

I have used all these terms in a loose sense, because hygienists believe that the so-called "disease" is itself the process of "cure"—as we have seen. What we really mean is that certain causes have been removed, and as they are removed the effects disappear... What are these causes, and how are they removed?

The human body is creating certain poisons within itself by the very process of living. If these poisons were not constantly being excreted we should die. Normally, they are disposed of through the various eliminating organs—the bowels, kidneys, skin, etc. If this balance is maintained, the person remains well. If, however, the poisons accumulate more rapidly than they can be disposed of, abnormal conditions develop. These conditions are the so-called "diseases."

Now, it should be obvious that the speediest way to regain health, when this condition develops, is to stimulate the eliminating organs, and at the same time introduce no new poisons into the system. The former is accomplished by means of exercise, bathing, water-drinking, etc. But it is highly important to prevent the entrance into the body of material which might further clog and block it. The material is our food, and obviously so; for, aside from air and water, this is the only material we ever introduce into our bodies, under normal conditions.

The necessity of fasting in times of stress thus becomes evident. Food supplies us with essential nutriment, it is true; but if the body is in no condition properly to utilize this food, it merely decomposes, creates poisons and is pushed through the body without really benefiting it. The thing to do, therefore, is to withhold food, so long as this abnormal state lasts, thereby giving the eliminating organs a chance to dispose of the surplus material already on hand, and at the same time rest the internal organs, permitting them to accumulate a certain store of vital energy, which would otherwise be expended in the handling and disposal of this extra mass of food-material. The system thus becomes cleansed and purified. It is the simplest and most effective means known to us—and is the course prescribed by nature when she deprives us, at such times, of our normal appetite.

### **All Diseases Toxic In Origin**

Practically all diseases thus have a common basis and a common origin. There is a unity and oneness of disease, based on a common denominator. This, in a word, is toxemia. The differing diseases, so-called, are but the various means by which nature tries to expel this poisonous material; and the symptoms noted are the outward and visible signs of such curative action. Naturally developed inherent healing powers alone "cure"—whether it be a cut finger, a broken bone or a so-called "disease." All that the physician can do is to assist Nature in this remedial effort. Anything which tends to reduce symptoms merely prolongs the effort to that extent. Give Nature a chance, and she will heal in every case. A "cure" will invariably follow—whenever such "cure" is at all possible.

Most drugs so destroy vitality that body efforts as evidenced by symptoms are stopped. Pain is a warning signal—calling attention to a certain local area which is in dire distress. But this condition is merely a localized manifestation of a general condition. As Dr. Samuel Dickson remarked: "Properly speaking, there never was a purely local disease." Rectify the general body condition, and the local manifestation will disappear. No matter what they may be or where located, they will vanish when the body as a whole is normal.

Drugs do not act *upon the body*; they are *acted upon by the body*. The action we perceive is the reaction of the body against the drug. It is the effort on the part of Nature to expel the poison introduced into the living organism... Much the same is true of stimulants. These seem to impart "strength" to the body; but as we know, this is a false strength, denoting merely the waste of the vital energies. If you dig your spur into a tired horse, it will run faster to the corner; but no one thinks that the spur has supplied the horse with fresh energy. It has simply caused the poor animal to expend its reserve energies more quickly. It is the same with stimulants. The false feeling of strength which they impart is fictitious. The same is true of many drugs; *and the same is true of food*, which also acts as a stimulant, giving us a false feeling of strength when a meal is eaten! It is because of this fact that many people feel "weak" when food is withheld.

The simple, basic idea back of the hygienic system is that practically all "diseases," so-called, are but the varied manifestations of a single underlying cause; and that, when this cause is removed, the symptoms automatically vanish. This cause is toxemia: waste materials and foreign poisons in the body.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > 1. The Essentials Of Life Listed

### 1. The Essentials Of Life Listed

Every factor in human well-being is also an element of nutrition. All needs are really nutritive needs. Deprivation of any single need may mean our demise or impairment of our growth, development or health. A single factor insufficiently or incorrectly supplied can lead to disease and suffering.

Most people are aware of the essentials of life. But they lose sight of these fundamentals as being factors and influences that are necessary to well-being within the context of society. Therefore, they're likely to violate the very laws of their existence and contribute to their own sickness and suffering.

When in a state of disease, most people do not realize they have brought it upon themselves. They are aided in placing blame outside themselves by a profession that takes the stance that they've had an unfortunate bit of bad luck or they have been invaded by some microbial enemy. Though the needs of the ill differ from those of well people only in that their conditions must be made favorable to recuperation, both ill people and the medical professionals undertake a course of treatment that compounds sickness. Both the physician and the sufferer enter into an attempt to poison the ailing body back into health. The fact is that drugging only makes a body worse.

The causes of health are very simple. Our needs do not change substantially when we become ill. Even illness itself won't occur if the needs of our bodies and minds are properly met.

The nineteen factor elements for optimal well-being are listed as follows:

1. Pure air
2. Pure water
3. Cleanliness—both internal and external
4. Sleep
5. Temperature maintenance
6. Pure wholesome food to which we are biologically adapted
7. Exercise and activity
8. Sunshine upon our bodies
9. Rest and relaxation
10. Play and recreation

11. Emotional poise
12. Security of life and its means
13. Pleasant environment
14. Creative, useful work
15. Self-Mastery
16. Belonging
17. Motivation
18. Expression of the natural instincts
19. Indulgence of aesthetic senses.

Let us explore the first two of these needs in detail.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > 2. Pure Air

## **2. Pure Air**

### **2.1 Air Contents Normal to Humans**

Pure air is relatively free of pollutants. It contains only the normal amount of carbon dioxide, carbon monoxide, inert ozone, formaldehyde, sulfur dioxide, nitrogen dioxide, ammonia and particulates, all of which the body is well-equipped to handle.

In other words, there is always water vapor, some carbon dioxide, and a minute amount of carbon monoxide in the air. Carbon monoxide isn't healthful in any sense, but we are equipped to handle it as naturally found in the air from natural sources. There are also particulates in the air including dust or the debris of decomposing products. Pollens, fragrant emanations and other natural effluvia are also present. There are inert gases in air—free gases in very, very minute percentages. Some may be inorganic and toxic, but many come from forms of life. All of these constituents are not a part of the air's chemical composition but are held suspended in it. They are known as variable components.

Air is composed of nitrogen (78.1%), oxygen (20.9%) and fractional parts of less than 1% of argon, hydrogen, methane, nitrous oxide, xenon, krypton, helium and neon.

### **2.2 Today's Air Is Loaded With Pollutants**

Humans have adapted to impurities in air over millions of years. Unfortunately, air today is loaded with immense amounts of pollutants not normal to our adaptations. Even those which we are equipped to handle in minute amounts often pervade the air in overwhelming quantities.

For example, carbon monoxide is often in the air in urban areas in amounts sufficient to seriously affect well-being. In these same areas are huge amounts of lead, hydrocarbons, and other unwholesome substances in quantities that we cannot handle. Today we get only a fraction of the oxygen-rich air we need for good health. Compounded with the problem of the general pollution of outdoor air, we tend to stay in our homes and workplaces where we constantly inhale our own aerial excreta and staggering amounts of pollutants otherwise generated.

### **2.3 Many Americans Pollute Their Homes and Bodies by Smoking**

Many Americans subject themselves to lung pollution from tobacco smoke. Smoking is a deadly, poisonous habit, a narcotic addiction that slowly kills. Nonsmokers are harmed by the fumes as well as smokers.

We should get as much fresh air as circumstances permit. The ideal is to live in completely fresh air in a pristine state of nature. If nothing changed in our current circumstances except that we lived in fresh air constantly, life expectancy would rise by many years.

## **2.4 Normal Air Is Continually Cleansed by Forces in Nature**

Normal air in nature has its fresh life-giving consistency because it is continually cleansed by the forces of nature. Particulates are continually taken up into the air due to activity in the form of wind and breeze. But, just as constantly, they are dropped down when the air masses become relatively tranquil.

For example, ozone constantly gets into the air but rises to the very top of the atmosphere where it remains. Methane gas constantly rises into the atmosphere from decaying organic matter, but other factors will decompose it back to some other form. Of course, much methane gets trapped within the earth by rock, by liquid overlay, and by other factors. Ozone and methane are both toxic, but it's rare that a great amount of them assault us at any given time or place.

## **2.5 Air Was Originally Brought to Its Present Consistency By Bacteria**

There are certain bacteria called anerobic bacteria. They've been around for a few billion years and were the first type of life on this planet. Anerobic bacteria were photosynthetic in the beginning because there was no organic matter for their soil. It is theorized that these bacteria were able to take on the spark of life, utilizing minerals, light and water.

It is not ours to conjecture too much about the derivation of the original form of life, but perhaps it was some kind of anerobic bacteria that could use sunlight as the spark of life. These bacteria began using water, sunlight and inorganic substances with which oxygen was associated. They could synthesize these raw elements into their life needs. One of the by-products of their metabolization was free oxygen. In time the great amount of oxygen accumulated in the atmosphere that gives it the consistency it now has.

Theory has it that life began in the water medium. No oxygen was present in the earth's gaseous mantle because all oxygen was bound in some compound until the bacteria freed it. The original bacteria evolved into many different forms of bacterial life and into many forms of plant life. All cells are said to be composed of many bacterial cells that united and cooperated for the greater good. Essentially, all life is symbiotic, that is, it is fundamentally in harmony with all other life from the most minute microbe to the largest of the Earth's creatures.

On a practical level, we are concerned with air quality so that we can benefit from it all the more. We seek means by which to take in plenty of air in its purest form. With knowledge and understanding we'll be able to help others conduct themselves in their environments so as to be optimally free of polluted air. Anything that gets into the lungs which the lungs have not been equipped to handle efficiently and naturally is a poison. The lungs have a tremendous capacity for expelling particulates and pollutants. But they can be devitalized by the pollutants and stressed by unceasing efforts to remove extraordinary types and amounts of impurities. The lungs will eventually be overwhelmed and lung diseases often result. You may have heard of black lung, brown lung, emphysema, pneumonia and other ailments of those who live and work in polluted environments. This is especially true of those who work in coal mines, who smoke or who live in highly-polluted cities such as Los Angeles or New York. The lint and dust in cotton mills is notorious for destroying the lungs of those who work in them.

You may know, or know of, people who have lung cancer, emphysema and other afflictions because they smoke, work in asbestos plants or work or live in other heavily-polluted environments. While an atmosphere laden with innocuous dust is pathogenic if exposure is unceasing or for long periods, many substances such as asbestos, tobacco tars and poisons are very virulent in themselves. Despite the lungs best efforts at ridding themselves of these poisons, they are always seriously and deleteriously affected.

## 2.6 Air Pollution in the American Home

Most homes in America are very polluted places. They have filthy air. (The words filth, poison and pollution are fairly synonymous terms in this context.) People who smoke deliberately and knowingly are intentionally poisoning themselves. Smokers do not seem to recognize that tobacco smoke is very toxic and is one of the biggest polluters of all. But most forms of pollution are unintentional, even unknown.

Humans must have sufficient fresh air. We often read of people jumping from hotel rooms to their deaths on a sidewalk in preference to the tortures of smoke inhalation and fierce heat. In many cases there is no heat and even no imminent danger of suffocation, yet agony and fear prompts the death jump. Yet, all too often, smoke inhalation alone kills. How many times have you read reports of people who die in homes, untouched by anything but smoke?

Cleansers and detergents are used heavily in almost all homes. All of these substances are poisonous although some are less toxic than others. Some exude almost no odor. They are called biodegradable or ecologically-viable cleansers, detergents and soaps.

There is much carbon monoxide in many homes. Carbon monoxide is one of the primary pollutants which emanates from auto exhausts; it is very deadly in the human system, binding the oxygen in the blood. Carbon monoxide also destroys animal and plant life. Plants cannot assimilate it and it actually causes leaves to wither. In the home carbon monoxide is a by-product of cigarette smoke, heating units, and cookstoves that use anything but electricity—and more.

Air that contains sulfur dioxide is extraordinarily poisonous. It is to be found mostly in the air of industrial areas that burn coal. In these areas homes are very likely to be polluted with sulfur dioxide as well as with the extraordinary aerial pollution to which most American homes are subject under conventional modes of living.

Air pollution is becoming quite an issue, especially in some parts of America. In the East, acid rains are a problem for food raisers of all kinds. They are also destructive of buildings, autos and everything else. In the Los Angeles area rare forests and plant life are dying off due to the highly-polluted air. Many crops in that area are adversely affected. Gardeners as well as growers are just giving up. Los Angeles is becoming an area in which neither plant life, humans nor other animals can thrive healthily.

The purity of air is of great importance. Polluted air is a great source of debility and disease. Pure air is necessary for best health. It behooves us to have the best air possible. Unfortunately, the most polluted air is to be found in the Average American home!

Polishes, waxes and other household items give off a large amount of gases. Whether pleasant or unpleasant they're usually poisonous. Aerosols and sprays have become widespread in their use in our homes. Even "foods" such as artificial creams, toppings, etc. come in aerosol containers. The vaporizer is usually a fluorocarbon and/or vinyl chloride. Both substances are toxic and a highly toxic material is used to thin these substances to make them aerate or expand when pressure on them is relieved.

Chlorine is a deadly poisonous element. During World War 1 it was used as a weapon. Many fighters succumbed to it. Even though chlorine is dilute in city water, we can still taste it. Most water supplies have been treated with this toxic element. How many times have you run bathwater or showers and gone into the bathroom to be assaulted by accumulated chlorine? In bleaches and in some other compounds that are frequently used in laundering and cleaning, high concentrations of chlorine are usually released.

Most people do not realize it, but certain types of plywood and other products in their homes are bonded with formaldehyde, which is in insulation, plywoods and plastics. Formaldehyde is given off as a particulate in the air. It may be given off for years in homes and trailers. This substance is quite toxic and many deaths have been attributed to breathing it. Formaldehyde is especially likely to be found in new homes, trailers, mobile homes and new rooms where plywoods and bonded plastics are used.

Oven cleaners are particularly toxic. They're designed to cut grease and to act as solvent for other debris

on enamel. Their fumes are particularly toxic.

Cosmetics are a very big source of pollution in some homes, especially where there are hair sprays and products containing fluorocarbons. The substances sprayed are usually very toxic in themselves, for they have copolymer residues of vinyl acetate. These residues are toxic when inhaled. Fumes from cosmetics that are in contact with the air may smell pleasant but they're also toxic. The only substances that are not toxic in our bodies are pure air, pure water and wholesome food. Anything else in our bodies is toxic and possibly a contributory cause of pathology.

Deodorants are extensively used in America, some one billion dollars worth annually. That's enough to mask quite a bit of body stench. Healthy people do not use deodorants because they emit relatively non-malodorous smells.

Deodorants and antiperspirants are used in minute amounts and the basic ingredients are quite toxic. They consist of a formulation of drugs designed to inhibit the body's secretory functions. This inhibition of body functions occurs because the deodorants are so toxic that the body keeps skin pores closed lest absorption of the toxic drugs occur.

Aside from their presence on the skin, deodorants give off particulates and vapors which are toxic to users and to others. They're particularly poisonous in homes because their pollutants tend to become cumulative. Air in homes, especially in winter, is retained for long periods of time and thus becomes stale as well as accumulating effluvia from the household.

Insect repellents are often used in homes. While they're not immediately as deadly to humans as to insects, the fact that they are deadly to insects establishes their poisonous relationship to all living things. Insect poisons should never be used in the home except under conditions of nonoccupancy.

As additional camouflage for odoriferousness and for its perfumes, many women use powder. Powders are formulated around a base of dust. There are toxic drugs in the formulation as a rule and the dust itself is also toxic. Its fumes or gases are toxic. Anything that gets into or on the body other than those substances normal to it are usually toxic and occasion irritation or intoxication. Usually their toxicity is on a low order, but they can cause pathology in sufficient concentrations. Added to other pathogenic factors of which there are multitudes in the human system and environment, maladies often develop. Certainly extraneous substances worsen and exacerbate existing pathology.

Carpeting can also be a source of pollutants. Long after the dust and odors that they normally give off may have subsided, the synthetics of which they're made decompose and pollute the air. The dust, dirt, filth and debris which carpets accumulate and the excreta that results due to their bacterial decomposition assault us. Among the poisons likely to accumulate in our homes from bacterial decomposition are carbon dioxide, methane gas and ammonia. Any decaying substance, whether it's garbage, meats or other foodstuffs, pollute the air with the byproducts of bacterial activity.

Electric motors in appliances give off pollution. Clothes driers give off carbon monoxide and nitrogen dioxide if they use gas. All drugs and "medicines," especially those that are sprayed into the mouth and nose, are toxic.

Preservatives and additives added to foods to enhance appearance, retard spoilage, etc., are toxic. In cooking their gases permeate our household air and are additional sources of pollution.

Volatile oils, especially from polishes; mustard oil, onions, garlic and other pungent herbs; teas and drinks, etc., are not wholesome in the lungs. If you eat an onion or a piece of garlic, the lungs are one of the eliminating organs through which their toxic components are expelled. The oils of frying foods are not only toxic and very carcinogenic, but, when inhaled, they tend to coat the lungs. Heated oils give off acrolein. While it may smell fine, it is really a trojan horse, for its pleasant odor is contrary to its toxic nature.

Cleansers are used almost universally. Most are chemical formulations that have a number of poisonous substances. Ammonias are usually a primary component, and they are very deadly.

It is possible for the airborne grease from frying foods to accumulate in the lungs. Workers in kitchens who fry food, even if they do not smoke, are likely to have lung problems faster than those who smoke. Grease is not easily expelled from the lungs. For example, a person who works in a fried chicken outlet and uses a fry-o-lator several hours each day may develop a chronic cough and even pneumonia from inhalation of aerated grease from cooking oils. (There are also many other causes of lung maladies and coughing.)

Mechanics get a different type of oil and grease on their hands. These oils are akin to the fats in foods. Mechanics do not leave oil and grease on their hands for very long, though many work with it throughout the day. They recognize the dangers because they suffer its irritations. Most mechanics scrub their hands frequently. Yet they suffer many problems, including skin cancer on their hands. Cells and tissues cannot withstand the unceasing assaults of oil toxicity.

Home air pollution occurs from anything that is burned, cooked or heated (except for boiling water). Stoves and heaters that produce heat by combustion within the home are especially heavy polluters. Wood stoves give off a lot of carbon dioxide, carbon monoxide, tars and other toxic particulates. If you can smell anything, you can be sure that the air is being polluted. However, some gaseous pollution is odorless. Combustion within homes is dangerous on two counts. Some of the pollution that occurs has just been listed. The other count is the partial use of oxygen from inside air. Partially deoxygenized air may not furnish our oxygen needs sufficiently.

Alcoholic drinks give off an effluvia that is unwholesome in the lungs. Of course, it is worse to drink alcohol. Alcohol, like the mustard oil of onions and allicin of garlic, is not used by the body because it is indigestible. The lungs are utilized as one of the avenues of excretion of alcohol. This is obvious because you can smell alcohol on the breath of anyone who has partaken of it. Breathing alcoholic fumes is not healthful and can occasion ill effects, especially for those subjected to breathing alcohol as in breweries.

Condiments, seasonings, spices, sauces and gravies are almost all toxic in the lungs. Black pepper, for instance, is toxic in the lungs, far more so than when in the stomach. All these substances stimulate and irritate when raw. But when heated their toxic components are liberated into the air, and some very toxic effects can result. Most condiments in the intestinal tract occasion irritation, indigestion and other discomfiting effects, especially laxative or diarrheal effects. These latter effects occur because the inflamed intestines rush the noxious matters, including food in the tract, to the nearest exit—the bowels. When condiments are in the air, due to diffusion in the air or due to heating, the irritation to the lungs is similar.

Perhaps you've heard of pruritus anus. This merely means itchininess of the anal region. It may be caused by body elimination of toxic materials through the skin in the anal region. However, it is more than likely due to the toxic components of condiments irritating the skin at the exit point. These can be deposited there by fecal matter before it is cleared from the area. Hot peppers and black pepper can cause this but so can any other condiment. The amount of irritation these occasion on the skin and in the anal region is an indication of their toxicity in the intestinal tract.

Cooking, brewing, boiling and baking of foodstuffs, especially as concocted in the average American home, occasions the pollution of home air with gases, particulates, tars and other unwholesome effluvia. Cooking destroys foodstuffs, and much of their substance is passed off into the air during the process. Cooked foods are harmful when ingested. Their aerial by-products are also harmful in the lungs no matter how much we say savor their fragrance.

Americans are inclined to bring all kinds of chemicals into their homes. Chemicals in the home, wherever stored, slowly oxidize and vaporize, unless tightly capped. But sooner or later they are opened for use. Some chemicals are quite common, notably toothpaste, gargles, lotions, cleansers, lighting fluids and antiseptics.

Antiseptics can also be called antibiotics. They're not in any way anti-septic because the term means "against poison." They're actually antibiotics for, indeed, they are destructive of life. They destroy

bacteria wholesale. Likewise, antiseptics destroy living cells of skin, mouth and lungs. If any odor can be detected from so-called antiseptics, the substance will be harmful.

If all the foregoing sources of home pollution are not enough, there are human wastes and air usage to be considered. Humans give off toxic wastes from lungs and skin throughout the day and night. These wastes include carbon dioxide, carbonic acid and minute amounts of other exudates. Also, the air expelled from the lungs is oxygen-depleted. In closed homes (as they're likely to be in winter) the air becomes polluted from our own effluvia and de-oxygenized from breathing. We're likely to breathe and rebreathe spent air and its load of toxic wastes. All this, coupled with the multitude of other pollutants in homes and the outside air taken into homes makes the average American home a very polluted place.

As a health practitioner, you will want to recognize all the deleterious factors to which humans are customarily subjected. You will be looking for causes of problems from all sources. Knowing that the air quality in homes, outdoors and in factories can contribute to pathology is essential. You may take it for granted that most areas of inhabitation in America are polluted to some extent.

## **2.7 What We Can Do to Insure a Constant Supply of Fresh Air**

By now you may be asking: "How can we insure that we get as much pure air as possible into our lungs in this polluted world?" Air that doesn't have more impurities than normal in nature is automatically pure.

Our message is that it is really impossible to have really pure air in this day and age. We can place ourselves in situations where we have the purest air possible. To get the freshest possible air we should keep our windows open. We should so live and conduct ourselves as to keep our home air free of all those processes and products that pollute it. There is no insurance that we'll have the best air possible no matter what we do or where we go but, relatively speaking, we can have pure air in the outdoors far from civilization, for nature is constantly cleansing the air.

If we live in colder climates where we must live in closed spaces for energy conservation, we can get heat exchangers. A heat exchanger brings in fresh air from the outside and removes air from the household. Through a dual piping and radiator system, the heat of the outside air is transferred to the incoming air to the point of equalization.

As an example, let's say the outgoing air is 72° and the incoming air is 32°. The air will tend to equalize at some temperature in between. The incoming air will tend to equalize at a temperature lower than their normal nominal midway point. This means some additional energy must be expended in heating incoming air to the desired temperature.

When you measure the benefits of heat exchangers in terms of health and the energy conserved through their employment, the cost is a good investment. In energy saved they're worth their cost in a few seasons. In terms of health they pay for themselves many times over very quickly.

Using a heat exchanger is just one thing we can do to insure more fresh air. Most of us can go out and exercise or play in fresh air most days. When we exercise heavily and vigorously in fresh air, we completely oxygenize our systems (in addition to gaining a multitude of numerous other benefits).

Exercise ventilates our entire body. Run, jog or walk. Play an outdoor sport. Any sustained activity that greatly accelerates body function will ventilate your system. Especially important is the oxygenation of our capillary system which results from exercise. Faster and more vigorous blood circulation insures better capillary health due to greater oxygen uptake and rejuvenation of function. Stagnation of the capillary system is a primary contributor to deterioration and disease. The intake of fresh air in conjunction with exercise is of inestimable value.

A device for improving air quality that is becoming popular is the negative ion generator. Research indicates that negative ion generators may have positive benefits, especially in the area of human response. Humans experience euphoria and well-being in ionized atmospheres. But little research has

been done to determine whether the effects are beneficial or drug-like. No evidence has been developed to suggest that either negative or positive ions are any more or any less healthful than the other. What has been determined is that negative ions precipitate dust, particulates and toxic materials from the air. If so, this is a positive benefit. I seriously doubt that ionized air gives a drug effect. In a very polluted home a negative ion generator might be helpful. Air cleaners that precipitate particulates, dust and other forms of pollutants are of benefit. Filters are also helpful. As health practitioners, you very well might have to live in or near a population center most of which are polluted, in order to reach more people. When we must place ourselves in a polluted environment, we must suffer the consequences. We can reduce the effect by employing all the technology we can in cleaning our air supply in polluted areas. Just as we are apt to close up our homes and pollute our air, likewise we can close up our home and bring in fresh air that has been purified or filtered. Then we should refrain from in any way contaminating our inside air supply.

Most auto pollution is along highways in most of our country and where there are concentrations of autos. In other areas the air is often stagnant and the exhaust pollutants of the auto become cumulative, sometimes until the air is deadly as in the Los Angeles area. The only suggestion we can make for avoiding carbon monoxide poisoning is to stay away from it. But this suggestion is of little value if you live in Los Angeles or New Jersey or similar areas. In low-pressure areas, carbon monoxide concentrates along the ground.

New Jersey, which is called "The Corridor State," has more auto traffic per square mile than any other state. It also has the most concentrated population. Further, it has heavy concentrations of chemical industries. So polluted is its air in industrial areas and along major highways that it is called "Cancer Alley." More cancer occurs in New Jersey than in any other state. Cancer among people who reside near highways in New Jersey is three to four times that of the average American.

These facts tend to indicate the dangers of, carbon monoxide. They are indicative that, along with all other causes of cancer, carbon monoxide and its concomitant pollution might be the additional straw that breaks the camel's back and causes cancer.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > 3. Pure Water

### **3. Pure Water**

Water deserves treatment equally as much as air. In fact, inasmuch as breathing is an automatic process and drinking is a consciously-directed process, water deserves more attention. Though every aspect of our well-being deserves adequate attention, those areas wherein our health is more likely to be endangered or undermined should receive the most detailed treatment. Getting the water we need is one of those areas.

Besides wholesome foods, only three items should ever be taken into our bodies. These are air (about which we've spoken), sunshine (which we'll speak about in another lesson), and water. We'll take up this subject next. At this stage suffice it to say that anything in or on the body other than wholesome foods, air, water and sunshine—all essential body nutrients—is unhealth! This stricture may seem severe. But we cannot exceed the limits of our adaptations. To do so is to subject ourselves to pathological consequences.

Your role as a health practitioner is to keep yourself and your clients in a regime of living as free as possible of the dangers inherent within the context of a "civilized" society. The word "civilization" is in quotes, for what kind of society can be said to be civilized if it harbors grave dangers for its members?

As promised, let's move on to the subject of water. What is water? What is its role in the body? Why do we need it so vitally? What kind or kinds of water should we have? What is the best source for our water requirements? As we get into the subject we'll endeavor to answer these questions.

The expression pure water is used throughout our treatment of the subject of water. If there's anything everyone wants, it is pure water. No one wants impure water. Yet, most people drink anything but pure water. Pure water is purely water-only water and nothing but water.

### **3.1 Best Sources for Humans**

The purest water is distilled water. Inasmuch as an individual lives as he should he will get all or almost all his water needs from a diet of proper foods. Therefore, very little distilled water will ever need to be consumed. Distilled water should be a secondary source of water. Humans are not naturally water-drinking creatures, for they have absolutely no equipment for it as have natural water-drinking animals. Therefore, the proper diet for humans is necessarily water sufficient. A correct diet must contain the pure water that we require.

Fruits contain the purest water of all and also are the finest foods of all. The water in fruits is completely pure; that is, it is without any trace of inorganic minerals or other matters that are likely to combine with body fluids and clog up blood vessels, cells or interstitial spaces. Most Life Scientists are primarily and almost wholly fruit-eaters. (Bear in mind that many so-called vegetables are actually non-sweet fruits and that, technically, nuts are fruits, too.) Because we were almost exclusively fruit-eaters in a pristine state of nature and because a fruit diet is water sufficient, humans never developed water-drinking mechanisms.

Why does the body need water? What role does water play in the body? Why is impure water harmful to the body?

The primary role of water in the body is as a transport medium. It is also the medium for storage of needed organic compounds and electrolytes within the cells. This is accomplished by the water holding molecules and nutrient reserves in suspension.

Impure water harms the human organism because the impurities are invariably poisons. While our foods contain water, water from non-food sources is not our medium for food or nutrients. Minerals in water are dissolved from soil and rock and have no more virtue in the human body than if the soil or rock itself was eaten. The body simply cannot handle inorganic minerals. Inorganic minerals circulate in the body as poisons. Anything at all in water aside from wholesome foods is, therefore, a pollutant or a poison.

Thus, people who drink water are likely to imbibe a plethora of poisons. Different people drink water for different reasons. For instance, many health seekers drink spring water, well water, sea water and other kinds of water in the mistaken belief that it is healthful.

Let's take a closer look at water drinking in America and examine certain probabilities in regard to water-drinking.

- Some people, including Life Scientists, drink little water because they are primarily fruitarians. Their diet is water sufficient.
- Some people drink distilled water either because they are health-aware and want pure water or because their regular water supply is unsuitable for drinking. By far the larger number of Americans who drink distilled water do so because their regular water is so bad, not because of any overall health orientation. They may be said to be undertaking a healthful measure in preference to an obviously unwholesome practice. In either of these cases of people who drink distilled water, water drinking is indulged because of a more or less unwholesome diet (a cooked diet containing salt and other condiments). Our natural diet is water-sufficient.
- Some people deliberately drink mineralized waters in the mistaken belief that their bodies need all the minerals they can get. These are usually "health-oriented" persons who do not realize that

minerals in water as picked up from soil and water are the very same as the minerals in soil or powdered rock and are not used by the body. They shun chemicalized waters from water systems.

- The majority of people drink whatever water is available—mineralized; chemicalized; from their local water system, wells or springs. These people consume a diet that is either water-deficient or so unwholesome as to require heavy supplies of water.
- Life Scientists sometimes drink distilled water. They may do so because they are fasting and not taking in water from food sources, or they may drink distilled water to supplement the water present in their diet. In the latter case, extra water may be required during particularly hot weather, especially if the individual engages in vigorous physical activity.
- Tens of millions of Americans drink soft drinks, coffee, tea, cocoa and a host of other water-containing concoctions when thirsty. These people entertain and stimulate themselves in the process of getting their liquids. While pure water is, in itself, very satisfying to the thirsty, many seek other gratifications which they get by consuming the kinds of drinks just mentioned. All drinking of anything but pure water is less than ideal and most often is quite unwholesome and disease-producing. For instance, many drink fresh vegetable and fruit juices to quench their thirst. Juices, though fragmented foods, are, nevertheless, foods. They should not be used as substitutes for distilled water.

### **3.2 Chemicals Used in Water "Purification" Are Toxic**

Most Americans drink liquids and most liquids taken contain inorganic minerals, fluorine, chlorine and other so-called "chemicals of purification." Bacteria in water are far less harmful than the chemicals that are used to destroy them. Their presence in water usually indicates that the water contains organic matter, but bacteria in water are no more harmful than those we constantly take in by air or those which populate our intestinal tracts. However, water we drink should be pure. No water system in this country furnishes pure water. Invariably it is polluted in some harmful way.

Drinking tap water is fraught with dangers. The US. Public Health Service released the results of research and surveys of waters from various water systems in the U.S. Over eighty carcinogens were found. Most of these were from the breakdown of chlorine in water systems or its combination with other chemicals. Chlorine itself is a carcinogen. Chemicals from agricultural fertilizers, chemical industries, pesticides and homes pollute our waters. Sulfur, iron, gypsum, calcium, magnesium and other inorganic minerals are toxic in themselves. Purification systems, so-called, do not remove these minerals. They are designed to remove bacteria, which are far less harmful. Purification systems add chemicals rather than remove them (except in some systems where the water supply is deadly at its source). This is especially true of some waters in Louisiana and New Jersey.

Fluorine is added to water, not as a purifier, but as a mass medication. This waste product of the chemical and metals industries has been rammed down our throats, so to speak, in the mistaken belief by many that it will prevent tooth decay. Obviously, it doesn't work, for tooth decay is just as rampant today as before—in fact, it is worse than ever. Fluorine is in the water of more than half our population's water supplies. Inorganic fluorine compounds are carcinogenic and deadly. Poisons are never the basis of health. Our teeth are sabotaged by dietary practices also.

### **3.3 Spring and Well Water**

As mentioned earlier, many people think mineral water, well water, spring water or other impure water is just what we need. Spring water, waters from mountain streams and waters to which certain minerals have been added are quite popular. In New York City and in some other places, such waters are the rage. Many people in these places will not touch their city water supply for drinking purposes. But processed waters which have had mineral concoctions added and waters from springs and mountain streams are in vogue. While these waters with their mineral content cannot possibly be as harmful as the mineralized and chemicalized water supplies, they are, nevertheless, very unwholesome. Distilled water is available

in New York City but it is relatively neglected in favor of so-called natural waters.

Many waters, especially imported spring waters, are prized for their peculiar tastes. Some waters are carbonated to give them extra attraction. But all such waters are harmful. Pure water is pleasant to drink and has no taste or kick whatsoever. If you're thirsty, pure water is the most satisfying of all, even without any taste thrill.

Though you should get most of or all your water from your food, you should never try to get anything from water but water.

For the purposes of emphasis and enhanced understanding, we will repeat what has already been stated about water: Anything in water as drawn from tap, well, spring or stream is inorganic and harmful. The body cannot digest or metabolize inorganic substances. Other than air, water, and sunshine, the body cannot utilize anything except organic compounds as found in food. All else is poisonous. Inorganic materials cannot be utilized; they clog up our bodies if not eliminated, and they combine with body fluids, oils, compounds and wastes and form substances that clog our vascular system. They are deposited in our joints and muscles, interstitial spaces, organs and lymphatic system. Both deranged foods, that is, those that have been cooked and processed, and impure water contain inorganic minerals, which are harmful to our organism.

People with the debris of impure water and cooked food in their systems usually do not eliminate all of it. When these substances are in an active state, that is, when they are circulating in the system, the body is in a frenzy. Leucocytes (white blood cells) proliferate, pulse rates increase, and often enough, these people are stimulated. The stimulation usually begins within 15 to 30 minutes after drinking or ingestion and lasts until the materials are eliminated or sidetracked in the system—as in plaques which form in arteries.

Just as impure water contains harmful, non-usable inorganic minerals, so do cooked foods. This topic will be covered in depth in a later lesson.

There are several schools of thought in this country that advocate drinking mineral-containing water such as well water, spring water and mineral water. They say that mineral-containing water is needed because the body requires the minerals from it. In addition, they say that distilled water causes heart attacks and leeches needed minerals from the body, causing tooth decay, pyorrhea and osteoporosis and that distilled water is dead water and fish cannot live in it. They contend that water containing minerals will correct these problems as well as preventing them from happening in the first place.

Proponents of mineral-containing water attribute the superb health of the Hunzas to mineralized water. The Hunzas are one of the healthiest peoples in the world. They supposedly drink a frothy white mineralized water from glacial runoff.

Of course there are valid responses to these arguments. To the implication that we need the minerals in impure water, we point out that, if our diet is proper, we get more than we need of minerals of all kinds. Further, the minerals in water are totally unusable, thus making them a toxic burden within instead of nutritional. Water is needed in the body for itself, not for any incidental impurities it may have picked up from soil and rock.

Rather than distilled water causing heart attacks, it is the other way around. Distilled water does not leave behind any indigestible debris from unusable inorganic minerals. Those who drink mineral-containing water are often found to have heavy plaque in their systems. The rejected minerals which the body cannot use often combine with cholesterol and other fatty substances to form plaque. These block the arteries. The rejected minerals are also likely to be put aside in the body in spaces that exist. Notably is this so in the cranial cavity where the spaces of lost brain cells are filled in by minerals, thus leading to ossification of the brain. This is a cause of senility.

How pure water could leech minerals from the body has received a thorough refutation from physiologists. An important thing to remember about water and everything else put into the body is that

it is done unto by the body. It does not do unto the body. Those substances which seem to act on the body, as in the case of unmanageable acids, compounds and chemicals, are poisons. The body is the master of its domain. Following this reasoning, soft water does not leech minerals from the body. The body uses water. Water doesn't use the body. Water and other foodstuffs are under the control of the body while in the body. The body does what it wants to with water. It excretes the water if it's not needed. Along with the water it excretes mineral matter that it no longer requires. The kidneys are the final arbiters of what will be excreted and what will be returned to the body economy for use. For instance, the body recycles about 95% of its iron regardless of the water we drink. It also recycles many other mineral compounds or salts. The body is very conservative with its nutrient supplies.

An example is eating watermelon. If you eat watermelon, your urine will be completely clear. There will be almost no mineral matter in it to color it. The very pure water of watermelon that is unneeded by the system is speedily expelled. Very little mineral or other matter will be in it, for the body is doing unto the water. The water does not circulate freely in the body. The body retains or expels the water according to its need.

On the other hand, if you are fasting or under any other condition in which you're not taking water from food and the body is conserving its water supply, your urine will become very dark yellow because the body is giving up more wastes and more mineral matter relative to the water it is expelling.

What the Hunzas (or North Pakistan) drink is not responsible for their health. Water is a need of life but total health is dependent on healthful living. Water is but one element of many. Travelers who have gone there find that the Hunzas really drink very little water. They're primarily fruit eaters. The water they do drink is permitted to settle first. As the glacial runoff comes rushing down the mountains it picks up minerals as debris rather than holding them in solution. That is, the water has silt in suspension rather than minerals in solution. This silt is the basis of Hunza health, true, but because it is deposited on their fertile gardens, not because they drink soil and rock in their water. The water itself comes from relatively pure snow. Very few minerals are in solution by the time it has rushed from the heights to their catch basins below. Only a few minutes of time in contact with minerals accounts for the mineral complement of these waters.

Again, how can waters be responsible for a condition of health? If drinking water was the secret for great health, then all we'd have to do is drink the kind of water we need and not worry about food, exercise, sleep or anything else. Water would take care of everything. Healthful living would be unnecessary.

Next let's examine the argument that pure water is dead water and that fish can't live in it. As you know, many fish live in the ocean. We can't drink sea water, for we'd quickly die. It has a heavy complement of minerals - sea water is richer in minerals than any water in the world. Other fish live in rivers, creeks, ponds and lakes. You don't drink water out of rivers, ponds and other places where fish live. Such waters contain the excrement of fish and other creatures, decaying leaves and other organic matter. In fact, we don't drink from fishy waters for a very good reason: It's unfit to drink. Further, water, whether fish live in it or not, cannot be described as living or as dead. In short, there can be no living water, for it is an inert lifeless compound at all times.

It is true fish cannot live in distilled water. Distilled water has no air in it. Neither does it have the food supply a fish requires. Thus it can be seen the argument is without any merit.

To repeat: If we're eating the diet to which we're biologically adapted, we do not have to drink water except on those occasions when we must use unusual amounts of it to refrigerate ourselves as in heavy physical labor in hot weather.

Why do most Americans drink so much water and other liquids? Cooked food eaters require copious amounts of water. People who take in so many irritants or poisons as found in heat-deranged foods; in condiments, especially salt and other seasonings; and in unsuitable foods such as grain and animal foods, need this water to help hold toxic materials in suspension so that they offer less harm to cells and

tissues.

People who eat a wholesome diet require less water than people who eat an unwholesome diet. On wholesome diets there is usually sufficient water in the foods to meet all needs whereas, on an unwholesome diet, abnormal amounts of water are required to help cope with the irritants, stimulants, excitants or poisons within.

Edema or dropsy, for instance, is a disease of those who eat cooked foods and/or salts and other condiments. The body takes on extra water to hold these toxic materials in suspension. Until the body can dump these they are stored in likely areas, often the feet and legs. A few days of fasting enables the body to catch up on its housecleaning. It thus will expel the waters and purify its fluids and tissues.

This concludes our examination in depth of the first two essentials of life, air and water. In the next lesson we'll keep up consideration of other of life's essentials.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > 4. Questions & Answers

#### 4. Questions & Answers

**With the catalog of things you've listed I feel uptight even considering using a bar of soap around the house. Isn't there anything we can use that is non-polluting with which to clean house, floors, clothes, dishes and our bodies?**

Yes, there are products that are relatively non-polluting and which yield excellent results. For cleaning clothes you should consider [Basic-L](#) from Shaklee products. For cleaning floors, dishes and even cars a solution of Shaklee's [Basic-H](#) will do wonders. [Amway](#) and other companies also produce similar non-polluting biodegradable products.

For your body you need no soap or cleanser. A good fiber brush or washcloth is all you need while under a shower or in a bathtub. If you want to use a cleaner on your body, Shaklee's [Basic-H](#) is fine.

**Can't we use any cosmetics at all?**

Of course you can use cosmetics, but keep in mind that not one is healthful. Moreover they are unneeded by a healthy person. They detract rather than add to beauty. And they only compound skin problems for an unhealthy person. Beauty is natural. When in health your eyes and skin radiate their condition, just as they look sallow, pallid and in poor tone when unhealthy. We advise against the use of cosmetics under all conditions. Also, skin creams and oils of all sorts, including suntan oils and lotions only complicate the problem they are used for and cripple the body's oil producing ability.

**I have a friend who smokes a pack and a half of cigarettes daily, drinks beer and eats junky foods. He appears to be in excellent health and is quite active. By all that you've said he should be a corpse. How can you explain something like this?**

How old is your friend?

Your friend is still, obviously, only a babe relative to potential and is still living on youthful capital. He might continue this pattern for another five, ten or even twenty years, but the penalty for not meeting life's needs correctly must sooner or later be suffered.

When you read the disease statistics and see the human wreckage resulting from the tobacco, alcohol and junk food habits, you'll know that most humans exhaust their endowments rather quickly, even in their thirties, and succumb to cardiovascular problems, chronic cough, cancer or other degenerative diseases.

Most smokers know the dangers of their habits but feel themselves to be exempt from them—it's something that always happens to the other person. All sins against our bodies must be paid. There is no dispensation in nature.

**You've condemned deodorants. Are they very harmful? What is a person to do to control body odor?**

Deodorants are poisonous. Their toxic effects cause the skin pores at points of application to close up so as to exclude their chemicals from the inner sanctum. This prevents body perspiration and exudation. They are properly called anti-perspirants for this reason. A person who has body odor should strive to go to the source of the problem. Body odor is not natural. Healthy persons do not have body odors. Foul smells are produced by a foul system. Clean up the body and it ceases to exude unpleasant smells.

**Do you mean that people who have body odors, bad breath and so on are really sick inside?**

That is the case. Healthy cells, tissues, fluids and organs do not smell rotten or foul. Obnoxious odors come from decomposing materials.

**Just the other day I read that distilled water, because it's heated in the distillation process, causes leukocytosis just as cooked food does. As you advocate distilled water, what do you say to this?**

This is untrue. Leukocytosis, the proliferation of white blood corpuscles, results from poisons entering the bloodstream. The inorganic debris resulting from cooked foods will cause this malady, but distilled water causes no decomposition or poisonous substances. The distilled water was water before, during and after the process of distilling. It was not changed except that impurities it held before distilling have been left behind. The truth is that mineralized water causes leukocytosis. The inorganic minerals of water are toxic and cause a toxic reaction by the body. Leukocytosis is but one of the body's defensive mechanisms against toxic materials. Those who employ this argument are trying to defend the use of mineralized waters, but there is no defense for using impure waters.

**I've heard it said that distilled water will cause heart attacks. In fact, this claim was made as a result of a scientific study in England. Do you deny this?**

Yes, investigators of the report found that, in a certain English city whose people drank hard (heavily-mineralized) water, the death rate from heart attack per 100,000 was 436 per year. The death rate in a nearby city that had soft water (water with fewer minerals) was 448 per year, just 12 deaths more. This implies that perhaps soft water causes heart attacks and minerals in solution prevents them. But these investigators found the following significant omissions from the report: The soft water drinkers had a lead pipe system throughout the city whereas the hard water drinkers had a copper pipe system for the most part. Lead is much more toxic than copper.

**Does fluoridation really make teeth stronger and healthier?**

Absolutely not! Fluorides in an inorganic form are toxic. Ingested fluorides have an affinity for calcium. Insofar as they unite with calcium they destroy bone and teeth. The body defends against fluorides by, at first, hardening the bones and teeth. Then they become brittle and break down under ordinary eating. St. David's, Arizona, has natural fluorides to the extent of about eight parts per million of its drinking water. Perhaps there is no worse example of poor teeth in America than there. About 50% of America's drinking water has been fluoridated for some 30 years. For all that, America's collective mouth is still the biggest disaster area of the body! Nearly 99% of Americans have bad teeth. One in every seven have no teeth at all. Inasmuch as almost all of these are adults, that means one in every five adults have no natural teeth.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > Article #1: The Importance Of Pure Water by John H. Tilden, M.D

### **Article #1: The Importance Of Pure Water by John H. Tilden, M.D**

Water is not looked upon as food by laymen, but it should be classed with food. It certainly is fully as important. An individual may live 40 to 100 days without food whereas survival beyond seven days without water is unlikely.

Water should be obtained from normal food sources as much as possible. It is easy enough to get our water needs from fresh fruits and vegetables, as most of these foods carry about 90% water.

The amount of water taken into the system by the average person amounts to from three to four pints daily. This can vary under different circumstances. In the summer more fluid is used than in the winter. Water is utilized by the body as a refrigerant through evaporation and, consequently, we require more in the summer. On the other hand we are more inclined to consume higher water content foods in the summer such as melons, peaches, grapes, tomatoes, etc.

Laborers consume more water, of course, because physical labor generates internal heat that must be reduced through evaporating water from the lungs and skin.

### **Water Is Actually a Food**

Water enters into the composition of every tissue and forms about 65% of the weight of the body. It is obvious that this percentage must vary in different individuals for many reasons.

Water should be recognized as one of the most important foods, for it is essential to the body.

### **Water Should Be Pure**

Rainwater is soft and supposed to be the purest of natural water, though this is doubtful due to widespread air pollution. Few people relish the taste of rainwater, for it has a peculiar taste. The fact of the matter is that most people are accustomed to water with some mineral content that gives it a little taste; but, on the other hand, they will shun waters of heavy mineral content, especially if those minerals be gypsum, sulphur, iron, etc.

### **Minerals in Water Clog Up Body**

What is called "hard water" is in fact water that is heavily laden with minerals. Wells in limy sections of

the world furnish water heavily charged with lime. Such water is not good to drink. People in such locales will be troubled with limy deposits in the body if they drink such water.

It is necessary to secure as pure water as possible. It is just as necessary as securing pure food. Nothing should be taken into the body that is not as pure as can be had. Impure water is the source of many diseases and general body degeneration.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > Article #2: Are Humans Drinking Creatures? by Dr. Herbert M. Shelton

## **Article #2: Are Humans Drinking Creatures? by Dr. Herbert M. Shelton**

"What a stupid question!" exclaims the reader, "Everybody knows that humans are drinking creatures and always have been."

It is quite true that universally, throughout history, in all countries, in all climates, at all seasons of the year and at all ages of life, humans have been drinking animals. It is equally true that all the evidence afforded us by protohistory reveals that throughout the protohistoric period, humans were universally drinking animals. Existing so-called savage cultures are commonly looked upon as survivals of prehistory. If this position is a valid one, then the evidence that is afforded us of the practices of prehistoric humans would reveal that they were universally drinking creatures.

### **Drinking Not Natural to Humans**

If we view the animal kingdom, we discover that there are animals that drink and animals that do not drink. Even many desert animals do not drink water. There are also animals that do not inhabit the deserts that do not drink. It has been seriously suggested that by his constitutional nature man belongs to the non-drinking section of the animal kingdom. This is to say, water drinking by man is an acquired and not a native practice. Many have taken this suggestion seriously and have refrained from drinking water for periods of years and have advocated the non-drinking practice for all.

Dehydrated protoplasm is lifeless dust. It seems to be true that where there is no water, there is no life for plants and animals and microscopic beings require Water in order to carry on the functions of life, that they may live. Nobody denies this. The question in issue is not the need for water, but the source from which it is to be derived and the manner in which it is to be taken.

### **Evidence Indicates Drinking as Perversion**

In 1815 a book by William Lambe, M.D. of London was published under the title *Water and Vegetable Diet*. In this book Dr. Lambe attempted to show the advantages of a vegetable diet over a flesh diet or a mixed diet and the advantages of pure soft water over hard water. At the same time and in this same book he raised the question: Is man a drinking animal?

Perhaps no one had asked this question before. But the question has been argued both pro and con by numerous intelligent men and women since Dr. Lambe propounded it, and it is still being argued, sometimes rather heatedly. Let us, at this time, consider some of the reasons put forth by Dr. Lambe for considering water drinking an acquired practice.

### **Historic Attitudes Toward Water**

As was the custom of his time, Lambe begins his consideration by quotations from the ancient works

attributed to the legendary Hippocrates and reveals the fear of water in acute disease which gripped the profession for so long had its origin at the very beginning of the medical system. He quotes "Hippocrates" as saying: "I have nothing to say in favor of water drinking in acute diseases: It neither eases the cough, nor promotes expectoration in inflammation of the lungs; and, least of all, in those who are used to it. It does not quench thirst, but increases it. In bilious habits it increases bile and oppresses the stomach; and is the most pernicious, sickening and debilitating, in a state of inanition. It increases inflammations of the liver and spleen. It passes slowly, by reason of its coldness and crudeness; and does not readily find a passage either by the bowels or kidney."

Following the quotation from Hippocrates, he quotes Van Swieten as saying: "While girls are daily sipping tepid water liquors, how weak and how flaccid do they become!" Lambe says: "And the same writer positively affirms that, by the abuse of tea, coffee and similar liquors, he had seen many so enervate their bodies that they could scarcely drag their limbs; and many had from this cause been seized with apoplexies and palsies."

Thus it will be seen that the evils that flow from drinking tea and coffee are attributed, not to the poisons contained in these brews, but to the water which composes most of the brew. Water and not caffeine and theine and the other poisons of tea and coffee is the evil.

### **Impure Waters Pathogenic**

Lambe next considers popular prejudices and tastes concerning water and its salubrity or lack of it as it is derived from various sources and contains, according to its source, different mineral or organic matter. He points out that many people in many parts of the world are very fastidious in their selection of the water which they drink, preferring water from one well or one stream or one spring and rejecting water from other sources. Lambe examines the drinking of mineral laden waters from marshes and swamps and the drinking of stagnant water and ascribes many evils to this habit. Many of the things he attributes to such water drinking are now known to be due to other causes; but even if he had been correct in all of his guesses, these facts could not properly be used to condemn water drinking. They condemn, not water, but impurities sometimes contained in water and form a basis for the condemnation of drinking, not water, but impure water.

Lambe suggests that the evil effects of water drinking have been the chief cause that has induced man to turn to alcoholic liquors. To escape from the evils of water drinking man plunged into the greater evils of alcoholism. It is not to be doubted that in some parts of the world where the inhabitants drink much beer and wine, there is a strong tendency to refrain from water drinking, not because water is regarded as essentially unhealthful, but because the waters of these areas are regarded as impure and unwholesome. Let us turn, however, to Dr. Lambe's effort to establish the soundness of his no-drinking plan.

He says:

"Having condemned water and attempted to show experimentally its noxious influence upon the system; having condemned spirits and fermented liquors, from the authority of the most enlightened medical writers and the common experience of mankind, it must follow that there is no species of drinking which I approve. And, indeed, I have already ventured to assert that drinking is an unnatural habit; in other words, that man is not naturally a drinking animal.

"To those who cannot raise their views above the passing scene, who think that human nature must necessarily be in every situation the same as they observe it in their own town or village; to those, in short, who look for knowledge in the prattling of the drawing room, or the gossip of the grocer's shop, I know that this appears a strange, if not a ridiculous assertion. We say, with great confidence, that water is absolutely necessary both to man and beast. But the strength of the evidence is not equal to the positiveness of the assertion.

"In fact, we know very little about the habits of animals, except of those whose natures we have changed and corrupted by domestication. All that the natural historian can do with regard to the wild species is to describe their forms and such of their qualities as have fallen under observations; these last must of necessity be very imperfect. Imperfect, however, as it is, we know enough to be certain that the assertion of the necessity of the use of water to animals is, to the extent to which it is carried, absolutely groundless."

### **Many Animal Species Do Not Drink Water**

" 'I have known an owl of this species,' (the brown owl) says M. White, 'live a full year without any water. Perhaps the case may be the same with all birds of prey.' There was a llama of Peru shown in London, a year or two ago, which lived wholly without liquids; it would not touch water. In some of the small islands on our coast, on whir-ther is not a drop of water to be found, there are, I am told, rabbit warrens. Bruce says, 'That although Zimmer (an island of the Red Sea) is said to be without water, yet there are antelopes upon it, and also hyenas in numbers.' To account for this, he suspects that there must be water in some subterraneous caves or clefts of the rocks. This, however, is only supposition. The argali, or wild sheep, from the country in which it is found, it is certain, does not drink. Mr. Pallas says of it, 'This animal lives upon desert mountains, which are dry and without wood, and upon rocks where there are many bitter and acrid plants.' He further says of it, 'There are no deer so wild as the argali; it is almost impossible to come near it in hunting. They have an astonishing lightness and quickness in the chase, and they hold it for a long time.' How wonderfully, therefore, is this animal deteriorated by domestication, and by being forced to live in situations and to adopt habits unsuited to its nature!"

### **Humans Have No Natural Drinking Equipment**

"Let us, therefore, consider man again, for a moment, as we may suppose him fresh from the hands of his Maker, and depending upon his physical powers only for his subsistence. We must suppose every animal so circumstanced, to be furnished by nature with organs suited to its physical necessities. Now I see that man has the head elevated above the ground, and to bring the mouth to the earth requires a strained and a painful effort. Moreover, the mouth is flat and the nose prominent, circumstances which make the effort still more difficult. In this position the act of swallowing a fluid is so painful and constrained that it can hardly be performed. He has therefore no organ which is naturally suited to drinking. He cannot convey a fluid into his mouth without the aid of some artificial instrument. The artifice is very simple, it is true. But still the body must be nourished anterior to all artificial knowledge. Nature seems therefore fully to have done her part toward keeping men from the use of liquids. And doubtless on a diet of fruits and vegetables there would be no necessity for the use of liquids.

"If it be true therefore that other animals require water, it would not follow that man, whose organization is different, would require it likewise. But we, in fact, know very little about the habits of animals. Our common domestic animals certainly drink. But it appears, as far as my information extends, that common water has the same effect upon them as upon man; and that they are more or less healthy, according to the purity of the water which they use."

### **Observations Upon Humans' Water Needs**

Dr. Lambe violates one of the cardinal principles of logic, to wit: Nothing can be used as evidence until it is known, when he predicates his argument for man as a non-drinking animal upon what was not known about the drinking habits of animals. Some of the observations which he records were faulty and these constitute a very insecure basis upon which to found important conclusions. It is now well known that many of the animals which he considers non-drinking animals do drink in the wild state. It should also be noted that animals that do not drink, many of them living upon the desert, do not become dehydrated for lack of drink, whereas man, under the same circumstances, dies from dehydration as

certainly as does the cow or horse. His argument that if man were intended to drink, he should have been born with a plastic straw in his mouth or a silver chalice in his hands, is hardly valid. It is true, however, as he points out, that with an abundance of juicy fruits and succulent vegetables in his diet, man can go, under ordinary circumstances, for long periods without drinking. In doing so, he does not go without water, but obtains his water free of organic and mineral contamination, in the form of fruit juices and vegetable juices. It is doubtful that this would suffice on the desert; it is certain that hard physical labor in the summer's sun will create a demand for water that such eating will not provide. Under such circumstances, one may be able to obtain all the fluid necessary by drinking fruit and vegetable juices between meals, but this constitutes eating between meals and is certainly a greater evil than would be the drinking of occasional glasses of distilled water.

## **Juices Are Food**

Fruit and vegetable juices should be regarded as food, not as drink, and should be taken as part of the fruits or vegetables containing them. Separated from the organic combination in which they occur, they lose much of their value. Drinking fruit and vegetable juices between meals definitely leads to overeating and most certainly disturbs the process of digestion.

It would be folly to try to meet the demand for water in the fever patient by filling him with fruit and vegetable juices. Pure soft water certainly does not have the effect in these cases described by the legendary Hippocrates. Neither does water affect the fasting individual in the manner described in the so-called Hippocratic writings. To condemn water drinking because in certain pathological states drinking distresses the patient is similar to condemning food because in certain pathological states eating causes distress. It is similar to condemning sunlight because in certain diseases of the eye, exposure to light causes distress and pain. The true test, as all Hygienists know, of the value of any substance or practice is its use or its rejection by the healthy organism.

[Home](#) > [Lesson 3 - Introducing The Life Science System For Perfect Health, Part I](#) > Article #3: Ama Says Fresh Air Bad For You by Frances Adelhardt

### **Article #3: Ama Says Fresh Air Bad For You by Frances Adelhardt**

In the February issue of *Moneysworth* appears the headline "Too Much Fresh Air Can Become Health Problem." The article is based on a report in the *Journal of the American Medical Association*.

What ills are attributed to fresh air? Listed in this article are insomnia, nightmares, weakness, exhaustion, heart irregularities, dizziness, numbness of hands and feet, shortness of breath, chest pains, yawning, stomach discomforts, muscle cramps, stiffness and anxiety.

This report is of the same warp and woof of a previous report that was discussed in Issue 3 of *Total Well-Being*: Medical opinion holds that "oversleeping" is unhealthy. Medical opinion here is that the body will "oversleep" if permitted and that sleep beyond 7 to 8 hours will lead to assorted illnesses—substantially the same ones as fresh air supposedly causes!

We need to breathe and we need to sleep to stay alive, but the medicos are telling us that we mustn't overdo it! They apparently put breathing and sleeping in the same category as eating, which we must also do to stay alive. We all know that overeating is harmful. But eating is a voluntary action. We are always consciously aware of it. If we would eat only when hungry and stop eating when hunger disappeared, we could not overeat. The body is self-regulating when its instincts are followed. But we eat for other reasons than hunger and genuine need, so our overeating results in health problems.

Now what about sleeping? This normal bodily need and function is also regulated naturally. We become sleepy when sleep is needed. If we don't fight it off by taking pep pills or coffee, we naturally drop off into a state of unconsciousness when our bodies need sleep. And we will remain in this state until our nerve energy is sufficiently recovered—unless our sleep is prematurely put to an end by a jangling alarm clock or other disturbing influence. It is impossible to sleep if we do not need sleep. Sleep cannot be "stored up" for future use.

Air is another of the normal needs of life, and breathing is nature's way of supplying our bodies with air. Breathing is the most automatic and unconscious of all our bodily functions that supply life's needs from outside sources. We can go for weeks or months without food and for days without water, but going for only a few minutes without air results in death. Air is such a constant necessity that breathing must be done unconsciously while we sleep.

Now medical expertise is telling us in this article that if we breathe too much fresh air we can become sick!

To be sure, there *is* such a thing as overbreathing. We can do forced deep breathing, but after a few minutes of it the body responds to our folly by cutting off oxygen to the brain. Hallucination and unconsciousness follow, putting an end to the conscious forced breathing, after which normalcy is restored.

This overbreathing is not what the physicians are talking about, for they say, "Hyperventilation—taking in air in excess of that required to maintain normal oxygen levels in the blood—is an *unconscious* action on the part of the individual..." How do they say we can "over-breathe?" By getting too much oxygen in our air. This is why they claim that too much fresh air is bad for us.

Just what is fresh air? It is the opposite of stale air. Stale air is air that has been breathed and expelled. The life-giving oxygen has been appropriated by the body, and carbon dioxide, a waste product, is given off along with other waste gases of elimination. If one had his head enclosed in a plastic bag that was sealed at the neck and he had to constantly breathe and rebreathe the same air, he would not live long. It would be much the same as trying to live on one's own feces and urine. Stale air, then, is polluted air. The air that most of us breathe in unventilated buildings and outdoors in metropolitan areas is further polluted by tobacco smoke, factory smoke, automobile exhaust, aerosol sprays and many other contaminants. Fresh air is air that is without such pollutants. Country air is called fresh because plants and trees growing there absorb the carbon dioxide and expel oxygen. What a wonderful symbiosis exists here! Plant life and animal life are constantly supplying each other with the needs of life. The air waste product of one is the necessity of the other.

Are the medicos telling us that nature goofed? Is there too much oxygen in the air for our health? Did nature mess up on her proportions? And should we regulate this imbalance ourselves by making sure that we breathe enough stale polluted air along with our fresh air? Well, they have actually stated that too much fresh air can cause health problems, so they really mean that we can get sick if the air that we are breathing does not contain some pollutants. Now aren't all the cigarette smokers going to love that! When they blow smoke in our faces or cloud up the offices that we must work in, they can tell us that they are performing a service for us, for haven't physicians said that air too fresh and pure is a health hazard? And this after the same medical profession has told us that smoking can cause cancer—and made the cigarette manufacturers post a warning on cigarette packages.

Physicians have observed that certain ailments and discomforts follow a person's change from a stale-air situation to a fresh-air situation, and so, without understanding the nature of these changes or the reasons for them, they conclude that fresh air is bad for us. What they fail to recognize is this salutary physiological principle: When the body's condition is improved, the body begins improving itself!

Most of us are living at only part of our health potential. Our bodies are clogged up with uneliminated debris and toxins. This morbid matter cannot be eliminated because of lack of vitality, and vitality is lacking because the body is getting insufficient rest, sleep, fresh air, etc.

The body begins a housecleaning when its circumstances are improved. When the body gets more sleep, better food, more rest and more fresh air, its vitality is enhanced. With increased vitality the body is better able to cope with life-threatening toxins. The expulsion of accumulated toxic matters occasions symptoms which are commonly mislabeled disease and recognized as dangerous. If we believed that such symptoms (which are actually healing crises) really were dangerous, then we should also believe that drug addiction is healthful and getting off drugs is a health hazard because the withdrawal symptoms experienced are pains, headaches, nausea and other illnesses. We should also believe that smoking is healthful because smokers who don't get their accustomed dose of nicotine suffer nervousness, irritability, sleeplessness, headaches, etc. Fortunately, we know that drug addiction and smoking are injurious to our health, and we know that it takes a bit of pain and discomfort to break such habits. We also know that it is desirable to do so and not a health hazard.

It should occur to us that polluted air is also a drug—a poison—and most of us are so steeped in air pollution that it amounts to an addiction. So when we indulge in fresh pure air and fail to get our usual dose of contaminants, we may suffer various discomforts which are actually "withdrawal symptoms" similar to those suffered by the dope addict. In both cases the real disease is toxemia, while the withdrawal pains, which are symptoms of toxin elimination, are a healthful sign.

If we will but suffer through these discomforts and the bodily housecleaning that they indicate, we will soon be more vital than before—just as the dope addict is in better health after he quits his habit.

It should be self-evident that no amount of polluted air could ever be healthful. The kind of illogical reasoning which says that pure air is unhealthy might be expected from those who have dethroned reason and ask us to believe that drugs restore health. It dates back to the previous century when medical advice would have us keep doors and windows shut while sleeping. Remember—the night air was supposed to be bad. At that time it was also popular medical practice to keep doors closed and shades drawn in sick rooms. Patients were denied fresh air and light and left to languish in their own effluvia. When feverish and suffering from thirst, they were denied water. No wonder so many of them died.

Be assured that fresh air is a healthful agency, and the symptoms it begets as noted in the AMA report are evidences of body improvement—not body destruction. Don't be taken in by error just because such reports are published in a prestigious journal.

Physicians think that they can regulate all our natural functions. They want us to think that they are wiser than the intelligence of the body when they tell us how much we should sleep, how many calories we should eat, how many glasses of water per day we should drink, and now, how much fresh air we should breathe!

Our own instincts, reason and common sense are far better guides than any such advice that comes from the medical profession. Remember the AMA is a trade association that is in business to make money. Their business flourishes on sick people—not healthy ones. Their advice and their ministrations can make us worse, but they can never make us better (except in the case of mechanical repairs). Under no circumstances can they confer upon us improved health. Only our own practices can lead to health.

So use your own good sense. Sleep when sleepy, drink water when thirsty, eat only when hungry and breathe the cleanest, purest air you can.

## **Article #4: The Breath Of Death by Prof. Hilton Hotema**

Our scientists agree that city air today is a deadly mixture of smoke, soot and fumes, which include carbon monoxide gas, sulphuric acid gas, benzene, methane, sulphur compounds and other dangerous chemicals too numerous to mention.

In addition, city air is saturated with the fumes of motor cars, trucks, buses, gas engines, etc. This exhaust consists of carbon monoxide, carbon dioxide, lead oxide, lead carbonates, free gasoline and complicated benzene chain compounds of the hydrocarbon series.

Let us consider just one of these many poisonous gases, carbon monoxide, and tell only a small part of the damage it does to the body. Tasteless, colorless, odorless, invisible to the eye, this gas takes and has taken a terrible toll of lives in our cities.

The large cities have a huge smoke-blanket over them that holds down these toxic gases and particulates. Especially is this so in damp weather. It tends to smother the people in it.

U.S. authorities have demonstrated a concentration of 0.62 parts of carbon monoxide per 10,000 cubic centimeters of air at street level in busy sections of cities of 500,000 population or more.

There are few poisons more deadly than carbon monoxide. Air containing as little as 150th of one per cent will cause headache, and 120th of one per cent may cause total collapse.

Dr. L. Burns examined blood specimens of more than 20,000 persons to discover the effect of carbon monoxide gas on the body. He said: "Carbon monoxide gas seeps into the blood through the lungs and mixes with the hemoglobin to such an extent that the blood cannot perform its normal function of carrying oxygen to the rest of the body."

The hemoglobin of blood has an affinity for this gas about 300 times greater than for oxygen, making the absorption of the gas by the blood very rapid indeed.

The first symptoms of this poisoning are headache and weakness. More serious symptoms appear as the condition progresses. People are told in food propaganda to eat this and that kind of food to offset weaknesses, as that could overcome poisoning effects.

Scientists at Harvard found that the average man can endure carbon monoxide only until his blood is one-third saturated. The danger of the gas was shown by the way it affected one of the scientists. He had just completed some tests requiring a high degree of skill and was feeling no ill effects of the gas when he suddenly collapsed and had to be carried out and revived.

Small concentrations of the gas can soon bring a man to the breaking point. Five per cent of autos and closed trucks on the roads have sufficient concentrations of the gas to be a menace to drivers and passengers. There is no natural nor acquired immunity to the gas. Repeated exposures produce the same effect each time.

The Chicago Health Department reported that in certain sections of that city the sulphuric acid gas in the air rots clothes hung on wash lines and eats away building stone and metal guttering.

These acids and gases in the air corrode and destroy in time everything they touch. They eat up stone and steel; they eat up clothing and metal guttering; they eat up the body by destroying cells and tissue. Many symptoms of the eating process appear as "mysterious diseases unknown to medical science."

The corrosive acids in the air attack cells and tissues, throat, nose, lungs, brain. They attack the heart, liver, spleen, kidneys and sex organs.

They attack the blood corpuscles and cripple them so seriously that they cannot carry on their normal function. That condition medical art terms "anemia." And for that they prescribe various iron

preparations, vitamin B-12 and other nostrums.

These acids and gases affect the nerves, and the resulting pains medical art calls "neuritis." As the nerves weaken, paralysis may result in whole or in part. And they have treatments for that while the cause continues. They affect the cells of the muscles, producing dull pains that puzzle medical art, and medical doctors cover up by terming it "rheumatism."

The acids and gases attack the tissues of the joints and the medical art calls it "arthritis." They attack the tissues of the air cavities of the cranial bones, and medical art calls it "sinusitis." They attack the throat, and medical art calls it "laryngitis," "tonsillitis," "diphtheria," etc. Hoarseness often follows, and in time one's voice weakens, or may be entirely lost.

Sulphuric acids and gases attack the cells of the blood vessels of the heart and medical art calls it "heart disease." They attack the cells of the pancreas, and medical art calls it "diabetes." They attack the cells of the lungs, and medical art calls it "tuberculosis."

Names, names—names that mean nothing aside from indicating the part of the body wherein degeneration is most serious and active from the action of the poisons absorbed from the air. Medical art, ruled largely by superstition and guesswork, and being nothing more than an updated version of ancient voodooism, makes a confusing mystery of what it calls disease. They do this for greed and profit, often, and sometimes from ignorance. The problem is readily solved by recognition of a few simple, basic principles.

The air of the Los Angeles area is exceptionally bad. The Los Angeles Herald said: "Heavy clouds of smoke close to the ground, intermingled smarting fumes that make people bleary-eyed and gasp for breath."

That account stated that "bleary-eyed men" were watching the factory chimneys to discover the source of damaging acrid fumes that killed small animals in the affected areas. During the worst of the "gas attack," nine out of ten persons on the streets were "bleary-eyed" from the smarting fumes. This black pall of smoke makes a ceiling over Los Angeles from 1,500 to 2,000 feet thick and extends outwards for as many as sixty miles.

John F. Gernhardt, M.D., of Los Angeles, stated that more than 30 persons died in the city of heart attack in 24 hours. Polluted air was the cause. It paralyzes the breathing centers of the brain and breathing stops. That is not heart attack.

The press reported that Southern California has lost about 60 percent of its valuable sunlight due to the smoke pall hanging over that area.

Still air, like still water, grows stale, stagnant and poisonous. Doctors appear not to know much about this. The maladies it causes are still attributed to viruses and germs.

Windstorms, tornados and hurricances are cosmic processes of air purification. And plants continuously detoxify and reoxygenize our air. These are yet other secrets of nature not yet discovered by the medical art.

But the discovery was made by a layman who did some thinking. He wrote a book that was published in 1944. It was titled *Floating Air*. It is hard to get a copy now, as medical art dreaded the valuable health guidance it contained and high-pressured the Post Office Department to put it out of circulation.

This man first tested his theory on poultry and was able to relieve in a few hours bad cases of croup and kindred respiratory ailments. That was bad news for medical art, and it had to be suppressed. There were no money-making possibilities in prescribing fresh unpolluted air.

In his chicken house this man put an electric fan to keep the air in motion, thus dissipating the foul fumes of poultry droppings, the inhalation of which makes chickens sick. How many poultry raisers know that?

Very simple. Too simple, It's a deep dark secret of nature the doctors seem not to have discovered. We

can be poisoned by the fumes of our own effluvia.

Many who drop dead or die suddenly are not afflicted with heart disorders as doctors claim. The cause of death is foul air.

The annual report of the Bernard Free Skin and Cancer Hospital asserts that city dwellers, breathing polluted air, "develop lung cancer" at a rate three times greater than inhabitants of rural districts.

The Mellon Institute of Pittsburgh issued a report of a two-year survey covering the damaging effect of polluted air on human health. The report said: "The inhalation of polluted air results in a gradual absorption by the body of the poisonous products. The insensible intake results in a condition of slow-poisoning which insidiously eats away at vital tissues."

Physicians go the other way. They favor still air. They favor the bad and condemn the good. They seem instinctively aware of what's good for their practice.

This man who knew that what applied to chickens also applied to humans put an electric fan and ventilators in his bedroom. This drew in fresh outside air and drove out the stale inside air.

Most homes and bedrooms are filled with stale air, unfit to breathe. People follow the advice of doctors and keep windows closed to keep out those "deadly drafts" of fresh outside air.

Even the gases and vapors expelled by the body are poisonous and pollute the home and bedroom, regardless of whether from lungs, or bowels, or the pores of the skin. When these facts are known, it is easy to understand why people get up in the morning with cold, sore throat and other respiratory disorders.

They blame the weather; so do the physicians. But it does not affect the animals who live out in it! The actual cause is the polluted air in home and bedroom.

So remarkable were the good results this man obtained that he was inspired to build his "miracle cabinet," consisting of a bed with enclosed sides and top, well ventilated and introducing air electrically with a fan through special vents.

He used the cabinet first for patients with respiratory ailments such as colds, hay fever, sore throat, diphtheria, asthma, influenza, pneumonia and tuberculosis. The good results were amazing, and he was encouraged to treat in the same manner patients with all kinds of disorders: fever, mumps, measles, rheumatism, neuritis, diabetes, etc.

His remarkable success proved that good, fresh air in motion will "cure" the sick who failed under other regimens that left them in the same polluted air. He got patients well after medical doctors had declared them incurable physical wrecks. He proved what a few great Doctors have declared: that there is no disease. There are just two conditions of the body—good health and the lack of it.

The symptoms of bad health the doctors are trained to study, group together and give them names (diagnosis) that mean nothing and term them diseases that are trying to kill the patient.

The scheme is supported by centuries of false teaching by which medical art has created a false psychology. They have taught that diseases are "entities" that attack us and mean to kill us. We enlist their aid in fighting these armies of invaders intent on our demise. For them this is very profitable. And just the opposite for us. Medical art is one of the biggest frauds on earth.

The truth bears repeating: Sicknesses are the body's cleansing and reparative efforts. They are friends, not enemies. If you would avoid the crisis of sickness, then don't indulge the causes of sickness. Polluted air is a primary cause of illness and disease.

The surprising results of the man's work and air shocked the medical art. Drugs, vaccines and serums would become obsolete if people learned of this. Something had to be done.

It was better that one good "man should die for the people," than that the medical art should perish. So the heat was turned on the Post Office Department and "this man died for the people." His great work of

helping the sick, after medical doctors had failed, came to a sudden and inglorious end.

In such cases big publications carry lying propaganda that a certain quack who was a menace to the people has been cast into oblivion. And the people believe this. Medical propaganda leads people to believe that medical art is trying to rid the world of so-called disease. In truth they are trying to end their competition. Who can be so silly as to believe that any organization or institution is working to bring about its own end?

The reason why people do believe it is because "better schools make better communities." That is another one of the lies taught in the schools, and people just grow up in it from childhood.

The facts show that all methods not taught in orthodox medical schools, regardless of their value and effectiveness, are banned and crushed by the medical art and their allies, and unorthodox practitioners are usually put in prison—all for the protection of the public health.

This may not be Russia, but many Russian methods are used to dispose of those who interfere with the money-making schemes of big business.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 1. A Survey Of The Lesson

### 1. A Survey Of The Lesson

The first two lessons dealt with the Life Science outlook on health and disease. The third lesson stated the essentials of life and presented in-depth scrutiny of two of these needs, namely air and water.

This fourth lesson encompasses seventeen other essentials of life in summary form. Exhaustive treatment of any single aspect of life's needs is not intended. Rather, it is intended to acquaint you preliminarily with each life need presented. Subsequent lessons will plumb the depths of the essentials treated in this lesson.

Assuring your body of all its needs might be likened to the care that must be lavished upon highly complex jet liners. Every item of equipment aboard the jet must be in working order and have an adequate supply of its needs in order to operate as designed. The jet may operate with many of its systems knocked out but it is crippled. Crippling of certain systems may send it to its doom. And so it is with the body.

The human body consists of approximately 125 trillion cells which live together harmoniously. Cells live both for themselves and for the welfare of the organism of which they are a part, and they are specialized into tissues and tissue organizations that perform services for every other cell and cell organization throughout the organism.

As a health professional aware of the many faculties of the body and the full needs of the organism, you'll undertake to assess your clients' compliances and transgressions of their needs. You'll endeavor to guide your clients into thoroughgoing compliance with their biological needs and total rejection of their transgressions.

With this purview in mind, we proceed to consider an important essential of life: Body cleanliness.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 2. Cleanliness Is An Essential Of Life

## **2. Cleanliness Is An Essential Of Life**

### **2.1 The Need for Cleanliness**

The body operates most efficiently when it is unfettered. Filth on the outside of the body most people will not tolerate. They readily appreciate external cleanliness and most keep themselves impeccably clean. While there is much to be desired regarding the ways in which most people maintain external cleanliness, nonetheless they are imbued with the necessity of a clean body—at least on the outside.

However, more important than external cleanliness is internal purity. Internal filth damages the body in two ways:

1. The mere physical presence of pollutants clogs and interferes with body processes. They hinder operations much as a crowd of people in a street hampers automotive traffic.
2. All contaminants within are poisonous! The body not only objects violently to the physical presence of filth but it also objects to its chemical presence. The body tries to maintain physical and chemical integrity. Anything that alters the consistency of body elaborated fluids and compounds; anything that threatens cell well-being due to its chemical nature is anti-vital, hence poisonous.

Thus we can see that for best performance the body must not be hampered physically or chemically in its operations.

### **2.2 A Clean Body Is Necessary to Health**

The sum total of all the processes whereby the body is cleansed or kept pure is called elimination or drainage. Elimination is the sequel of feeding or alimentation. Ideally the body must eliminate the unusable debris from food ingestion, spent cells, the wastes of metabolism and extraneous substances that may be admitted in some manner. The more thoroughly elimination is effected, the purer is the body.

A thoroughly clean body is necessary to realize the highest level of function—to achieve the highest level of health. Inasmuch as the basic cause of disease is body toxicity, we need to realize the importance of keeping our bodies clean internally as well as externally.

## **2.3 Body Elimination Must Be Equal to the Need**

Obviously, to remain free of burdensome accumulations, both physical and chemical in nature, the body must have full use of its eliminative faculties. If these faculties are impaired by lack of nerve energy, if they have been disabled by toxic materials or if ingestion of toxic matters exceeds ability to cope, then elimination is likewise impaired. Accumulations further vitiate the elimination process until the body must undertake an eliminative crisis (disease) to free itself of its morbid load.

We Americans are habituated to many eating and drinking practices that fill our bodies with alien materials that must be eliminated. Alien materials always take their toll on the eliminative organs. Nonfood materials are usually inherently toxic, especially the alien substances the average American eats and drinks. A constant load of toxic materials taxes the eliminative faculties. Thus we Americans wallow in toxic materials from exogenous sources and, due to their impairing influences, from endogenous sources, too.

By waste we mean all end-products of all the metabolic activities occurring in every cell and organ of the body. Elimination must equal the processes of supply if balance and health are to be maintained. Just as we can be made sick by living in rooms with our fecal and urinary accumulations, so, too, can we be made sick internally if elimination does not occur apace.

To cope with its eliminative needs, the body must enjoy conditions favorable to elimination. As well, it should not be taxed with toxic materials from without.

## **2.4 The Body's Daily Cleansing Cycle**

Eliminative processes never cease. Every exhaled breath is an act of elimination of toxic gases. The skin exudes some small amount of wastes continuously. But there is one time in each day when the body heightens its eliminative processes. This time is, roughly, from three to four o'clock in the morning until from ten to twelve o'clock noon.

The body's stepped up elimination during this time is evidenced in many ways. A particularly toxic person may have a furred tongue upon arising. Hunger will not be in evidence. But, if the body is fed just the same, the eliminative processes are depressed though the tongue may still remain somewhat furred.

The body passes through rather distinct cycles daily. These are roughly as follows:

4:00 a.m. to 12:00 a.m. — eliminative

12:00 a.m. to 8:00 p.m. — alimentary

8:00 p.m. to 4:00 a.m. — assimilative

In view that few studies of these phases of physiological activity have been made, little is known about them. The information presented here comes from studies made in Switzerland. These cycles are consistent, more or less, with the way things are with healthy humans who observe the natural norm of working days and sleeping nights. Thus we eat when hungry. This is followed by body assimilation and, upon completion, the body turns its energies to elimination of wastes.

## **2.5 A Brief Look at the Body's Primary Organs of Elimination**

You should strive to master physiology and anatomy to understand the body and how it operates. You will learn much about these subjects as called for in each lesson. Nonetheless, it would be wise to consult basic books on anatomy and physiology. Despite its medical orientation, Reader's Digest publishes some excellent books on how the body works. We advise you to acquire and study them.

The organs of elimination are as follows:

1. Lymphatic system (adenoids, tonsils, appendix, spleen, nodes, vessels, etc.). These chemicalize wastes in such a manner as to render them less toxic in preparation for expulsion. The lymphatic system also plays other roles.
2. Liver. The liver further detoxifies wastes. It is the largest organ and performs myriad nutritive and eliminative tasks.
3. Kidneys. The renal system filters non-utile wastes from the blood and dispatches it to the bladder. The kidneys perform many other functions as well.
4. Lungs. The lungs, like most body organs, perform a dual role as supplier and eliminator. They obtain oxygen from the air and supply it to the bloodstream. In addition, they remove carbon dioxide and certain other wastes from the bloodstream.
5. Bowels or colon. The bowels perform few nutritive tasks other than supplying the body with water in emergencies, and electrolytes should the body require them. On the other hand it carries out of the body digestive wastes and metabolic wastes as may be excreted into it by tubes from other organs.
6. Skin. The skin is the most extensive organ of the human body. Among its many functions are protection of the body from outside influences that would disturb homeostasis, temperature maintenance, cooling and warming and elimination of certain wastes in extremely small amounts. In vicarious eliminative processes such as acne, boils, psoriasis, eczema, rashes, measles, poxes, itches, etc. the skin is used as an organ of elimination. The skin performs a nutritive role in receiving sunlight for conversion into vitamin D.
7. The tongue is sometimes used by the body as an extraordinary organ of elimination. This is very noticeable when you have a furred tongue. The tongue is not a regular organ of elimination but incidentally one in vicarious processes of extraordinary elimination.

There are occasions when the body will undertake massive eliminative measures. The respiratory system and mouth may be utilized in vomiting; the bowels in diarrhea; the mucous membranes as outlets from the circulatory systems (lymph and blood); the kidneys are used for diuresis; and the skin is sometimes used for diaphoresis and eruptions.

## **2.6 Supplementary Organs of Elimination**

We have cited the regular organs of elimination. Those nonregular organs through which the body eliminates in crises are called vicarious organs of elimination. As mentioned, the tongue, skin, respiratory system and mucous membranes (internal skin) are pressed into eliminative tasks in emergencies. The body can cause ulcers or lesions for the purpose of elimination, or it may utilize ulcers caused by tissue destruction as an extraordinary outlet. In emergencies the body may press any tissue system or organ into service as a vicarious organ of elimination. These may be the eyes, sinuses, bronchioles, lungs and so on.

## **2.7 The Liver as an Organ of Detoxification**

The liver detoxifies internal wastes and also attempts to detoxify exogenous poisons. It passes these detoxified materials either through tubes to the small intestine for passing on to the colon or back to the bloodstream for forwarding to the kidneys where they will be excreted in the urine.

An example of liver detoxification may be seen in the case of alcohol ingestion or its formation within the body by bacteria due to indigestion. The stomach and intestines do not digest alcohol. Alcohol is absorbed into the bloodstream as alcohol and circulates until eliminated. The liver detoxifies the alcohol to a great extent and passes it on to the kidneys for excretion. The liver, the body's foremost chemical factory, varies its chemicals to the need in neutralizing or detoxifying poisons in the blood which pass through it.

## **2.8 Cleanliness at the Cellular Level**

A book we heartily recommend you acquire is Dr. Lewis Thomas' *The Lives of a Cell*. Though the cell is generally regarded as the basic unit of life it may not be, for it contains bacteria-like components that act as living entities.

So varied and multitudinous are the functions within a cell that one can spend a lifetime of fascinating study of them. It is said that their operations are more complicated than the most marvelous computer systems—more varied and complicated than the activities in a major city like New York City.

The cells take on supplies and they defecate. It is the lymphatic system, not the bloodstream, that constantly bathes the cells in a liquid medium. From the lymph fluids the cells derive their nutrients by diffusion, pinocytosis and phagocytosis. The cells pass their wastes back into the lymph. Cell wastes are partially detoxified by the lymph organs in preparation for passing them into the bloodstream. The bloodstream, in turn, transports the wastes to the lungs, liver and kidneys for excretion.

Cells are self-cleansing of their metabolic debris. They expel it to the lymph fluids through carriers that, our physiology books tell us, are not yet clearly understood.

## **2.9 Illnesses as a Cleansing Process**

The body keeps itself clean by thousands of different techniques employed by an army of faculties. A hundred trillion cells represents quite a population to be served. It is an unimaginably large aggregation of living units cooperating as an entitative organism for the good of each and every cell and for the organism as a whole.

Due to unnatural practices or influences, humans frequently accumulate toxic substances in their bodies beyond normal capacity for elimination. When the accumulation becomes intolerable within the context of residual vitality, the body will preempt its nerve energy and redirect it to the task of extraordinary elimination or cleansing. When the body does this, disease exists. Acute disease is a body process. The energies normally available for muscular or nervous (brain) activities, digestion, etc. are preempted and redirected. Hence, the sick person has little or no energy for normal pursuits.

When a person is ill, fasting is indicated as a remedial measure. People should also fast periodically even when not ill to help the body effect extraordinary cleansing and healing.

## **2.10 How the Body Becomes Befouled**

There are more ways to accumulate filth in the body than we can chart. Basically, all unwholesome influences and practices debilitate body eliminative faculties and especially lower the body's supply of nerve energy. The key to keeping the body clean is a way of life that neither distresses nor pollutes it.

## **2.11 Normal Activities of Life Essential to Internal Cleanliness**

The eliminative capacity of the body is truly immense. The body has over-capacity in almost all its faculties. We can live well with one lung, one kidney, etc. The organism thus has safety margins to insure survival.

Most of the world's people manage to exceed their generous capacity for elimination. Therefore, the necessity for illness or healing crises in order to remove excesses that accumulate. If we live within our capacities as developed in nature, our system will never become befouled in the first place; hence, there is never the necessity for a healing or eliminative crisis—disease.

The living practices that are attuned to our adaptations will not fetter the organism; rather, they will enable us to thrive optimally. Those acts and indulgences which are contrary to human adaptations are bound to interfere with normal functions in many ways, the result of which is to burden the organism

with uneliminated toxic materials.

Health depends on internal purity, and this, in turn, depends on practices that promote health rather than practices that result in the retention of morbid matters.

## **2.12 Fasting as an Extraordinary "Housecleaning" Measure**

Whether the organism is befouled or not, fasting is a constructive condition! During the disease process, fasting is imperative to efficiently restore high-level function. In health, fasting rests the faculties, rejuvenates the cells and heightens functions.

Since all diseases have the same underlying cause; that is, body intoxication, there is a nigh universal remedy for the condition. Fasting affords the body the rest it needs so that it may redirect its energies to the task of "housecleaning." Under the condition of the fast the body will expel retained wastes and impurities. A thoroughgoing rest is, thusly, an almost 100% effective remedial measure.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 3. Temperature Maintenance

## **3. Temperature Maintenance**

### **3.1 The Need for Temperature Maintenance**

The human body has been developed in nature over eons of time to maintain homeostasis, chemical and mechanical consistency and a consistent temperature. The body operates best at a temperature range between 97° and 99°F. Various parts of the body vary in temperature.

Warm-blooded animals have many mechanisms that maintain temperature. Skin, hair and wool act as insulators to help maintain body temperature. Overheating is guarded against by perspiration and respiration. The body, in an intoxicated condition, may institute accelerated function to free itself of unwelcome toxicity. In this case it may also increase the metabolic rate, hence increase temperature. Heightened temperature is called fever.

The body maintains temperature through a basal metabolism controlled by many sensors throughout the body that act as thermostats.

### **3.2 Normal Temperature Is the Best Functioning Temperature**

While bodies have been drastically reduced in temperature and overheated greatly and survived, the prevailing view is that serious deviation from normal temperature will cause the body to fail in some way to supply cells with needed oxygen and nutrients, thus impairing them. Notably is this true of brain cells which, if destroyed for any reason, are not regenerated. They are lost forever. It is generally accepted that a brain temperature exceeding 108-110°F destroys brain cells. While cases of overheating beyond this range have been recorded without damage, overheating is to be avoided. Cooling is far less harmful than overheating. At a temperature of 118°F enzymes begin to be destroyed and other body fluids become labile.

Frequenters of turkish baths and saunas sometimes experience surface temperatures of 140 degrees without apparent damage, but it is doubtful if the skin temperature actually ever reaches more than 110-115°F due to the body's capacity to cool itself. Needless to say, all overheating is unhealthful. Those who live in climates that reach 110-120°F during the day are not in danger, for the body can easily

maintain its temperature by its refrigerating faculties, especially in view that humidity is usually low in most areas where such high temperatures are likely to occur. High humidity inhibits evaporation which is necessary to body cooling.

### **3.3 Questions as to What Constitutes Normalcy of Temperature**

The generally accepted normal body temperature is 98.6°F. We do not have a uniform temperature at all times. At or near the end of a night's rest, with lowered metabolism the pulse is considerably lower than when active and the body temperature may be somewhat lower.

When the body has been vigorously active for an extended period, as in sprinting or running, the internal body temperature may rise to 105°F. This is not dangerous, for the body quickly normalizes this temperature when a state of relative rest is resumed. The body creates fevers that have been known to go as high as 108°F. The body will not create conditions that will injure itself.

### **3.4 Keeping the Body at a Comfortable Temperature**

It has been observed that, when they are crippled, humans will devise crutches. The use of crutches further cripples the organism. This may be readily observed in individuals who use a crutch because one leg has been disabled. The disabled and unused leg will atrophy while the extraordinarily used leg will overdevelop.

Humans have become dependent on artificial means of temperature maintenance. In nature humans can live at extremes of temperature comfortably in their naked condition. Indians survive temperatures in the freezing range with vigor in many areas of South America.

But, because most of us are not physically able to cope with extreme cold, we must employ clothing to help maintain warmth. Warmth must be maintained lest we suffer functional disturbances due to reduced temperatures.

A comfortable temperature must always be maintained. Deliberate cooling or heating of the body is exhausting of nerve energy and lowers the body's functional abilities.

### **3.5 Some Problems of Temperature Maintenance**

There are conditions under which temperature maintenance is difficult. One such condition is the fast. A person who is fasting must be kept warm. While fasting, a person can easily become chilled. The body's lowered metabolic rate will not produce sufficient heat to maintain warmth under all conditions. It is, therefore, important that fasters have sufficient clothing and bedding to maintain warmth.

### **3.6 Types of Clothing to Use for Warmth**

Clothing should be loose fitting, as a rule. Being bound by tight-fitting clothing is unhealthful. Clothes should be equal to the warming task required. If you live in Alaska, heavy wool clothing may be required, whereas in Texas light cottons do for most of the year.

Cotton, linen and wool are to be preferred over other type of materials though silk and other natural fibers are also very good.

Clothing that is white or light-colored is preferred over dark colors because they admit more light. Natural light on the body (and eyes) is healthful.

### **3.7 Pathological Effects of Clothing**

Clothing that is binding, tight fitting or otherwise constricting is unhealthful. Belts, girdles, garters, etc. should be avoided.

Synthetics sometimes cause poisonous reactions in the body. Synthetic clothing and plastics should not come into contact with the skin.

Porous clothing made of natural fibers are always to be used when possible for both wear and bedding.

### **3.8 Temperature as a Factor in Toxin Retention**

When the body becomes chilled the skin pores close and other body reactions take place to protect against chilling as much as possible. In these instances, energies being redirected to temperature maintenance may result in temporary neglect of regular chores of elimination. The skin normally respire and the closing of pores throws an additional burden of elimination onto the respiratory system. If the body is already toxic, the added toxin retention may reach a level that will trigger a body cleansing crisis, such as a cold or flu.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 4. Sleep Is An Essential Of Life—The Role Of Sleep In Life

## **4. Sleep Is An Essential Of Life—The Role Of Sleep In Life**

Inasmuch as there are other lessons devoted specifically to the subject of sleep and its great significance, we'll touch upon sleep only briefly here.

Sleep is the condition under which the brain generates nerve energy with which to conduct body activities. The deeper the stage of sleep into which the body enters, the more efficiently can nerve energy be generated. There are five stages of sleep if we include the R.E.M stage, popularly called the dream stage, when there are rapid eye movements. Other stages are named after the brain wave frequency. The threshold stage of sleep is the alpha stage and the deepest stage is delta wave sleep.

As nerve energy is the spark of vitality for vigorous activity and high level function generally, adequate sleep is very essential to well-being.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 5. Food Is An Essential Of Life—The Role Of Food In Health

## **5. Food Is An Essential Of Life—The Role Of Food In Health**

Several later lessons are devoted to the subject of food. We will not, therefore, treat it extensively here.

In no other area of life practices are our transgressions against ourselves so great as in the food we ingest. Consequently, most diseases of humanity arise largely because of eating wrong foods.

Food supplies us with essential nutrients other than the three inorganic ones we need. Even water, an inorganic food, can normally be obtained in quantities needed from a proper diet.

Correct diet consists of mostly fruits. Constitutionally humans are frugivores or fruitarians. Wholesome ripe fruits contain all the food factors necessary to sustain human life at the highest level.

All our food should be eaten raw as nature delivers it to us. All heating of foods destroys vital nutrients.

Suffice it to say that nature did not equip humans or any other animals with stoves.

The essential categories of nutrients we require are as follows: (NOTE! These percentages are relative to total food intake by DRY WEIGHT!!!! Further, they are approximations.)

- 85% to 90% simple carbohydrates for fuel. Simple carbohydrates and monosaccharides such as glucose, fructose (levulose), galactose, etc. If complex carbohydrates are taken, the body must break them down into monosaccharides before absorption.
- 1% to 5% fats, which supply fuel and other needs, especially essential fatty acids (EFA).
- 4% to 8% protein.
- 3% to 5% mineral matter in organic form.
- 1% in vitamins, auxones and other catalytic nutrients.

Like water, fibers in food are a neutral factor. Cellulose, of which fiber is composed, is indigestible and is passed on through the body. Contrary to popular impressions, we do not have to have a high fiber diet in order to have bowel movements. We are not defecating machines—neither are we hay balers. Wastes will be expelled as they accumulate sufficiently to require voiding.

Condiments, seasonings, free oils—in short, anything and everything except whole ripe fruits with some vegetables, nuts and seeds, all in the raw state, should never pass the lips.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 6. Exercise And Activity Are Essential To Well-Being

## **6. Exercise And Activity Are Essential To Well-Being**

Humans live to function and functioning is the very essence of life. That which is not used is abused. Human faculties were developed for use. Disuse results in atrophy and loss of function. Without exercise, well-being ceases.

Abilities, intelligence and every aspect of well-being are greatly enhanced by exercise. Almost every account of exercise speaks of its marvelous benefits to the body. Activities should be daily indulged that bring all the body's some 700 muscles into play.

The subject of exercise is exhaustively treated in a later lesson.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 7. Rest And Relaxation Are Essential To Health

## **7. Rest And Relaxation Are Essential To Health**

In present-day society there are many tensions and stress-producing situations. Relaxation, which also involves rest, should be indulged two to four times daily for periods of from 15 to 30 minutes. The body recoups under rest and relaxation.

If eyes are bleary or the eyelids heavy, relaxation for a few minutes with the eyes closed will accomplish wonders. A nap is even better, for little revitalizes the body as well as sleep.

Sleep should be obtained daily to the extent that sleepiness dictates, whether this be as little as six hours or as much as ten hours. The healthier an individual, the less sleep required (to a point). As a concomitant to sleep the body obtains rest. Rest enables the body to catch up on its eliminative activities and to resupply its stores of body starch (glycogen) for the following day's energy needs.

While sleep regenerates a fund of nerve energy, rest enables the body to restock physical stores as well as to "clean house." Relaxation relieves tension buildup. A period of vigorous exercise followed by relaxation will perform even more dramatic results.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 8. Sunshine Is An Essential Of Health

## **8. Sunshine Is An Essential Of Health**

While it is known that vitamin D is created through the agency of sunshine and ergosterol in the cutaneous tissues, little else is known of the benefits of sunlight. Of late it has been discovered that natural light from the sun is of immense benefit in vision compared to vision debility under unnatural light.

Another lesson will present the subject of sunshine in depth.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 9. Recreation And Play Are Health Essentials

## **9. Recreation And Play Are Health Essentials**

Just as the body is rejuvenated by rest, sleep, relaxation, fasting and other healthful measures, it is also kept young by constructive games, hobbies and participation sports.

Americans are more likely to dissipate themselves during leisure hours than participate in body and character building activities. The pursuit of sex in an overstimulated society is of a debilitating nature. Watching TV for the most part amounts to adult babysitting.

There are many Americans who swim, run, play ball, enjoy hobbies, participate in drama, attend cultural events, hike, participate in sports, garden, master musical instruments, compete in games that require strength and so on. Unfortunately they are a minority. Most Americans are inclined to spectator rather than participant activities. Even many of the participant activities such as drinking, carousing, etc. are destructive of human faculties.

Recreation and play can further the development of humans. In the fresh air and sunshine we can participate in numerous games of play, sports and exercise that are truly healthful and that promote well-being. Unfortunately, most of our people seek out sensuousness for its sake and suffer as a result.

They bring suffering and inconvenience upon those who make better use of themselves too, for, in society, acknowledge it or not, we are our brother's keeper more than we realize.

In reviewing your clients' habits, it is always wise to have a look into their leisure time pursuits. Many may be dissipating and debilitating.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 10. Emotional And Mental Well-Being Are Necessary To Health

## **10. Emotional And Mental Well-Being Are Necessary To Health**

While emotional and mental well-being are born of the physical conditions of the body already cited, they are also vitally dependent upon other influences. While emotional and mental well-being are dependent on physical well-being, physical well-being is also dependent upon emotional and mental well-being.

Our division of humans into a multitude of entities (physical, mental, emotional, etc.) is erroneous. Rather, we are a unitary organism with many aspects to our being. Nonetheless, we use these categorizations for the sake of convenience in communication.

"Feeling like a million" is an emotional and mental condition which is the exhibition and expression of the well-being of our tout ensemble or our faculties in toto. Just as nutrition is dependent upon the condition of all body faculties, so, too, are all body faculties dependent upon nutritive repletteness. The emotional and mental aspects of our lives will be treated in depth in a later lesson.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 11. Assurance Of Life And Its Means Is Necessary To Health

## **11. Assurance Of Life And Its Means Is Necessary To Health**

Humans are creatures of providence almost the whole world over. Equatorial peoples have no need of providing for the future as have northern peoples but are, nevertheless, provident in many ways. On the other hand, northern peoples are often overly provident. They provide against needs, both real and imagined. This has made many northern peoples acquisitive at the expense of humaneness. Of course acquisitiveness in itself is not the sole evil but is a contributing factor to valuing possessions over fellow beings.

Our basic needs are food and shelter and the productive facilities for making them. We have yet other needs which we strive to satisfy plus many pursuits that engender yet other wants.

Ours is a society of abundance. Within the capabilities of our means of production is a surfeit of goods and services beyond our capacity to use and consume them. Our distribution system is not compatible with our productive capacities, hence there are gross inequities in the amount of the goods and necessities various of the world's peoples receive. Some are almost totally deprived by circumstances attendant upon these inequities while others are surfeited beyond any possible need.

These inequities give rise to anxieties, worries and concerns that seriously impair health. Even many in what would be considered good circumstances are assailed by fears that they will not be able to maintain their circumstances. Qualms, fears and concerns about loss of the requisites of life are a drain upon the mental and emotional well-being of a majority of people. Worry is a disease of our society.

In tropical climes we see tribes and groups of people living "hand-to-mouth" among plenitude. They always have the needs of life at hand. They are carefree, happy and playful. They do not work much, for

their style of life does not require much.

The farther north we travel, the more humans become provident and acquisitive until we reach such a harsh environment that almost all endeavors are directed at providing the basic needs of life and little more.

In conducting your professional practice, you may find it wise to delve into your clients' economic and social concerns as sources of tension, stress and enervation. This will be explored further in subsequent lessons.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 12. Pleasant Environment Is Necessary To Well-Being

## **12. Pleasant Environment Is Necessary To Well-Being**

Humans fare better in environments in which the needs of life are abundant. However, these needs are so varied within the context of our culture as to be difficult of ment in this lesson.

Environment means the total context of our setting. It includes not only our homes, grounds, climate, geography, etc. but also our family, neighbors, associates, acquaintances and, indeed, everything and everyone that makes up the social and economic atmosphere in which we live.

Humans are naturally aesthetic and love beauty in everything. Beauty in environment is essential, not only in the physical surroundings, but also in the persons who people it. Happy people beget happiness in the lives of those whom they touch.

Our social environment is far more important than our physical environment. Humans always dream of better physical environments but achieve happiness primarily within the context of their social circle regardless of climate and geography. Inasmuch as human industry creates special environments for living that are pleasing, we can live rather happily while insulated from the harshness and sparseness of clime and geography.

Thus it can be seen that the environment of most concern relates to the social circle in which we situate ourselves.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 13. Creative Useful Work And Its Role In Life

## **13. Creative Useful Work And Its Role In Life**

Naturally and normally humans have within them certain qualities that we regard as virtues. All are naturally imbued to perform those labors that are productive of their needs. This is readily seen in tribal societies. Within complex societies where we lose sight of the products of our productive efforts-where we have been instilled with ambitions to consume without corresponding opportunities to produce, we tend to parasitism upon the productive efforts of others.

Unfortunately, our society legalizes parasitism upon the economic body. That is one of the characteristics of our society that begets inequities that breed crime, ugliness, poverty and other life-sapping features.

Work which we can directly relate to fulfilling a need is most deeply satisfying. If it calls upon our innermost resources and abilities, it is even more satisfying and fulfilling. People most happy and contented are those who have created lovely homes with gardens, orchards and beautiful flowerbeds and grounds.

When our creative urges are elicited, we humans can create wonders, not only for our enjoyment and welfare, but also for the pleasure of those with whom we are associated.

In your relationships with your clients you'll find that some absorbing pursuit may be suggested that will greatly benefit their health and well-being. In this society creativity is lacking in too many lives. Encourage some creative and productive hobby or pursuit in the lives of those whom you serve.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 14. Self-Mastery Is Necessary To Best Well-Being

## **14. Self-Mastery Is Necessary To Best Well-Being**

Self-mastery means self-control. It means keeping passionate influences within the bounds of propriety. Intelligently guided responses to situations and yearnings that may arise within our vitiated society—a society with inhumane and unhealthful values—is essential to our welfare. Unbridled pursuits in any direction, especially those that have been commercially tied to our appetencies for food, sex and sensualism are usually exhausting of our precious resources, further pervert and vitiate us and beget conditions of disease and suffering.

The joys of self-mastery are unknown to most. Most of our people are apt to act unthinkingly in response to impulse and an aroused appetency for some sensual delight. You might well explore the qualities of self-mastery your clients exert in their lives. Wisdom dictates that you encourage in them self-discipline for their better well-being.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 15. Gregariousness Is An Element Of Health

## **15. Gregariousness Is An Element Of Health**

Humans are social creatures. To achieve our highest level of happiness and well-being, we must belong to a group or circle. We must be in association with others in some manner. Sheer aloneness or being forsaken is deadly to well-being. Even the mental giants amongst us suffer. There are very few Robinson Crusoes.

Our requirement is for associates with whom we can identify. In this day of specialization we tend to restrict ourselves to circles that run along cultural, occupational or special interests. In rural areas neighbors are the basis for associations even though occupations may be different. In large cities cultural pursuits and special interests may be the basis for associations and, more so, occupational lines.

While people can survive rather well alone if they develop some consuming hobby or pursuit, most people are not capable of this within today's society.

You'll do well to probe the social life of your clients. Lack of social life in any form can be a detriment to welfare. Likewise, people of dour dispositions can adversely affect those with whom they associate. It may be a case of "not what's wrong with you but who's wrong with you."

Encourage your clients to participate in social activities in conjunction with friends or acquaintances.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 16. Motivation: Having Purposes Or Causes To Serve

## **16. Motivation: Having Purposes Or Causes To Serve**

Few humans are content with feelings that the world will not be a better place for their having been in it. Most of us are imbued with urges to improve and excel. Most humans strive to better both themselves and their environment. Failure to cultivate goals leaves an individual indifferent and most likely a useless drone in life and society, neither good for self or society. People without ambition and objectives are usually dullards and dissipators.

In observing others whom we serve, it is wise to assess their drives and ambitions. If they lack these, the will to live may also be lacking. People who consult others in health matters have a will to live but may not be sufficiently endowed with aims in life to make living a challenge.

Needless to say, the healthiest and happiest people amongst us are those who are striving to fulfill ambitions and meet life's challenges.

Just as you may be motivated by an urge to help others and receive reward and recognition for it, others are motivated by any of a multitude of objectives. A great artist may thrive on recognition and appreciation while a ditch digger may have pride not only in his service but in some hobby or other constructive activity.

Without purpose in life there is little drive to live it. We Life Scientists hold that life is sacred and should be imbued with meaningfulness.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 17. Expression Of Natural Instincts Relative To Health

## **17. Expression Of Natural Instincts Relative To Health**

This is rather broad territory. While we have instincts to survive and thrive which have had prior considerations in this and the previous lesson, there is also the instinct to procreate our kind. This instinct must be given voice if we are to realize the utmost well-being. While self-discipline can normally control the mating instinct so that it does not exceed its need, it must, nevertheless, have adequate expression. Few there are amongst us who can sublimate an excessive primal urge to more constructive pursuits.

Next to our transgressions in food indulgence stands our collective dissipation in pursuit of sexuality. Most of this amounts, not to satiation of actual need for sexual expression, but satiety of a sexual appetite aroused and stimulated in a society gone awry. Our society regards sexual sensuousness and indulgence as an end in itself and it is stimulated to overindulgence because of dietary and other factors that represent life-threatening factors. The body responds to these life-threatening factors by bringing to the fore and emphasizing survival mechanisms, the act of reproduction being one of the foremost.

Basically, the instinct to reproduction is for one purpose only—the perpetuation of the species. In animals the sexual act occurs only during that time when the female ova are ripe for impregnation. Only in humans has the instinct been perverted and then only within the context of certain societies, ours being among them.

You, as a health professional, need to recognize the heavy role sexuality plays in well-being. There are

many among us who feel inadequate because they cannot enjoy mating as often as they would like. The urge may be for excessive indulgence or it may spring from inadequacy. In any event, the role of unsatisfactory sexual relationships in disease and poor health must be recognized. A return to health always restores sexuality but, in the face of overindulgence, it is not possible to restore health. Reorientation of the client must be made so that limitations in this area are recognized and respected.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 18. Aesthetic Well-Being

## **18. Aesthetic Well-Being**

Why should a fruit-laden orchard of aromatic fragrance be so lovely and beautiful? Why should a dry barren rocky gulch present such an inhospitable and ugly facade?

Anything that promotes life and its values is appreciated, treasured and deemed beautiful. Anything that is untenable and harmful to life is looked upon as ugly with but few exceptions.

In keeping with this, it would seem that all creatures have standards of beauty. But the greatest capacity for appreciation of beauty is inherent in those creatures that have the greatest capacity for life. We proclaim ourselves undisputed aesthetes among all in the animal kingdom. This is not necessarily true. Almost everything in nature has great beauty. Dolphins (porpoises), whales and other creatures have a very high order of intelligence and likewise appreciate beauty.

That which is fit for food is beautiful to us as it is available to us in nature. That which is poisonous and unfit for food usually has no aesthetic appeal. For purposes of food we do not ascribe beauty to a squirrel. Yet the squirrel fascinates as a lovable and beautiful creature. A peacock is a beautiful and lovely bird. We admire it for its great beauty. Yet it is difficult for us to visualize ourselves breaking its neck, stripping it of feathers and eating it as natural as meat-eaters do—skin, bone, flesh and guts, all raw and uncooked. We can't do that. The picture is an ugly one. It is in discord with our welfare.

The human sense of beauty is, as far as we know, unparalleled. The visual and sonic arts have been highly cultivated. The development of art has been constructive, healthful and ennobling for humankind.

In assessing your clients' practices, it is wise to survey their cultural dispositions. Everyone has an aesthetic sense—everyone has a sense of beauty. This is a saving grace, for it is an inroad to inspiring and motivating people. Almost everyone appreciates beauty in themselves most of all! Life Science as a way of life will restore health. Simultaneous with rejuvenation, much beauty is restored.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 19. About This Survey Of Life's Essentials

## **19. About This Survey Of Life's Essentials**

The list of the essentials of life presented here is not complete. These are some of the salient ones. Also, some aspects of life's essentials presented may be somewhat redundant, for some imply others presented.

But, as you will have noted, the needs of life are simple! Nothing is complicated about it. It seems self-evident that these are the essential means for a happy and healthy life. We can see that the science of health does not come from so-called scientific laboratories but, instead, proceeds from the lap of nature.

As Life Scientists or Hygienists we maintain that these requisites were developed in our sojourn in nature and that, just because we have exceeded nature's provisions with our own industry, we have not exempted ourselves from need of these basic essentials.

In yourself and your clients you can pursue no wiser course than invest these factors and influences in your life and theirs.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > 20. Questions & Answers

## 20. Questions & Answers

### **How many cells are in the body? Does anyone really know?**

It's generally agreed that a mature adult possesses cells somewhere in the 100 trillion range. Some medical texts proclaim as few as 75 trillion and others as many as 125 trillion. No one can, of course, really say.

### **Why do cleansed bodies need less sleep than toxic bodies. Isn't eight hours of sleep the norm for everyone?**

Perhaps I can begin an answer by citing an illustrative example. Lions normally sleep 18 to 20 hours daily. Their dietary consists of almost all flesh, bones and other animal parts which contain many toxic substances. On the other hand cattle sleep only two to four hours daily. Their diet is grass which has almost no toxic substances whatsoever.

In humans we find those who eat meat, cooked foods and condiments, and who habitually overeat, often requiring from seven to ten hours of sleep daily. And they're often sluggish at that, a condition often labelled hypoglycemic. Those who live on fruitarian and vegetarian fare sleep one to three hours less and are usually much more vital and active. People who are fasting usually sleep about two or three hours less than those who are eating.

Sleep is a condition under which the brain regenerates nerve energy for the body's needs. It appears obvious that a toxic body requires more nerve energy than a body relatively free of toxin. The more work the body must do, the more nerve energy is required. Sleep varies in length with the amount of nerve energy that must be generated and also by the ratio of efficiency with which nerve energy is generated during sleep.

### **I've heard of the body having a biological clock and I am familiar with circadian rhythms. This is the first I've heard of certain body processes being conducted more intensely at certain times of the day. Why should anyone become hungry in the morning if the body is in an eliminative phase?**

Hunger in the morning is not natural. The body has been marshalling its resources during a night of rest. Liver and cells are charged with some 2,000 calories of glycogen for the following day's consumption and hunger is not likely to occur until the brain's appestat notes a considerable depletion of blood nutrients.

Most people have never experienced natural hunger in their lives. Eating in the morning after a night's rest and sleep when the body has ushered in a heavy eliminative phase that is incompatible with hunger reminds me of a smoker's need for a fix immediately upon arising. When the body is toxic because of habits such as coffee, tobacco, condiments, cooked foods, animal products and so on, a prolonged absence of ingestion gives the body more opportunity to begin the unpleasant task of housecleaning.

When the body begins the eliminative phase, feelings are those of lethargy, headache and dullness. These are but a few of the symptoms of pronounced elimination. Those who toxify their bodies with alcohol call eliminative symptoms a hangover. Those who toxify their bodies with opium, heroin and other drugs call eliminative struggles withdrawal symptoms. But the symptoms are not much different for coffee drinkers, cigarette smokers, condiment eaters, cooked food eaters, overeaters and so on. When the body has a heavy toxic load and it has entered the eliminative phase the symptoms are unpleasant.

Rather than hunger being experienced in the morning, the urges to eat are morbid just as are the smoker's urge to smoke, the coffee drinker's urge to drink and so on. When the "fix" is again indulged, the body must divert its energies from extraordinary elimination to the task in hand of processing the new incoming load of food or drug. When its energies are thus diverted the unpleasant symptoms experienced while elimination was heavy cease. This, incidentally, explains the nature of addictions—new fixes are desired to palliate the pathogenic effects of old fixes.

Hunger does not naturally occur in the morning except in rare cases.

### **You've said the body can recycle about 70% of its protein wastes. How does this happen?**

When cells disintegrate from the action of lysosomes upon their death, the debris floats in the lymph. The lymph is the media of supply and drainage for the cells. Other cells may remove proteinaceous debris from the lymph by the processes of phagocytosis or pinocytosis if the amino acid supply is otherwise insufficient. The cells then break down the proteins into their amino acid constituents in a special little vesicle or stomach they have created for the process. Then the amino acids are diffused into the cells for use just as if they been absorbed as amino acids from the intercellular fluids in the first place.

The kidneys play a role in eliminating protein wastes normally, but, if there is a protein shortage, it will recover protein wastes and recycle them into the blood for reuse. The liver prepares wastes for excretion, also. It is involved in innumerable body chemical processes. However, protein recovery is primarily a cell activity rather than that of kidneys and liver.

### **I fasted for my first time last weekend for two days. I got a horrible headache and a terrible taste in my mouth. I become so weak for the last day I could hardly get around. Is this the usual thing? My bowels didn't move. Is it possible I absorbed some poisons from there?**

What you experienced were the symptoms of extraordinary body elimination. Should you have fasted to repletion, your tongue would have cleared up. In fact, your headaches would have soon ceased. The fact that you experienced such marked symptoms is some indication of the amount of filth you're carrying around in your body and of the great need for a much longer fast. In two days the body has eliminated relatively little of its accumulated toxins in a first time faster.

In some Hygienists who fast the tongue may not become coated at all. Their breath may not become strong. Nor do they experience headaches, lassitude, lethargy, weakness nor any

other symptoms of elimination. This condition throughout a fast means the tissues, cells, organs and fluids are not polluted. Most Americans, even those who are Hygienists, will have a coated tongue within 24 hours after their last meal, indicating accumulated morbid matters within.

Your bowels are a one-way street out of the body. The colon's skin and walls are developed to hold back all normal wastes and toxic materials that body and bacterial flora generate. Only water and electrolytes are withdrawn by the body through the colon walls and nothing else.

**Why do you advocate a low-fiber diet? For years now the importance of a high-fiber diet has been publicized.**

I do not advocate a high-fiber or a low-fiber diet. I advocate a diet of our best foods regardless of their fiber content. It seems those who advocate a high-fiber diet are persuaded that the objectives of eating is for the purpose of defecating. We are not defecating machines. We eat for purposes of nourishment. Waste materials will be excreted by the bowels, however much or little. The body is excellently equipped to deal with fermentative waste whether they be in the bowels 24 hours or 24 days. Those who overeat on proteins or eat them in incompatible combinations have a putrefactive colonic environment. While the bowel walls are still proof against the entry of toxins into the body, some terrible diseases can result from a chronic putrefactive state of the colon. Colitis, bowel cancer, hemorrhoids and numerous other destructive diseases can result.

**If we can't have condiments, what should we use to make our salads tasty? I love a little vinegar and oil on my salad.**

The fact that you find salads not very tasty in an unadorned state indicates that you're not an herbivore. Of course salads of green leaves are extraordinarily nutritious except in caloric values. Many of us do cultivate a taste for salad greens. I consider an occasional salad worthwhile, for they contain far more nutrients than do fruits, pound for pound. It's not that fruits do not furnish enough nutrients—it's that many of us eat salads to be satisfied we're getting enough of the variety of nutrient factors we need.

In a vinegar and oil addition you're stimulating your taste buds, not enhancing the taste of the salad. You can get better condiment effects with wholesome foods such as tomatoes. They will give you an acid flavor tastier and more wholesome than vinegar. Avocados or ground nuts as an oil will prove extremely pleasing. You can make a meal of this kind of salad.

Vinegar is indigestible and will retard digestion of other foods considerably. Fragmented oils require a long time for digestion in the first place, whereas salad ingredients normally are digested and passed on within two hours. Free fatty acids from salad oils coat other foods and retard their digestion, also.

Avocados, nuts and tomatoes, on the other hand, are compatible with green salads though they do slow up digestion somewhat.

Many fruitarians thrive in good health and eat few vegetables.

## **Article #1: The Importance Of Body Temperature by Dr. Herbert M. Shelton**

Warmth is one of the necessities of life. Vital activities are possible only between certain narrowly defined limits of temperature. Cold inhibits and excessive heat suspends them. Body heat is energy. It is employed not just in resisting cold, but also in accelerating cellular activities. Temperature, within certain narrow limits, is so absolutely essential to life that all functions are excited by any attempt at its variation. Animals are roughly divided into two major classes: warm-blooded and cold-blooded. This is according to whether they have means of producing and maintaining their own temperature or are dependent upon the surrounding medium (water or air) to provide it.

The invertebrates, although they breathe oxygen and circulate fluids throughout their bodies, have no red blood corpuscles and are cold-blooded animals. Fishes and reptiles, vertebrates with red blood cells, are also called cold-blooded animals, although they are able to maintain an internal temperature above that of the surrounding water or air. Invertebrates have no heat of their own, but receive their temperature from the surrounding media and adapt to it. Except for fishes and reptiles, whose heat-producing and heat-regulating powers are very limited, we may say that all vertebrates are warm-blooded, having red corpuscles, while the reverse is true of the invertebrates which have no red corpuscles.

It may be suggested that since animals can live without red corpuscles and exist without internal heat, the primary office of respiration is more universal than to provide for the production of animal heat. Using a popular phrase in biology, heat production is only a "secondary adaptation."

If we look at a large number of lower animals, we find them to be small and living in water. This medium directly and powerfully reduces them to its own temperature, and they are surrounded and permeated with water. In the radiata water actually mingles in large quantities with their digested food, so that they must of necessity remain at or very near water temperature. Even if they possessed sources of heat within themselves, it becomes evident that heat production cannot be the great end of respiration in these animals. Its primary function must be something very different from this.

If we take a second look at these animals, we discover that large numbers of them, especially those that live in fresh water, vary in temperature with the medium in which they live. Often they vary to a great extent, being sometimes near the freezing point and at other times fifty to one hundred degrees above it. Although a particular temperature may be best for each of them, still, many of them can live an active life in temperatures seventy, sixty, fifty and even forty degrees less. It is obvious that the small extent they could raise the temperature of their bodies above that of the water, when it is forty or fifty degrees, would be of no great importance. In their case at least, there must be some more important end for respiration than production of heat.

Heat supplies a necessary condition of vital activity. The activities of cold-blooded animals rise and fall as the temperature goes up or down. The higher the temperature, providing it does not go so high so as to destroy life, the greater the activity. If it becomes very cold, they suspend activity. It is not in inorganic chemistry alone that heat promotes the energy and intensity of action. In "vital chemistry," that is, in living functions, the same phenomenon is observed. An elevation of temperature accelerates all vital functions, both in the cold-blooded and in the warm-blooded animals. A similar thing is seen in plants.

Acceleration of activity increases with the rise in temperature until the temperature reaches a certain variable optimum, after which any added increase in temperature reduces activity. The rate of activity for some of the lower forms may become so great as the temperature rises that they "live too fast" and wear themselves out.

When temperature is lowered, vital activities are lowered. In the cold-blooded animals, some of which may be frozen for long periods and then revived, all activity ceases after the temperature is reduced below a certain variable minimum. Most of the warm-blooded animals die when frozen, their vital activities ceasing before they reach the state of freezing.

Higher animals are not so dependent upon the surrounding temperature. They are not only equipped with internal sources of heat and mechanisms to control its production and radiation, but they also in most instances have outer coats of hair, feathers or wool to protect them from the cold. They possess means of lowering heat production and increasing heat radiation if the external temperature or their own internal heat due to activity is increased. (By the operation of the same internal heat-regulating mechanism they produce fever when needed.)

Thus, while the very form and habits of the lower orders of life are determined by external surroundings, the forms and habits of life of the higher animals are very largely determined by powers within them. These often prevail over powerful antagonistic forces without.

The lower animals are more or less slaves to the external world; the higher animals make the external world serve them. It should be noted that this independence of the higher animals, this internal energy, is in great measure due to a capacity for maintaining their normal temperatures amid the changes in that of the surrounding water and air.

The uniform temperatures maintained by higher animals promote and secure a constancy, precision and energy in the nutrition of their tissues, and in the vital functions that supply the animal with resources to carry on active life in the face of opposing influences in the world.

A brief glance at the method of maintaining body temperature may be helpful. In the chapter on respiration we learned of the office of oxidation in the production of heat. It is necessary that we understand that the body is capable of both increasing and decreasing its rate of heat production as the external temperature falls or rises. These processes are rigidly controlled by the nervous system and fail only in greatly enervated and diseased organisms.

But the body also increases and decreases the radiation of heat from the body as need arises. While oxidation warms the body, evaporation (as in sweating) cools it. These physiological processes are carried on in relation to vital wants. The human body, to narrow our considerations at this point, is based upon a system of self-regulation and equipoise, and its temperature relations are beautifully provided for. In a cool atmosphere less heat is lost by evaporation and more produced within the body, while a reverse process is seen in a warm temperature.

In all changes of temperature outside the body, some compensatory effort is required. But if our other relations are correct, the internal heat-regulating capacity of the body will be efficient. The maintenance of the heat-making mechanism of the body is an indispensable condition of health. Feeble and sick individuals who find it difficult or impossible to maintain normal temperature in a cold climate need to be kept warm. Chilling inhibits all functions of life and reduces their already greatly reduced stock of energy. The escape to a warm climate is no mere luxury for such persons. Warmth of some degree is certainly a normal requisite of life. But experience and experiment have shown that when the temperature of the surroundings is out of all proportion to the needs of the body and to its capacity to adjust itself, the body must and does suffer. There is not only discomfort, which normally causes us to seek relief from extremes of heat or cold, but there is some expenditure of energy in resisting extreme temperature.

In lands where fogs, frost and darkness cramp the energies of man, as well as in regions where excessive and long-continued heat depresses his vital activities, life is handicapped. By means of clothing, housing and artificial heating arrangements, we are able to live in cold climates. By means of cooling systems and a reduction of clothing, we live more comfortably in hot regions and seasons. But none of these arrangements are ideal. A warm climate serves man best; first-class habits of living enable him to live better in whatever climate he resides.

## **Article #2: Are You Suited For Health by Mike Benton**

Do you dress for success? Are you a fashion follower or a "clothes horse?" Is your clothing bought for style and status or comfort and durability?

Like food, shelter and the other necessities of life, clothing can be as natural or unnatural as we choose. Just as the businessman who orders steak at a luncheon to impress others with his financial success, there are people who wear the latest styles in clothing and name brands to make impressions.

However, from the body's standpoint, clothing serves two functions only: 1) To protect us from climatic variations, and 2) To protect the skin from injuries. Clothing is not a necessity if we live in an agreeable climate and a non-threatening environment. If we need to cover the body, clothing should be chosen for only these reasons:

1. Comfort;
2. Environmental harmony;
3. Aesthetic pleasure.

Clothing is comfortable if it allows unrestricted natural movement. High-heel shoes are not comfortable. They throw the body out of alignment and place undue strain on the feet and calves. They make a woman's natural gait into a wiggling, mincing movement which prevents full strides. Neckties are not comfortable. They serve no protective function. Instead, they may restrict circulation about the neck and create tension and headaches.

All tight clothing, be it jeans or pantyhose, prevent natural air circulation over the body. Vaginitis and yeast infections have increased as rapidly as the popularity of the smothering pantyhose. All underwear, especially, should be of light natural fibers that allow the skin to breathe.

Most shoes are made from leather and are tightly-laced or high-topped. Again fresh air is shut off from the skin and fungus and odors result. Belts bind the waist. Brasieres constrict the chest. In fact, fainting was very widespread in the nineteenth century not because of the gentility of the women, but because the corsets they wore were so tight they could not take a deep breath.

The human metabolism depends upon the free flow of air over the exposed skin. Tight, constrictive clothing blocks air and sunshine. We become trapped in an envelope of toxic gases emitted from the skin during its process of elimination.

If we desire harmony with our environment, we must wear clothes made from natural fibers. Synthetic materials do not allow the skin to "breathe" and are responsible for many of the heat rashes experienced in the summer. The plastic diapers used on babies are the culprits behind diaper rash. Our skin is repelled by the synthetic clothes that prevent natural body moisture from evaporating.

Synthetic fibers are also made from non-renewable resources and harm the environment. Such "natural" materials as leather and furs require the slaughter of animals, either directly or indirectly. Wearing leather and furs while espousing a meatless diet makes the ethical vegetarian an unconscious hypocrite.

This leaves us with cotton, linen, straw, and wool as optimum materials for clothing. These are from renewable resources (wool does not involve the killing of the sheep), and they allow the skin to breathe. They require no undue exploitation of the environment or animals.

Aesthetic pleasure is also a valid reason for choosing our clothes. We humans have a deep love of beauty

and this love should be expressed in our living surroundings and personal effects. Clothing should be pleasant to the eye, colorful, and pretty without being merely ornamental. Beautiful clothes, of course, cannot hide the ugliness of a diseased body or unhappy mind, nor should beauty be confused with fickle style.

The most aesthetically pleasing clothes are those that are simple and have stood the test of time. Sexual attributes should not be emphasized by clothing, nor should they be hidden, unduly. No piece of clothing in the world is as beautiful as the healthy body. Neither artifice nor deception can improve upon nature's work.

So, are you suited for health?

You are if you wear clothing made from natural fibers which are comfortable, pleasing to the eye, and simple. Give your body as much freedom from clothes as possible. Nudity, when weather and personal feelings permit, can be an important factor in regaining health. Overdressing is much like overeating—it weakens the body's natural vitality.

A warm smile, sparkling eyes, healthy hair and a radiant complexion are the best attributes in your wardrobe. The rest is only window dressing.

[Home](#) > [Lesson 4 - Introducing The Life Science System For Perfect Health, Part II](#) > Article #3: Mental And Emotional Poise by Lee Bauer

### **Article #3: Mental And Emotional Poise by Lee Bauer**

You may eat the finest food, get daily exercise, sunshine, fresh air, pure water, proper rest and sleep, live in a near-perfect climate, and yet be miserable and unhappy. Why? Because life is more than bread alone, more than creature comforts, more than well-disciplined physical health procedures. Total health and well-being depends upon so many factors—each important and necessary. Each demands a share of our time and energy. But, unless we watch our mind and emotions at work, our psychological responses, our inner urges and demands, a complete state of health and happiness will surely elude us. This is to say that the physical and mental are tied together as one. They are not separate. But, much of the time we treat them as if they were. Actually, we can only separate them for the purpose of discussion. Since, as Dr. Shelton has remarked, "The human being is a physical, mental, emotional and spiritual unit, and not a mere bundle of separate and more or less antagonistic elements. Health is a matter of vital, nutritive and physical hygiene."

So let's examine that part of us which is not too often talked about at our conventions, or written about in Hygienic literature. Perhaps this may be because of the complexity, the vastness, and the difficulty usually experienced in trying to explain it satisfactorily. By no means do I consider myself an expert in this field. I am merely a bystander, noticing what is going on with myself, wondering about it, and asking questions which have led me to some rather satisfying answers over the years. I would like to share them with you.

Let's begin at the beginning. What is it that most of us are seeking? What are we after? Why is it that we often go from one religion to another? Why are we engaged in trying different disciplines, gurus, masters and mystics? Could it be that most of us are searching for a permanent state of peace, happiness, satisfaction, security, or the ultimate: God? Whatever it is, it is described by many names. But, since the name is not the thing, it really doesn't matter what we call it. Maybe we could simply refer to it as permanent happiness. Before we get involved in the search, as to whether there is such a thing, should we not want to understand the person that seeks this happiness?

## **Know Thyself!**

In order to know the seeker, I must first know myself. I must want to see how my mind works: why I think as I do, react as I do, and so on. No book, no person, regardless of how intelligent, gifted or famous can help me. It's a do-it-yourself process. I must see it for myself, first hand. No other method that I know of has been found that works unless I step in the direction of knowing myself. If I can see that my mind works as it does, because of my conditioning, I have taken a giant step towards freedom and eventual transformation. Conditioning is the cause of my beliefs, my patriotism, my politics, my attitude towards others, and towards the world. In fact, I am the world! Getting in touch with this knowledge of myself reveals why I think in the particular way that I do. It exposes to me the background of all my thoughts. It enables me to perceive the reasons for my hurts, bitterness, jealousy, and disappointments. It reveals the source of my conditioning, which lies behind all my relationships.

## **Tracing Our Conditioning**

We come into the world, as a baby, equipped to start life as a human being. Within us are all the human characteristics and attributes which have been in existence for over two million years. Along with these, we also inherit the tendencies and instincts of the animal. They go back and back, into the timeless past, perhaps to the origin of life on earth. And, before that, to life in the sea, where it is possible that all life began.

Our subconscious or unconscious mind contains the images and memories that lead to self-preservation, fear and violence. These are gleaned from the lives of our ancestors who have preceded us. From the moment of birth, or even before birth, we begin to gather knowledge through our senses. We learn by observation, imitation and instruction. The conscious mind now makes its appearance. It becomes evident that both subconscious and conscious are one.

History and further study reveals that in spite of some two million years of human life, and 2,000 years of religious training, the animal instinct of even the cream of society is still the driving factor. In the course of time we are cautioned to resist these animal emotions as they come up, and to subdue them or control them. To get this message across to us, we are instructed in various ways. In religion, for example, we absorb the instruction through pictures, sayings, books and in places of worship. Depending on where we grow up, in what part of the world, we learn about Jesus, Allah, Buddha and so on. So that, at an early age the Christian child has no doubts about Christ being the true God. In turn, the Muslim boy or girl will think of Allah as being the only God. And, as a member of a Buddhist family, the youngsters grow up regarding Buddha as the Most Compassionate One. Children of other religions are also brought up in a similar way. Thus, each child is indoctrinated with the faith and beliefs given to him by his parents and teachers. As they grow and mature, most of them stand ready to lay down their life for these beliefs. Conditioning is now well underway. It goes on in every area of our lives, from birth to the grave. It colors our thinking and actions. It touches our lives in so many subtle and obvious ways. It motivates our feelings, our political leanings, our way of speaking, walking, eating, going to the bathroom, and even our dreams.

## **I Really Don't Know**

As we grow up we begin to take a stand on issues. We gather a few facts and figures and then come to a decision. It's either right or wrong, so help me God. Our decisions become more solid as we grow older. With some of us, we write them in granite. We become fixed as the stones on which they are inscribed. We defend and justify them, sometimes even to the end. Examples in any field could be used, but since we moved into our conditioning through religion, mentioned before, let's pursue the matter further.

For instance, some say emphatically that there is a God. Others, just as strongly point out that there is no God. Both cannot be right. If one is true, the other is false. To see the truth, we are not in a position to accept or deny. If we do either, that ends the investigation. To find out for sure, I must admit that I do not

know. I really don't! True research begins from there.

## **About Listening**

Now, how do we go about our search for the truth? Much depends on how we investigate, but even more important is—how do we listen? Say we go to a lecture or talk. The speaker says something. Immediately we tend to agree or disagree. Or, we compare him with someone else, and what he is saying, with something we may have read or heard. Accordingly, we nod and shake our heads. Throughout the talk our mind continues to talk also. Have you noticed how the mind is continually yakking with us? This constant chatter of the mind causes our attention to be divided between what the speaker says and what our mind is saying. If our listening is to put us in touch with the facts, we must give our entire attention to what is being said. In this way, and this way only, do we come to understand the speaker and what he is really saying.

We find ourselves agreeing or disagreeing according to our conditioning. Listening, that is proper listening, demands that we be aware of what is being said without the bias of our conditioning. In other words, being aware, without choice is necessary to get the full impact. I must neither agree nor disagree, as I listen. I must not judge or evaluate to any degree. I must listen, pay attention, be aware, with my whole heart, mind, body, nerves, senses, everything!

If I am able to do this, I see that eventually my mind and its chatter slows down. I listen and watch my thoughts as they pass through my mind, as I would watch a movie. I greet each thought as a friend. Welcome it to my mind. Investigate it. Challenge it. Question it. Pursue it to the very end, without hurry or anxiety. See it for what it is, and then let it move on, pass away, drop dead, to return no more. If I am successful in following each thought from rise to fall, I soon begin to take notice a slowing of the thinking process. This entirely normal way of handling thought is within the ability of everyone. After a period of time, perhaps several weeks, a month or so, depending on your interest and attention, the mind becomes silent. Thinking comes to an end. There is no further chatter to disturb our listening and observing. If, perchance, a thought does enter the mind, see it for what it is, treat it hospitably, and let it die away. These moments of non-thinking will gradually lengthen. The ease of doing this extends itself. This could be called a state of pure listening, pure observing. Pure because there are no thoughts to contaminate the mind while it is listening and attending to the speaker, or the situation at hand.

So far as I know, this is the only way to be in direct touch with a speaker. It works effectively when used in any situation or relationship. You don't have to use any effort to do this. It happens by itself. There is no method or system to bring it about. One merely listens, watches, observes, becomes aware, gives his complete attention to the thought at hand, to the feeling experienced, and notices its passing. Understanding our thoughts leads to further understanding of ourselves. And, by understanding ourselves, we can better understand the other fellow. Eventually, this culminates in a radical change or transformation within, which radiates outward, and extends to every facet of our life. So that the things we are unhappy about, clear up in the process of daily living. We don't have to use willpower, control or any tricky stuff. Pure listening and observing without the distraction of thought, puts us in touch, moment by moment, with exactly what is taking place.

## **There's More I Must Learn**

There's a lot more to experiencing mental and emotional poise. I must find out who I really am. I must discover that the ego, the self, the "I" is not an entity, but merely my memory. That thinking is great when applied to everyday use, for solving problems, technical engineering, finding my way home, recognizing friends and family...but it gets in the way when we want to observe, be aware and sensitive to life that is going on all around us.

Poise means balance, equilibrium, stability, ease of mind and body. Mental and emotional poise is a normal state of being, in which we experience harmony and ease within ourselves. It does not mean we

have no challenges or problems. We are faced with these even in the vigorously healthy state of being at peace. It means we need not be hurt or disturbed in any way by them. It means also that life is a joy, and each moment offers us another opportunity to learn, to love, and to understand.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 1. What Constitutes Nutrition (Definitions And Concepts)

### 1. What Constitutes Nutrition (Definitions And Concepts)

Conventional attitudes regard nutrition as being almost exclusively involved with foods and feeding, but this is only one facet of the nutritional scene (albeit an important one). At the outset it is prudent to define what nutrition is and, in view of the many misconceptions, what nutrition is not.

#### 1.1 Nutrition Is the Sum of All Processes That Promote Growth and Function

Nutrition does not mean food only. Nutrition is the sum of all the processes that supply, develop and sustain an organism's faculties and functions at the optimal level of existence. In short, nutrition is the total of all that supplies life's needs. It embraces all requirements for perfect health and supplying these requirements constitutes nutrition.

#### 1.2 Nutrition Is Modified By the Entire Spectrum of Life Conditions and Activities

The sum of nutritional processes adds up to our health quotient; that is, our state of health equals the total of the nutritional processes that created it.

Anything that modifies nutrition or the processes of supply and usage also modifies health. Everything we get involved in or do in all spheres of life affects in some way our nutritive disposition, either for the better, for the worse or equivalently.

With respect to foods and feeding, we have specific adaptations for acquiring and processing particular foods to meet our nutritive needs. Anything that changes in the whole process affects our nutrition and, consequently, our health.

Because of its importance, we re-emphasize: Nutrition is largely dependent upon our health and, likewise, our health is dependent on nutrition.

### **1.3 Nutrition Involves the Processes of Growth, Development, Supply and Invigoration**

Dr. Herbert M. Shelton has defined nutrition as follows:

*Perfect nutrition is dependent on perfect organs, perfect functions and normal health. Each is dependent upon and grows out of the other. All processes and functions are interdependent and interact harmoniously for mutual well-being. They cannot be taken apart and categorized. Every aspect of life is but a part of a unified whole.*

*This idea of interdependence and interaction leads to the principle that the appropriate way to recover and develop strength and vigor is through the activities and processes that give rise to growth. We recover and develop strength and vigor in the same way that we keep well, in the same way that a babe grows into vigor and adulthood. The powers and forces that brought us into being, that sustain us in existence, that cause us to grow through all the phases of life to manhood and womanhood, are sufficient to restore us if health becomes impaired.*

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 2. Food Is An Element Of Nutrition

## **2. Food Is An Element Of Nutrition**

As stated earlier, food constitutes only a part of the needs of life. It constitutes some of the raw materials which become part of the overall nutritive processes. When the body receives food, it breaks it down mechanically and chemically into components which can be absorbed and synthesized by the organism into special substances to meet the special needs of the organism.

### **2.1 Food Is an Inert Substance—Merely Raw Materials**

Many people believe that foods have different actions in the body. However, this is erroneous. Foods do not act in the body but are, instead, acted upon by the body. To be appropriated the food must lose all its character. It is mechanically crushed, comminuted and mixed with digestive fluids, then chemically reduced to basic components for absorption, synthesis and use.

Let us again review nutrition as Dr. Shelton has expressed it in yet another definition:

*Nutrition is a vital process carried on only by a living organism. It is a process of growth, development and invigoration. To eat good food and enough of it, to drink pure water and breathe pure air, in and of themselves, are very desirable, but something more is needed in order to acquire health, strength and vigor. Nutrition is dependent on function. We can have better nutritive function only when we have a capacity for better nutrition.*

*Food is of value only in its physiological connections with air, water, sunshine, rest and sleep, exercise or activity, cleanliness and wholesome mental and moral influences—in short, all the natural or normal circumstances which we know to be necessary for the preservation of health.*

What Dr. Shelton is saying is but a reiteration of what has been emphasized here, that the better your

health the better will be your nutrition and the better your nutrition the better will be your health. Every factor and condition of life must be supplied optimally to assure best health.

Again, to highlight its importance, we repeat that food does not use the body or do anything to the body. The body does unto the food and uses it. In creating foods, plant life designed them to be utilized by animals in exchange for a service to the plant. This is symbiosis. Human service to plants is the incidental broadcast of their seeds. Was ever a reward so great for such a small service?

As a nutritionist you must ever keep this in mind: Foods do nothing in the body. They have no powers of cleansing, healing or anything else. Foods have no will or purposes of their own. To be consumed and used is their inherent design.

## **2.2 Food Use Is Subject to the Body's Ability to Process, Appropriate, Assimilate, Metabolize and Eliminate**

A body that is impaired is unable to properly process and use food. To the extent that the impairment causes withdrawal of functional energies from digestive processes, the body is unable to be fed. When the body's nutritive functions are in any way impaired, and this will usually be evidenced by depressed or lost appetite, make this a standing rule: do not partake of food. Guide clients away from food. Missing a meal or a few meals is most constructive.

If the body is in any abnormal condition, food should not be taken or given. In fever, pain, emotional upset, fatigue, worry, sleeplessness and many other conditions, the body is unable to muster the needed energies for the processes of digestion, appropriation, and assimilation. In such conditions the body does not create the condition of hunger or give rise to appetency.

## **2.3 Food Is But One of Many Needs in Nutrition**

Our capacity to receive, process and assimilate food is necessary to the nutritive process. In the absence of functional energies in these areas, feeding results in lowered body energies and the waste of foodstuffs. It is passed on to the bowels and the body is worse off for it.

To appropriately receive, digest and assimilate foods, other physiological needs must also be present. Oxygen, water, digestive fluids, nerve energy and a multitude of other factors and influences must favorably coalesce to effect these processes. Should any impairment in the nutritive faculties exist, the interference may prove insurmountable and result in indigestion.

This leads to this inescapable conclusion which you must ever bear in mind: proper nutrition is dependent upon and is affected by the entire spectrum of the organism's activities and conditions.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 3. Physiological Criteria Foods Must Meet

## **3. Physiological Criteria Foods Must Meet**

Every creature in nature has become adapted to securing and nourishing itself on particular foods. All natural equipment and faculties dispose to this specialization. Humans are not exceptions to this rule. Because we have developed tools using our capabilities and can supply ourselves with an abundance of anything on earth as food does not in any way alter our physiological adaptations and specializations.

Every creature has basic nutritive requirements. Our biology books detail these rather impartially and correctly for animals. But the books and teachings that concern human nutrition do not deal impartially

with the subject. Our educational establishment is the captive of our mammoth industrial complex. This means they prostitute their teachings to cater to the needs of those whose grants support them. Thus, human nutrition as taught in our society is dictated, not by physiological faculties and needs, but by the wishes of those food industries that stand to gain from the miseducation that panders to their products.

### **3.1 Food Adaptations of Various Species**

The food specializations of various species are categorized by general designation. Some of these categories are as follows:

- Herbivores (grass and vegetable eaters such as cattle, sheep, goats, deer, horses, rabbits, etc.)
- Graminivores (animals that subsist on grains—birds primarily)
- Insectivores (bats, birds and creatures that subsist on insects)
- Frugivores (fruit-eating animals—primates and anthropoids, humans, orangutans, apes, monkeys, etc.)
- Carnivores (animals that live on the flesh, bone, offal, etc. of other animals—cats, dogs, lions, tigers, wolves, buzzards, hawks, eagles, jackals, etc.)
- Omnivores (animals such as swine (pigs, hogs) that live off a mixed diet of fruits, vegetables, grains, flesh, offal, etc.)

As you're aware, the bee lives on the nectar of blossoms and flowers and the pollen with which it becomes incidentally contaminated. All the bee's equipment befit it to seek out flowers, land upon or hover over them, withdraw nectar the flower has secreted especially for the bee, and to return to its hive where it shares its harvest with other bees, the surplus being stored as honey. The bee is excellently equipped to meet its needs amply in this manner. Humans cannot meet their needs this way. Neither can cattle, horses or pigs. They're equipped in their own special ways to meet the needs of their adaptations.

As a sidelight on the symbiotic relationship of life, we might note that the flower created the nectar for the bee in exchange for a service. The flower or blossom is a step in the plant's creation of seeds. Before a seed can be formed, fertilization must take place and to insure this fertilization the bee is enticed by nectar. Incidental to the taking of nectar the bee contaminates itself with pollen. At the next flower the bee contaminates the flower's pistil with this pollen. This incidental fertilization is the service the plant induced the bee to perform with the nectar secretion. Who said plants weren't smart?

### **3.2 Range of Food Processing Capabilities**

Humans are endowed with certain natural capacities and limitations in the acquisition, processing and utilization of foods. Human development (which endowed us with our faculties and capabilities) specialized and restricted our equipment and capabilities for food gathering and processing to certain foods just as in the case of other animals. The faculties of most creatures are developed so as to make disposition of surpluses or to survive scarcities. Surpluses are either stored as reserves or are excreted. Redundancies beyond needs and ability to readily excrete founder humans and other animals that are so unwise as to overeat.

In ascertaining the criteria that a food must have to satisfy human needs, we must be cognizant of the capacities and capabilities of the organism as well as the properties of the food.

### **3.3 Food Adaptations of Humans**

Humans are classified as frugivores because they have the equipment to harvest and efficiently process only a class of foods called fruits. Humans are not alone in this class. For millions of years humans subsisted solely, exclusively and only on fruits. That is the way it was expressed by Dr. Alan Walker of Johns Hopkins University, an anthropologist who conducted extensive research into the dietary background of humans. Even though humans have eaten foods outside their dietary adaptations off and

on for perhaps hundreds of thousands of years and have eaten some cooked foods for tens of thousands of years, there has been no physiological change that would justify straying from our natural dietary.

Our adaptations are strictly as fruit-eaters as you will see in subsequent lessons.

### **3.4 The Dietary Requirements That Determine Our Ideal Foods**

Natural foods for humans must satisfy the following criteria and nutrient needs:

#### **Foods Must Be Non-Toxic**

First and foremost the food must be toxin-free. None of the compounds and substances in the food should present a digestive problem. The body must have enzymes adapted to handle every substance within the food. Toxic substances are those which the body cannot use as food. Substances that the body cannot use but which it cannot prevent absorption of (as in alcohol, cholesterol, drugs, etc.) are toxic.

#### **Foods Must Be Edible in the Raw State**

The food must be edible in its living or raw state as nature delivers it up for us as food. If we cannot eat our fill of a food in its raw state with relish and make a meal of it that meets all or most of our nutrient needs, then it is not a natural food for humans and should be shunned in favor of foods that do.

#### **Foods Must Have Sensory Appeal**

Foods of our adaptation have great sensory appeal. They are a delight to the eye, their aromas tantalize the sense of smell and their substance is an unqualified gustatory delight.

#### **Foods Must Be Digested Easily When Eaten Alone or Properly Combined**

Foods of human adaptation undergo practically no digestion in the stomach and humans can absorb the chyme and chyle of their natural foods with very little chemical elaboration in the stomach and small intestine.

#### **Foods Must Be Digested Efficiently**

While ease of digestion necessarily also implies efficiency of digestion, this entry relates to another aspect of efficiency. That which is eaten represents a certain amount of energy potential. To derive this energy from food, the body must expend energy to obtain it. The ratio of energy obtained relative to energy expenditure determines the ratio of efficiency.

For instance, we spend a mere 30 calories of energy in the process of appropriation, chewing, absorbing, transporting and assimilating 400 calories of watermelon. On the other hand, we may spend 280 calories in the digesting meat to obtain 400 calories. The efficiency with which we handle foods with monosaccharides versus the inefficiency with which we handle protein foods indicates most emphatically the types of food to which we are naturally adapted.

In processing food for use, we expend two kinds of energy. We expend metabolic energy, which is the chemical and mechanical energies expended, and we expend nerve energy. For instance, we use very little nerve energy in digesting watermelon. But, in processing foods to which we are not biologically adapted, an enormous expenditure of nerve energy is occasioned. Meats may cause nervous exhaustion due to the body's frenzied activities in dealing with proteins, uric acids and other toxic substances in them. Though we may feel exhilarated while expending nervous energy just as we feel "a pick-me-up" when taking coffee (which really drains nerve energy), the stimulation occasioned by eating unsuitable foods such as meat is an indication of the inefficiency with which the body handles it.

### **Foods Must Have Protein Adequacy**

Our natural foods must supply us with our protein requirements of about 25 grams daily. The less protein eaten down to the point of adequacy, the better. Protein is taken into the body for replenishing amino acid components needed for a multitude of applications. There are three things you should keep in mind relative to protein digestion:

1. the body can recycle up to two-thirds of its proteinaceous wastes to meet its needs;
2. protein digestion requires an expenditure of energy equivalent to about 70% of its total caloric content; and
3. neutralization and elimination of the toxins of protein degeneration (putrefaction) uses up vast amounts of nerve energy which, though stimulating at the time, exhausts and debilitates the body.

We must not feel compelled to eat protein foods as such in order to achieve protein adequacy. Almost every food natural to humans has about 4% protein dry weight, an ample amount to supply our needs. Further, most of our natural foods contain the amino acids we need.

### **Foods Must Be Adequate in Vitamin Content**

Some 30 vitamins have been determined to be needed in various quantities in the human diet. The vitamins must be in the diet in an organic context with other nutrients to be useful.

### **Foods Must Be Adequate in Mineral Salts**

Our only source of the minerals of life is from food. Only in food are they in the organic context which we can use. Under no circumstances can the body make use of inorganic minerals as might be ingested with water, supplements or powdered rock (as with dolomite).

### **Natural Foods Must Supply Our Needs for Essential Fatty Acids**

Those food factors which the body requires but cannot itself synthesize are said to be essential. The essential fatty acids are linoleic, linolenic and arachidonic. Essential fatty acids are unsaturated fats. They occur in practically every fruit, nut, seed and vegetable in ample quantities to supply human needs.

### **Natural Foods Must Supply Our Needs for Caloric Values**

The energy we expend must be derived from our food intake. The foods which most efficiently and easily supply our caloric needs are those with high monosaccharide content. Sweet fruits are at the top of the list in meeting these requisites.

### **Natural Foods Are Water-Sufficient to Meet Our Needs in Most Cases**

Foods to which we are biologically adapted normally meet all our water needs. This is obvious, for we have no water-drinking faculties other than suction which is necessary for swallowing food. Fruitarian species normally do not drink water.

### **Natural Foods Are Alkaline in Metabolic Reaction**

We require foods that are alkaline- or base-forming when metabolized. Almost every food of our adaptation is base-forming, even if it has an acid pH in its natural state. Should we eat any acid-forming foods, such as nuts, they should be offset at the same meal with alkaline-forming foods such as green leaves or other vegetable fare.

These are the criteria or requirements for foods that are natural to the human dietary. Only fruits, and especially sugar-containing fruits, meet all these needs ideally. Nothing else meets all these requirements. As further lessons will demonstrate, the requisites of life can be amply met on a totally

fruitarian regime.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 4. Nonfood Nutritional Factors

#### **4. Nonfood Nutritional Factors**

The first part of this lesson has emphasized the great breadth of the nutritional scope and perspective. This introduction is but a preview of some nutritional factors. In-depth treatment is given to most aspects of nutrition in subsequent lessons.

Among the nonfood nutritional factors are the following:

- Sunlight and natural light
- Fresh air and the oxygen it supplies
- Pure water
- Exercise, play and recreation
- Rest and relaxation
- Sleep
- Emotional poise
- Other requisites of life
- General body conditions

Inasmuch as you've already had a glimpse of nineteen essential factors and influences for great health in a previous lesson, and they included the above, the details will not be repeated here. You may refer back to lessons three and four if necessary. The above listing is to emphasize the great dependence of proper nutrition upon other needs of the body (besides food) being appropriately met. Nutrition does not occur in a vacuum. It is not an independent process. It involves the organism in every aspect of its being.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 5. Discussion Of Conventional Nutritional Teachings

#### **5. Discussion Of Conventional Nutritional Teachings**

As perhaps you know or may have long suspected, and as was stated earlier in this lesson, conventional nutritional teachings are distorted to accommodate the "food" industries that dominate America. In fact, these distortions and fabrications predominate, not only in America, but also in most of the Western world.

If we follow conventional nutrition, we are bound to end up with malnutrition and toxemia and the pathologies they lead to. As Life Science serves no commercial masters, it has no interests to be served in teaching you false concepts. Further, we do have the benefit of knowing the truth. With respect to conventional nutritionists, it might be said that "It is better to be ignorant than to know so much that isn't so."

## 5.1 Do RDAs Represent Our Actual Needs?

The recommended dietary allowances of the Food and Nutrition Board of the National Research Council reflect the many fallacies to which a wrong philosophy of nutrition leads.

First, the RDAs are educated estimates and are sometimes revised upwards or downwards in view of "new findings."

Second, the board has been very liberal in its allowances. In almost every case, the allowance or suggested daily intake is two to ten times the amount needed by healthy persons. Likewise, they are far in excess of the needs of unhealthy persons, for unhealthy persons usually have impaired nutritive faculties, do not function as efficiently as do healthy individuals and should have a physiological rest in the form of a fast.

Third, the allowances are based on conventional diets which are comprised largely of cooked foods. Not only are cooked foods so deranged that a substantial portion of their nutrients are not usable, but they so vitiate the nutritive faculties as to impair them and lower their efficiency.

Healthy individuals eating a raw diet of proper foods have highly efficient nutritive faculties and thrive on a fraction of the intake on which the RDAs are based for conventional eaters.

## 5.2 The Concepts of the Basic Four Food Groups

The pathology and suffering resulting from the abominable nutritional concept of the four basic food groups is a national disaster! This concept and its promotion stems from a national policy of catering to industrial behemoths rather than to the welfare of consumers. While today's "food" industries are outgrowths of incorrect eating going back into the past, the justification for them is relatively recent in origin. The concept has been to acclaim as science the eating of "foods" that cover, not human needs, but the gamut of foods produced by powerful food interests.

The basic four food groups are as follows:

1. The milk group, which includes milk and all milk products.
2. The meat group, which includes meat, eggs, fish, legumes and nuts.
3. The bread-cereal group, which includes grains and grain products.
4. The fruit-vegetable group, which includes all fruit and vegetable fare excepting nuts and legumes which are in the meat group because of their protein content.

Eating specified amounts from each of these groups daily is proclaimed "balanced nutrition." In truth it is a "balanced market" for the commercial "food" interests that share the food market. The selection of foods in the typical American diet has nothing to do with meeting human needs. The typical American diet is gravely pathogenic and is mostly responsible for our deplorably diseased population.

In subsequent lessons you'll learn why milk and all milk products are unfit for human consumption and the physiological grounds for this unfitness. You'll also learn why all meats, eggs, fish (and legumes except sprouted) should be rejected as items of diet. Additionally, the relative unsuitability of grains and grain products (compared with fruits, vegetables, nuts and seeds) in the diet will be highlighted. Bread, cereals and other starchy foods, if included in the diet, are a far less than ideal part of the diet.

To comment on group four, we point out that some vegetables can be added to the human diet with benefit, though their rich content of nutrients is really unneeded if we partake liberally of fresh raw fruits (and abstain from eating unwholesome foods).

Tubers such as potatoes constitute a large portion of the vegetable intake in America. Inasmuch as most tubers are cooked to make them palatable, and cooking significantly lowers the nutritive value of the food, they, like cereal grains, are less than ideal as foods. In addition, many other vegetables, such as onions, garlic, radishes, spinach and others contain toxic substances (such as mustard oil in onions and garlic and oxalic acid in spinach) that make them unsuitable as foods.

So, while certain vegetables (such as lettuce, celery, broccoli, cabbage and others) may supply "nutrient insurance," many, if not most, vegetables have liabilities that make them less than ideal, even undesirable, as foods. Besides, we can obtain most, if not all, the nutrients we need from fresh ripe fruits, especially if we also include the non-sweet fruits often called vegetables (such as tomatoes, bell peppers, cucumbers, etc.) plus a few nuts and seeds in our diet of fresh fruits.

It bears reiterating that the items of diet to which we are not biologically adapted are, to some degree, pathogenic. Subsequent lessons will probe the ill effects of wrong diet in greater depth.

### **5.3 Eating Practices of Americans**

Most of us are keenly aware of American eating practices. A typical breakfast may include every member of the four basic food groups. The typical American breakfast usually includes from the meat group ham, bacon or sausages and eggs, from the grain or cereal group bread (toasted or untoasted) and/or some pastry or perhaps a donut, and a bowl of cereal. From the fruit and vegetable group may be an "appetizer" in the form of grapefruit, an orange, orange juice or cantaloupe. Also from this group may be some fried potatoes and possibly banana or other fruit on top of the cereal. From the milk group there is usually milk for cereal, cream for the coffee, butter for the toast and perhaps a glass of milk on the side. Sugar, salt, pepper and other sweeteners and condiments may be added.

An American lunch usually includes a meat dish with servings of vegetables, tubers or grains on the side. It usually includes bread and may include milk, ice cream, butter and other dairy products. An American dinner is not substantially different than an American lunch except there's usually more of it.

The typical American diet is heavy on members of the four food groups promoted in America as nutritious fare. There has not been in all history more pathogenic fare than this!

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 6. Discussion Of Human Eating Habits The World Over

## **6. Discussion Of Human Eating Habits The World Over**

Diets vary widely over the face of the globe. We have the Lapps and the Eskimos who live pretty much as carnivores on one end of the spectrum, and we have groups of peoples in the equatorial regions who live as almost total fruitarians at the other end of the spectrum.

### **6.1 The Origins of Paradises and Edens**

Up until relatively recent times in human history, humans have been primarily fruitarians. To this day in Java and other Malaysian islands there are enclosures known as para desas where people live among fruit-bearing trees. (The word paradise derives therefrom.)

All over Europe and much of the Far East there were walled enclosures of heavy stone where people resided and tended orchards. These were called paradises or edens. The walls kept out animals, helped capture and retain the sun's heat and protected against winds and frosts.

Many words with roots of ava, and aval (such as Valhalla and avalon) evolved from terms born of a fruit culture. Valhalla originally meant apple hole or a place where apples were stored. Avalon merely meant the land of apples. The cultivation of fruits had attained scientific status long before formal histories were kept. We know of them through folklore legends and the remains of the incredible stone walls of these edens.

## **6.2 The Origins of Today's Eating Practices**

If humans are natural fruitarians, how have they come to stray from the diet of their physiological adaptation? .

In nature, such animals as gorillas, cattle and horses will die of starvation rather than eat flesh; but chimpanzees and some other fruit-eating animals will rend and eat another animal on occasion.

Humans, in addition to being possessed of a strong survival instinct, possess extraordinary intelligence to employ in support of that instinct. About three to four million years ago humans begin wandering out of their homelands in tropical regions. In time they peopled most of the earth accessible to them. Over the whole globe, according to geological records, climate was hospitable and favored their frugivorous habits. The remains of tropical plants have been found in Alaska and other northerly latitudes.

Due to some cataclysmic event or events that resulted in cold and freezing temperatures and ice ages, humans in northerly climes retreated south. Those that remained had to survive on the fare available to them or perish. For a part, this meant meat and animal products. Humans had to learn providence against the seasons and to survive on the foods available in harsh seasons or disappear from the scene. This led to meat-eating and to the use of non-fruit foods. These dietary perversions, born of necessity, became fixed in many peoples and gradually spread to people who had no necessity to resort to non-fruitarian diets. Despite this, many pockets of people throughout the world never deserted their natural fruit diet and remain fruitarians unto this day.

Even such a harsh seasonal climate as found at the 8,000 foot level in the Himalayas in Northeast Pakistan has a fruitarian culture, that of the Hunzas. While the Hunzas do partake of some pulses and grains, theirs is primarily an ecoculture of orchards, and their dietary consists mostly of apples, apricots and other fruits that thrive in their climate and growing season.

The use of meat and animal products, grains, roots and other non-fruitarian fare has arisen in relatively recent times in human history and undoubtedly originated in the adversity humans faced in certain climates, especially northerly ones. The cultivation of grasses for grain is only a few thousand years old, perhaps less than ten thousand.

## **6.3 A Look at Some Diets over the World**

If you were a Mongolian you'd probably be a nomadic appendage to an animal flock. You'd have some vegetables but, for the most part, you'd fare on meats, cheeses, milks and milk products.

If you were among groups of people in tropical Brazil and other tropical cultures, you might live almost entirely on a banana diet, on breadfruit or on some other fruit. The same might be true if you lived on many Pacific islands or Indian Ocean cultures.

If you lived in Southern China you might adopt a diet heavy in fruits, rice and vegetables, whereas in Northern China you might adopt a diet heavy in fruits, soybeans and vegetables.

Eskimos and Lapplanders live almost exclusively on animal fare. With the exception of some areas where fish is consumed extensively, most Asian cultures are vegetarian and fruitarian. Most Asian countries have what is called a rice economy, though some Asian cultures utilize other grains and legumes as staples.

Europeans, immediate ancestors for most Americans, are heavily into grain culture and make it a substantial part of their diet, though they also partake heavily of fruits and vegetables. Meat and animal products form but a small part of the diets of most Europeans. English-speaking people the world over are the heaviest meat-eaters with the exception of Argentinians and Finlanders.

When we look at the world's healthiest people we observe the Hunzas, Vilcabambians, Abkhasians and other primarily fruitarian cultures. These peoples are healthy for more reasons than just fruit-eating, however. They also live mostly in the outdoors in rather unstressful circumstances.

Wherever you look at cultures and their dietary practices of long standing, you find that people have adopted as foods that which they can most easily cultivate and harvest in their regions. They fare well or poorly in accord with the beneficence or lack of it in their dietary.

## **6.4 Do Different Dietary Habits Change Human Physiology?**

Faculties usually require hundreds of thousands of years to develop. Who knows how many millions of years were required to develop human hands to the present stage? In some of our primate relatives the hands have yet to reach the facile stage which humans have attained.

In physiology changes are equally slow in coming about. Humans may eventually adapt to cooked foods and meats just as jackals and buzzards adapted to the roles of scavengers of dead rotting meats. But we might first become extinct! Many creatures have not survived drastic dietary changes. The weakness and diseased condition of most present-day humans is ample warning that our dietary is incorrect and death-dealing with portents of disaster for that part of humanity that indulges in it. The evolution of adaptations to new foods may not occur at all or so slowly as to be of no good consequence.

In view of the ecological and health benefits of fruit culture and its ease of cultivation, it behooves humans to stay with the diet that developed them into the magnificent creatures that they were, that some are and all can be. By consuming fruits we'll thrive and, at the same time, place a demand on the marketplace that will spur the development of orchards and even more fruit!

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 7. Negative Nutrition: Harmful Foods And Practices

## **7. Negative Nutrition: Harmful Foods And Practices**

Foods have varying degrees of beneficence in the human diet. They also have varying degrees of pathogenicity in the diet. Our finest foods are the raw materials of our nutritive processes. Our worst foods are vitality-sapping junk the body must struggle to contend with.

### **7.1 Condiments Are Drugs**

Condiments are substances used to enhance or modify flavors and tastes. That could include sugar, lemon juice, salt, pepper, vinegar, onions or anything else added to a dish to alter its flavor. In using the term today, we mean specifically pungent substances that are excitants, not whole foods that we'd eat liberally of for their own sake.

If we cut up bananas and then mix in some diced mango, the flavor enhancement is really stunning. Yet we would, not refer to the mango as a condiment. It is a food that we could make a meal of for its own sake. Likewise, tomatoes and nuts or avocado added to a vegetable salad really give the salad zest. Yet we do not usually call tomatoes, nuts or avocados condiments, for they are whole foods, any of which we can easily eat alone as a meal.

Thus condiments narrow down to those substances that are used exclusively and only to modify flavors. Vinegar, salt, pepper, basil, MSG, mint, sage, garlic and hundreds of other herbs and substances are used only as excitants to the taste buds.

There is one quality about all condiments that make them unfit for the human diet: they are all pathogenic. As excitants or stimulants they are inherently poisonous. The body has thousands of guardian angels. The fact that taste buds and other cells and senses of the mouth, esophagus and stomach

are put into a frenzy by certain substances is a warning. Accelerated functions and senses make us more aware of flavors in the foods condiments are combined with, but the excitation is a guardian faculty broadcasting an alarm. If you were trying to eat salt, pepper or vinegar in and of itself, you wouldn't get very far. They have no food value at all and, in fact, are indigestible! And that's the key to the body's objection to them. Body senses can detect the difference between foods and nonfoods. Foods are welcome and those items which the body cannot utilize for lack of enzymes to digest them or because of an outright anti-vital character, the body becomes excited or stimulated as a response. Unfortunately, humans have become so perverted as to seek this excitement as an end in itself. Many, if not most, people are seeking kicks.

Anything which the body treats as an anti-vital substance; anything which it cannot digest and use easily and efficiently; anything that presents problems by making chemical unions with body fluids and cells that excite and stimulate, are to be shunned. They all fulfill the definition of drugs which is another name of poisons. Discontinuance of them by habitues begets "withdrawal" symptoms just as occurs in deprived drug addicts.

Nature seasons foods natural to our palates with all the taste-satisfying nutrients we require. Flavors galore abound in them. Artificial seasonings do not really enhance their taste. Only a perverted palate seeks the kicks and "thrills" that are unnatural to our dietary.

## **7.2 Cooking Is Pathogenic**

Cooking creates diseases on several counts. The most salient are as follows:

1. Cooking deranges and destroys nutrients. To the extent that this occurs, we are denied needed vitamins, minerals, proteins, essential fatty acids and other nutrient factors.
2. The deranged nutrients become, via cooking, unusable substances that are toxic in the system. This is readily evidenced by the doubling and tripling of the leukocyte count in the blood in half an hour to an hour after eating a meal of cooked foods. Any poison or drug taken into the body occasions the same body response.
3. The body must expend tremendously of its nerve and other energies to expel the offending substances of cooked foods and to clear itself of their contamination. Cooked food eaters have "hangovers" and "withdrawal" symptoms just as do drinkers of coffee, tobacco smokers or other drug addicts who forego their regular round of stimulation.

The body cannot build really healthy cells and tissues with poor quality materials. That which must be cooked to be palatable is not worthy of the human diet. Cooking makes it less so! Shun cooked foods and guide your clients to raw foods. Living foods of our adaptation are the road to magnificent health, and anything less than the ideal results in development, growth and functions that are less than ideal.

Thus cooked foods as articles of diet are pathogenic in that they poison us on one count and result in deficiencies on yet another count.

## **7.3 Processed, Refined and Preserved Foods**

Anything used as food that is not in its original natural state has been tampered with.

Processing is altering or preparing foods or both.

Refining means "making finer" or reduction to a purer state. Thus white flour is refined wheat. Though some chemical processes are used in making it white, essentially the process of refining of wheat flour is mechanically accomplished by milling. Refining sugar is the extraction of sugar from sugar cane or beets and, through cooking and chemical processes, obtaining sucrose.

Preserving involves treating foods so they will be usable for a much greater length of time than is normal in nature.

The processing of foods involves anything that alters foods (including steps that do not alter them significantly or nutritionally). While the shelling and vacuum packing of nuts is processing, these processes do not detract from the value of the nuts. On the other hand, cooking fruits and adding sugar, preservative chemicals such as salt, etc., and then sealing them in cans and jars are very destructive processes. Drying the same fruits alters the fruits so that they can be preserved but does not alter them so significantly that they're, a liability in the human diet. Most processed foods in the marketplace are unsuitable in the human diet in the first place before any alteration, refining or preserving occurs. Examples of this are processed meats, refined cereals, pasteurized and homogenized milk, etc.

Canned foods have a shelf life of years and years. But they are not acceptable in the human diet even if they were good foods prior to canning. They might be acceptable only against the reality of eating them or starving to death. If canned foods only are eaten, death is rather quick and certain. That happened to many who were involved in the great Alaska gold rush, to those who were involved in the digging of the Panama Canal and to others in similar projects. This contrasts with excellent health that results from a diet of proper foods eaten in the raw state.

Freezing is a method of preserving foods. Frozen foods are not as wholesome as fresh foods. Their primary drawback is that the freezing bursts many cells and occasions degeneration due to oxidation. Freezing does not affect some foods at all, notably foods with low water content or very oily in texture. Dates, dried fruits, nuts and seeds may be frozen and kept fresher. Dried fruits, though not as wholesome as their fresh counterparts, are wholesome. Nuts and seeds are well-preserved by lack of moisture and air in their own shells. Vacuum packing and a nitrogen media do not harm many foods and preserve them with food values intact.

Some foods are coated with paraffin, oils, waxes and other preservatives. If these substances have not penetrated the protective skin or covering and can be readily removed, they are suitable for food if they meet other dietary criteria. Removal may be accomplished by a bath in a mild solution of hydrochloric acid, vinegar, chlorox or even very warm water in some cases. If the solution is warm it will be chemically more active and more readily unite with the oils, waxes or paraffins. Moreover, the warmer the solution the more likely waxes and paraffins are to liquify.

Processing, refining and preserving are done commercially to give foods longer shelf life, to change their structure so as to make them marketable, to make them more palatable, to enhance flavors or for a number of other reasons. However, refining renders foods deficient in one or more ways even if they were suitable items of diet to start with.

But the final insult is in "embalming" foods with preservatives to protect from spoilage, bacterial degeneration or oxidation. Preservatives are, one and all, poisonous. That is the character of a preservative. It must be an antibiotic, an antioxidant or have some quality to maintain appearances of wholesomeness. Needless to say, that which is poisonous to bacteria is likewise poisonous to human cells. That which is poisonous interferes with digestion as much as do deranged portions of cooked foods.

As a rule/steer away from all preserved foods and give preference to fresh ripe fruits with some vegetables, seeds and nuts.

Food processing is also done in the home, as well as commercially, for, as stated earlier, it comprises anything done to alter foods from their original form. Cooking, grinding, chopping cutting, peeling and blending are all at-home food-altering processes. Of these, however, cooking is by far the most destructive of foods' nutritional value and is, therefore, the primary at-home process to avoid (or keep to a minimum). Even the other at-home processing should be limited to some extent. For example, you may serve juices sometimes but whole fruits (and vegetables) most of the time. Or you may prepare cut-up salads sometimes but, serve whole fruits or vegetables most of the time. A larger portion of the nutrients are left intact in whole foods as a rule. One notable exception to this, however, is sesame seeds. Because they are so tiny, they normally do not get thoroughly masticated, even by very conscientious eaters. Therefore, grinding them and using them immediately may be a beneficial at-home process. Food

preparation will be studied in depth in a future lesson.

## **7.4 Foods Not Suited to the Human Dietary**

Any food that does not meet all the criteria heretofore cited is not a food of our natural adaptation. Foods of our adaptation meet our needs in every respect. Only fruits meet all our various needs.

Humans would not survive very long on a total meat diet. Shorter yet would be our lives if we ate a meat diet that had been cooked—well-done. We can survive two to three times as long on our fat reserves as we can upon an exclusive diet of meat. The body lives very poorly on a protein diet, being only about 30% efficient in converting proteins into fuels (carbohydrates), our primary need. This compares with about 90% to 95% efficiency in converting the sugars of fruits into energy.

Humans cannot live on condiments and seasonings, raw or cooked. Condiments are used for their poison content, not for their nutrient content. Nor are we physiologically equipped to live on milk or milk products, eggs, fish or other animal products. Also, we are not suited to handle a diet heavy in fats and proteins, even if they are consumed totally raw, something most unlikely in our society because it can abide unnatural foods only if denatured by cooking. We need fats and proteins only in small amounts. Larger amounts are a toxic burden, tax our digestive systems and use up too much vital energy.

Humans cannot live on herbs in the current frame of reference because they, like condiments, are toxic and do not possess food values for the most part. Vegetables or plant fare as leaves, stalks, stems, grasses, etc. cannot comprise the mainstay of the human dietary because we cannot obtain our caloric needs from these types of foods. Few vegetables appeal to the palate as such anyway. Some vegetables, notably lettuce, are prized because of their relative sweetness and texture. Chlorophyll is normally bitter and we're turned off by bitter substances. Our natural foods appeal to our senses, and none appeal to our senses as do fruits, a sure indication that fruits are our natural preference because of natural adaptation. In the cooked state, vegetables appeal more because of the conversion of their starches to dextrin, a form of sugar.

A diet consisting almost entirely of oily foods is not suited to our needs. We can utilize a small amount of oil with benefit. This need can be met incidental to primarily carbohydrate fare. Oily foods are handled very slowly. (Digestion usually takes four to six hours.)

While oils are highly concentrated sources of calories, the body cannot make use of them with the facility it utilizes monosaccharides. Those who eat heavily of nuts and oily fruits exhibit problems and are not as healthy and vigorous as those on primarily carbohydrate fare.

There are groups of people who practically exist on coconuts. But they are eaten at a stage when the oils have not been formed to any extent. The coconuts are still primarily carbohydrates.

Starches also comprise an incidental part of our diet. We cannot survive on an exclusive diet of raw starches. First, we have a very limited capacity to digest raw starches. In light of this capacity, we cannot meet our needs for fuels and other nutrients on a raw starch diet. Secondly, most starches are contained in microglobules of cellulose that neither chewing nor digestion will break down. Hence we are not naturally equipped to eat raw starches as are birds with crows or animals that have a plethora of starch-splitting enzymes.

Our ability to utilize grains, tubers and other starchy foods relies upon the agency of cooking. However, some of these foods, notably the turnip, rutabaga, sweet potato, carrot and others, can be utilized raw only because of their sugar content. The traditional potato is entirely unsuitable, being repulsive to normal tastes when raw. Raw grains are repulsive to normal tastes for the same reason—we reject starch foods naturally with our natural equipment that evaluates foods beneath a conscious level. We can force ourselves to eat these foods and even pervert ourselves to the point we value them just as we value condiments and drugs. But this is contrary to our nature, not in accord with it.

Humans cannot utilize milk in its raw or cooked state. Raw we do not have the enzymes (rennin which

ceases to be secreted in humans at about age three, the proper weaning age) to break down casein with which milk proteins, calcium and other nutrients are bound. At about the same age we lose the ability to secrete lactase, an enzyme that reduces lactose, the milk sugar, to monosaccharides. Therefore, most of our people are said to be "lactose intolerant." We cannot utilize fermented milk products because lactic acid and putrefaction by-products are toxic to humans just as they are to the bacteria that excreted fermentation by-products as bacterial defecation. There are very few products of bacterial activity that we can use. (Vitamin B-12 is a notable exception.)

Humans cannot live well on exclusive vegetarian fare even if it includes fruits referred to as vegetables (such as tomatoes, cucumbers, peppers, eggplants, squashes, pumpkins, etc.). Foods that must be cooked are third- and fourth-rate foods and should form no part of the dietary. Only the stark reality of being deprived for inordinately long periods of proper foods should force us to eat foods that are less than ideal in the diet.

## **7.5 Dietary Follies of Health Seekers**

Seeking out wholesome organic foods free of unnatural fertilization and pesticides is most laudable. But it is relatively meaningless and ineffective if a person then proceeds to take organic foods and cook them. Much of the advantage is wiped out. Organically grown foods are always superior to their nonorganic counterparts undergoing the same amount of processing, cooking, etc. But it is preferable healthwise to eat conventional produce uncooked than organic produce in a cooked state.

Many health seekers believe food supplements are necessary because we have deficient soils. We do have truly deficient soils, as they would not produce foods that require the minerals in which they're deficient. We have many soils, even in their virgin state, that are deficient in something or other that makes them unsuitable for certain plants or trees. We have many soils that have lost the capability of growing corn, potatoes, wheat and other staples but which will still grow grasses and legumes. These soils can be built up very quickly if certain minerals are judiciously added (using organic methods). The deficient soil/deficient food complex is fostered among health seekers by fractionated food purveyors who are peddling a synthetic manufactured supplement or so-called natural supplements, both of which are far inferior to whole foods. Supplements can in no way make good any partial deficiency that may exist. The synthetic supplements are not usable in any circumstances, and the body treats them as drugs. It is the stimulus of drug effects that we mistake for health effects. We mistake the energy an exhausted horse shows under the whip as beneficent when, in fact, it is pathogenic. Even if part of the supplements are obtained from organic sources (as a fraction of a given supplement, say 5 to 10% only) so they can be represented as natural, they are still worthless. They're also worthless if extracted entirely from organic sources. The body uses nutrients in context with other nutrients as a team. The shameful reality is that these supplements are obtained, as a rule, from the same products grown on the same "deficient" soils about which they warn us.

Health seekers often buy waste products that are sold as health products. An example of this is the beer manufacturers' waste product—brewers yeast. Another example is the waste product of sugar manufacturers—molasses, which is a totally unusable and harmful product. Some health seekers buy or have bought the wastes of other manufacturers, too, especially the wastes of cheese manufacturers and meat processors. Whey, liver, gelatin and other wastes are thought to be healthful when, in reality, they are worse than worthless.

Many health seekers also buy minerals from unusable sources. Many drink sea water, eat sea salt, drink hard mineralized waters, eat molasses, dolomite and/or take mineral supplements. All these contain inorganic minerals which are not only not usable by the body but which harm it grievously. In seeking health, many people fall victim to pathogenic practices foisted upon them in the name of health.

Many health seekers are likely to (or do) fall victim to alternate schemes of drugging. They are often persuaded to take a multitude of herbs and toxic plants because they are supposed to cure or prevent disease. Molasses and other waste products are also touted as medications. However, the truth is that

health is built only by healthful practices. Diseases do not have to be prevented for the body will not initiate and conduct diseases unless the need exists. If everyone discontinued those practices that pollute their bodies, there would be no occasion for disease. In any event, so-called medication can never help and will only cause further harm to the body.

Among the many pernicious plants and herbs touted as healthful because of their toxin content, not their food content, are onions, garlic, comfrey, aloe, cayenne peppers, mints and innumerable others. In seeking health, many concerned individuals end up further polluting their bodies, thus creating more disease.

## **7.6 Drinking Habits Are Damaging to Health**

Humans are not naturally drinking animals, for we have no natural equipment for that practice. Drinking is done artificially with the aid of tools. Our natural diet is usually water sufficient.

In addition, drinking as practiced today is almost totally pathogenic. Drinking pure (distilled) water is not pathogenic, but substances which occasion its drinking are usually pathogenic. (Sometimes, of course, extraordinary heat and/or vigorous activity lay the bases for drinking pure water.)

Most drinking is of poisoned drinks. Sugared and flavored drinks are toxic, as are coffees, cocoas, sodas, beers, wines, whiskeys, teas of all kinds, etc. Even fruit and vegetable juices are far less than ideal because they represent fragmented rather than whole foods.

Most drinking amounts to drug habits rather than acts supplying needed water. It bears reiterating that almost all drinking is pathogenic.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 8. A Survey Of Unconventional Dietic Schools And Their Fallacies

## **8. A Survey Of Unconventional Dietic Schools And Their Fallacies**

There are many schools of thought concerning the content of the human diet. We have viewed conventional eating which embraces the concept of the four basic food groups. Other schools are called macrobiotic, vegetarian, fruitarian, vegan and yet others. Let's take a brief look at some of these one by one.

### **8.1 The Macrobiotic School**

This school was founded by George Oshawa, a native of Japan. The emphasis is on a so-called perfect diet consisting mainly of cooked rice, along with some cooked vegetables. Such a heavy diet of cooked rice provides primarily fuel (carbohydrates), but carbohydrates from cooked foods also render the toxic by-products of heat degeneration. Very few fruits are included in this diet, and, while the macrobiotic diet is a great improvement over conventional diets on many counts, it is far from ideal.

Even a brief discussion of the macrobiotic diet would be incomplete without the mention of the concepts of yin and yang. These concepts represent many sets of qualities, such as acid & alkaline, sweet and salty, and hot and cold. Without going into the subject, suffice it to say that, in macrobiotics, determinations of wholesome foods are made based on this yin-yang concept.

## 8.2 Supplementation and Special Foods

This might well be called the megavitamin or megafeeding school. Even though the only way to render a deficient diet adequate is to eat a diet adequate in natural nutrient factors, this school goes beyond that.

They say that if it's a good thing there is no such thing as too much. For example, the RDA for vitamin C may be 60 milligrams daily. People in this school, such as Dr. Linus Pauling, advocate up to 10,000 milligrams daily. If 4,000 international units of vitamin A are the RDA, the megavitamin people advocate 100,000 to 200,000 units daily.

However, the body cannot use more than it needs, and it must excrete that which is in excess of needs. But the massiveness of the dosages is just one aspect of the harm wreaked by the supplementation advocates. The synthetic products that dominate the market are treated as outright drugs by the body! Even if these supplements were extracted entirely from natural sources, they'd still be unusable. The body uses foods, not individual nutrients. It uses them synergistically as nature puts them up, not as extracted or laboratory synthesized and compounded in imitation of nature.

## 8.3 Herbs Used as Alternate Medications

Some health seekers eat poisonous plants daily in the belief that they need "medicines" for health. Entrepreneurs harvest weeds from the wilds and from cultivated fields by the hundreds of tons for people who believe in "natural medicines."

Herbs are not consumed for their nutrients and none could be consumed as foods in themselves. Death could result from an "overdose" if too much of any of these were eaten as a food. People have died on rather small amounts of some herbs.

## 8.4 The Vegetarians

There are about 25 million people in this country who eat only fruits and vegetables or who consume either what is known as an ovo- or a lacto-ovo vegetarian diet. Vegetarians who eat no animal foods whatsoever are called *vegans*; lacto-vegetarians include dairy foods in their diet; ovo-vegetarians include eggs but not dairy products; and lacto-ovo vegetarians include both eggs and dairy foods in their diet.

Many, if not most, vegetarians are ethical vegetarians, but this is especially so with the vegans, as they refuse to cause suffering to animals. Vegetarians may eat lots of cooked foods, or they may consume an all-raw or almost all-raw diet. Many, if not most, vegetarians use herbs, especially if they are vegetarians for, or partly for, health reasons. Some vegans are Natural Hygienists. The common bond of vegans is non-exploitation of animals.

Vegetarians generally are healthier than the population at large, for, while many of their practices are not healthful, per se, they are less harmful than those of conventional eaters. Some vegetarians will eat just about any kind of non-animal food, even alcoholic beverages (really drugs and not foods) and junk foods (also more like drugs than foods in the system). These people are vegetarians, not for health reasons, but for moral reasons relating to the killing of animals. However, most people who are vegetarians are more health oriented than non-vegetarians.

## 8.5 The Bircher-Benner School

This school is essentially a vegetarian school that is heavy on grains with some fruits.

## 8.6 The Mucusless Diet

The founder of this school, Arnold Ehret, reasoned that anything which results in mucus formation is unhealthy. This reasoning is correct, for anything that causes the system to secrete mucus is an

indication that toxic or unwelcome materials are in the organism. Ehret thought that the foods themselves formed mucus, however, when, in fact, the organism creates the mucus in response to unwelcome foods.

Through trial and error Ehret discovered that a diet of non-oily fruits and some vegetables built high-level health and function and did not result in mucus formation. Thus he called his diet the mucusless diet.

## **8.7 The Waerlanders**

Ebba Waerland of Sweden spent most of his life studying the touchstones of health. He was greatly influenced by the Bircher-Benner school and advanced their dietary philosophy to include more fresh raw vegetables and fruits. However, though he still advocated the use of various grains, he recommended they be prepared in a more conservative manner.

In many of his teachings Waerland added to the science of nutrition and health and paralleled the teachings of the Natural Hygienists. As a worldwide traveler and a deep student, he undoubtedly was well acquainted with the philosophy and practice of Natural Hygiene and added to his own system those features he liked. Especially did he advocate fasting as a course to follow during illness (and in good health!) as a health measure.

## **8.8 The Fruitarians**

There are relatively few raw food fruitarians, but there is much interest in fruitarianism and sentiment for it. Humans are naturally frugivores and there is a sound basis for fruitarianism. But, except for the most ardent of fruitarians, most are likely to eat some nuts and vegetables. Many fruitarians are Natural Hygienists, though many Natural Hygienists are not fruitarians. The primary difference between the fruitarians and the fruit-eating Hygienists is that many fruitarians do not adhere to principles of compatible food combining. Raw food fruitarianism is a fast burgeoning element in our society though, as yet, their numbers are only in the thousands.

## **8.9 The Natural Hygienists**

This dietary school embraces many divergent outlooks on dietary fare. All Hygienists advocate a mostly raw diet of fruits, vegetables, nuts, seeds and sprouts, although some advocate the eating of cheese and raw egg yolks. Some Hygienists advocate "complex carbohydrates" as important items of fare. They feel that conservatively cooked rice, squashes, potatoes, yams and other starches are good in the diet if eaten in conjunction with hearty vegetable salads. Likewise, they are often heavy eaters of nuts and avocados if consumed in conjunction with a hearty salad of green leafy vegetables and some fruit fare popularly considered vegetables.

Hygienists originated and fostered the concepts and practices of food combining. Also, they advocate regimes in which diet comprises only a part. As a Life Scientist you'll also call yourself a Natural Hygienist, for these are identical philosophies. But the dietary score has yet to be settled in practice although many Hygienists are idealistic raw fruitarians. It is our endeavor in this course to present data sufficient to settle this score for you. Even the least healthful Hygienic diet is such a great improvement over conventional diets that those who adopt it must improve their health. Almost no one is so far down the road of life that they cannot improve dramatically upon the adoption of the Hygienic regime, even if they adopt a less than ideal version of it.

As a health professional you must keep in mind that anything less than ideal begets less than ideal results. But, on the other hand, every improvement you inspire in your clients will result in corresponding improvement in well-being.

## **8.10 Foods as Medicines**

Like the herbal school which looks upon herbs as medicines, this school tries to employ foods as therapeutic tools. There are those who swear by the use of raw egg yolks; there are those who swear by blended salads, often with egg yolk. Many look upon fruits as cleansing foods. A multitude of foods are taken with the idea that they will prevent or "cure" diseases.

We must repeat that foods are raw materials which the organism acts upon. They have no actions of their own, much less cleansing and healing abilities.

## **8.11 The Juice Therapy School**

This school advocates a diet heavy in or consisting primarily of juices extracted from fruits and vegetables. It was founded nearly a century ago, and Benedict Lust was one of its luminaries. Today N. W. Walker is perhaps its most articulate exponent.

Juices are fractionated foods subject to oxidative deterioration. Oxidation occurs quickly. For example, orange juice can lose up to 60% of its vitamin C within an hour after juicing. Iron is oxidized very quickly in all foods. This may be observed visually if an apple is broken open and exposed to air. Oxidation creates toxic byproducts. An example of this is cooking, which is a much accelerated process of oxidation as well as heat degeneration.

Juices are not whole foods. Many valuable nutrients are lost in the pulp. Further, those who "drink" their foods are often guilty of consuming inordinate amounts of it to secure satiety. While we can safely partake of several pounds of watermelon and like amounts of some juices, there are other juices that a few pounds of constitutes far too much food. Carrot juice drinkers are notorious over-eaters.

Nature did not furnish humans with juicers outside of those implicit in chewing.

## **8.12 The Blended Salad Diet**

There is a small school that believes that blended salads three times a day are beneficial in the human dietary. While blending involves the whole food, it still has the objection of oxidation and enzymic degeneration.

Blended foods are never as tasty as their whole counterparts, even if eaten immediately after blending because enzymes and oxygen degenerate foods and destroy their goodness so quickly.

## **8.13 Conclusion**

As you can see, there are many different schools of thought on diet and nutrition. The macrobiotic school is based on the concept of yin and yang and is rooted in Oriental tradition; vegetarian diets are based either on the ethics of killing animals or on the unhealthfulness of meat (and, for some vegetarians, dairy foods and/or eggs) or both; the mucusless diet is determined by which foods do and don't result in mucus formation by the body; and the herbalists and "foods as medicines" schools base their diets on the supposed curative properties of foods.

However, the only diet that is totally based on sound physiological principles, that is based on science and not on tradition, is the Natural Hygienic diet, which is the same as the Life Science diet. Some Hygienists are fruitarians, most are vegans and all are vegetarians. Oftentimes individuals adopt and popularize diets that reflect their own individual ideas and experiences with diet, and the best of these diets have some commonalities with the Hygienic diet.

The diet of the Natural Hygienists is the only one that is particularly concerned with food combining, and this aspect of the diet is not only unique, but it is based on physiological principles.

## **9. The Physiological Necessity Of Proper Food Combining**

One of the cardinal principles around which Natural Hygiene/Life Science is built in dietary practices is that of food combining when more than one food is eaten at a meal. Humans are capable of digesting with great ease a single food of their adaptation. However, when more than one food is consumed at a meal, the foods thus combined must be compatible in their digestive chemistry.

If the digestion of a meal's various items requires differing digestive tasks, digestion will suffer. Digestion may be retarded and vitiated whether or not we are aware of it, whether we suffer the discomforts of indigestion or fail to feel them. Indigestion may be suffered beneath the level of awareness for decades before its debilitating effects show up as diseases and symptoms. On the other hand, the sufferer may be keenly aware of distresses resulting from indigestion on practically a meal-to-meal basis.

The ill effects of wrong eating and improper food combining are commonly treated with a raft of drugs, primarily antacid drugs such as Turns, Roloids, bicarbonate of soda, poisonous aluminium preparations, Milk of Magnesia and so on.

### **9.1 The Chemical Character of Digestion and the Rules It Decees**

Further along in this course a complete lesson is devoted to food combining. The physiology of digestion recognizes that different foods present dissimilar digestive tasks. For instance, protein foods require an acid medium for digestion. Pepsin, the protein digestive enzyme, requires an acid gastric secretion, more specifically hydrochloric acid. Starchy foods, on the other hand, require an alkaline medium to enable the enzymes of salivary amylase (ptyalin) to perform their digestive task. Below a pH of 4.0, starch digestion is totally suspended. Pepsin will not break down proteins at a pH higher than 3.0. Thus starchy foods and protein foods are incompatible in digestive chemistry. From this physiological fact of life emerges this feeding rule: Do not eat a protein food and a starchy food at the same meal.

There are many foods that do not combine with others. It is the practice of many to eat oils and sugars together. Sugars undergo no digestion in the stomach and melons and sweet fruits may stay in the stomach as little as ten minutes or remain for as long as thirty to forty minutes. They are expelled rather quickly and absorbed very quickly from the small intestine. Oils remain in the stomach for several hours for processing before being forwarded to the small intestine for further elaboration. If eaten with fruits they hold up the sugars and fermentation is very likely to occur, thus vitiating the meal.

### **9.2 Differing Digestive Times Dictate Selectivity in Food Combinations**

Even different fruits have differing digestive tasks. The body readily digests acid fruits and it also readily digests sweet fruits. But acids must first be changed and become alkaline before absorption can occur. This involves some delay in the stomach. Any delay in the stomach of a sweet fruit may dispose to fermentation. Thus, again, combining foods improperly may vitiate digestion and contribute to physiological problems, immediately and down the road, if unhealthful physiological practices continue.

Sweet fruits have their own digestive characteristics. Watermelon is perhaps the fastest digested of sweet fruits. Other melons are passed through the stomach quickly, too. But bananas, grapes and apples may remain in the stomach for two or three times as long. Hence, if bananas, apples or grapes are eaten with melon, fermentation and upset stomach may result.

### **9.3 Character of Food Determines Suitability in Diet**

Humans are adapted to a narrow spectrum of the world's foods, just as are most other animals. Our anatomy and physiology are highly specialized to handle efficiently the fruit foods of the earth. We have developed limited capacities to digest oils, proteins and starches. But under no circumstances are we primarily protein-eaters, starch-eaters or oil-eaters.

Inasmuch as some 85% to 90% of our diet by dry weight is for the purpose of fueling our body, it behooves us to eat primarily foods that most efficiently furnish our fuel requirements. Inasmuch as foods of our natural adaptation furnish this ratio of fuel values relative to other necessary nutrient factors within their context, we can most healthfully devote ourselves to a raw fruitarian regime.

Many, including a great number of Hygienists, will object to the all-fruit diet and cite supposed dangers that fruits are inadequate in the needs of life, especially proteins, essential fatty acids, mineral salts and vitamins. Thus they advocate green leaves and other vegetables, seeds and nuts and even cheese. They condemn "the more is better school," yet tend to side with them in practice.

Close scrutiny of our physiological character decrees that we eat sparingly of nonfruit foods. It is erroneous to assume that the fruit diet is deficient in the needs of life, as will be demonstrated in other lessons.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 10. Nutritional Miscellany

### **10. Nutritional Miscellany**

The body supposedly uses eleven calories per day per pound of weight for metabolic purposes only! Hunza men who have superb physiques and perform labor that would exhaust our best on a daily basis have a total intake of only about 1,900 calories per day, about 12 calories per pound of weight! There must be some terribly wrong calculations here or else the needs of healthy individuals for fuel values is far below our diseased average.

In Vilcabamba, caloric intake is lower yet, being only about eight to ten calories per pound of weight per day. The average caloric intake there is about 1,350 calories per day. The Peruvians of Vilcabamba work hard in their gardens and fields, as do the Hunzas.

The work these two groups of people do would require, according to our nutritionists, from 3,500 to 7,000 calories a day! Something is amiss! In dealing with your clients, you'll keep these facts in mind. The less feeding, down to a point, the more efficient the body is. This is even true if you're feeding highly efficient fruits rather than very inefficient meats and other high protein/fat foods that dominate in our American diets. Keep in mind that our high-powered dairy, poultry, cereal and meat industries have a heavy bias in having our populace consume as much of their products as possible. Perhaps they have influenced the RDAs so that people are pushed to overeat on their products.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > 11. Questions & Answers

### **11. Questions & Answers**

**What are our real protein needs and how can we possibly get these from fruits? Fruits aren't**

## **protein foods.**

Tests conducted by Professor Chittenden of Yale and others indicate that an average man requires about 25 grams of protein daily. There are people in some South Pacific Islands and elsewhere that live primarily on starch foods, especially cassavas. Their diet is low in protein—only about 15 grams daily. Yet these people are reported to be in excellent health. The body has the capability to recycle most of its protein wastes. Cassava, the main starch food eaten by these South Pacific people, has only about 1/5th of 1% protein, about one sixth of that of bananas. Moreover, these people cook their cassava. They are said to eat six to ten pounds of this food daily.

Our real protein needs are about 25 grams daily. The average fruit contains 1% protein. We should eat 2,500 grams of fruits daily, about five and a half pounds with water content. For an average man, this is not a tremendous amount of food. The average American consumes about seven pounds of food daily and ingests 94 grams of protein. Moreover, this diet is so heavy in fat that about 44% of America's caloric intake is derived from that source.

True, fruits aren't protein foods. But neither are we protein eaters as are carnivores. But look at those who do eat protein foods such as meats, cheese, etc. They are a diseased lot. In fact, most Americans are sick and the fact that they daily take in about four times their protein requirements is a contributing factor.

Fruits, we repeat, furnish us amply with our protein needs in an easily used form. This is particularly true if you include avocados and/or nuts, both of which are technically fruits.

**You've never had one good word to say about drugs. In fact, you've knocked them so much and carried the definition so far as to make almost everyone a drug addict of one kind or another. If they were so harmful, surely we'd all be long since dead.**

Humans are a hardy lot. They represent an aggregation of some hundred trillion cells with thousands of guardian angels. The impulse to life is great. We have a tremendous capacity for eliminating poisons. Despite this, most of us are diseased. How many assaults of food poisoning from condiments and cooked foods can we withstand? Most Americans have 50,000 to 70,000 bouts of leucocytosis before they die from it in the form of some degenerative disease, usually cancer or cardiovascular problems. We cut our life potential in half. If drugs had any value in the organism they would be foods, not drugs. Drugs are one and all poisonous regardless of their source. Almost every American is hooked on drugs of some kind.

**Is there a science of correct feeding? It seems that the term nutrition covers much more than correct feeding.**

There are two technical words that have to do with feeding, whereas nutrition covers all processes of supply and elimination and everything that effects those processes. Orthotrophy means correct feeding. Ortho means correct and trophy means to feed. Aristophagy means best eating. In the sense that correct feeding is the best eating, both words mean the same.

**Don't certain types of foods help you get well? Juices and fruits help you clean out. Garlic is well known to help high blood pressure cases. Aloes helps heal wounds and ulcers.**

Can you imagine a fruit or a fruit juice with an inborn intelligence and will such that, when consumed, instead of being digested, it goes into the blood stream and promptly starts rounding up toxic materials and putting them out of the body? Let's emphasize again and again that foods do not act in the body, that all the action is from the organism. Chemical

actions may occur from chemicals in ingesta, yes, but any actions other than body actions are toxic actions.

However, fruits and juices are so easily digested and used and introduce so little food debris into our bodies that they do leave the body with extra energy to perform its duties. When freed of the burdens eliminating toxins from polluting foods and digesting unsuitable foods, the body devotes itself to extraordinary cleansing with the extra energies available.

Garlic does not help high blood pressure. In the presence of allicin and mustard oil, two of the toxic substances in garlic, the organism dilates its blood vessels to more quickly circulate blood and expel these toxins. The heart beats faster and leucocytosis occurs, sure signs of the toxicity of allicin and mustard oil. These substances freely permeate all body cells and tissues. They are not digested and used but excreted through the kidneys, bowels, skin and lungs.

After expulsion the blood pressure will be just as high as before if the same regime that caused it remains in effect. The garlic has helped nothing. Rather, it has complicated an already diseased situation. The drug effects of garlic are mistaken for beneficial effects. The problem is not solved by garlic, and high blood pressure is not the problem. Rather, it is but a symptom of the problem. The problem remained even though the symptom was lessened or suppressed.

Aloes applied to ulcers and wounds do not heal them. The toxic material in aloes, aloin, is absorbed by the body when applied to the skin and to open sores (which the body uses as an ejection site for toxic wastes and ingesta). When the poisons begin coming in from the outside the body closes the wound promptly, shutting down eliminative operations at the site. While the poisonous aloes have been the occasion for the body closing the wound, they have not healed the wound but were a source of a poisonous alkaloid. The body does the healing.

**I read recently that an 80-pound chimpanzee was so strong that two handlers could not subdue it: Are they so strong? What kind of super foods do they eat?**

Chimpanzees in nature have the strength to do acrobatic feats and handle their weight with such ease and facility as to put humans to shame. A four hundred-pound gorilla has about thirty times the strength of a 180 pound man. This attests not so much to the strength of these animals as to the degeneration and weakness of humans. In nature we were equally strong. We can achieve this strength again if we adopt our natural diet and practices akin to those that we developed in our natural habitat.

A substantial part of the diets of chimpanzees and gorillas consists of fruits. This is fruit-power for you.

**Will an all-fruit diet cause nervous breakdowns and nervous problems as I've so often heard?**

You will find no evidence of this among fruitarian societies or among fruitarian animals. Diets that are sufficient in the raw materials we require are the basis of health. They cause neither health nor ill health. Nervous breakdowns can come from nutrient inadequacy and from stressful situations, especially those that constantly drain the organism of nervous energy. In this society, millions have nervous breakdowns. We have only a few thousand fruitarians and they are faring well rather than poorly.

**What is wrong with eating starchy foods? Doesn't cooking change the starch to usable sugars?**

We actually use very little of the starch components in starchy foods, as most of the starch is not penetrated by our digestive amylases and thus is not broken down. The starch that is available cannot be digested to a great extent by humans because they quickly exhaust their limited supply of salivary amylase or ptyalin. Thus we fail as starch eaters.

Cooked starches are dextrinized, and more of the fuel values are available to us, yet, on the other hand, much of the food components are degenerated by heat and are, therefore, toxic in the system.

### **We're not meat eaters, then why do we secrete hydrochloric acid and pepsin?**

Proteins from whatever source (meat or nuts, for example) require the enzyme pepsin and an acid medium in which to be digested. We need only small amounts of protein and we digest it with an efficiency ratio of only about one to two. Animals that live on protein diets have hydrochloric acid solutions so strong that unchewed flesh is readily digested. A tiger's stomach secretes a hydrochloric acid solution some 1,100% more concentrated than that in humans. Again, proteins form but a small part of the diet of humans in nature, whereas tigers eat heavily of proteins in the meat, bone and offal of their prey.

### **How do you, as a fruitarian, manage to control your hunger? Fruit meals leave me mostly unsatisfied. Further, I feel empty and ravenously hungry within an hour or two after eating fruits. I have to eat five or six times a day if I'm on fruits just to keep my hunger under control. If I eat some nuts or an avocado right after my fruits I feel satisfied, though.**

I've eaten a diet of 80% to 90% fruit for many years now. I rarely eat my first meal of the day before noon and I rarely eat more than two fruit meals in a day. Further, I eat about three or four meals weekly with some avocado or perhaps nuts and a hearty salad. I find my desire for vegetables and nuts waning and my desire for fruits increasing with the years. I feel very comfortable after fruit meals whereas sometimes I feel a bit uncomfortable after vegetable meals. I sleep more and feel more sluggish when I've had a nut and vegetable meal. I don't feel as alive, alert and zippy on mornings after vegetable and nut or avocado meals.

On occasion I have eaten a salad and nut meal at noon. As a result I usually missed the evening meal because even the best foods repulsed me—I had no hunger. It's as if my body closed down digestive operations. That is how "satisfying" vegetables and nuts are to me.

The fact that most people mistake irritation and vital symptoms of recovery for hunger does not mean hunger exists. An emptiness in the stomach means that the food has been passed from it. That is not hunger. Hunger is felt in the mouth and throat just as thirst is. It is not unpleasant and it urges us to eat just as thirst urges us to drink.

What we commonly mistake for hunger that drives us to eat are pathological symptoms not unlike the "withdrawal" symptoms of tobacco, coffee, alcohol, condiments and other drug addictions that drive us to go back for another fix. When the body is without its fix for a while, it begins clean-up operations. These usually involve unpleasant symptoms that drive us to get another fix. Another fix engages the body in activities that depress vital functions, especially eliminative functions. Thus we are satisfied for a while, in fact, quite a while in the case of foods that are not of our adaptation.

The fact that fruits are so easily digested and used permits the body to quickly reassert its vitality and devote itself to the cleansing and eliminative processes. The symptoms are not pleasant as the body restores itself from the effects of a previously unsuitable diet. We thus try to smother those symptoms with another meal. Those symptoms do not constitute hunger.

Eating suppresses them in the same way that a cup of coffee suppresses the hangover of previous coffee-drinking.

As a mostly fruitarian I rarely experience any demand for food before noon and I'm satisfied until the evening meal. Sometimes I miss the noon or evening meal and I'm not particularly uncomfortable from the lack of food. I think most of this so-called hunger is psychological and pathological in nature.

**You have said that the Vilcabambians of Peru get along well at hard labor on 1,300 to 1,400 calories daily. It's well known that hard working men need 3,000 calories and more a day. How can that few calories support vigorous work which these people are supposed to do?**

Let us think about this. The world's healthiest and longest lived people eat a primarily carbohydrate diet. They eat very little protein foods in the form of legumes and very little oily foods in the form of legumes and nuts—in fact they consume almost no oily foods. Contrast this with Americans, especially laboring men, who take in 40% or more of their calories as fats and oils and a substantial part of the remainder in protein foods, especially meats, eggs and cheeses. Obviously the human organism isn't very efficient in dealing with these foods, as the studies indicate.

Further, we must recognize that the average American is a walking pathological museum, requiring far more energy just to deal with the pathology than healthy people. Further, impaired organisms do not operate efficiently, whereas healthy people operate efficiently and make full use of their foods.

**How can you build muscle on a total fruit diet?**

The average man uses about 75 grams of protein daily. Of this he needs only about 25 grams from the diet. The remaining 50 grams is obtained by recycling wastes. Fruit amply furnishes the 25 grams needed from outside sources daily. The healthier an organism becomes, the better use it can make of its nutrient supply. It is a myth and a delusion that we need more protein than normal to build muscles. It's like saying that we need more bricks to build a house than the plans call for. Once the structure has been built, replacement and additional bricks are needed but little.

**How can we get vitamin B-12 from fruits? Vegetarians are warned about the lack of vitamin B-12 in vegetables and certainly fruits have none of this vitamin.**

There's no vitamin B-12 in grass either, yet cattle have plenty of vitamin B-12. Almost no food in nature has vitamin B-12 in it.

We get our vitamin B-12 needs the same as other creatures in nature. We were not cheated in this regard. We do not have to eat animal products as the meat and dairy industries urge us to do. The bacteria of our intestines create vitamin B-12 which we absorb just as with other animals.

Almost all cases of anemia and B-12 deficiency occur in meat-eaters, not in vegetarians, which, if it happens, is given publicity like you wouldn't believe.

**Shouldn't we eat locally-grown fruits for best nutrition? Animals in nature must live on locally-grown fruits and, as you have said, they're very healthy.**

Here in Texas that would be great advice and we can do it. Our forefathers did that to a great extent on self-sufficient farms. But, as fruitarians, this is not presently possible. We must get

our fruits from subtropical sources during the winter season. Of course we can develop and preserve our fruits, especially by drying and secondarily by freezing.

But fruits do not necessarily make us less healthy if they have been grown in other areas. Tropical bananas properly grown furnish no less nutritive benefits if eaten 2,000 miles away from their growing area as if consumed in that area. Nutritive adequacy is the need. Local produce may and may not be nutritively adequate. A good mix of foods from various soils is more likely to give us adequacy.

### **Aren't whole wheat products good to eat? The first Hygienists advocated whole wheat bread and other products. Graham advocated it so strongly that whole wheat flour came to be known as Graham flour. Why has that changed with Life Science?**

By the end of the nineteenth century Hygienists had already begun to reject wheat as an unwholesome food no matter how eaten. Dr. Densmore and others began advocating an all-fruit diet with some nuts. Humans can't eat wheat raw and, even if cooked, the gluten protein component is almost wholly indigestible.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > Article #1: The Paradise Diet by Dr. Herbert M. Shelton

### **Article #1: The Paradise Diet by Dr. Herbert M. Shelton**

According to an ancient tradition, when man first appeared he lived in a beautiful orchard in which grew fruits of many kinds and all of which were pleasing to the eye and good for food. For an undetermined length of time he lived in this beautiful area of the earth and satisfied his physiological needs by trees.

According to this tradition, he was expelled from the garden and condemned to live upon the green herbs of the field. The indications of this story would seem to be that herbs are a second choice as articles of diet for man. It is common to scoff at this ancient tradition and label it a fairy tale, but it may possess more truth than poetry.

The noted anthropologist Edward B. Taylor, in Vol. I of his *Primitive Culture*, stresses a very important psychological fact in relation to traditions, legends, myths and folklore. Questioning the popular belief that man is possessed of a boundless power of *creative imagination*, he says, "The superficial student, mazed in a crowd of seemingly wild and lawless fancies, which he thinks to have no reason in nature or pattern in the material world, at first concludes them to be new births from the imagination of the poet, the storyteller and the seer." Then he points out that a more detailed study of such things reveals that there is a cause for each fancy, an education that has led to the train of thought, a store of inherited materials from out of which the fancies and thoughts of poet, seer, storyteller, etc., has taken shape. This is to say, the human mind works with the materials it has on hand and does not create something out of nothing.

In this same vein, the author of the article on the myths of Sumer in the Larousse *Encyclopedia of World Mythology* says, "Sumerian mythology drew its material from the permanent principles of Sumerian culture. ...The myth and the form it adopted were a function of the society from which it stemmed. It told of creation in terms of human experience. Its very elements were those at the basis of Sumerian society. ..."

This statement, that the myths of a people mirror the ways of life of the people, if applied to all mythologies, should prove fruitful in their interpretation. It should not be assumed that a people gather their myths and traditions from thin air or that they are purely imaginative creations.

If we can accept as valid the principle that the traditions, legends, myths and folklore of a people are reminiscences of past experiences, that they mirror for us actual conditions through which the people have passed, we are practically forced to accept the ancient and well-nigh universal tradition of paradise as a report, blurred, no doubt, by the passage of time, of a period when the human race resided in some favorable locality and lived upon the "fruits of the trees of the garden." A tradition that antedates the beginning of recorded history and that is possessed by almost all people cannot be lightly cast aside as a figment of the imagination of a poet or of some designing priest-craft.

It is impossible to account for the origin, persistence and widespread existence of a tradition that early man was a frugivore on the basis of the hypothesis now so widely held by anthropologists, that early man was a carnivore and offal eater. Such a being should have left us traditions of swarms of locusts, ponds filled with fish, happy hunting grounds and other rich repositories of their favorite sources of animal foods, with occasional mention of dead elephants or sick horses around which they gathered and feasted. Not fruits, but brutes, not figs, but pigs should be featured in the myths and legends of a carnivore.

It may be objected that tradition and legend constitute a flimsy base upon which to erect a philosophy of human diet. A more scientific basis may be demanded. To this I reply that none of the many *scientific bases* for correct human dietary practices that have thus far been offered possess as much validity as the paradise tradition. The paradise tradition possesses the virtue of being in conformity with the evident dietetic character of man as revealed by comparative anatomy and physiology. It also agrees in principle with the basic eating practices of man throughout history. Man's diet throughout the historic period in all favorable regions of the earth has been predominantly fruitarian.

Many efforts have been made by men and women in the present century to live upon a diet composed exclusively of the fruits of the trees. These efforts have not been without success, but they have rarely been completely successful. From South Africa comes the news—the *Pretoria News*, February 22, 1971—that some research has been done into the effects of an all-fruit diet. Under the headline "Fruit diet worked well," the News summarized the findings of the researchers in the following words: "A team of research workers have come to the conclusion that pure fruit diets now receiving wide publicity cause weight to level off more or less at the 'theoretically ideal' weight for the subject, according to an article in the latest issue of the *South African Medical Journal*."

The item does not indicate the time through which the experiment was carried out but does state that the diet consisted of fruit juices, fruits and nuts. It says "a considerable number of the subjects claimed their physical condition improved while they were on the diet. Some were convinced that their stamina increased and that their ability to undertake strenuous physical tasks and to compete in sports improved."

No doubt, in view of the known nutritive values possessed by tree fruits and nuts, which are also fruits, it is entirely possible to be well and adequately nourished upon such a diet, providing only that one has a sufficient and varied supply of fruits and nuts. If one lives in a climate where the fruit and nut supply is abundant throughout the year, he should have no difficulty in providing himself with adequate nourishment without eating vegetables and without taking animal foods of any kind. Man's expulsion from his primitive paradise was probably due to climatic change that reduced his fruit supply and necessitated his constant search for means of survival.

Commenting upon the African experiment, in the July 1971 issue of *Health For All* (London), Dr. Harry Clements says "It is true that such a diet would be possible in a subtropical climate with its abundance of fruits and nuts, but it would not be so easy in a climate like we have in this country, to maintain an all-the-year-round complete fruit diet on indigenous fruits. Of course, we should bear in mind that a limit is set on food by the use we make of it. There is no doubt that the kind and amount of fruit grown in this country could be vastly increased if we saw the need for it and regarded it as an important part of our diet rather than merely as a trimming to a meal. On the other hand, no climate is better adapted than ours for the growth of vegetables and salads which can play so important a part in proper nutrition."

Dr. Clements further says: "It is interesting to recall that in the latter part of the last century a Natural Food Society existed in this country, its object being stated as follows: 'The Natural Food Society is founded in the belief that the food of primeval man consisted of fruit and nuts of subtropical climes, spontaneously produced; that on these foods man was (and may again become) at least as free from disease as the animals are in a state of nature.' The main contention of this Society was that the starchy foods, especially those made from cereals are 'unnatural and disease-inducing foods and the chief cause of the nervous prostration and broken-down health that abound on all sides.' "

The Natural Food Society to which Dr. Clements refers was organized and spearheaded by Dr. Emmet Densmore and his wife, Helen. This society not only promoted fruitarianism but also propagated Dr. Densmore's no-starch dietary. Dr. and Mrs. Densmore edited and published a magazine devoted to fruitarianism and general Hygienic work. Densmore found that the fruit supply in England was not adequate to meet the nutritive needs of man throughout the whole of the year. After some experimentation, he suggested supplementing the fruit diet with milk and cheese. He even went so far as to endorse the Salisbury meat diet. Because of his frequent shifts of opinion about diet, he gained the reputation of being eccentric. When he returned to America he practically retired from active work in this field. When Mr. Carrington was preparing his work, *Vitality, Fasting and Nutrition*, he attempted to engage Dr. Densmore in correspondence about fasting and feeding, but Densmore declined to lend his services to furthering this work.

Dr. Clements recalls as interesting the fact that in America Dr. John Harvey Kellogg maintained that fruits, with the addition of nuts (which, I should point out, are also fruits), constitute an adequate diet that will sustain human life for its normal lifespan. He mentions what he calls the *therapeutic* use of fruit by Dr. Tilden and by Kellogg. Dr. Kellogg, Cajori and Ragnar Berg demonstrated experimentally the biological adequacy of the proteins of nuts. With the exception of the hickory nut, they all contain an adequacy of amino acids to support growth and reproduction.

In the halcyon days before World War I, a professor in a German university, after much thought and study, concluded that the coconut tree is the tree of life, mentioned in the paradise tradition. Professor Englehart (I have forgotten his first name) lectured and wrote on the subject and finally took a group of German men, women and children to a German possession in the South Sea Islands, where they expected to live exclusively upon a diet of coconuts. According to his accounts, the experiment was proving very satisfactory. He wrote very glowingly upon the success of the coconut diet. Dr. Benedict Lust published an English translation of Professor Englehart's book under the title, *Cocovarianism*. The experiment was brought to an abrupt end by World War I. Professor Englehart and his group of cocovarians were all pacifists and Dr. Lust told me that when the War broke out the Kaiser's government had them all shot. In a world dedicated to war, it is dangerous to be opposed to war.

I do not think that there has been a single period of five-minute duration during my lifetime of seventy-six years that there has not been fighting somewhere in the world. There have been five or six major wars in the world during my lifetime and brush fires innumerable. There may be some connection between man's choice of war as a way of life and his choice of flesh as a diet. In spite of his constant fighting, all the evidence points to the conclusion that man was originally a peaceable being. European man conquered America with considerable ease due to the fact that the original inhabitants of these western continents were, for the most part, peaceable peoples who had not learned the arts of war. Many of the tribes refused to fight, even in self-defense, but permitted themselves to be annihilated and driven westward rather than learn the arts of war. Many so-called primitive people, and not merely those in America, have retained their original peaceable character. War is as foreign to man's original way of life as flesh-eating.

Someday, after we have abolished social systems that breed war, it may be possible for students of the subject to determine whether or not man learned war at the same time he learned to kill and eat animals. The two practices have much in common, although we do find some flesh-eating tribes, such as the Eskimo, who have remained peaceable. Certainly the fruit diet, with its cultivation of fruit, is incompatible with human slaughter.

It is doubtful that the fruit diet can ever be entirely satisfactory in those regions of the earth where long and severe winters prevail. Man must, it seems probable, continue to rely heavily upon herbs and perhaps grains and legumes for a part of his diet. This is not to say that fruits and nuts are not suitable for a cold climate, but that the supply of these foods in cold climates is not sufficiently abundant throughout the whole of the year, and, except for nuts, cannot be stored and kept in adequate quantities to meet the needs of a large population through the winter months. There is no food factor in vegetable and animal products that is not also available in fruits. Cold climates are simply unsuitable to the cultivation of fruits. Some nuts do thrive well in climates that are cold much of the year. Although a nut diet has been advocated, it is doubtful if such a diet would be ideal. The paradise diet would seem to be an ideal one for a paradisiacal climate.

[Home](#) > [Lesson 5 - Introduction To Nutritional Science](#) > Article #2: The Elements Of Nutrition by Dr. Herbert M. Shelton

## **Article #2: The Elements Of Nutrition by Dr. Herbert M. Shelton**

Nutrition is the cardinal function of organic evolution and growth. It is the sum of all processes by which raw materials (foodstuffs) are transformed into living structure and prepared for use by the body. It is the appropriation of nutritive material by the plant or animal and its transformation into cell substance and structural units. It is the means by which food is transformed, in the case of plants, into sap, pulp, woody fiber, leaf, flower, fruit and seed, and, in the case of animals, into blood, muscle, bone, nerve and gland.

It is the process by which living organisms develop, grow, repair and maintain themselves, wounds and broken bones are healed, functions are carried on, and reproduction accomplished. It is the process of converting food into cell substance. This occurs in living organisms and nowhere else, and in the case of man, vegetable substances are transformed into human tissues.

Organic existence is perpetual creation (or evolution, if you prefer) and renewal. There is no resting, only continuous activity. Nutrition is the grand process by which creation and renewal are accomplished. Though we can observe the results, we know little of the process.

Let us think of an egg composed of material previously prepared by the nutritive processes of the hen out of which a new bird is to be made: Nutrition is the process by which the simple homogeneous material of the egg is transformed into the complex heterogeneous structures of the bird. But a microscopic speck of the egg, the germ, is alive. It is this germ that begins the work of nutrition by which it grows and becomes two cells, by which the process of cell division is continued and, finally, differentiation, organization and integration are accomplished.

In the seed of the plant a similar process takes place. The germ of the seed is microscopic in size, the remainder of the seed being prepared food. Utilizing the stored food, the plant germ evolves into the complex structure of a young plant. Thus, in the plant as in the animal, nutrition is the process of converting food into cells and organs.

Nutrition is a highly complex process carried on by all living organisms from the smallest, simplest one-celled organism to the most complex organism in nature: man. Food is not nutrition, but the chief material of nutrition. Water, oxygen and sunshine are nutritive materials, while activity, rest, sleep and warmth are vitally important to normal nutritive processes. Vital structures and functional products can be created only out of food, but it is the process of nutrition that builds and maintains organic structure.

Viewing the whole domain of live-vegetable and animal-nutrition is the fountain out of which flow structure, function, capacity, strength, growth, development and reproduction. It is the process of

building, repairing and vitalizing organs and organisms. All structure is made by processes of nutrition; all repairs are accomplished by nutrition; it is through nutrition that we come to have organs in the first place; it is only through nutrition that they are constantly repaired; it is through it that we come into being and maintain life.

The tissues of man are woven on a loom that no Eastern rug designers or Western carpet machinery can rival.

Where strength is needed, an iron-like power of resistance is given to man's tissues, though these strands of fiber are finer than spider's thread. Yet where elasticity is required, the fibers rival rubber in flexibility.

The size and development of a man's muscles and the strength and functioning power of his nerves are the products of nutrition. Even his brain is a product of this process. The human infant, like the bird in the egg, starting as a single cell, grows organs and other parts by the process of nutrition, deriving its food supply, water and oxygen from its mother's blood. After birth, utilizing food, it develops and grows to maturity by processes of nutrition. Reproduction, which is merely discontinuous evolution and growth, is achieved by the process of nutrition.

The digestive system should not be thought of as the nutritive system. The respiratory system supplies the organism with needed oxygen. If it is cut off, even for a very few minutes, the whole nutritive process comes to a halt and cannot be started again.

In man and other higher animals, the many and varied functions contributing to the grand overall process of nutrition are, to a great extent, each performed by a separate organ. In the human system there are a large number and variety of organs, each of which fills a peculiar and appropriate function. In the human sphere the viscera may be regarded as a tree, the digestive system of which represents the roots, the lungs, the leaves, the blood and lymph, the sap. Given the organic structure that circulates the juices, choosing the best food and refining it, we finally arrive at human structure.

As we are primarily interested in human nutrition, I shall attempt to picture in broad outlines by use of the following diagram, the means by which the body appropriates its foods:

<b>Substances Appropriated</b>	<b>Ways of Appropriation</b>	<b>Results of Appropriation</b>
Food	Locomotion	Development
Air (oxygen)	Prehension	Growth
Water	Mastication	Repair
Sunshine	Deglutition	Maintenance
	Digestion	Healing
	Absorption	Reproduction
	Respiration	
	Circulation	

	Assimilation	
--	--------------	--

The organs and secretions involved in this work of appropriation and the preparation of raw materials for use are: hands, teeth, tongue, salivary glands, esophagus, stomach, gastric glands, small intestines, intestinal secretions, pancreas, pancreatic juice, liver, bile, villi, lacteals, lymphatic system, heart and vascular system, the several ductless glands and their hormones, the nose, bronchioles, lungs, diaphragm, chest walls, long bones and skin.

The long bones, in which the red blood cells are formed may be properly regarded as part of the body's nutritive system. Millions of these cells are formed daily and are essential in removing oxygen from the lungs to the body's cells, then carrying carbon dioxide from these cells to the lungs. Without this process in the bones, oxygen could not reach the other bodily cells.

Because the skin is the channel through which we receive the sun's rays and regulate their uses, this investing membrane may be properly included in the body's nutritive system.

It will thus be seen that in the higher animals, especially in man, a great number and variety of organs and organ-systems and their functions are subservient to the overall process of nutrition, and all of them converge towards a common center.

Certain functions like digestion, circulation and respiration are common to all types of animals, who must receive, elaborate and circulate the materials necessary to build and sustain their tissues. Locomotion and prehension are essential parts of the nutritional process in most animals. Locomotion is denied to some forms of animal life, and these depend upon water and waves to bring their food supplies to them.

In the final analysis, the whole body is engaged in carrying on the process of nutrition, every part contributing to the whole and no part selfishly assimilating alone. Some parts, however, are more involved than others, especially in the preparatory work. Reciprocity and mutual service characterize the work of the bodily organs. The lungs take in oxygen for the whole body and not for themselves alone; the stomach digest food for the entire organism and not merely for its own food needs; the heart receives and circulates the blood throughout the body, not merely through its own tissues. The living organism is a model of cooperation.

The production of food is a reciprocal process, plants and animals being co-equal partners in the vital synthesis. For this the forests and their myriad inhabitants have been industriously working since the beginning of life on our globe; for this the flowers have been working since they were self-sown from the miraculous garden; for this the bees and birds and wind have been pollinating flowers since the beginning of organic existence; for this the birds and mammals have scattered seed. From time immemorial, for this the soil bacteria and earthworms have labored incessantly throughout uncounted ages; for this the un-cropped earth has rested in the balmiest latitudes, while the great sun, supporter of all life, has poured her tropical spirit upon its unexhausted islands, so that spring, summer and autumn provide us with an abundant supply of tasty green leaves, delicious fruits packed with food values and baited with delightful aromas, delicate flavors and pleasing colors, and with tasty, life-sustaining seed.

Not in the animal alone is assimilation in progress. The plant is the prime assimilator, absorbing the minerals of the soil and the nitrogen and carbon of the air, the fertile soil being the great storehouse of plant food and the source of their many aromas and flavors. The animal returns the soil's fare, as fertilizer and carbon dioxide, to the original storehouse from which it was taken. In the great workshop of nature we witness progressive assimilation and refinement: The pioneer plants prepare the primitive soil for the advent of the higher plants; the higher plants refine and synthesize food for the animals above; these, in turn, compensate the plants in a variety of services for the goods received.

Through every change, by secret processes, the surface of the planet is steadily fitted for a greater edifice of society. All things normally work together for the good of the whole. Even the wrathful violators of her fundamental law of reciprocity serve her ends.

The mineral kingdom supports the plant kingdom, which in turn supports everything above it. Living plants arise—rich, delicate and lovely from the ground—created from a few simple elements. Through the subtle alchemy of life, disintegrated rock becomes stems and leaves, flowers and seeds with power to reproduce themselves. In the plant this amounts to taking the lifeless materials of air, water and soil and raising them to the status of living structure.

The animal appropriates parts of the plant and transforms them, by the subtle alchemy of animal nutrition, into sentient flesh and blood. As a result of processes of living plants and animals (assisted in the initial stages by bacteria), which we call collectively nutrition, sentient flesh is made from what otherwise would remain inert stone. The oxygen, nitrogen and carbon of the air plus the minerals of the soil are passed through the leaves and trunks of herbs, trees and other growing things. Each enriches its tissues through a division of labor and succession of touches at least as great as the processes employed in the laboratory in the manufacture of synthetic products.

Animals cannot appropriate the raw materials of the soil and air, except for oxygen and water. They cannot utilize the carbon and nitrogen of the air but must receive carbon (carbohydrates) and nitrogen (proteins) from the primary producers: the plants. These elements must be refined and synthesized by the plant and transformed into substances that the animal can appropriate. The earth might as well be bare granite and the atmosphere untinted gas if the vegetable kingdom lacked organic qualities to bestow upon the animal in the foods it turns out in great profusion.

The assumption that plants do not impart to the elements of the air and to water and soil, qualities that they do not possess in their gaseous and mineral states, is a form of ungratefulness in the inhabitants of any land whose fields are laden with fragrance and savoriness each year.

Plants, like factories, feed us and clothe us; they spin out our cotton in their looms and turn out their fruits and juices in profusion. Whether it be fruit and flavor for our bodies, or beauty and symbolism for our minds, plants support us. They yield up their substances to be transformed into new substances by us.

Thus, in the normal course of the nutritive processes of nature, vegetables draw their sap from the underground, from the dark scurf of the mineral kingdom; whereas, the animal takes its nutrient juices from among the children of the air, light and motion, from the succulent tops and fruits of the vegetable kingdom, from the results of an elaborate predigestion in the bosom of the earth and sun-kissed leaves of the plant.

By the marvelous processes of plant nutrition, lifeless matter drawn from air, water and soil has been raised to the status of living structure. Undergoing further refinements, transformations and organization in the animal, it is raised to the status of dynamic structure. The inert and unorganized is now highly organized and alive. The breath of life has been breathed into the structure and it has become a living soul. Such is the marvelous end-result of plant and animal nutrition.

### **Article #3: Nutrition, A Hygienic Perspective by Ralph C. Cinque, D.C.**

*The following article by Dr. Ralph Cinque is reprinted from Dr. Shelton 's Hygienic Review.*

Nutrition has become a popular subject, indeed, a fad. Never before have people been so concerned about being well nourished. The barrage of information that is being promulgated in books, magazines, newspapers, talk shows, etc., about food and nutrients is, of course, commercially motivated.

Consequently, the knowledge that most people have about nutrition is a mixture of facts, half-truths, exaggerations and outright fallacies.

Our purpose in this writing is not to discuss all of the intricacies of nutrition. The reader is referred to any of the standard texts on the subject for his information. Instead, our objective will be to investigate nutrition from a Hygienic viewpoint. We want to consider nutrition not as a sequence of chemical reactions but, rather, as a process of life. We want to put aside, for the time being, the specific role of various vitamins and minerals and consider the overall process by which the body attains nourishment.

Strictly speaking, nutrition refers to the processes by which the cells of the body utilize the components of foods. Nutrition does not refer to the processes by which food is eaten, digested, absorbed, transported and circulated. Nor do all of the changes that the components of food undergo metabolically constitute nutrition. Glycogenesis, for example, the process by which the liver and muscle cells convert glucose into glycogen, removes glucose from the circulation and makes it unavailable to the cells. Therefore, it must be regarded not as a nutritional process but rather as a process of food storage. Only those processes by which the cells oxidize foodstuffs for chemical energy or utilize substances to manufacture cellular constituents and secretions can be considered nutritional. All of the processes that precede the actual utilization of nutrients by the cells must, therefore, be considered as antecedents to nutrition. They make nutrition possible. They must occur in order to make nutrients available to the cells. They are vitally important, but they do not constitute nutrition.

Nutrition takes place at a cellular level. It results from the diffusion and active transport of nutrients from the tissue fluid that bathes the cells into the cellular protoplasm. At this point, nutrition begins. It is only here that the body derives any real use from the food eaten. Up to this point, there has only been an expenditure of energy in processing and transporting food in preparation for cellular assimilation. But, at the cellular level, there is finally a compensation for the physiological work done previously in relation to food.

Nutrition is not something that we can directly influence. We cannot force it to happen. If the organs of the body effectively perform their roles in relation to food, then, and only then, will optimal nutrition occur. All that we can do is supply an adequate amount of high quality food under favorable conditions. The rest depends upon what the body does with it. We do not nourish the body; the body nourishes itself. No one is a nutritionist; the body is the only nutritionist because only the body itself can accomplish nutrition.

If we recognize that nutrition takes place at a cellular level and that an elaborate and complicated sequence of events must occur beforehand, it should be obvious that the quality of physiological performance is as vitally important as the quality of food eaten. If nutrition is a distant link on a long physiological chain, a break at any point in that chain will suspend nutrition, partially or totally. Hygienists are well aware that food is of no value until it is digested and absorbed. For example, consider the diabetic, who may be fully capable of digesting, absorbing, transporting and even generating sugar from internal sources. In the absence of insulin, the active transport of sugar is impeded, and, as a result, the abundant supply of sugar is unavailable to the cells. The infant with phenylketonuria (PKU) lacks a specific metabolic enzyme that catalyzes the conversion of phenylalanine into tyrosine, and consequently tremendous amounts of phenylalanine and its by-products accumulate in the blood. These disrupt body chemistry and may bring about mental retardation.

Obviously, interference at any point on the physiological assembly line can thwart the final outcome and defeat the ultimate objective, which, of course, is nutrition. Therefore, what can we think of a "nutritionist" who decides that a protein deficiency exists and has the patient take some protein powder dissolved in water every day in order to enhance nutrition? This kind of "shotgun approach" does nothing to enhance nutrition. On the contrary, it disrupts nutrition by adding one more enervating influence to the life of the individual, an influence that stresses various organ functions and biochemical processes.

Our task is not just to provide nutrients but to provide them in a gentle manner that maximize the

efficiency of our organic functioning in order to promote the most effective utilization of food. The manner in which we eat, the conditions that prevail at the time of the meal, the state the food is in and the way in which it is prepared, the abundance of nerve energy, the presence of hunger—these factors have as profound an effect upon nutrition as nutrients, per se. We cannot emphasize too strongly that it is not what we eat, but what we appropriate at a cellular level that determines the state of our nutrition.

Therefore, as Hygienists we must recognize that nutrition involves a great deal more than food, that every aspect of our lives affects the state of our nutrition. This would include the manner in which we eat, sleep, exercise, emote, rest, think, etc. Those who ingest large quantities of extracted and concentrated nutrients have a very distorted view of nutrition and show a lack of understanding of the biological facts of life.

Now that we have defined nutrition, we shall discuss its nature and characteristics. We have already stated that the cells of the body are bathed in tissue fluid and that it is from the tissue fluid that they extract nutrients. The cells also excrete their wastes into the tissue fluid. So there is a constant movement of materials across the cell membranes in both directions. This movement is a continuous, fluid and constant process. It is not sudden. It does not occur in starts and stops. It is happening all the time, at mealtime and between meals, during the day when we are active and at night when we are sleeping. It speeds up under some conditions and at other times slows down, but it never stops. It is completely controlled, determined and regulated by the body.

The body is like a food store with a large cold storage room in back. As the consumers remove items from the shelves, the owner replenishes the shelves with wares from the storeroom. The owner may also be receiving a delivery of fresh goods daily, but these are used to replenish his reserves in back and not to stock his shelves directly. The food that he makes directly available to his customers comes from his storage room, so that if by chance a delivery fails to arrive one day it will have little or no effect upon the availability and selection of foods in his store. His own reserves are more than ample to supply his needs for several days.

A similar situation exists within the body. The body is constantly drawing upon its reserves to maintain the chemical constancy of its tissue fluids so that at no time are the cells subject to being depleted. The body is not directly dependent upon raw materials to accomplish nutrition because it is constantly living upon its reserves. Eating replenishes these reserves. The body is much less dependent on food than most people think.

The common notion is that the only thing that maintains normal blood sugar levels is the frequent ingestion of food. The tremendous magnitude of the body's ability to make sugar available from glycogen and certain amino acids, and its capacity to rely more heavily on fat combustion, if necessary, is often overlooked. Most hypoglycemics think that the distress that they experience between meals is the result of an inherent need for infrequent meals. They fail to recognize that their symptoms are manifestations of impaired organ functioning, enervation and toxemia. What they require is not more food, but more rest.

It is a well-known fact of physiology that stored food within the body is in a constant state of flux. Fat stored within fat cells, for example, is constantly being consumed and replenished. Obese individuals with vast midriff bulges think that they have been living with the same fat for years. They don't realize that they have been continually using and replenishing their fat, and that this year's fat is entirely different from last year's fat.

If the body is not directly dependent upon meals to accomplish nutrition, what effect does eating a meal have on nutritional processes? We have already stated that the availability of nutrients depends upon the composition of the tissue fluid and that tissue fluid is a filtrate of the blood. Therefore, the composition of the blood and tissue fluid must remain constant in order for the fluidity of nutritional processes to be undisturbed. When we ingest a meal, the products of the meal are obviously markedly different from the composition of the blood. The body constantly seeks to nullify change in its blood chemistry as a result of the ingestion of a meal.

Converting excess glucose into glycogen and gradually releasing it into the bloodstream in response to the body's constantly fluctuating needs for sugar is one way in which the liver "buffers" the effects of eating a meal. Taking a large quantity of Vitamin C may temporarily achieve "super-saturation," but the body will immediately go about excreting the excess and re-establishing normal tissue levels of ascorbic acid. This requires usually no more than several hours. The liver also removes excess carotene (provitamin A) from the blood and stores it, but, as we all know, people have varying capacities to do this. Some turn orange after one glass of carrot juice, while others can drink a quart at a time without a noticeable effect. All of the food materials that are absorbed into the blood are first transported via the portal circulation to the liver where they are processed before entering the general circulation. The body seeks to minimize the impact at a cellular level that would otherwise occur from eating food.

Quoting Ian Fowler from his excellent article, "Fundamentals of Feeding" which appeared in Dr. Shelton's *Hygienic Review* in June 1978, "Consuming extracted and artificially concentrated items results in a sudden influx of nutrients which necessitates rapid accommodation and adjustment of blood nutrient levels, of liver metabolism, adrenal, pancreatic functions, and so forth. This is debilitating, inefficient, wasteful and enervating." This profound and explicitly stated fact of physiology will never be taught by vitamin manufacturers, health food store owners, "metabolic nutritionists," or "orthomolecular psychiatrists." All they will ever teach people is how wonderful calcium is and how much Vitamin X the body needs. The fact that taking their products exerts a tremendous stress upon the body, that it is a shock to the system to be suddenly overwhelmed with "megadoses" of vitamins, that taking unnaturally concentrated nutrients tends to disrupt and not enhance nutrition, is not the kind of knowledge that promotes vitamin sales. Even eating whole natural food constitutes a slight stress that requires internal adjustments to restore homeostasis. Why magnify this stress by consuming large quantities of concentrated nutrients? Nutrition is not a matter of violently battering, dosing, saturating or treating the body with nutrients. "Nutritional intensity" is not our objective. Our objective is to gently supply needs. Let the body establish its own blood levels of Vitamin C, calcium, etc. Eat a simple diet of whole natural foods with a preponderance of raw, succulent high-fiber foods. This will minimize the rate at which nutrients are introduced into the blood and thereby minimize what Dr. Alex Burton, a well-known Hygienic practitioner in Australia, refers to as "nutritional shock." Why not make the process of appropriating nutrients as easy as possible for the body? Why not harmonize with the body's internal processes instead of trying to thwart them?

We might also consider that when we consume isolated nutrients, we offset rations of various nutrients and that this constitutes an additional stress. It is known, for example, that the body requires ten times as much niacin as it does thiamine or riboflavin. Therefore, when we consume a large quantity of extracted thiamine, we produce a relative deficiency of niacin. We should note that the proportion of various nutrients in natural foods parallels the body's needs for different nutrients. Natural foods contain many times more niacin than thiamine, which is in keeping with the body's needs.

Other important nutrient ratios include: sodium/potassium, calcium/phosphorus, iron/copper, Vitamin E/selenium, zinc/molybdenum and Vitamin C/bio-flavinoids. The proportion of these nutrients within natural foods accurately reflects the body's needs; thus, the greatest synergy of nutrient utilization is achieved. The body requires many times more potassium than sodium, and this is exactly what we find in natural foods. Processed foods that are loaded with sodium disrupt the delicate balance between these two mineral elements that exists at the neuronal membrane, thereby impairing the function of the nerves. Diets that introduce excessive amounts of phosphorus into the system may produce a relative deficiency of calcium even though an adequate amount of calcium may be consumed. A deficiency of copper prevents a thorough utilization of iron.

The important point to realize is that nutrients are utilized in concert and that it is the total ensemble of the diet that determines the state of our nutrition. Consuming isolated nutrients is more likely to do harm than good. This is true even in relation to proteins and amino acids. It is now known that the body has a limited tolerance for sulphur-containing amino acids and that excesses can be very taxing on the liver. Plant proteins, which contain a lesser proportion of methionine and other sulphur-containing amino

acids than do animal foods, are not only less burdensome on the liver but they more accurately supply the body with the proportion of amino acids that it was designed to process.

Understanding the physiology of nutrition will quickly dispel misconceptions that exist about the role of foods. One common misconception is that foods (or nutrients) have specific effects on different organs and tissues. "Vitamins for the hair" are a popular drugstore item, and glandular extracts that supposedly "feed" specific organs are peddled by practitioners of all the various so-called "schools of healing."

If we consider that the cells obtain nourishment from the tissue fluid and that tissue fluid is a filtrate of the blood, then it should be obvious that all of the different organs and tissues are on a mono-diet of blood. The blood supplied to the kidney is virtually the same as the blood supplied to the big toe, which is identical to the blood supplied to the left elbow. The cells are capable of extracting from the tissue fluid (hence, the blood) nutrients in the proportion that they require, but all of the cells are fed from the same table. The differences that exist in the chemical composition of different tissues come about as a result of active processes of the cells themselves in selecting the nutrients that they require. It does not result from any assumed differences in their food supply. Therefore, eating fish because it is "brain food" or taking adrenal gland extract because "it has the exact proportion of nutrients required to rebuild the adrenal gland" flaunts ignorance of the most fundamental laws of physiology. Health food notions that "beet juice is good for the kidneys," or "wheat grass juice cleans out the liver," are equally as ridiculous. All a food or juice can possibly do is contribute to the blood nutrient pool. It can not have specific effects on specific organs. Remember also what was mentioned earlier, that the body constantly seeks to nullify any changes in its blood chemistry as the result of the ingestion of a meal. The rationale of "nutritional therapy" is as much a fantasy as the rationale of any other form of therapeutics. Foods do not act on the body. The body acts upon foods. Nutrients do not act on the body or perform roles within the body; they are used by the body. The body itself is the only active agent in nutrition.

Nutrition is an autonomic function, that is, it takes place below the conscious level. Just as digestion, absorption, circulation, glandular secretion and other autonomic functions take place without conscious perception or awareness, so also do the processes of nutrition (at a cellular level) occur without our direction or participation. Everyone will admit that stomach function will only produce symptoms when it is impaired. No one will deny that under ideal conditions we are totally unaware of the functions of our livers, intestines, etc. These are autonomic functions and they do not produce symptoms.

Nutrition is the same way. It is an autonomic function. Just as the digestion of food does not produce symptoms, the appropriation of nutrients, internally, should not produce symptoms. However, when digestion is disrupted symptoms arise and, likewise, when nutrition is disrupted symptoms arise. Russell Thacker Trail stated in 1871 that "Pure and perfect nutrition implies the assimilation of nutriment material to the structure of the body, without the least excitement, disturbance or impression of any kind that can be properly called stimulating." Here is a profound statement to come from a man who lived over 100 years ago, before the explosion of knowledge about nutrition and biochemistry began at the turn of the century. Yet he realized then what few people realize today, that any specific effects that occur from the ingestion of foods or nutrients are the results of stress and irritation and are not the result of an enhancement of nutrition. If a person is manifesting the symptoms of a cold, and taking vitamin C aborts those symptoms, this effect can no more be regarded as nutritional than can the effects of taking aspirin. The vitamin C is having a pharmacological effect (that is, a drug effect), not a nutritional effect. If a woman has severe menstrual cramps and taking dolomite relieves her symptoms, it is foolish to think that a need for calcium has been satisfied. The calcium is exerting a pharmacological effect. Crude calcium was one of the first drugs used as an anesthetic in surgery because it impairs the conduction of nervous impulses and thereby reduces sensibility. To call this nutrition is a shame, a travesty, an outright lie. Any food or nutrient that "suddenly gives you pep," "makes you feel warm all over," "cures your headache," "helps you sleep" or has any other specific effect should be avoided like the plague. It is obviously irritating, disrupting and enervating.

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > 1. What Constitutes Body Wisdom And Providence?

### Introduction

The human body is possessed of an intelligence and order that is incomprehensible to our intellects. While many humans are vain and will not admit to an inability to know and understand, let's face it—we are all finite in our capacities. We cannot comprehend the concept of infinity and we are mystified by many realities of existence.

From miseducation, ignorance, vanity and authoritarianism amongst our professionals flow arrogance and incorrect action that brutalizes those whom they profess to serve. From intellectual wisdom and understanding flow humility, kindness and other humane virtues. Wisdom recognizes our finite nature and admits to ignorance, an act of humility. Humility does not stifle the innate drive to seek knowledge. Rather, humility is born of a realization that spurs the quest for greater wisdom. True wisdom motivates us to continual exploration and improvement.

This lesson treats an area largely unexplored and uncharted. When we view the vastness of the incredible multitude of faculties possessed by the human body, we must stand in awe of the enormous intelligence displayed in each of the quadrillions of processes conducted within the body daily . We must stand in wonderment at the precision we observe. We cannot help but conclude that the body operates on principles that manifest the reign of law and order within the organic realm. We must observe that we are constituted on such an order as to comply in every act with the universal laws of existence.

We want to charge you with an overwhelming realization of the enormity of innate intelligence—of inherent body wisdom that exceeds by thousands of times the intellectual powers we arrogantly boast of. So vast is this innate intelligence that it is positively staggering. The immensity of inborn intelligence is not an easy subject to present. Very few studies touch upon this subject. However, we can delineate and point out some of the many manifestations of inherent body wisdom.

In this lesson, you will become aware of an internal providence that should be respected. So great are our body endowments that you should adopt this attitude: Never interfere with the vital domain. You cannot possibly help it—you can only harm it. All the knowledge and wisdom of civilization to date does not equal the intelligence exhibited by the operations of a single cell within the body! The best you can do is to order the external environment to make it more favorable for the organism. The only thing you can do for the body is to leave it intelligently alone! It knows what it is doing. You don't!

# 1. What Constitutes Body Wisdom And Providence?

Providence is the ability to anticipate needs and provide for them. This providence may be instinctual, as in the case of the bear that stores tremendous amounts of fat in preparation for hibernation or the squirrel that stashes nuts, acorns and seeds, or it may be due to acquired wisdom, as in the case of humans who store foods during plenitude in preparation for the season of scarcity.

The body is always provident. All providence exhibits wisdom.

Reproduction of kind is providence. It is provision that the species shall survive. The complexities of reproductive provisions defy human inquiry and intellect in their profundity and detail.

Nutrition and elimination are provisions insuring that the organism survives. Likewise, the complexities and subtleties of these many provisions defy human inquiry and intellect, though compliance is easily accomplished.

The immensity of the wisdom exhibited in all things so staggers the human intellect that many often retreat into the comfort of some all-encompassing outlook that relieves them of the burden of inquiry, assessment and understanding.

As students of this course, you are undertaking to delve into life's provisions sufficiently to ascertain a valid course for uplifting yourself and fellow beings to the uttermost possibilities.

Wisdom is really a difficult word to assess and define. It can be said to be all-knowing and all-understanding within a given sphere. Wisdom is at once the comprehension of a matter in both depth and breadth and an expertise or mastery that enables the possessor to pursue a correct course of action.

In pursuing this study, we must not confuse inherent wisdom or intelligence with intellect and acquired wisdom. The ability to think is a property of the conscious intellect. It involves wisdom and intelligence of a different order than the wisdom which is the subject of this lesson.

While there are books on body wisdom and its inherent programming, these books have little substance. This sphere of our existence is little explored, though the mechanisms of inherent wisdom have been charted extensively. What we can do here is to, by observation and deduction, invoke your realization of the colossal wisdom of the body.

Body wisdom comprises the multitude of faculties within the body that recognize, communicate and effectively respond. For example, if you bite into a luscious apple, the whole system is coursed with delight. If you bite into an apple that has been injected with a solution of caustic soda, you'll immediately recognize the danger, begin spitting and sputtering and run for water to dilute and remove the deadly poison that contacted your mouth tissues. Rejection of toxic matters is just as natural as delighting in beneficent materials and influences.

## 1.1 Cell Wisdom and Providence

The wisdom of a single cell is said to exceed all the accumulated knowledge of the human race so far! Each cell is, quite literally, a city in itself. It is a self-contained organism. The membrane is like the wall around a great city. Within are numerous inhabitants, many of them enjoying an existence within the cell on the order as the cell enjoys within the body. These forms of life, called mitochondria, have independent metabolic systems and can thusly be said to operate symbiotically with the cell and in concert with each other. All the components of a cell act for their mutual welfare and for the welfare of the cell as the host organism.

If we marvel at the extensiveness and complexity of the cell, then we must be even more astonished with the human body. The human body is said to possess 125 trillion cells, give or take a few trillion. (Some texts say there are 75 trillion and others say there are as many as 300 trillion cells in the human body.)

To say that the cell is a self-contained city in itself is no exaggeration. Cells vary in size from midgets to

giants. But even the smallest cell is about one billion times the size of its smallest component! There are thousands of organelles within each cell. These are the cell's life support system. Among these organelles are mitochondria which appear to be an independent form of life within the cellular context. Mitochondria are analogous to, or like, bacteria in their organization and functions.

A cell seems to be a city of specialized bacteria united into an organic unit to maintain a favorable environment and to more effectively secure the needs of existence.

Additional to its mitochondria, a cell has many organelles (functioning systems within their own membranes) that complement the mitochondria in making the cellular *organism* self-sufficient in its operations. Thus the cell, like the human body, requires only that its needs be supplied within the context of a favorable environment. Just as humans strive to create favorable environments for themselves, cells have long since ordered their environment by organizing into a super city known as a body. The human body can be said to be the super city.

The wisdom manifested in the faculties, organization and operations of a single cell stun the intellect. By observation we must admit that it is there and regard it with respect, even if we do not know or understand it.

## **1.2 Multicellular Intelligence and Intercellular Relationships**

If wisdom characterizes the seemingly infinite faculties of the cell, then think of the wisdom that unites a hundred trillion of them into an organism! Think how great must be the wisdom that guides the destiny of each and every cell within the body complex.

Cells are organisms within themselves. They contain mitochondria which have the characteristics that would earn them the ascription of an organism, too! Thus, if the human body contains over a hundred trillion cells, and each cell contains a complement of mitochondria, then there must, in reality, be several quadrillion organisms within the human body. If a cell is a colony of sophisticated bacteria that have banded together for their mutual welfare, then the body may be said to be made up of sophisticated cells that have banded together for their mutual welfare.

Cells have allied themselves within a unit we call an organism to specialize in functions in complementary coordination for mutual good. If we hypothesize that bacteria have confederated and specialized in carrying on the functions that make the cell a self-contained functioning organism, then cells have likewise affiliated and specialized to better create an ideal environment and to secure the needs of life.

If we observe the life cycle of a tree, we must marvel at its tremendous intelligence. From an acorn that sprouts and slowly grows over the years into a stately oak, we see the unfolding of an intelligence that is beyond our knowledge and understanding. Within the genetic encoding of each and every cell of the acorn and the resulting tree is the knowledge, understanding and operational expertise to secure needs from environment, to fashion them precisely into its specific requirements, to utilize them and to eliminate the wastes.

In making alliances with other cells, a supra-cell coordinator is created to coordinate the activities of the cells. This is called the nervous system or brain in multicellular organisms.

## **1.3 Ascertaining the Intelligence of Physical Phenomena**

What kind of intelligence does it require for the body to recognize food and secrete the correct enzymes for its digestion? What kind of intelligence is required to create the enzymes?

When we start asking questions exhaustively, we begin to discover the immeasurable wisdom and providence of every faculty of life.

Below is an excerpt from a physiology text. It is quoted merely to highlight certain body processes so

that we might divine some of the body faculties and the intelligence they exhibit:

*Often tissues of the body regress to a much smaller size than previously. For instance, this occurs in the uterus following pregnancy, in muscles during long periods of inactivity and in mammary glands at the end of the period of lactation. Lysosomes are probably responsible for much if not most of this regression, for one can show that the lysosomes become very active at this time. However, the mechanism by which the lack of activity in a tissue causes the lysosomes to increase their activity is completely unknown.*

*Another very special role of the lysosomes is the removal of damaged cells or damaged portions of cells from tissues—cells damaged by heat, cold, trauma, chemicals or any other factor. Damage to the cell causes lysosomes to rupture, and the released hydrolases begin immediately to digest the surrounding organic substances. If the damage is slight, only a portion of the cell will be removed, followed by repair of the cell. However, if the damage is severe, the entire cell will be digested, a process called autolysis. In this way the cell is completely removed and a new cell of the same type ordinarily is formed by mitotic reproduction of an adjacent cell to take the place of the old one.*

What this really means is that body parts not in service atrophy and that it is believed that lysosomes are responsible for regression or atrophy. But, whether or not we divine the wisdom of loss of unused faculties, there is an intelligence that creates and regresses faculties involved in pregnancy, lactation and musculature.

In the paragraph that follows, we will study one way in which the body uses lysosomes for special purposes. As you may already know, lysosomes are powerful digestive enzymes the body creates, stores and uses. When a cell is to be scrapped, the old cell is autolysed (self-digested) and the remnants are passed off as wastes into the lymph and then into the bloodstream. The wastes may be recycled in part and excreted in part. The point here is that cells have their own "self-destruct" mechanisms in the form of lysosomes.

The processes described evince tremendous body intelligence in their performance. The vital domain does not tolerate unneeded baggage. Therefore, it disposes of the useless and the surplus to the extent it can. Cells that are crippled are either repaired or replaced. High-level function is the objective of the body. The welfare of the remaining cells decrees that they dispatch crippled cells if not repairable.

The body secretes lysosomes and uses them for special purposes. Let's examine a boil or carbuncle. The little hole that extends from the body surface to the fleshy interior represents a real body disaster! But the purposes served decree the ravage that the body inflicts upon itself. When there is deadly toxic accumulation that threatens the integrity of the organism—when this toxic accumulation cannot otherwise be eliminated through regular channels of elimination—the body autolyzes a tube, hole, passage, duct or fistula-like opening to the surface. Perhaps a hundred million or so body cells will be destroyed by lysosomes. After the completion of the tube, the body collects the toxic material and forces it to the surface through the specially-created duct. There it is quarantined until drained or detoxified.

In fasting, for instance, lysosomes are utilized in destroying and digesting growths. The materials destroyed are utilized as food. These growths may be breast tumors, cancer cells, warts, cysts, etc.

The order of intelligence involved in sensing errant conditions, communicating them to the brain, assessing the reports, determining a course of action and responding with coordinated orders to all the body cells and systems involved to effect a result is beyond human comprehension. We can only intimate the vastness of the wisdom involved with our limited concepts and expressions.

This is just one of the many kinds of body wisdom that further fortifies the Life Science stricture: Leave the body intelligently alone.

## 1.4 The Brain as the Kingpin Behind the Human Show

For us to comprehend the magnitude of the brain's dominion and the cooperation of each cell member of that dominion, we'd have to have an intellect infinitely more developed than it presently is. The limits of intellect leave too much that is "not clearly understood."

In one of the articles used as text material in this lesson, it is pointed out that the body possesses some 125 trillion cells. Each cell consists of a multitude of organelles or life support systems that keep the cell functioning. This article points out that it is difficult for us to conceive a few thousand people getting together and cooperating harmoniously in all things. If that seems difficult, then imagine all the four billion individuals on earth acting in unison. But then, compared with the body, that is nothing! Can you imagine 36,000 earths, each with four billion inhabitants, acting in unison?

Only with such staggering thoughts as these is it possible to grasp some idea how infinite is the, knowledge, understanding and expertise of the human brain. It coordinates the activities of an astronomical number of cooperating cells. We emphasize the word cooperating because all cells are completely subservient to the brain, which, in turn, serves the whole organism. The brain exists as the controller of the body cells collectively. It serves the cells by providing them with needs they cannot obtain on their own.

Sometimes a cell may become "independent" in that its control mechanisms are affected and it either no longer possesses innate intelligence or can no longer focus its innate intelligence to cooperative endeavors. Such a cell becomes a parasite cell in that it draws from organic stores but is so "crazy" it cannot contribute to function. It is called a cancer cell. Its operations disrupt physiological harmony rather than contribute to it. A cancer cell is created by continual assault by toxic substances that eventually derange and destroy its encoded blueprints and intelligence. When such a cell exists, the brain will bring the residual powers of the organism to destroy the errant cell.

The brain, though the creature of its cellular constituents, is nevertheless supreme in the organism of which it is a part. The cells have created it as president to preside over and direct their affairs.

As the supreme faculty of the body, the brain is protected and served by its cell constituency preferentially. The brain thus is treated royally. It receives the best of everything; it is served and kept operational, even if this means the sacrifice of millions upon millions of cells. Thus, we can say the brain is the kingpin behind the human show.

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > 2. Cell And Brain Programming

## 2. Cell And Brain Programming

Each cell has a blueprint called genetic encoding. As a matter of fact, each mitochondrion within the cell has its own genetic material, too. This encoding enables the cell to reproduce itself faithfully. Further, it enables the cell to perform chemical, mechanical and electrical activities with exactness. The cell is a chemical factory performing more chemical feats than all the chemical factories in the world combined. Incredibly, it performs them within its membranous confines, the volume of which is so small as to be undetectable to our eyesight.

The intelligence of a cell does not have to be learned. A new cell comes into existence just as experienced and knowledgeable as the cell that begot it. The intelligence is inherent and is automatically transmitted to progeny. The endless duplication of phono discs might be compared with cell replication. The programming is within.

The brain and central nervous system, likewise, are possessed of most of the knowledge, programming and expertise needed for operating an infinitely complex organism. The programming necessary to internal operations is automatically transmitted through reproduction of genetic codes in the developing organism. We marvel that the blueprint for the whole organism in all its incomprehensible number of faculties and functions exists within a fertilized ovum. Our stupefaction must be thorough when we realize that the microscopic fertilized ovum has all the instructions encoded that will create a grown "human being with 125 trillion cells. A perfectly developed and symmetrically formed organism of 125 trillion cells will result from the blueprint born of the union of sperm and ovum.

Everything about this organism is at all times perfect in faculties and functioning potential. It is faithful in every detail of the blueprint. It carries within all the accumulated experience and knowledge of billions of years of development. It will reliably produce a human being to the highest standard to which humans have developed. The perfect precision with which millions and trillions of formulas, processes and procedures are exactly transmitted and performed (some for just once in the whole life of the forming organism) is truly mind-boggling. (All this presumes no vitiating interference from toxicity or injury.)

We can throw up our hands and dismiss probing into such baffling complexities because of their irrelevance to the practical plans of human existence. Indeed, we can! We can live in bliss and never inquire once into our origins or the intricacies of our being. Humans lived happily unaffected lives in nature, just as animals, long before we plumbed the depths of our bodies and minds. Hence, we do not pursue this course to teach the profundities of the organism. You can procure books on physiology, biochemistry, cytology, anatomy and kindred subjects if you choose to do so. But that will add little to your effective knowledge of how to guide errant humans. That know-how is much simpler and easier, at least insofar as it involves learning.

Our objective is to imbue you with an awareness of the extensiveness of inborn intelligence and an understanding that it is to be trusted implicitly at all times and in all cases. Never be so presumptive or arrogant as to imagine that you can second-guess the body. Neither you nor anyone else can. While we can fathom the vast intelligence within, we cannot begin to substitute for it. We cannot help it a smidgeon. All that we do to the vital domain constitutes morbid interference.

The brain consists of fifty billion cells that are the most highly developed of any known. They have the potential to live for hundreds of years. They do not reproduce as do other body cells—they do not reproduce at all. But even the healthiest of us lose perhaps a hundred thousand of our brain cells daily. At this rate, it would take 150 years to lose 10% of our brain capacity. But humans often squander this precious heritage and become senile in their sixties, seventies and eighties, still in the relative youth of life's potential, with loss of perhaps more than 50% of their cerebral matter.

On the conscious level, we are babes in the woods. While our intellects have been millions of years in developing, cell intelligence has been developing for billions of years, and our subconscious faculties have been hundreds of millions of years in development. Our infant intellects are at a stage where it can most appropriately be said that "a little knowledge is a dangerous thing." If the human race survives long enough, we may come to a general intellectual level consonant with Life Science ideals. We may all come to realize that our own well-being is indelibly bound in following nature's mandates—in living in complete harmony with our fellow sojourners—in total non-exploitation of humans or of other creatures.

## **2.1 Wisdom and Precision of Body Processes**

Some 100,000 different proteins are synthesized within the body. The blueprints or formulas for these proteins exist within almost every cell. The exact procedures involved for making these proteins most efficiently are a part of cell encoding or programming.

Likewise, the cells have a wealth of abilities—to store and use all the raw materials they need, to create the compounds they need and will need, to create the energy they need, to create and apply the energy

commanded of them in behalf of the organism—the multitude of capabilities of the cell overwhelm the intellect. It is said that if all the processes and capabilities of the cell were to be taken over by a computer, a computer of the dimensions of New York City could not cope with them.

A cell might better be likened to a self-contained universe rather than a self-contained city.

Adenosine Triphosphate (ATP) is the source of energy for most cell functions. Most ATP is created by the specialized organelles called mitochondria. Mitochondria create this complicated molecule, ATP, which "fires" when given a proper signal. When the ATP is used, the resulting spent molecule is recycled or "reloaded" for reuse. The know-how, providence and expertise involved in these chemical processes stagger the imagination.

## **2.2 Cognitive Faculties**

At every level of its being, the body has highly-developed sensors that can readily recognize that which is good, bad or indifferent. All our senses coalesce to recognize foods, dangers, pleasurable and enticing situations, unpleasurable and repulsive situations, and so on.

Externally, our conscious faculties and intellect fulfill sensory and cognitive roles. Within the vital domain there are millions upon millions of specialized faculties for sensing the electro-chemical-mechanical nature of everything that enters.

Nerves translate all sensory data into electrical impulses and transmit them to the brain for a coordinated and purposive response that will effectively deal with the situation.

To provide an example, let us propose that many cells are short of an amino acid needed to synthesize a crucial protein requirement. This need is communicated to the brain, which relays a message to cells for inventories of surplus amino acids. Those required for deamination and reamination into the needed amino acids are directed to the liver, where deamination is conducted and the new amino acid is synthesized. The order of intelligence that can perform these immensely complex inventory and chemical activities makes our intellects, as marvelous as they are, look rather miniscule by comparison.

## **2.3 The Body Communications System**

The body has some 50 billion brain cells. It has billions of nerve cells involved in message transmission. Messages travel within and around the body with the speed of electricity—nerve transmissions are almost all electrical. There are chemical communications within the body as well.

If we viewed a city like New York with eight million inhabitants, millions of telephones, hundreds of exchanges and thousands of switchboards, we can only begin to understand how intricate and complex are the body communications systems. The body has a communications system that serves at one time the equivalent of 36,000 earths, each earth having over four billion residents! Each of those inhabitants has a telephone.

If you knew what was involved in turning over during the night during sleep, you'd be astonished. An area of the body involving countless billions of cells becomes cramped or distressed in some way. An urgent request goes to the brain—rather, the brain has been monitoring the situation all along. But movement is not initiated as long as matters remain within certain parameters. When the situation threatens the integrity of certain areas, the brain, entirely beneath the level of wakefulness, will mobilize trillions of cells that comprise hundreds of muscle systems and effect a shift of body weight to a more comfortable position.

## **2.4 The Body's Master Coordinator**

We have commented upon the brain as the kingpin in all body operations. The brain is the supreme creation that trillions of cooperating cells have devised to serve them as a master communications and

coordinations center. The brain has been developed to administer the many needs within. As well, the brain has been developed to aid the organism to deal with the external world on its own terms.

The thoughts we have on a conscious level are marvels when viewed from one aspect. But our intellects are hardly capable of conducting more than one line of thought at a time. In comparison, the brain conducts millions of processes simultaneously beneath the level of awareness! This service never ceases, going on every second for our entire lifetime. The busyness of the brain in serving the equivalent of 36,000 earths with four billion inhabitants each is unimaginable. We can only hint at it.

For example, one of the brain's responsibilities is overseeing the maintenance and circulation of the blood—among a few million other things. And speaking of a few million things, while you read this sentence your body has created 10,000,000 new blood cells! That is, it creates ten million blood cells per second! The body has some 25 trillion blood cells, and their average life expectancy is only about thirty days. Blood maintenance and circulation have unimaginable intelligence behind them.

The luxury of abstract thought is possessed by only a few creatures on earth. Some races of humans, notably the negrillo or pigmy, are said to be incapable of mastering abstractions. Yet there are other creatures, most notably whales, dolphins (porpoises) and elephants, who may be able to think in abstractions. Perhaps even dogs and wolves are capable of abstract thought. We don't really know much about the subject. Certainly no other creatures approach the capacities of humans for abstract thought.

The brain is absolute master of all the cells within its domain. Yet it is totally subservient to its cells and is very responsive to their needs. But the organic order of the body system is such that the brain is at the very apex in importance. While the brain was the last development of the human organism, it is the first in importance. Every cell, tissue and organ system other than the heart are slowly sacrificed, in critical periods such as starvation, that the brain might survive. When the brain can no longer survive, death occurs.

The brain is the prime instrument in establishing, supplying and maintaining the needs and stable environment of the trillions of cells. Each cell has yet other organisms that thrive within its internal environment called mitochondria. The brain exists for every cell in the body and, in turn, the brain's welfare is dependent upon the well-being of the cellular system it serves.

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > 3. Knowledge, Expertise And Resources For Healing Processes

### **3. Knowledge, Expertise And Resources For Healing Processes**

Can anyone doubt, after a study of the countless control mechanisms within the body, after observing what happens with predictable reliability when cuts, broken bones and other injuries are suffered, that the body is completely self-repairing?

Can anyone not see that the body has vast resources, that it is completely self-sufficient and that it is fully capable of coping with internal exigencies that beset it to the exclusion of all other agencies?

Can anyone of average intelligence not see that any intrusion upon the vital domain is grossly wrong? That it obstructs and interferes with processes revealing far more wisdom and expertise than we can ever hope to master?

Can anyone doubt that all body action is intelligent, purposeful action?

Can anyone doubt that symptoms of sickness evince body action in purifying and healing itself? Can anyone doubt that, in conducting disease processes, the body is manifesting wisdom and physiologically

correct remedial activities?

Can anyone doubt that an organism with the power to develop itself into a superb human being from a fertilized ovum is less than capable of managing its internal affairs?

Can any person presume a knowledge of internal needs better than the body itself?

It is very unwise, even dangerous, for anyone to presume an ability or knowledge superior to that of the body. Leave the body intelligently alone!

### **3.1 Body Actions Always Are Right Actions**

It has been said in jest that "we are our own worst enemies." The facade of a joke often conceals an element of truth.

What humans often do relative to their bodies reminds me of a story. Two husky men were going down the street. They observed a huge piano apparently stuck in a doorway and two workmen inside trying to move it. They offered their help and started struggling to get the piano into the house while the two workmen inside struggled also. After about half an hour of fruitless efforts, one of the workmen inside yelled for a break so they could get their heads together on this thing. Upon convening, one workman commented that he'd never had such great difficulty in getting a piano out of a house before.

"Getting it out of the house?" asked one of the volunteers. "We been trying to help you get it into the house."

When we deem our intellects superior to the obvious demands of the body in a crisis, we exhibit gross ignorance. The only way to help the body is to cooperate with it, to meet its needs in accord with its condition. That is the only wise thing to do. This means "leave the body intelligently alone" to do its thing in full confidence that all body action is right action.

### **3.2 Intervention of Intellect in Body Affairs**

If you hold your breath or force yourself to breathe in a manner that is contrary to normal breathing, you are interfering in a vital body process. Not many people hold their breaths long nor perform forced breathing (often called deep breathing) such that they underventilate or hyperventilate their bodies and beget hallucinations and *acapna*.

The body is the best arbiter of its needs. It is autonomous and operates from a cumulative fount of wisdom that we can never hope to emulate.

Often the body will make its demands upon us in some gentle manner, such as in thirst, sleepiness, hunger, etc. But when we figure that wine, beer or soda pop are just fine as ways to satisfy thirst, we are imposing upon the body a health-sapping burden. The body demanded water, and only water, in thirst. To supply it with anything other than water is a mistake.

At some time in our past the current superstition about diseases began. The present idea about disease is the result of a gradual evolution from the ideas of evil spirits and demons. The people who held these ideas admitted that they were wrong by the fact that they changed their minds and replaced them with new ideas. However, the new ideas have the same roots as the old ideas and are, therefore, equally wrong.

The misconception that still prevails in matters of sickness or disease is that the body is being attacked. The misconception further holds that the attacker or attackers must be counterattacked and routed from the body. Under this misconception many people have been harmed (by drugs). Death occurs in some cases. In fact, when physicians go on strike, the death rate usually plummets by 50 to 60%!

One of the prime dicta of the Hygienic philosophy is noninterference in the body. Each cell of the body possesses more knowledge and expertise than the whole of the human race collectively on the conscious

level. Our voodooistic rituals with drugs are based on conjectures about what the body should be doing or what it needs when ill.

It bears repeating that sickness is vital body action. It is right action. The body initiates and conducts the disease process to accomplish physiological objectives. To mistake that action as an attack by an invader that must be routed is disastrous in practice.

Refrain always from second-guessing the body—what it needs or what should be done. We'll repeat over and over: "Leave the body intelligently alone." Establish the external conditions of health based on the body's capabilities of the moment and that's all. That is a simple enough dictum to follow.

### **3.3 Building Confidence in Inherent Faculties**

This lesson cannot pinpoint body wisdom any more than have our many researchers and thinkers. We know its there and we perceive how extensive it is when we explore it. But, by and large, most of our population is unaware of their bodies' tremendous faculties. They violate the laws of their being and then seek "help" when problems arise.

Not only must you build your confidence in the unfailing powers of the organism, but you must establish this confidence in your clients. There are many approaches to accomplishing this. Methods that make a deep impression are to be preferred. Among the educational aids Life Science is developing are graphic presentations depicting the incredible powers within.

When the resources and powers of the body fail to restore health under favorable conditions, then the condition is irremediable. Life Science is the court of last resort for many who have tried everything but healthful living. Many turn too late—they're already over the hill.

Everyone can benefit by the employment of healthful practices within the context of their condition. As a professional, you cannot promise miracles but you can say truthfully that the methods you propose are the only factors that will enable the body to rebuild health.

### **3.4 A Medical Assessment Of Body Wisdom**

Dr. David Reuben, M.D., has authored two best-selling books. One, *Everything You Always Wanted to Know About Nutrition*, contains much erroneous guidance. But it also shatters many commercially-fostered myths in the field of foods, feeding and nutrition.

The following quote from the book illustrates the body's needs and powers:

*Look at it this way. A plain old apple contains 191 known chemical compounds, each of which plays an important role in human nutrition. When you eat that apple, over 1,300 chemical reactions occur to break it down into its component molecules. Those molecules are then dispatched to exactly the areas of the body where they are required. The pectin goes to the large intestine, the vitamin C is sent to the skin, the vitamin A goes to the retinal area of the eyes, and so on times 191. You don't make it happen because you don't even know it's happening. There are 160,000 edible plants on this earth—you didn't put any of them there. But most of them help keep you alive. Your digestive system was designed by God—not by you, not by IBM and not by a government agency. It can take almost any animal that walks by or any plant that springs up in an empty field and convert it into brain, bone, heart, muscle and energy to keep you alive. Even the most arrogant and self-important "scientist" must admit that a Being far wiser than any human must have devised and implemented that will-uncomprehended nutritional system.*

*So don't think that the people who make instant breakfasts or imitation orange juice or yucky white imitation bread have the slightest idea what your body needs. That applies as well to those who turn out vitamin pills and nutritional supplements. Those fumbling human*

*brains cannot improve on the Master Design that brought you here and allows you to survive from day to day.*

### **3.5 Law and Order Reign Within the Body**

Pick up any book on physiology, nutrition, biology, cytology, biochemistry, anatomy and related sciences. Each attests to the multitude of activities the body conducts. Each bespeaks the orderliness and precision with which the activities are conducted; each witnesses the enormous wisdom—the vast know-how and expertise possessed within; each tells of the multitude of faculties and resources within the body.

However, for a person who elects to make a practical application of the world's most needed expertise, a pursuit of esoteric knowledge would be luxurious entertainment. Most of it is meaningless, for we cannot change nature. It does not need to be changed. We can always rely on it. The multitudinous processes and relationships proclaim the unalterable reign of law and order within. All body wisdom is based soundly upon the immutable physical relationships of matter. Entitative existence depends entirely upon fixed principles and undeviating physical relationships. Bodily survival depends upon taking charge of and utilizing needed natural substances in accord with invariable laws.

The order of intelligence evinced in the mastery of nature's forces dwarfs our intellects beyond our ability to comprehend. The best we can do is bend our knees in awe and acknowledge our inner wisdom and resources as our master. We must make our intellects totally subservient to our bodily wisdom. Our intellects will thrive ever more if we learn to cooperate with our inner wisdom.

By teaming up with your body intelligence in all matters, you can become a winner in the game of life. You can help others become winners in the game of life, too!

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > 5. Programming The Intellect For Exuberant Well-Being

## **5. Programming The Intellect For Exuberant Well-Being**

By now you are no doubt persuaded that the body is constructed for perfect operations.

The body is a perfect instrument within the environment of its adaptation when its needs are correctly furnished. Because intellect often misinterprets body processes and actually contravenes its needs—because cumulative institutionalized errors regard the body and its needs incorrectly, much suffering and disease prevail today.

Learn to trust the body implicitly. Learn how to properly supply it and know that it will perform correctly whether in struggle or great health. Struggle is occasioned when the body is incorrectly supplied or interfered with. Lacing our bodies with toxic fare, miscalled food and drink, is incorrect supply, and the administration of drugs, treatments and anti-vital modalities constitutes gross interference.

From wrong intellectual programming flows errors that undermine and destroy health.

The purpose of this course is to present you with ready-made programming you can employ in helping your clients reprogram themselves so that they may enjoy wonderful health.

Clients will seek you out because they want to free themselves of nagging problems and suffering. They are not necessarily looking to change their habits or programming—they want to be made well within the context of their status quo—most are fixed in their habits (programming) and resist changing their

ways. Even if they wanted to, most are in situations that do not make breaking habits an easy matter.

To break bad habits, it is wise to take an individual out of the mold in which the habits were forged and indulged and place that person for awhile in an environment where only good habits can be followed. Within a directed or controlled environment, all the experiences are usually pleasant—even happy, memorable occasions. Those who are fasting or living within the atmosphere of a health retreat improve themselves, enjoy fellow guests and enjoy body rest. Frequently they are in a heady state. Tensions that ordinarily beset them within conventional society are relaxed and often nonexistent.

Within the context of a euphoric paradise, clients improve rapidly. Their intellects are largely reprogrammed in support of an inner drive to continue the benefits and happiness realized.

More healthful living has been inspired in Americans at health retreats than any other single way. The great value in establishing a controlled and ideally directed environment for health seekers is thus evident. Nothing reprograms the mind so quickly or so well as living and doing in rapport with others going in the same direction.

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > 5. Questions & Answers

## 5. Questions & Answers

### **If the body has the wisdom you say, then why should it ever get sick?**

The body becomes sick because of its wisdom. You must not look upon sickness as a punishment or as a stupid thing. The body always strives to the highest level of well-being as possible. If it becomes loaded with toxic substances due to whatever reason, it requires a lot of wisdom to withdraw energies from many normal channels, redirect it to purification processes and accomplish expulsion of morbid matters. If the intellect insists on unhealthful habits, including stuffing on pathogenic substances, what would happen if the body were equally unwise? Morbid matters would collect until sufficiently concentrated to dispatch the organism.

### **Isn't the cell the smallest unit of human life? You have said there are yet smaller forms inside the cell. Please comment on this.**

There are other inhabitants within a cell. These are called mitochondria. Each mitochondrion fulfills the qualities of life, i.e., it has its own metabolism, nucleus, genetic material (DNA) and so on. Just as the atom becomes complicated with protons, mesons, electrons and neutrons and becomes even more complicated when formed into molecules, so too, the human body seems to be at least a three-step organization with mitochondria, cells and, finally, the organic whole.

### **How can you say that everything the body knows is already programmed into the fertilized ovum? Wouldn't you say a minor detail like 1,500 miles of specialized tubing called blood vessels in our bodies is the result of a far greater wisdom and power than could possibly be blueprinted on a pinhead?**

It is as easy to say things one way as the other. Both truth and misconceptions can be reduced to words. However, intellectual honesty bids me to say that what we observe is evidence only of itself. In the matter of reproduction we observe the microscopic fertilized ovum carrying within all the blueprints needed to create a perfectly functioning adult with

millions of times more faculties than just the 1,500 miles of circulatory tubing.

Thank you for bringing to our attention an additional aspect of the body's really immense programming and how that programming is so readily reproducible. Because we cannot understand how the complexity of a human organism can be blueprinted into a fertilized ovum does not mean it is not there. It merely pinpoints another facet of how limited are our intellects. We can see the unfoldment of this blueprint in all its detail as it develops a human being. We cannot see any other agency involved nor can we logically infer it.

**You have intimated that the body has infinite intelligence. Is this really the case?**

No. The body has very finite intelligence, and that wisdom relates to internal and external matters only to the extent that it must alter its operations of the moment to maintain equilibrium or an ideal internal environment. Relative to our intellect, internal wisdom is infinite in my portrayal only because it is so much more vast, relatively. I would also impress you with this: Despite its imperfections, we must marvel that we have the luxury of the intellect. Intellectual faculties are at the very apex of body intelligence. That they have been vitiated and misdirected does not detract from them.

**You've said that bacteria have been around for billions of years and that they have evolved to being part of the human body. Aren't you assuming Darwin's theory is scientific?**

I know of the great controversies of our day on creationism versus evolution. Darwin's theory is that life forms evolved and developed. This is out of the class of being a theory in view of the many types of plant and animal life humans have developed by guided breeding. Recognizing that development can be guided is also to recognize that it can happen without guidance from the human intellect.

**What do you have to support your statement that the death rate goes down 50% to 60% when doctors go on strike?**

There were two physicians' strikes in Israel, one in Holland, one in Belgium, one in Canada and several in the U.S.A. In every case the death rate went down sharply. You have our book, *The Myth of Medicine*. Why not take time out and read it. You'll find substantiation in its pages.

**How are we going to get people to fast if that is the only way to help them.**

Clients will seek you out because they are looking for benefits. Fasting is but one condition under which great benefit can be derived. If the client really needs a fast, it is a procedure to be outlined to him/her in honest terms with the benefits that always accrue correctly portrayed. Not all clients who should fast will do that, but that is their responsibility. You will have done your duty to your client by introducing them to the solution to their problems and by making your best effort to present that solution as a simple, easy and desirable way to go.

## **Article #1: The Great Power Within You by T.C. Fry**

*The following is based on the writings of the great Natural Hygienist, health educator and true Life Scientist, Dr. Herbert M. Shelton.*

Living organisms are fully self-sufficient and self-governing entities. Supplied appropriately with the needs of life, they thrive in perfect health, completely free of disease.

From conception all living organisms are endowed with a built-in program for a full, fruitful and joyous life.

Living organisms are self-programmed to meet all life's needs within environments of their adaptation.

All living organisms are self-directing, self-constructing, self-defending, self-preserving, self-maintaining and, in the event of injury or illness, self-repairing or self-healing.

*The healing principle is always in the living system itself.*

The only power that can heal is the power that repairs; the only power that can repair is that power that produces; the power that now produces is the power that originally and always produced. The power that constructs *a full-grown individual from a fertilized ovum is the only healing power!*

Healing is, therefore, a continuous, unceasing and exclusively intrinsic power of every organism.

The power that produces an organism and keeps it alive and functioning is the only power capable of governing, maintaining and healing it.

Mastering and relying upon this great power within will yield a life of bliss and goodness *with complete freedom from ailments and suffering.*

The simple, self-evident truth enunciated in this article embodies a long train of guiding principles that can enable you to avert miseries, woes and suffering.

Knowing your tremendous inner capabilities frees you of many burdensome illusions and provides a key to true life enhancement.

Recognizing the truth and implications of this lesson's text is the basis upon which you can immeasurably improve your life and its circumstances.

Recognizing the fundamental truth outlined herein sets the stage for fulfilling the obligation you have to yourself and fellow beings, that of reorienting and reprogramming yourself for superlative well-being.

### **The Need For Reprogramming yourself**

Standing in the way of total well-being for all too many who otherwise have the knowledge, the understanding and the dedication to achieve their highest potential are many ingrained bad habits, physiological addictions and erroneous concepts.

*"Tis better to be ignorant than to know so much that isn't so."*

Humans are creatures of habits. Habits are conditioned responses which we rely upon for personal efficiency. We spend many years from infancy on learning responses to many thousands of situations and circumstances.

With set response patterns we do not have to go through time-loss and trouble in solving problems anew every time we face them—we humans solve our problems once and for all and adopt the solutions as fixed and automatic responses known as habits. When situations reoccur, we unconsciously employ our habit patterns.

That many of these habits amount to error fixation and that our accommodations to many of these habits amount to life-destroying perversions gives rise to the need to reprogram ourselves.

Most of our habits are learned from people who learned from others back into the murky reaches of time. Habits are always adapted and employed in accord with our own peculiar abilities.

Likewise, we learn most of our concepts and misconcepts from others and adopt them in the shape or fashion our individual peculiarities dictate.

Habits are wonderful, for they are the foundation upon which our advanced human attainments have been built. As the most programmable beings in existence, we have more "conditioned responses" to carry us through more and greater complexities than other creatures in existence. By and large, our habits are constructive and get us along in this world remarkably well.

On the other hand, there are many "klunkers" in our personal armentarium that sabotage our well-being.

Thus it follows that we can perform no better than the limitations of our self-programming. Our programming is at the same time our boon and our bane. To the extent that it guides us correctly, it is a boon. Insofar as it locks us into wrong conceptual frameworks, perverted outlooks, unwholesome practices, vitiated and antisocial dispositions and many other self-defeating characteristics, programming is a bar to our well-being.

It is unfortunate that most or all of us are incorrectly attuned to a greater or lesser extent in many of our life programs.

But we are fortunate in that we, like computers, can be reprogrammed for better performance and more rewarding results.

*If you want to capitalize upon the colossal potential within yourself, then you must reprogram yourself.*

Reprogramming yourself is difficult because you will be burdened heavily by the weight of previous conditioning and the drives, good, bad and indifferent, which initiate and impel your activities.

You'll have to dispel a lot of myths and superstitions which infest your concepts and burden your thinking processes. What you take for granted is difficult to overcome. But you must and can do so.

To reprogram yourself for a better life on a higher plane of existence, the first order of business is to admit to yourself that you could harbor a lot of beliefs and practices that are responsible for your and your fellow beings' generally poor condition and overall suffering.

We all know mental anguish and frustrations. These will flow from lives not led in accord with the course our innate nature decrees.

You can reprogram yourself to understand and practice the course you must follow. You can avoid those pitfalls that hamper you from assuming the position on the pedestal that all humans should occupy.

## **How To Reprogram Yourself For Superlative Well-Being**

Following are the steps necessary for the ordinary person to become a Life Scientist, that is, to become an individual who conducts his or her life activities in accord with the dictates of the human biological heritage:

1. You must come to an awareness or knowledge that all is not right in this world of ours, or even with yourself. While almost everyone is self-satisfied that he or she has the answers to life's and society's great vexations, the generally deteriorating condition of almost everyone seems to be self-evidence against such smugness. Therefore, you must be willing to admit to holding many erroneous notions. *We do not perceive our errors and often reject the truth when faced with it, but we must, first, cultivate an open, receptive mind.*
2. You must seek knowledge and understanding with open arms. That you are reading this is in your favor. In seeking knowledge with the perspective of understanding, that is, wisdom, you'll be

dependent upon your ability to master ideas and concepts.

3. You must seek knowledge, nonetheless, if you want to better your life situation. It is essential for correct reorientation. The fundamental principles, if applied on an individual and social scale, will salvage humanity from its depravity.
4. You must master an insight and understanding of what you learn—in your cosmogony you must fit all the parts and pieces of your knowledge such that you have perspective; it all must make good sense.
5. You must become the absolute master of your personal activities and circumstances. You must be willing, to the extent need dictates, to snap all ties with existing habits, intellectual stances and practices, no matter how deeply imbedded or how dear to you they may be.
6. You must be willing to end all fealty to anything that you believe, if need be. Keep in mind that the use of the word *believe* is a confession of ignorance, for it is not necessary to believe that which you know. To insist upon what you merely believe, may be insisting upon ignorance and misconception. Face up to the fact that many of your beliefs may be nothing more than myths and popularly-accepted superstitions that hamstring you.
7. You must be willing to change your circumstances, if necessary, to effect self-reprogramming and to follow a correct life style.
8. You must undertake and study the conditions of health and well-being. Your greatest task is not the one of learning so much as unburdening yourself of a lot of burdensome intellectual baggage.
9. You must undertake to observe in your practices that which the truths you learn dictate.

[Home](#) > [Lesson 6 - The Immense Wisdom And Providence Of The Body](#) > Article #2: Life's Engineering by Dr. Herbert M. Shelton

## **Article #2: Life's Engineering by Dr. Herbert M. Shelton**

The greatest engineering feat of which we know anything is the building of a complex animal organism from a microscopic ovum. Think, for instance, of the marvels of the human body with its pulleys and levers to perform mechanical work, its channels for distribution of food and drainage of sewage and its means of regulating its temperature and adapting its actions and functions to its varied environments and needs. Its nervous system and the eyes, ears, etc. are constant sources of wonder. We regard the radio as a wonderful invention, as indeed it is, but we are all equipped with more wonderful "sending" and "receiving" sets than any radio manufacturer will ever produce. All human inventions have their prototypes in the animal body.

In studying the wonders of the body, its structures, functions, development, growth and its varied powers and capacities, it is well to keep in mind that the building and preservation of all these things is from within. The power, force or intelligence that evolves the adult body from the fertilized ovum is in the body, is part of it and is in constant and unceasing control of all its activities. Whether it is an intelligent power or a blind energy, it works determinately toward the latest results in complexity of structure and function. In development and maintenance, and in health and disease, the movements of life appear to be guided by intelligence more often than the conscious intelligence of man. Indeed, unless we grant that something can come out of nothing, that intelligence can come out of that which has no intelligence, we must believe that the conscious intelligence of man is a subordinate part of that broader intelligence that evolves his body and which inheres in it.

If we view a few of the engineering feats performed by the body in cases of injury and disease, we are forcibly struck with the truth of Sylvester Graham's remark: "*In all these operations the organic instincts act determinately, and, as it were, rationally, with reference to a final cause of good, viz., the*

*removal of the offending cause.*" Some of these wonderful feats have been presented to you in previous chapters. We will here present a few of a different class.

To begin with, let us consider the natural healing of a wound, scratch or broken skin. We have become so accustomed to this familiar phenomenon that we have come to regard it as an almost mechanical process. But a close examination of the process shows us the presence of that same marvelous intelligence that built the body from a tiny microscopic speck of protoplasm to its present state.

Whenever the skin is broken or cut there is an exudation of blood which coagulates and forms an airtight scab. This scab serves as a protection to the wound and remains for a shorter or longer time as is needed.

Underneath this scab a wonderful thing occurs. Blood is rushed to the injured part in large quantities. The tissues, nerve and muscle cells, etc. on each side of the wound start multiplying rapidly and build a "cell-bridge" across the gap until the severed edges of the wound are reunited. But this is no mere haphazard process. Everywhere is apparent the presence of directing law and order. The newly-formed cells of the blood vessels unite with their brothers on the other side so that, in an orderly and evenly manner, the channels of circulation are re-established. In this same lawful and orderly manner the connective tissues reunite. Skillfully, and just as a lineman repairs a telegraph system, do the nerve cells repair their broken line. Muscles and other tissues are repaired in a similar manner. And what is a wonderfully marvelous fact to observe, no mistakes are made in this connective tissue, but each tissue connects with its kind.

After the wound is healed, when a new skin has been formed so that there is no longer any need for the protecting scab, nature proceeds to undermine and get rid of it. As long as the scab was useful it was firmly attached to the skin so that it was not easy to pull it off, but when there was no longer need for it, it was undermined so that it fell off of its own weight.

What more evidence than this does one require to know that the same intelligent power that built our bodies is also the power that heals it? What better evidence do we want that the healing process is accomplished in the same orderly manner and by means of the same functions with which the body is built, maintained and modified to meet its present needs.

We get a still more wonderful view of how nature performs her work if we observe the healing of a fractured or broken bone. If an arm or leg be broken, this same marvelous intelligence that has brought us from ovum to adulthood immediately sets about to repair the damage done. A liquid substance is secreted and deposited over the entire surface of the bone in each direction from the point of fracture. This section quickly hardens into a bone-like substance and is firmly attached to the two sections of the bone. Until nature can repair the damage, this "bone ring" forms the chief support whereby the limb can be used. By the same process of cell multiplication which we saw in the healing of the wound, the ends of the bone are reunited. The circulatory channels are re-established through the part. It is then that the "bone ring" support is softened and absorbed, except about an eighth to a quarter of an inch about the point of fracture.

If you strike your finger with a hammer, a very painful bruise is the result. There is an effusion of blood under the surface, with inflammation and discoloration. The tissues are mangled, the cells are broken and many of them are killed. But does the thumb always remain so? No. As time passes, new tissues are formed to replace the dead ones and the dead blood and tissue cells are carried away by the bloodstream. The inflammation subsides, the pain ceases and the bruise is healed and soon forgotten. Thus again is manifested the marvelous intelligence of the power that superintends the workshop which we call our body. Once again we watch its work and see its marvelous efficiency as a workman.

A similar manifestation of the body's self-healing, self-adjusting and self-repairing powers is seen in the common accident whereby a sliver becomes embedded in the flesh. If it is not removed immediately, nature, or vital force, does a skillful little piece of engineering and removes it for us. Pain and inflammation are soon followed by the formation of pus, which breaks down the tissues, towards the surface of the body. Gradually increasing in amount, the pus finally breaks through the overlying skin

and runs out, carrying the sliver along as a souvenir.

A remarkable engineering feat is presented to us in abscess formations. Ordinarily the abscess is limited by a thick protective wall of granulation tissue which prevents the abscess from spreading and prevents rapid escape of the pus into the circulation.

In appendicitis the loops of the bowels around the appendix form friendly adhesions. They adhere together and form a strong wall against further spread of the trouble. Within this enclosure the abscesses form. The line of least resistance normally is into the bowels so that practically every case, if not interfered with by meddling doctors, will rupture into the bowels and the pus will pass out with the stools.

Where the ice bag is employed for one or two days prior to the usual operations, there is a noticeable lack of effort on the part of nature to wall off the appendix from the rest of the abdominal cavity. However, where the ice bag has not been employed, a distinct walling off of the acutely inflamed and gangrenous appendix from the general peritoneal cavity is found. So greatly does the ice bag interfere with the curative and protective operations of nature that one of the leading abdominal surgeons of this country declares: "I have entirely discarded the use of the ice bag, and in cases brought to me in which it has been used, I always announce beforehand that I expect to find a gangrenous appendix and am seldom surprised. *Clearly the ice bag should never be used in cases of actual or suspected appendicitis.*" Nature can do her own work in her own way, and all our so-called aiding of nature amounts to is nothing more than meddling and pernicious interference.

Acute inflammation of the liver usually terminates in resolution, but sometimes it terminates in suppuration with abscess formation. This is more apt to be the case in hot climates. The amount of matter discharged from an abscess of the liver is sometimes enormous, and it is wonderful to see in what ways nature operates in getting rid of it.

There are several channels through which the pus may be sent out of the system. The inflammation may extend upward until an adhesion to the diaphragm is accomplished. A dense wall of scar tissue is first formed around the abscess. The abscess then extends through the diaphragm to the lungs, which become adherent to the diaphragm. Liver, diaphragm and lungs form one solid piece. A tight union of these organs prevents the pus from pouring into the peritoneal or pleural cavities. A hole is eaten through the lung and the pus is poured into a bronchial tube and is coughed up, emptying the abscess and leaving a clean hole. The wall of scar tissue thrown up around the path of the abscess grows stronger and contracts until, finally, only the scar remains, it having closed the hole, and the patient is well.

The abscess may be directed downward or to the side of the liver. In such a case the process is the same except the liver becomes united to the stomach, the intestines or the walls of the abdomen by adhesions produced by inflammation. If it adheres to the stomach or intestine, the abscess will perforate into these and the pus will pass out in the stools. If it becomes adherent to the wall of the abdomen, the abscess will "come to a head" under the skin and the pus will be discharged on the surface of the body. In either case cicatrization follows and the patient is well. In some cases the abscess discharges into the gallbladder and passes from there into the intestine. It has also been known to "point" on the back.

It sometimes happens in weak individuals that nature is not able to make proper connections along the line of march and the pus ends up in the pleural cavity, resulting in empyema, or in the abdominal cavity, where it results in peritonitis and, usually, death.

Another daring engineering feat is often accomplished by nature in the case of gallstones that are too large to pass through the bile duct directly into the small intestine. She frequently causes the gallbladder to adhere, by means of inflammation, to the wall of the intestine. An ulcer forms, making a hole through both the wall of the gallbladder and the wall of the intestine. The stone slips through into the intestine and passes out with the stools. The hole heals up and all is well again. In other cases the stone may be sent out through the abdominal wall and skin, on the outside of the body.

An unusual piece of engineering which shows, in a remarkable manner, the ingenuity of nature in her

efforts at prolonging life in spite of every obstacle, is recorded by J. F. Baldwin, A.M., M.D., F.A.C.S., in a surgical paper dealing with blood transfusions. He performed an operation on a middle-aged woman who had been having frequent hemorrhages from her bowels for several years. He says:

*At the operation I removed a snarl of small bowel, making the usual anastomosis. Examination of this snarl showed that there had been an intestinal obstruction, but nature had overcome it by ulceration between adherent loops of the bowel above and below the obstruction. The ulcer persisted, however, and it was its persistent bleeding that caused her anemia. She made an excellent recovery and got fat and hearty.*

It looks like a real intelligence at work when nature causes two folds of the bowels to adhere together and then ulcerates through them in order to make a passage around an obstruction. There cannot be the slightest doubt that the ulcer would have healed, leaving a passage, and the bleeding stopped, had the opportunity been afforded it. Nature probably cried out day after day in unmistakable language for the cessation of feeding long enough for her to complete her engineering feat. But this was never given her. The ulcerated surface was kept constantly irritated with food, and drugs as well.

Abscesses everywhere in the body are limited and walled off by the formation of a thick wall of granulation tissue. Gangrene is also walled off in the same manner. The necrosed portion then sloughs off; nature grows new tissue to take the place of the destroyed tissue and the place is healed.

Encapsulation is the process of surrounding a body or substance with a capsule. A cyst or capsule consists of a cavity lined according to its origin by endothelium (in preexisting cavities of connective tissue—exudation cysts) or epithelium (in pre-existing epithelial cavities—retention cysts) with a fluid or semifluid content.

Those of chief interest to us here are known as *distention cysts* and are divided into:

(a) Retention cysts, which are due to the obstruction of the excretory ducts of glands. The cavity becomes filled with the secretion of the gland which later becomes altered and circumscribed by a fibrous wall. These may develop in any glandular structure, as pancreas, kidneys, salivary glands, mammary glands, sebaceous glands (wens).

Around a foreign body like a bullet, such a capsule forms. There is first inflammation and perhaps suppuration. But if this fails to remove the bullet, a capsule of tissue also containing fluid is formed, and the bullet is rendered innocuous. A similar thing frequently happens in the lungs in the case of germs. Rausse thought this fluid was a variety of mucus and thought that chemical or drug poisons were enveloped in this same "mucus" to render them harmless and that they were then deposited in the tissues. He says with regard to the fact that this theory cannot at present be demonstrated:

*This theory is founded upon the incontrovertible principle of nature in the alimentary and organic world, that nature operates similarly under similar circumstances. Hence, the theory here offered loses none of its certainty because we are unable to recognize with the unaided eye, on account of their minuteness, the inimical atoms and the minute network around them, and to exhibit them by section.—Water Cure Manual, p. 92, 1845.*

The encapsulation of exudates, excretions, extravasations, disintegrating tissues, germs, parasites, bullets and other foreign bodies renders them harmless. The process and structure it evolves are plainly defensive measures. They once more remind us of the many and varied emergency measures the body has at its command.

The formation of gallstones and other stones is in itself an engineering feat that serves a useful purpose and even extends and saves life. In the lungs, for instance, in those who have tuberculosis, the affected spots are often the seat of the formation of stones. When this takes place, the disease in that part ends. Medical authorities consider that nature employs this means to wall up the tubercle bacilli.

The formation of stones in the gallbladder and kidneys, just as in the lungs, is the end result of

inflammation and undoubtedly serves a definite and useful purpose. Sometimes, it is true, they are made so large that they are the source of much trouble, but it is safe to assume that they are never made larger than the gravity of the situation demands. Most gallstones are small enough that they pass out without causing pain, and the individual is never aware that he or she has had them. A large number of people examined at autopsies are found to have gallstones in the gallbladder and were never aware that they had them. They never cause trouble until they go to pass out and only then if they are small enough to get into the gall duct but too large to make the entire passage. A stone that may easily travel through the common duct may be forced, with extreme difficulty, through the small opening of the duct into the intestine. This causes severe pain. As soon as the stone is forced through, the pain ceases. (The sufferer then thinks that it was the last treatment he employed that relieved the pain and "cured" his troubles.)

A *thrombus* is a small blood clot formed inside a blood vessel. The condition is called *thrombosis* and the vessel is said to be *thrombosed*. They are the result of injury and inflammation and may completely plug the vessel.

In the intestines are many small glands composed of lymphoid structure just as are the tonsils of the throat. They are known as Peyer's patches. In typhoid fever these patches are swollen or enlarged (hypertrophied), and frequently they suppurate. They may slough off. This peeling off may result in a hemorrhage or it may not, depending on whether or not all the vessels in that locality are tightly *thrombosed*. If they are all tightly *thrombosed*, no hemorrhage occurs. If the work of sealing the vessel is not complete or perfect, then a hemorrhage occurs with more or less loss of blood before it finally ceases. This is but another evidence of nature's engineering work. These *thrombi* may later be swept into the general circulation and carried to some vital spot where they are too large to pass through the artery and may there cut off the blood to parts of the organ, causing it to die of starvation. Starvation would only occur in cases of stopping of an "end artery."

"Anastomosing" arteries would soon establish sufficient collateral or compensatory circulation to supply the part with blood.

If heat or friction of sufficient intensity and duration is applied to the skin, a blister forms; that is, a watery exudate or serum is poured out of the surrounding tissues and circulation into the "space" between the dermis and epidermis and detaches the dermis from this, raising it up and thus protecting the tissues beneath. The accumulated fluid holds back the heat or, in the case of sunburn, the actinic rays, and protects from the friction. This little piece of engineering work is quite obviously a defensive work. In both burns and sunburn, inflammation and healing follow the blister, and in the case of sunburn pigmentation occurs to protect from future sunburn.

Of a similarly defensive nature are corns and callouses that form on the feet and hands or any other surface of the body that is subjected to constant friction. The clerk who deserts the store for manual labor finds his hands are tender and blister easily when he handles tools. However, before many days have passed, the skin on his hands has become thickened and hardened, ultimately becoming almost horn-like. When this occurs, he finds that no reasonable amount of hard work blisters his hands.

Tumors likely begin in this same manner. They probably begin as hardening and thickening of the tissues at a point of irritation as a means of defense.

Hardening and thickening of the tissues occurs in any and all parts of the body to resist constant irritation. This can be seen in the mouth, stomach and intestines of those who employ salt and condiments. It is seen in the constant use of drugs. Silver nitrate, for instance, if repeatedly employed, converts the mucous surface upon which it is used into a kind of half-living leather. Other organs harden and thicken as a result of toxic irritation. Toxemia, with or without the aid of external irritation, often necessitates, at certain points of the body, the erection of greater than ordinary barriers against it. When the normal cells of a local spot become so impaired that they no longer successfully resist the encroachment of toxins, not only are the usual defense processes brought into activity, but also, since a more than usual condition is to be met, nature calls into play her heavier battalions. She begins by erecting a barrier of connective tissue cells. Then, with a slowly-yielding fight against the toxins, she

continues to erect her barriers. This may continue until the tumor becomes so large as to constitute a source of danger itself. Were it not for the erection of this barrier, the causes against which it is erected would destroy life long before they ultimately do. The tumor actually prolongs life.

A process similar to this is seen in plants that have been invaded by parasites. The large, rough excrescences seen on oak trees form about the larva of a certain fly. This fly lays its eggs beneath the bark of the tree. The larva which develop from the eggs secrete a substance that results in the formation of the huge tumorous mass. Large tumor-like masses form on the roots and stalks of cabbages as a result of parasitic invasion. The olive tree also develops tumors from a similar cause, while cedar trees present peculiar growths called "witches' brooms" as a result of a fungus growing on them. There are many other examples, and they are all quite obviously protective measures. Tumor formation is undoubtedly due to a variation in the complex relations determining normal growth and is of a distinctively protective nature. A tumor is not a source of danger until it begins to break down.

In inflammation of the kidneys due to the impairment of kidney function, the normal constituents of the urine are decreased. They remain in the blood instead of being eliminated. Due to the necessity of removing from the circulation, the salts, etc., that are normally eliminated through the kidneys, and due also to the necessity of keeping these in dilute solution so long as they remain in the body, and to the equal necessity of removing them from the circulation, dropsy develops in various portions of the body, particularly in the tissues immediately under the skin. It may also collect in the cavities of the body. When kidney function is restored, the dropsical fluid is gradually absorbed into circulation and eliminated.

An aneurism is an inflated portion of an artery. If the walls of an artery become weak at a given place, they either burst, some of its coats are strengthened or else it becomes bulged out due to the pressure of the blood from within. The body at once sets about to protect itself by forming a vail of new tissue around the aneurism. Should it rupture so that the blood finds its way along between other organs, a wall of scar tissue is thrown up around the aneurism to limit the escape of blood. This is called a dissecting aneurism.

Thus we might continue giving example after example of the wonderful engineering feats of the body and show with what marvelous powers and works it meets emergencies and protects its own vital interests. When we consider the wonderful mechanism of the human body, the certainty with which all organs perform their allotted work, the marvelous ingenuity with which the body meets emergencies, its almost limitless powers of repair and recuperation, we develop a large respect and admiration for the healing powers of the body and learn to view with contempt and disgust the means that people employ in unintelligent efforts to "cure."

Well did Jennings affirm:

But at every step of her (nature's) downward progress (in the face of pathoferic causes she cannot overcome), her tendency and effort have been to ascend and remount the pinnacle of her greatness; and even now, in the depth of her degradation, the tendency of all that remains of her, of principle or law, power and action, is still upwards.

### 1. Introduction

Before embarking on a study of carbohydrates—their role in the body, their sources, etc., we will begin by highlighting the importance of carbohydrates, defining what carbohydrates are and learning how they are formed, as well as glimpsing at a brief history of carbohydrates in the human diet.

#### 1.1 The Importance of Carbohydrates

As mentioned in the RATIONALE earlier in this lesson, even the process of digestion could not occur without the energy provided by carbohydrates. Without carbohydrates we would not be able to think or move and our heart couldn't beat.

Whether it be digestion or circulation, thinking or walking, all life activities are dependent upon carbohydrates. When insufficient carbohydrates are available from the diet, the body converts fat reserves to carbohydrates for its use, and amino acids are utilized as carbohydrates instead of being used to make body protein.

#### 1.2 What Are Carbohydrates?

As the lesson title implies, carbohydrates provide fuel, or energy, for the human body. These organic (carbon-containing) compounds are an integral part of both plant and animal life, and, as stated above, life as we know it could not exist without them.

Carbohydrates are made up of three elements: carbon, hydrogen and oxygen—carbohydrates. As you will learn in a later lesson, fats are also comprised of carbon, hydrogen and oxygen, but they have less oxygen and more carbon and hydrogen than carbohydrates.

Carbohydrates, along with proteins and fats, comprise the major components of living matter and are used for maintenance of cellular functional activities and as reserve and structural materials for cells. Because they are the primary source of energy for the animal kingdom, carbohydrates are particularly important in a study of nutritional science.

### **1.3 How Carbohydrates Are Formed**

Carbohydrates are formed by green plants in the process of photosynthesis. In photosynthesis, plant chlorophyll, plant enzymes, sunlight, carbon dioxide from the air, and mineralized water from the soil combine and, in a complicated process, synthesize carbohydrates. Humans obtain their carbohydrate needs most efficiently from the plant world.

### **1.4 Carbohydrates: Past and Present**

In the past and in some parts of the world today, people's diets consisted largely of carbohydrate foods, especially those growing locally. In most of the Western world today, however, meats and other protein/fat foods comprise a disproportionate part of the diets of many people, and processed and refined carbohydrate products are being consumed in lethal quantities.

While people do survive, at least for a relatively short lifespan, on diets high in proteins and refined carbohydrates, this survival is low-level survival, with suffering from illnesses of numerous varieties being considered the norm. A high-level state of health and well-being is possible only if our needs are met in keeping with our biological adaptation and if destructive practices are removed from our lives. The further we carry this, the healthier and happier we will be, for joy is supposed to be our primary experience in life— not suffering.

During the past 70 years or so, more and more food processing and refining establishments have been created, and they are producing horrendous quantities of highly-refined, highly-processed and highly-chemicalized so-called "foods." An extremely large proportion of these "foods" are carbohydrates—that is, they provide energy in the form of calories. But they are not real foods because they lack many of the elements from the original food source that make a food a food. For example; the germ and bran are removed from wheat, leaving only starch; and the vitamins, minerals and fiber that need to be with the starch to make the wheat a whole food are missing. Removing natural food components and then attempting to put them back by adding specified amounts of synthetic vitamins and minerals, by using bran separate from the whole wheat berries, and by taking food supplement pills and powders is the height of absurdity. First of all, it's not effective, and secondly, it's expensive, time-consuming and, most of all—UNNECESSARY!

Even physiology texts, which are medically oriented rather than health oriented, say that a casually selected diet of carbohydrates is likely to be poor in the essential amino acids, vitamins and minerals. Life Scientists/Natural Hygienists recognize the necessity of high-quality carbohydrates in the diet and the need to eschew the products marketed by the food industries; Hygienists advocate a return to a high-carbohydrate diet consisting of whole foods, with fiber intact, that provide our needs for complete proteins, vitamins and organic minerals.

## 2. Classification Of Carbohydrates

Carbohydrates, also known as *saccharides*, are classified according to the number of single carbohydrate molecules in each chemical structure. Carbohydrate compounds having just one carbohydrate molecule are called *monosaccharides*; compounds with two carbohydrate molecules are called *disaccharides*; and those compounds containing more than two carbohydrate molecules are named *polysaccharides*. All carbohydrates either are monosaccharides or can be hydrolyzed (broken down) into two or more monosaccharides.

For further understanding of these different classifications of carbohydrates, the monosaccharides and disaccharides can be grouped together and compared with the polysaccharides. This can be done because monosaccharides and disaccharides have certain things in common.

For one, they are both water soluble. In addition, they have a sweet taste and a crystalline structure. The monosaccharides and disaccharides are called *sugars* and all share the suffix, *-ose*, meaning *sugar*.

Polysaccharides, in contrast to mono- and disaccharides, are insoluble in water, do not taste sweet and do not form crystals. Also, they do not share a suffix and have no group name (such as sugars, in the case of mono- and disaccharides). They are sometimes called starches, but this is technically incorrect because there are many other classifications of polysaccharides besides starches (cellulose and glycogen being two and dextrin being another).

### 2.1 Monosaccharides

These are the only sugars that can be absorbed and utilized by the body. Disaccharides and polysaccharides must be ultimately broken down into monosaccharides in the digestive process known as *hydrolysis*. Only then can they be utilized by the body. Three monosaccharides are particularly important in the study of nutritional science: glucose, fructose and galactose.

### 2.2 Glucose (also known as dextrose or grape sugar)

This monosaccharide is the most important carbohydrate in human nutrition because it is the one that the body uses directly to supply its energy needs. Glucose is formed from the hydrolysis of di- and polysaccharides, including starch, dextrin, maltose, sucrose and lactose; from the monosaccharide fructose largely during absorption; and from both fructose and galactose in the liver during metabolism.

Glucose is the carbohydrate found in the bloodstream, and it provides an immediate source of energy for the body's cells and tissues. Glucose is also formed when stored body carbohydrate (glycogen) is broken down for use.

In the plant world, glucose is widely distributed. It is found in all plants and in the sap of trees. Fruits and vegetables are wholesome food sources of glucose. It is also present in such unwholesome (to humans) substances as molasses, honey and corn syrup.

### 2.3 Fructose (also known as levulose or fruit sugar)

Fructose, a monosaccharide, is very similar to another monosaccharide, galactose. These two simple sugars share the same chemical formula; however, the arrangements of their chemical groups along the chemical chain differ. Fructose is the sweetest of all the sugars and is found in fruits, vegetables and the nectar of flowers, as well as in the unwholesome (to humans) sweeteners, molasses and honey. In humans, fructose is produced during the hydrolysis of the disaccharide, sucrose.

## **2.4 Galactose**

Galactose differs from the other simple sugars, glucose and fructose, in that it does not occur free in nature. It is produced in the body in the digestion of lactose, a disaccharide.

## **2.5 Disaccharides**

Disaccharides, on hydrolysis, yield two monosaccharide molecules. Three particular disaccharides warrant discussion in a lesson on nutritional science: sucrose, maltose and lactose.

## **2.6 Sucrose**

The disaccharide, sucrose, consists of one molecule of each of two monosaccharides—glucose and fructose. Sucrose is found in fruits and vegetables and is particularly plentiful in sugar beets (roots) and sugarcane (a grass). Refined white and brown sugars are close to 100% sucrose because almost everything else (including the other kinds of sugars present, the vitamins, the minerals and the proteins) have been removed in the refining process. Maple syrup and molasses are, like refined sugars, unwholesome sweeteners; both contain over 50% sucrose. It almost goes without saying that any foods, so-called, containing significant amounts of refined sugar are high in sucrose.

## **2.7 Maltose (also known as malt sugar)**

This disaccharide, unlike sucrose, is not consumed in large amounts in the average American diet. It is found in malted cereals, malted milks and sprouted grains. Also, corn syrup is 26 percent maltose and corn sugar is 4 percent maltose. None of these "foods" is wholesome, with perhaps, the exception of sprouted grains.

Maltose occurs in the body as an intermediate product of starch digestion. (Starch is a polysaccharide.) When maltose is hydrolyzed, it yields two molecules of glucose.

## **2.8 Lactose (also known as milk sugar)**

This disaccharide is found only in milk. Human milk contains about 4.8 g per 100 ml and cow's milk contains approximately 6.8 g per 100 ml. When lactose is hydrolyzed it yields one unit of the monosaccharide glucose and one unit of the monosaccharide galactose. The enzyme lactase is needed to digest lactose, and this enzyme is not present in most, if any, people over age three. This is one of the many reasons why milk is an unwholesome food for people over three years of age.

## **2.9 Polysaccharides**

Like the disaccharides, the polysaccharides cannot be directly utilized by the body. They must first be broken down into monosaccharides, the only sugar form the body can use.

Polysaccharides contain up to 60,000 simple carbohydrate molecules. These carbohydrate molecules are arranged in long chains in either a straight or in a branched structure. There are four polysaccharides that are important in the study of nutritional science: starch, dextrin, glycogen and cellulose.

## **2.10 Starch**

Starch is abundant in the plant world and is found in granular form in the cells of plants. Starch granules can be seen under a microscope and they differ in size, shape and markings in various plants. The starch granules of wheat, for example, are oval-shaped; whereas the starch granules of corn are small, rounded and angular.

These starch granules are laid down in the storage organs of plants—in the seeds, tubers, roots and stem pith. They provide a reserve food supply for the plant, sustain the root or tuber through the winter and nourish the growing embryo during germination.

Most starches are a mix of two different molecular structures, amylose and amylopectin. The former has a linear structure and the latter has a branched or bushy structure. The proportion of the two fractions varies according to the species of plant. For example, potato starch and most cereal starches have approximately 15-30% amylose. But the waxy cereal grains, including some varieties of corn plus rice and grain sorghum, have their starch most entirely as amylopectin. The starches in green peas and in some sweet corn varieties are mainly amylose.

The polysaccharides, as mentioned earlier, are not water soluble as are the mono- and disaccharides. Though not water soluble, starches can be dispersed in water heated to a certain temperature. The granules swell and gelatinize. When cooled, this gelatin sets to a paste. The jelling characteristics of starches are considered to result from the amylose present, while amylopectin is considered to be responsible for the gummy and cohesive properties of the paste.

## **2.11 Dextrin**

There are several "varieties" of this polysaccharide. Dextrins are most commonly consumed in cooked starch foods, as they are obtained from starch by the action of heat. Dextrins are intermediary products of starch digestion, also, and are formed by the action of amylases on starches. They render the disaccharide maltose on hydrolysis.

## **2.12 Glycogen**

Glycogen is the reserve carbohydrate in humans. It is to animals as starch is to plants. Glycogen is very similar to amylopectin, having a high molecular weight and branched-chain structures made up of thousands of glucose molecules. The main difference between glycogen and amylopectin is that glycogen has more and shorter branches, resulting in a more compact, bushlike molecule with greater solubility and lower viscosity (less stickiness or gumminess).

Glycogen is stored primarily in the liver and muscles of animals. About two-thirds of total body glycogen is stored in the muscles and about one-third is stored in the liver.

## **2.13 Cellulose**

Like starch and glycogen, cellulose is composed of thousands of glucose molecules. It comprises over 50% of the carbon in vegetation and is the structural constituent of the cell walls of plants. Cellulose is, therefore, the most abundant naturally-occurring organic substance. It is characterized by its insolubility, its chemical inertness and its physical rigidity. This polysaccharide can be digested only by herbivores such as cows, sheep, horses, etc., as these animals have bacteria in their rumens (stomachs) whose enzyme systems break down cellulose molecules. Humans do not have the enzyme needed to digest cellulose, so it is passed through the digestive tract unchanged.

### **3. The Role Of Carbohydrates In The Body**

Five subheadings follow in this lesson subdivision, but there is actually only one basic role of carbohydrates in the human diet: to supply energy. It should always be kept in mind that carbohydrates or calories alone cannot adequately supply our energy needs, for we must have our carbohydrates in combination with other needs, such as proteins, water, vitamins, minerals, fats, etc. This means that a diet of refined sugar, refined rice, flour products and other "food fragments," though it supplies calories, cannot satisfactorily comprise the bulk of anyone's diet. A person on such a diet would suffer many problems, for the organism is not capable of living long or well on bare carbohydrates alone. They must be obtained in combination with the other essential food factors to be truly useful in the overall energy production and nutrition of the organism.

#### **3.1 Carbohydrates Supply Energy**

The body uses carbohydrates directly from the monosaccharide glucose. Glucose is in the blood and extracellular fluids (lymph) and can be made from glycogen. Glycogen is stored in the liver and muscles and in smaller amounts in the other organs and tissues of the body. Energy is derived from glucose by the splitting of the glucose molecules into smaller compounds and oxidizing these to form water, which frees quite a large amount of energy.

When carbohydrates needed for the functioning of the central nervous system, the muscles and the other body systems and functions are insufficient in the diet (as during a fast or on a weight-loss diet), stored adipose tissue (fat) is broken down into glucose to make up the caloric deficit. Some amino acids, instead of being used to make proteins, are deaminated and used as carbohydrates to supply energy. The formation of glucose from amino acids is called gluconeogenesis. This phenomenon enables one to maintain normal blood sugar levels during a fast.

Practically the entire fat store of the body can be used up without detriment to health. Because of this fact, and the fact that the body can also create carbohydrates from amino acids, fasting is a very safe practice from the standpoint of maintenance of normal blood sugar levels, of normal neurological functioning and of meeting all the body's various energy needs.

#### **3.2 Carbohydrates Provide Fuel for the Central Nervous System**

Nerve cells are very dependent upon glucose for their functioning. According to physiology texts, the glycogen in nervous tissues remains constant and is not mobilized for conversion to glucose. When insufficient carbohydrates are consumed to meet the energy needs of the central nervous system, besides the occurrence of gluconeogenesis, another phenomenon occurs during a fast of three weeks or more: The cells of the central nervous system adapt their metabolic apparatus to use ketone bodies in place of glucose. (Ketone bodies are substances synthesized by the liver as a step in the metabolism of fats.) The nerve cells obtain their needed functional energy from these metabolites. This explains why patients with blood sugar problems (diabetes or hypoglycemia) do not suffer ill effects during a fast. In fact, they benefit by fasting. (This topic will be discussed in depth in a later lesson.)

#### **3.3 Carbohydrates Provide Fuel for the Muscular System**

Carbohydrates provide the major fuel for muscular exercise. Fats and proteins can be used only indirectly—by first being converted into carbohydrates. For this reason, a proper diet should consist primarily of carbohydrates—not primarily of proteins and fats as are commonly consumed in conventional nonvegetarian (and some lacto- and lacto-ovo vegetarian) diets.

The muscles use the glycogen present in the muscle cells and glucose in the bloodstream. However, glycogen from the muscles is more efficiently used than glucose because the breakdown of glycogen for use does not require energy input at the time, whereas a certain amount of energy is used to bring the blood sugar into the metabolic system of the muscles. (It does require energy to build up the glycogen supply in the first place, but this happens during periods of rest when plenty of energy is available.)

If a diet high in carbohydrates is not consumed, tremendous muscular exertion over long periods and/or extreme and prolonged stress (as being stranded for weeks in Antarctica) can result in accelerated breakdown of body protein and stored body fat. The protein breakdown is evidenced by an increased excretion of nitrogen in the urine, and the fat breakdown is evidenced by a rise in the level of ketone bodies in the urine and in the blood. The blood sugar level is simultaneously lower.

The body works much more efficiently from carbohydrate intake than from broken-down body protein and fats because protein and fat molecules, when used as fuel, yield less than their total caloric value in the form the muscles can use. The remaining portion is used for the conversion of these molecules into suitable fuel. This conversion takes place in the liver and adipose tissue, which supply the body's organs with fuel via the bloodstream.

The fact that the body can and will use body fats and proteins when the supply and stores of blood sugar and glycogen are not great enough to meet the demand for energy exemplifies two facts: 1) The organism is provident. It has many back-up arrangements for survival in emergency situations when sufficient carbohydrates are not available. 2) An appropriate balance between supplying body needs (such as rest and carbohydrates) and expending energy (muscular, nervous or other) should be strived for to attain optimum health and well-being.

It has been found that people who are accustomed to doing prolonged or strenuous work have larger stores of glycogen (and of phosphate esters) in their muscles than those not accustomed to much physical activity. It is, therefore, beneficial to do regular vigorous exercise to increase our storage of muscle glycogen. We will then be prepared to expend energy for longer and more strenuous exercise—whether it be in an emergency or in pursuing pleasure.

### **3.4 Carbohydrates Supposedly Spare Proteins**

Physiology textbooks refer to this so-called role or function of carbohydrate in the body as "its protein-sparing action." However, it is incorrect to attribute action (other than chemical action) to carbohydrates or other inanimate substances. Besides, "sparing protein" is not a function or role of carbohydrates at all. Carbohydrates simply furnish our fuel or energy needs—and nothing more.

What is being said in the textbooks is that proteins consumed will be used for tissue building and maintenance rather than being used as an emergency source of energy as long as the carbohydrate intake is sufficient. This is true, but it is only another way of saying that carbohydrates are the primary and most efficient source of energy or fuel and that it is best not to try to meet our fuel needs from proteins. It is stating the true fact that carbohydrates, not proteins, supply our primary nutrient needs.

"Sparing proteins" is not a separate and distinct function or role of carbohydrates any more than preventing scurvy is a separate and distinct function of vitamin C in the body. Vitamin C supplies body needs, but its role is not prevention of scurvy or of anything else. Viewing nutrients as preventative agents of diseases is another way of saying that diseases are normal, that they are an inevitable part of life that will and must occur unless prevented by the proper nutrients. That is a backwards way of viewing health—it's the disease approach, or the medical approach. Just as good things happen to us if we think positive thoughts and visualize success, harmony, etc., good health will exist as long as we live healthfully—and that includes consuming the correct amounts of the foods to which we were biologically adapted in nature to eat.

In short, the so-called "protein-sparing action" of carbohydrates is not only not an action, but sparing proteins is not a distinct role of carbohydrates separate from their energy-providing role.

### 3.5 Carbohydrates Supposedly Supply "Dietary Fiber"

"Dietary fiber" is a fairly new term coined to describe the cellulose inside plant cells. Cellulose is known to be indigestible by humans, though it is digested and used for energy by herbivores. The claims made about "the beneficial role of dietary fiber in preventing diseases" are so popular and so widely made that they are practically accepted as fact. However, cellulose, though in fact a carbohydrate because it is utilized as such by herbivores, does not serve the role of a carbohydrate in human physiology. Because it cannot be digested and utilized by humans, it cannot provide us with energy—and providing energy is the only role of carbohydrates in human nutrition.

The above statements may come as a surprise to most readers—but read on and we'll clarify further.

It has been observed that certain so-called primitive tribes in Africa and elsewhere who consume diets high in fiber are less likely to develop certain colon diseases and metabolic disorders than their kinsmen who live in urban areas and eat low-fiber foods similar to those consumed in so-called developed countries. Based on the high correlation between low-fiber diets and human gastrointestinal diseases, many hospitals and clinics have changed their dietary management of diverticulosis. They are experiencing good results with a diet containing more instead of less cellulose.

We do not deny that high-fiber diets are more wholesome as a rule than low-fiber diets, nor do we deny the fact that people who consume diets closer to nature and therefore higher in fiber (cellulose) have fewer gastrointestinal diseases and a lower rate of bowel cancer. What we argue against is the thinking that the fiber itself is primarily responsible for the prevention of these diseases and disorders.

Since cellulose is indigestible, it cannot be utilized by the body as a nutrient. It is simply passed through with the other wastes. Its presence or absence in the feces is insignificant. What is significant is how much and what kinds of toxins are there (and elsewhere). The ingestion of too many toxins from all sources, as well as the retention of toxic wastes produced within the body, results in diseases. The presence or absence of indigestible plant fibers does not prevent or cause diseases.

Processed, highly-refined, so-called foods (they do contain carbohydrates) do not deserve the label *foods* because they are not *whole foods*. Parts of processed foods are missing—they were removed intentionally in the refining process. (Fiber [cellulose] is one of those missing parts.) This makes them incomplete or fragmented foods. Eating fragmented foods results in problems in the body. Therefore, they should not be eaten.

Refined sugar and products containing refined sugar, as well as refined flour products, are the most salient examples of processed food fragments that produce toxic effects in the body. Being devoid of vitamins and minerals in their natural form (the only form they can be used in), these products are like drugs within the body. In addition, calcium and other minerals, as well as B vitamins, must be utilized by the body to metabolize refined products. Because the refined products are devoid of nutrients except carbohydrates, calcium is taken from the bones.

Most "civilized" diets contain cooked foods, foods not normal to humans, refined and processed foods and drugs and medications. Refined sugar, flours, white rice and processed cereals are some of the worst culprits, but there are many, many more sources of toxins in the diet. Also, incompatible food combinations result in the production of toxins in the stomach and elsewhere in the digestive tract, and these toxins also contribute to gastrointestinal disturbances and diseases.

Much more could be said about the sources of toxins within the body that result in disease, but this has been discussed in previous lessons and will also be further discussed in future lessons. For now, it is sufficient for us to explain that low-fiber diets not only lack the natural cellulose which should be left intact in the whole food, but they also contain or give rise to a host of toxins that result in disease conditions. It is not the lack of fiber itself that causes diverticulosis and other gastrointestinal problems but the overall unwholesomeness of the foods ingested in so-called civilized society. (Of course, you should understand that what is eaten is only part of the picture and that how it's eaten, how much is eaten, the amount of exercise, sleep, fresh air, etc., indulged are also important factors in human

nutrition.)

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 4. How Carbohydrates Are Digested And Used By The Body

## 4. How Carbohydrates Are Digested And Used By The Body

### 4.1 Introduction to Digestion

Before discussing carbohydrate digestion in particular, let's give a little attention to digestion in general. Complete and thorough digestion of foodstuffs is extremely important for good health. A tremendous amount of toxin elimination and accumulation puts a great stress and burden upon the organism and results in a large variety and number of diseases. This happens both directly, from the presence of accumulated toxic substances that the body was unable to eliminate, and indirectly, from a decrease in the body's digestive capabilities due to overworking the digestive system and depleting the body's supply of vital energy.

It is, therefore, important for us to do everything we can to insure thorough and complete digestion of all foods eaten. This can be done by eating primarily (or only) easily digested and uncomplicated foods such as fruits; by eating compatible combinations of foods; by eating moderate amounts of foods; by eating at well-spaced meals; by abstaining from drinks during or too soon before or after meals; and by refraining from eating while under stress or emotionally upset.

One of two things happens to foods that do not get thoroughly or completely digested: 1) Sugars may ferment or 2) proteins may putrefy (rot). These processes result from bacterial activity which breaks down (decomposes) undigested or undigestible foods in preparation for their elimination from the body. The "trick" to, getting nourishment (nutriment) from the foods you eat is to see to it that they, get digested quickly, before the bacteria (present within every healthy digestive tract) have a chance to decompose them. The results of bacterial decomposition are toxic and do not provide nourishment. Foods that don't digest relatively soon after ingestion will ferment or putrefy and contribute to body toxicity and disease.

Keeping the above facts about digestion in mind, let's take a look now at carbohydrate digestion.

### 4.2 Salivary Carbohydrate Digestion

Disaccharides and polysaccharides must be digested before the body can use them, while monosaccharides do not require digestion. For this reason, as well as for other reasons (to be discussed in depth later in this lesson), our best source of carbohydrates is from fruits. Fruits require much less of the body's energies and render primarily monosaccharides that, as stated, need no digestion.

Digestion is both a mechanical process (chewing) and a chemical process (enzymic actions). The class of enzymes that hydrolyze carbohydrates are broadly known as *carbohydrases*. We will be concerned in this lesson with carbohydrases known as *amylases*.

While the digestion of all types of foods (proteins, carbohydrates, fats, etc.) begins in the mouth with the mechanical process of mastication, certain carbohydrates—namely, starches and dextrins—are the only food types whose chemical digestion begins in the mouth. Here an enzyme known as *salivary amylase* or *ptyalin*, secreted by the *parotid glands*, is mixed with the food during the chewing process and begins the conversion of glycogen, starch and dextrins into the disaccharide maltose.

What happens when the starches, dextrin, and glycogens that were not converted to maltose in the mouth and what happens to the maltose when these carbohydrates reach the stomach depends upon several factors—what other types of foods are eaten with the starch, how much food is being eaten and how fast, the emotional condition of the eater and the condition of the eater's digestive system. If a relatively uncomplicated starch such as potatoes or yams is eaten alone or with nonstarchy vegetables, and no proteins (as meats, cheese or milk, or even nuts or seeds or acids (as tomatoes, lemon or lemon juice or vinegar—as in salads or salad dressings) are consumed with the starchy food, salivary amylase (ptyalin) can and will continue the digestion of starches and dextrins in the stomach for a long period.

For thorough digestion and consequent good health, this continuation of starch digestion by ptyalin in the stomach is a necessity. Therefore, for good health, it is important to consume starchy foods at separate meals from protein foods and acids. (This and other facts relative to the topic of food combining for good digestion will be discussed in depth in later lessons.)

Briefly stated, ingestion of protein foods causes a secretion of hydrochloric acid in the stomach, and hydrochloric acid destroys ptyalin; that is, it destroys the amylase activity and substitutes acid hydrolysis. Physiology texts state that "if this acid hydrolysis was continued long enough it could reduce all the digestible carbohydrates to the monosaccharide stage. However, the stomach empties itself before this can take place."

The acids of tomatoes, berries, oranges, grapefruits, lemons, limes, pineapples, sour grapes and other sour fruits and the acid of vinegar will, like hydrochloric acid, destroy our only starch-splitting enzyme, ptyalin. Therefore, these foods also inhibit starch digestion. For good digestion and consequent good health, acids should not be eaten at the same meal with starches.

Another factor that can impair salivary starch digestion is the drinking of water or other liquids with or too soon before or after meals. Water or other liquids do not aid in the digestion of foods. On the contrary, they interfere with digestion by diluting the digestive juices and cause them and their enzymes to be passed through the digestive tract too quickly for digestion to occur.

To summarize this aspect of starch digestion, taking proteins, acids, water or other liquids with starches interferes seriously with their digestion by the salivary amylase, ptyalin. This first stage of starch digestion is of great importance because there is a great likelihood that the food will be acted upon by bacteria and ferment before it reaches the intestine where further starch digestion can take place. Digestion, rather than fermentation and its resulting toxic byproducts, is much more likely to occur soon after the food is put into the mouth than further along in the digestive tract.

From the above, you can see why thorough mastication of food is so important when starches are eaten. No one who seeks health should eat starches in a hurry, nor should they have them with a beverage or with proteins or acids, for good digestion of foods is imperative for good health.

A special note should be made here about glycogen—animal starch. Glycogen should not be consumed by health seekers because much disease results from the ingestion of animal flesh and animal products. This will be discussed in depth in later lessons. For the purposes of this lesson, suffice it to say that glycogen ingested cannot be digested in the stomach because, of the hydrochloric acid that will be secreted to digest the protein, which is the primary nutritive component of foods that contain glycogen. Therefore, whatever glycogen that is not converted to a disaccharide by the salivary amylase, ptyalin, must be converted in the intestine. The likelihood of the glycogen reaching the intestine without fermenting before it can get there is small. This is just one of the many hazards of consuming animal flesh and animal foods.

### **4.3 Starch Digestion in the Intestine**

Now that we have discussed starch digestion by the enzyme ptyalin, let's get into starch and sugar (disaccharide) digestion in the intestine.

Whatever carbohydrates make it to the intestine quickly enough to escape fermentation by bacterial action will be acted upon in the first part of the small intestine, the duodenum, by *pancreatic amylase*. This enzyme, secreted by the pancreas, converts any remaining dextrin and starch to maltose. The reason this amylase can act in the intestine is because of the more alkaline medium which prevails there. As stated earlier, amylase must have a somewhat alkaline medium to do its job and is destroyed by acids.

At this stage in the digestive process, that is, after the polysaccharides (starch, dextrin and glycogen) have been converted to the disaccharide maltose, maltose and the other disaccharides (sucrose and lactose) must be converted to monosaccharides since, as stated earlier, the body can absorb and use sugars only as monosaccharides. This is accomplished by the amylases maltase (to convert maltose), sucrase (to convert sucrose) and lactase (to convert lactose). These amylases are secreted by the wall of the small intestine and are capable of splitting the particular sugars for which they were designed to the monosaccharide stage.

#### **4.4 Carbohydrate Absorption**

Even though some substances (water, ethyl alcohol, small amounts of monosaccharides) may be absorbed into the bloodstream through the mucosa (mucous membrane) of the stomach, most absorption of the soluble products of digestion occurs in the small intestine. There the absorptive surface is increased about 600 times by villi, which are fingerlike projections in the lining of the small intestine. Each individual villus contains a network of capillaries surrounding a lymph vessel, and each cell on the surface of the villus is made up of smaller units called brush border cells or micro villi.

Substances or nutrients pass through the intestinal membrane through the process of *osmosis* in one of two ways: 1) *diffusion* or 2) *active transport*. Substances and nutrients in the intestinal tract that are in higher concentration than across the membrane in the blood and lymph pass through by diffusion. This is a simple osmotic process in which no energy has to be expended. Fructose is absorbed by diffusion.

Active transport is the osmotic process used when substances or nutrients are absorbed from an area of lower concentration across a membrane to an area of higher concentration. This process requires energy for the absorption, as well as a "carrier" to transport the substance. The carrier substance is thought to be a protein or lipoprotein (a combination of a protein and a fat). Glucose and galactose are absorbed into the bloodstream by active transport. Monosaccharides are absorbed by the capillaries, which empty into the portal vein, which in turn carries them directly to the liver.

#### **4.5 Carbohydrate Metabolism**

Metabolism is the term used to describe the many chemical changes that occur after the end products of digestion have been absorbed into the body. There are two phases of metabolism: 1) *anabolism*, which is the chemical reaction by which absorbed nutrients are utilized for replacement of used or worn-out body substances (maintenance) and to create new cellular material (growth), and 2) *catabolism*, which includes the chemical reactions whereby cellular materials are broken down into smaller units. An example of anabolism is the use of monosaccharides to build up stores of muscle and liver glycogen, and an example of catabolism is the breaking down of these glycogen stores to supply energy to the muscles during physical exertion. Anabolism and catabolism occur simultaneously in the body cells.

#### **4.6 Sources of Glucose**

The body's immediate needs determine whether carbohydrates that have been digested and absorbed are used for immediate energy, converted and stored as glycogen or changed to fat and stored in adipose tissue.

Glucose is the principal sugar used by body cells and tissues. It is, therefore, important to know the sources of this nutrient. It may come from carbohydrates or from noncarbohydrate sources. Following

are the four primary sources of glucose:

- a. *From the digestion of dietary carbohydrate.* Glucose is formed from the digestion of starch, dextrin, maltose, sucrose and lactose from the foods we eat.
- b. *From the conversion of fructose and galactose.* The three monosaccharides—fructose, galactose and glucose—share the same chemical formula. However, they differ in the arrangement of the hydrogen and oxygen units along the carbon chain. During the metabolic process, the liver cells convert absorbed galactose molecules and some fructose molecules. However, fructose is mainly converted to glucose during its absorption through the intestinal walls, where a metabolic interconversion (mutual conversion) occurs.
- c. *From the breakdown of glycogen.* When the body's need for glucose is greater than the supply available in the blood, glycogen reserves in the liver and muscles are broken down and converted to glucose.
- d. *From noncarbohydrate sources.* If the body cells require more energy than can be supplied by glucose and glycogen reserves, noncarbohydrate sources can be used to supply glucose. The noncarbohydrate sources used include certain amino acids from protein, glycerol from fat and, indirectly, fatty acids from fat.

## 4.7 Regulation of Blood Glucose Concentration

The liver, the pancreas and the adrenal glands play roles in keeping the blood sugar level at a normal concentration of around 90 mg. per 100 ml.

- a. *The liver serves as a buffer.* As stated earlier in this lesson, absorbed monosaccharides are carried in the portal vein to the liver. This blood in the portal vein may have a very high concentration of sugars, as much as 180 mg per 100 ml of glucose. In the liver, about two-thirds of the excess glucose is removed from circulation. This glucose is converted to glycogen, the storage form of carbohydrate for animals (sometimes called animal starch). At a later time, when the blood sugar level is low, the glycogen is split back into glucose and is transferred out of the liver into the blood.

In essence, the liver serves as a "buffer" organ for blood glucose regulation because it keeps the blood glucose level from rising too high or falling too low.

- b. *Hormones that regulate the blood sugar level.* After a meal is eaten, the increased glucose level in the blood (about one-third of the glucose is not removed from circulation by the liver) stimulates the pancreas to produce the hormone, insulin, which promotes the rapid transport of glucose into the cells, thus decreasing the blood glucose level back toward normal. Glucose cannot enter the cells through simple diffusion because the pores of the cell membrane are too small. Therefore, it is transported by a chemical process called *facilitated diffusion* (also called active transport), in which the glucose combines with a carrier in the cell membrane and is transported to the inside of the cell, where it breaks away from the carrier.

Insulin greatly enhances this facilitated transport of glucose through the cell membrane. In fact, only a very small amount of glucose can combine with the carrier in the absence of insulin, whereas, in the presence of normal amounts of this hormone, the transfer is accelerated as much as 3-5-fold. (Larger than normal amounts of insulin increase the rapidity of glucose transfer as much as 15-20-fold.) As you can see, insulin controls the rate of glucose metabolism in the body by controlling the entry of glucose into the cells.

Three hormones are involved in increasing the concentration of glucose in the blood when necessary: *norepinephrine*, *epinephrine* and *glucagon*. Norepinephrine and epinephrine are secreted by the *adrenal glands* and glucagon is secreted by the *pancreas*. These hormones cause liver glycogen to split into glucose, which is then emptied into the blood. This returns the blood glucose concentration back toward normal.

## 4.8 How Energy is Derived From Glucose

Energy is derived from glucose in one of two basic ways: 1) by *oxidation* and 2) by *glycolysis*. By far the major amount of energy from glucose is released in a series of reactions in the cells in the presence of oxygen; but some energy from glucose is released by a process called glycolysis. This is an involved process which does not require the presence of oxygen. (A detailed explanation can be found in a physiology text such as *Physiology of the Human Body* by Arthur C. Guyton, M.D.)

## 4.9 Carbohydrates in Relation to Other Nutrients

Not only are fats converted to carbohydrates for energy when carbohydrate intake is inadequate, but when carbohydrates are consumed beyond need, the excess is converted to fat and stored in adipose tissue. Also, the B-complex vitamins and the mineral calcium are known to play an integral part in carbohydrate metabolism.

- a. *The transformation of carbohydrate into fat.* Fats and carbohydrates eaten in excess of caloric expenditure are deposited in the adipose tissues as fat. It is, therefore, incorrect to label carbohydrates as being "fattening." Fats eaten in excess of caloric need are also stored as fat. In the diets of many people, however, carbohydrates comprise the foodstuffs most commonly eaten in excess. There are many reasons for this. One reason is because refined sugar and flour are used so heavily and widely in the processing of the foods most widely advertised and distributed to the retail food outlets. Carbohydrates are, as a general rule, less expensive than fat-containing foods (such as cheeses, nuts, many meats, etc.) therefore, they are more likely to be overeaten. In addition, because humans naturally "have a sweet tooth" (because we are biologically frugivores, adapted in nature to eat fruits), we are more attracted to carbohydrates than to fats.

The chemical pathway glucose follows on its way to fat is well understood. You may study this in a good physiology text.

- b. *The vitamin B complex in carbohydrate nutrition.* The importance of the B vitamins in carbohydrate metabolism was discovered because of the health problems that resulted from the industrial processing of foods which removed (and still removes today) the B vitamins from their whole food sources where they were packaged by nature side-by-side with carbohydrates. The large-scale introduction of white (refined) rice in the Orient resulted in beriberi, a vitamin B complex deficiency—specifically, a thiamine deficiency. This phenomenon led to the recognition of the existence of this group of vitamins.

Prior to the widespread processing of foods, humans did not suffer as a result of their lack of knowledge about the existence of the B vitamins because in nature there is a union between the vitamin B complex and carbohydrates in foods. This union was broken by the industrial processing of foods.

As will be discussed in greater depth in later lessons, taking vitamin B complex supplements or using so-called "enriched" processed food products will not and cannot substitute for whole foods in their natural state. It is, therefore, very important for health-seekers to consume unprocessed foods—also uncooked, as cooking is an in-home method of food processing that is very destructive of the quantity and quality of vitamins and other nutrients in foods.

B-complex vitamins are also depleted (and/or not synthesized in the body) when various drugs and medications are taken, most notably birth control pills, alcoholic beverages and antibiotics. Other drugs also deplete B vitamin supplies and/or hinder the synthesis of B vitamins in the intestine. A future lesson will be devoted to the effects of various drugs and medications upon nutrition.

Physiology texts also mention the fallacy of regarding any one B vitamin in the complex as more important than another because of the fact that the normal chain of events, physiologically speaking, can be broken by a lack of any one of the B vitamins. The texts also recommend a

dietary supplement containing all the factors to "avoid the evils of modern food refinement." It is appropriate to make a comment here on this subject: It is fully possible, in fact, easily possible, to "avoid the evils of modern food refinement" much more completely and many times more effectively as far as good (healthful) results are concerned than by eating refined foods and taking supplements. Actually, it is not only easily possible and desirable to completely avoid ever eating refined foods, but it is essential for anyone who wants and expects to regain and/or maintain good health. It is not possible to have truly high-level health while continuing to indulge those very practices which undermine it, and eating processed foods and taking food supplements both undermine health.

Please make special note of the above, for it is one of the most important facts you need to completely understand and accept if you are to bring yourself and your clients to a high level of well-being.

- c. *Calcium in carbohydrate metabolism.* Like the B-complex vitamins, calcium is essential in the metabolism of carbohydrates. When calcium is present in context with the carbohydrate source (whole foods), there are no problems. But, with today's high consumption of refined foods, lack of natural calcium in these foods creates a myriad of very serious health problems. Refined sugar and flour, as well as rice, breads, packaged cereals and pastas, have been robbed of the calcium in the plant during processing and refining. Even whole-grain products may completely lack calcium because of the destruction of this mineral during the destructive processes of cooking and baking.

Calcium is taken from the bones and teeth to meet the needs for this important mineral in carbohydrate metabolism. Dental caries, osteoporosis and other bone diseases result.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 5. Sources Of Carbohydrates

## 5. Sources Of Carbohydrates

### 5.1 Carbohydrates Are a Component of Every Food

As mentioned earlier in this lesson, carbohydrates, along with proteins and fats, form the major components of living matter. They maintain the functional activity of the cells and serve as structural and reserve materials. Carbohydrates provide the primary source of energy for humans.

There is not a single living thing—plant or animal—that does not contain carbohydrates in some form. Though the quantity and form of carbohydrates varies, the presence of carbohydrates as an integral component of life is constant. This means that all foods are potential sources of carbohydrates. However, some foods are better sources than others, and this is what we will discuss now.

### 5.2 Carbohydrates Are a Primary Component of Some Foods

Most foods can be readily classified according to the organic compounds (proteins, carbohydrates, fats, etc.) they contain in greatest abundance. These classifications are not only useful for identifying where to obtain the nutrients we need, but they are also invaluable in selecting compatible food combinations for best digestion and nutrition (to be discussed in depth in a later lesson).

## 5.3 Starches As Sources of Carbohydrates

Starch-containing foods can be divided into four classifications:

*Starchy Vegetables* All kinds of potatoes are in this classification. Also included are yams, winter squashes (such as buttercup, hubbard and banana squashes), pumpkin, caladium root, taro root, cassava root and Jerusalem artichokes. (Note: Technically, squashes and pumpkins are fruits.)

*Mildly starchy vegetables* This classification includes carrots, cauliflower, beets, rutabaga and salsify.

*Cereal grains* This includes all cereals, whether they're whole or refined, raw or cooked. Examples are wheat, rye, barley, rice, millet, buckwheat and oats.

*Legumes* This includes peanuts, lentils, peas and beans.

## 5.4 Fruits As Sources of Carbohydrates

Because some nonsweet foods such as nuts, bell peppers, squashes, cucumbers and tomatoes are technically fruits, fruits can be divided into two classifications: 1) sweet fruits and 2) nonsweet fruits. In our discussion of carbohydrates, we will limit our discussion primarily to the sweet fruits, even though the nonsweet fruits do contain some sugar.

For purposes of food combining for digestive compatibility, the sweet fruits can be divided into four groups: 1) sweet fruits, 2) subacid fruits, 3) acid fruits and 4) melons. The fruits in each category and how to combine them for best digestion will be discussed in a future lesson on correct food combining.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 6. Why Starches Are Less Than Ideal Sources Of Carbohydrates

## 6. Why Starches Are Less Than Ideal Sources Of Carbohydrates

There are many reasons why starches are less than ideal as sources of carbohydrates for humans.

### 6.1 Many Digestive Steps Use More Body Energy

A larger amount of the body's limited supply of nerve energy is used up when starches are used for fuel than when fruits are used because starches are, as you know, polysaccharides and must be broken down (digested) into monosaccharides before the body can use them. Fruits contain a preponderance of monosaccharides, which, as you also know, need no digestion at all. Therefore, fruit eating leaves more of the body's energies available for other activities. This explains, in part, why people feel so "light" when they eat fruits and so heavy when they eat beans or bread.

### 6.2 There Is a Greater Tendency to Overeat on Starches

Because starches usually lack the amount of water content found in fresh fruits, it is much easier, to overeat on them than on fruits. It takes larger amounts of starch foods to get the same feeling of fullness that you get from a fruit meal. When starches are consumed, it is best to use only one kind of starch at a meal, as this helps control the tendency to overeat on starches.

### 6.3 Many Digestive Steps Take Longer and Fermentation Can More Readily Occur

For good digestion (an important prerequisite for good nutrition), not only do foods need to be

compatibly combined with one another, but they also need to be digested fairly quickly. As stated earlier, food that remains in the stomach too long will be decomposed by the bacteria that reside there.

The only starch-splitting enzyme secreted in the saliva, as previously stated, is ptyalin, also known as salivary amylase. The available amount of this enzyme is somewhat limited, and it is unlikely that large amounts of starch foods can be completely digested by salivary amylase, even if no proteins or acid foods are eaten with or too soon before or after the starches. Therefore, complete digestion of the starches eaten, especially if more than a very small amount is eaten or if they are eaten with protein or acid foods, is dependent upon the starch-splitting enzymes in the intestine—pancreatic amylase. However, the likelihood of indigested starches reaching the intestine without first fermenting in the stomach because of the action of bacteria there is rather small. Conditions of emotional or mental stress or anxiety, lack of sleep or rest, eating too fast or a digestive system weakened by years of past abuse are some of the reasons why fermentation may occur before undigested starches can reach the small intestine for digestion by the pancreatic amylase.

Fruits, on the other hand, if eaten with other fruits of like character, pass through the stomach very quickly into the intestine, where their monosaccharide content is rapidly and efficiently absorbed. Unless fruits are eaten with slower-digesting foods such as fat/protein foods (such as nuts, seeds or avocados) or starches, they are not likely to ferment in the stomach. Their need for almost no digestion makes it possible for the body to pass them through the digestive tract quickly, before fermentation by bacteria can occur.

#### **6.4 Starches Are Poorly Digested Raw But Cooked Starches Are Unwholesome**

Only very small amounts of raw starches can be digested because of the nature of the starch granule. Even the most thorough mastication of raw starches breaks open only a small fraction of the starch-containing globules, as each of these globules has a thin but strong protective cellulose covering which acts as a protective membrane for the plant's storage product (starch).

Neither salivary amylase (ptyalin) nor pancreatic amylase can commence digestion of the starch until it is released from its globule. These starch-containing globules are, therefore, not digested at all and must be eliminated from the body as so much debris. Undigested materials such as these are toxic in the body and pose an eliminative burden without providing energy or other value.

Cooking makes starches more digestible. As stated earlier, starches are not soluble in cold water and need to be heated to break down the cellulose coverings that surround starches. Heat also converts some of the starches to dextrans, and the more and longer heat is applied to the food, the greater will be the amount of starch that is converted to dextrans by this method. Undextrinized starches which have been freed by heat from their protective globules will be hydrolyzed (digested) by the salivary and pancreatic amylases. The resulting dextrans are large polysaccharide molecules that yield the disaccharide maltose upon hydrolysis. Maltose is, in turn, hydrolyzed into molecules of the monosaccharide, glucose.

Despite the greater digestibility of cooked starches, cooking is a very unwholesome process for many reasons, some of which were mentioned in previous lessons and more of which will be elaborated on in a future lesson dedicated to this subject. Basically, cooking destroys vitamins, partially or completely, depending on which vitamins are involved and how long and hot the cooking is; it converts minerals from their usable organic state back to their unusable (and therefore harmful) inorganic state; and it deranges (or deaminizes) the proteins present. (Starch foods do contain small amounts of protein, as protein is a component of all living matter.)

To summarize, while cooking might improve the digestibility of the starches in starch foods, it certainly does not improve the usability of the other nutrients and components of the food. On the contrary, it renders the minerals and proteins present at least partially toxic and unusable. Therefore, we recommend that neither raw starches nor cooked starches be included as part of an optimum diet.

In the case of legumes such as lentils and beans, however, there is one alternative: sprouting. The

starches in legumes are converted in the sprouting process at least partially to dextrins, which can be hydrolyzed by body amylases into the appropriate sugars. Grains which have not been processed (whole grains, in other words) can also be sprouted, but usually with less success because they often sour before their enzymes can complete the conversion of most of the starches to sugars.

The only starch foods we recommend are sprouted lentils, sprouted mung beans or sprouted azuke beans. A later lesson on food preparation will discuss sprouting in more depth.

## **6.5 Starches Are Usually Unpalatable Raw**

Because we are physiologically fruit-eaters, most of us are not especially fond of nonsweet foods, at least not compared with how much we love sweet foods. We are not physiological starch eaters, and this is evidenced by our disinterest in foods such as raw potatoes, grains, beans, etc. Most starches just don't taste that good in their raw state.

Carrots, sweet potatoes and yams are notable exceptions, however, because these tubers, in addition to containing starches, also contain enough sugars to give them a sweet flavor. The main problem with eating these vegetables is that their sugars are likely to ferment in the stomach while they are held up there with the starches, which digest more, slowly than do the sugars. As stated earlier, sugars are normally passed swiftly through the stomach to the intestine for immediate absorption, but if they get held up in the stomach they ferment because of bacterial action. Carrots, sweet potatoes and yams may be used juiced, as long as they are eaten alone or about a half hour before a meal of compatible foods.

Some of us enjoy certain mildly starchy raw vegetables such as cauliflower and carrots. Eaten in moderate amounts, these vegetables are fine. Grated carrots and/or cauliflower flowerettes are nice additions to vegetable salads, but these salads should not contain nuts, seeds or tomatoes, which are poor combinations with even mild starches.

Remember: Although some starches can be sprouted or juiced, and others may be fine in moderation, especially if they're only mildly starchy, starches are, as a rule, unpalatable and indigestible raw and unwholesome cooked. As stated earlier, humans are not biologically adapted to starch eating.

## **6.6 Some Starch Foods Also Contain a Significant Amount of Protein**

A future lesson on food combining will discuss in detail why it is unhealthful to consume starch foods and protein foods in the same meal. Basically, the two kinds of foods require very different digestive environments and enzymes, starch requiring ptyalin and an alkaline digestive environment, and protein requiring the enzyme pepsin and an acid digestive environment. Both foods cannot be digested simultaneously, and if eaten together or close to the same time, protein digestion will occur, at least partially, leaving the starches and sugars to ferment because of bacterial action in the stomach. Fermentative byproducts interfere with the protein digestion in progress, and protein digestion will most likely be incomplete. Undigested protein will putrefy (rot).

Most foods contain either a predominance of one factor or the other. For example, tubers and grains contain predominately starches, whereas nuts and seeds can be classified as protein/fat foods. But there are some foods which contain a lot of protein along with a lot of starch. Examples of some of these foods are beans of all types, peas and peanuts. Unless these foods are sprouted, which converts their starches to more easily digestible sugars, they are to a large extent indigestible. This is why beans are often referred to as the "musical fruit." They ferment and putrefy in the stomach and intestine, and this is an unwholesome occurrence because fermentation and putrefaction byproducts are toxins which must be eliminated as quickly as possible so that the body doesn't suffer great harm from them. Much body energy is used up in toxin elimination, energy that could be much more wisely used for other activities. Also, not all toxins are eliminated before some harm has resulted.

## 6.7 Wheat Poses Special Problems

Wheat is the most popular of the grains used in this country, especially commercially. But this popularity is undeserved because wheat poses special digestive problems that make it unwholesome. Basically, besides the digestive problems that wheat shares with the other starchy foods, the special problem with wheat is that it contains gluten, a protein substance that humans do not have the enzyme to digest. As you know, undigested substances are toxic in the human body and must be eliminated at a great expense of vital energy.

We might add at this point that beets are a mildly starchy root food that have a special problem: They contain too much oxalic acid which the body neutralizes by binding calcium. We recommend that you not use beets as an item of diet.

## 6.8 Grains and Legumes Are Acid-Forming

A later lesson will discuss in depth which foods are acid-forming and which are alkaline-forming and why we should have a predominance of alkaline-forming foods in our diet. Suffice it to say here that most grains and legumes are acid-forming and, for this reason, should be eaten in extreme moderation, if at all.

Grains contain phytic acid, a substance which binds calcium and iron, both in the grains themselves and the body stores of these minerals. This fact only complicates and aggravates the problem of calcium being taken from the bones and teeth by the body in the metabolism of carbohydrates that have been refined and their minerals, therefore, removed.

Anyone concerned about getting enough calcium should not eat grains. People who suffer with nervousness, sleeplessness and/or cramps may already be experiencing some of the symptoms of calcium deficiency. Getting carbohydrates from fresh fruits, and consuming dark green leafy vegetables, possibly along with a few occasional nuts, seeds and/or avocados, will insure adequate intake of usable calcium. Consuming grains in addition to the wholesome foods mentioned above is defeating of your purpose and is to be discouraged.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 7. Why Fruits Are The Ideal Source Of Carbohydrates

## 7. Why Fruits Are The Ideal Source Of Carbohydrates

Fruits are the ideal source of carbohydrates because they are the foods humans are physiologically and anatomically adapted to eating. (These adaptations will be discussed in greater depth in a later lesson.) Humans have a natural "sweet tooth" because that's our inherent nature. We're supposed to eat fruits, mostly sweet fruits. Incidentally, we can enjoy some nuts, seeds, vegetables and sprouts. But sugar-containing fruits should be the primary items in our diet.

The sugars in fruits, being mostly monosaccharides, pass through the stomach and are absorbed through the walls of the intestine without undergoing any digestion. This leaves a great surplus of body energy available for living and all the activities that make living a joy. We should not waste our precious energies digesting complicated, heavy foods unless it's a matter of life or death. Instead, we should eat simply of our natural foods—fruits—and use our energy for higher-level pursuits of life.

Fruits, except for dates and dried fruits, contain significant amounts of water in its purest and most delicious form. Therefore, they supply most, if not all, of our needs for water. Cooked starches, on the

other hand, are water-deficient and make us thirsty, especially if they're eaten with added salt or soy sauce and/or in very large amounts. Water is an extremely important need of life, and pure water as is in fruits is the only kind we should have. (Distilled water is also acceptable and is, in fact, the only kind of water we should obtain from nonfood sources. The subject of water will be treated in depth in a later lesson.)

Fruits do not have to be cooked or seasoned to taste great. In fact, they should never be cooked, though they can be dried for storage purposes. It is easy to make a meal on fruits, even mono-meals (just one fruit type at a meal), for other foods added to the fruit meal do not enhance it. Fruits are so delicious that they don't need enhancement and they digest so easily and quickly, eaten with each other or alone, that fermentation and the resulting toxicity of fermentation is unlikely to occur.

Since carbohydrates, quantitatively speaking, are the greatest nutrient need we humans have, it follows that fruits, loaded with sugars, should comprise the bulk of our diet. Fruits, besides being replete with ample carbohydrates, have relatively small amounts of proteins, vitamins and minerals—in just the right amounts for the specific needs of humans. If (anything other than fruits are eaten, it should be small amounts of nonsweet fruits, vegetables, nuts, seeds and sprouts.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 8. Amounts And Variety Of Carbohydrates Needed By Humans

## **8. Amounts And Variety Of Carbohydrates Needed By Humans**

When most people think about amounts of carbohydrates to consume, they think in terms of calories—units for measuring heat. One calorie is the amount of heat required to raise the temperature of one kilogram of water one degree Centigrade. The amount of heat liberated by a complete breakdown of a food into its metabolic end products is expressed in calories.

For purposes of this course, however, calories are unimportant. Obtaining them is important, but numbers are not. Texts say that an average person needs a minimum of 1800 calories per day for just existing and more for any activities indulged. But, as mentioned in an earlier lesson, the variance is so great when it comes to individual needs, and people on conventional high-protein diets that include meat, etc., require so much extra energy to handle the constant input of toxins, causing an additional variance between "norms" and the actual needs of a truly healthy person, that the guidelines in the texts are practically useless. Besides, humans have always been able to get all the calories they need without counting them—and without even knowing about their existence.

So, in this section, we will take a more practical approach to the question of how much carbohydrate we need in our diet.

### **8.1 Amounts**

Because protein, minerals and vitamins are present in sufficient quantities in carbohydrate foods to meet our needs for these nutrients, virtually the entire human diet can consist of carbohydrate foods (fruits). Some individuals, for various reasons, may find it desirable to include some protein/fat foods such as nuts, seeds and/or avocados and/or nonsweet fruits and/or vegetables in their diet of sweet fruits. However, if these foods are eaten, they should not be consumed with, immediately after or less than four hours before sweet fruits—to insure proper digestion of all foods involved and, specifically, to insure that the fruits pass quickly through the stomach to the intestine for absorption rather than getting held up by slower-digesting foods in the stomach and fermenting.

Whether an all-fruit diet is consumed, or other foods are included in the diet, the fact remains that an all-carbohydrate diet will amply supply not only all our energy (carbohydrate) needs, but it will also supply the proteins, fats, vitamins and minerals we need. (Fats are easily obtained by an occasional avocado, a nonsweet [oily] fruit.)

## **8.2 Variety**

As far as food variety goes, foods grown on different soils in various locations will provide the broadest range of nutrients possible. Eating foods from one locale only, if not organically grown, could result in nutrient deficiencies, especially if only one or a few kinds of foods are consumed. This is probably not a concern for most people in the U.S., however.

While a diet consisting of a broad variety of wholesome natural foods may provide interest and a broad range of nutrients and nutrient combinations, it should be remembered that most foods to which we are biologically adapted contain most of the nutrients we need—in varying amounts. People worldwide have been known to live in excellent health on diets consisting of primarily or only one or a few foods. Some examples of such foods are coconuts, dates and bananas. There is much proof that a large variety of foods is not necessary for good health, though there is nothing to be said against variety, as long as the foods are wholesome, raw and correctly combined.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 9. Disease Conditions Related To Carbohydrate Consumption

## **9. Disease Conditions Related To Carbohydrate Consumption**

The following plus many more diseases are considered, by the medical world and by some lay people alike, to be either caused by or related to carbohydrates of various kinds in the diet. At this place in this course, we will not delve into any depth on these disease conditions, as they will be treated in separate later lessons. Here we will just briefly mention a few of the more common conditions related to carbohydrate consumption.

### **9.1 Lactose Intolerance**

Humans, like the other mammals, provide milk for their young from their mammary glands. This milk is perfectly suited for the very specific needs of the developing human infant, but it is not designed to meet the needs of calves or kids or other baby mammals. It is meant for feeding human infants only. While the above statement may seem ridiculously obvious, it is not as obvious to many people that human babies should not receive milk from cows or goats except in emergencies where human milk is simply unavailable. In those exceptions, milk from another species of mammal is preferable to no milk at all.

The reason we introduce the subject of lactose intolerance the way we did in the above paragraph is to show two things: 1) how far we have strayed from nature in feeding cows' milk to our human babies and 2) that mammary milk is specially created for babies up to three years of age and is not designed for humans above that age.

The idea that we need calcium, fats, proteins or anything else from milk beyond the age of three is not only entirely false and totally ungrounded in fact, but it has caused a tremendous amount of harm and suffering for humans. "How did these ideas get started and popularized so widely, then?" you may ask. The simple but sad answer is that the, dairy industry is primarily responsible. (This entire subject will be treated in greater depth in a future lesson devoted entirely to the subject of milk and dairy products in

the diet.) As incredible as it may seem that so many people would actually put profit before human health, it is, nonetheless, true.

The problem of lactose intolerance is very widespread. The fact that from 18% to 100% of various peoples across the globe exhibit symptoms of lactose intolerance exemplifies the extent of the problems of consuming nature's formula for calves. Large numbers of people experience symptoms such as abdominal pain, diarrhea and flatulence (excessive formation of gas in the stomach or intestines). Many so-called allergies, skin disorders, so-called upper respiratory "infections," hay fevers and numerous other diseases—in fact, all diseases—are caused largely or to some extent by the toxic substances resulting from the inability of most (if not all) humans over age three to utilize the sugar, lactose, found in milk.

After age three, most, if not all, people do not secrete the enzyme, lactase, which is needed to break down the disaccharide, lactose, into the simple sugars, glucose and galactose. As you know, undigested sugars are fermented in the stomach and intestine by bacteria. However, it is not the bacteria that are causing the problem, for they are doing what their role in nature requires of them. The bacteria simply play their part in preparing the offending substance, in this case, lactose, for elimination from the body. The cause of the problem is the ingestion of food not appropriate for humans over three.

The solution is obvious and simple, but the powerful and influential dairy industry will do (and does) everything it can to keep this information a secret and to try to disprove it. Besides this, governments are on the side of industry, and individuals in government who can't be coerced to change are removed from positions that enable them to act in favor of human health.

It is a common misconception that the overall health of people is more dependent upon maintaining the jobs and industries that are now in operation than maintaining physical health. Too many people like to think that the connection between eating wrong foods and disease conditions of all kinds is only vague and questionable, when, in fact, the connection is very direct and the solution very simple. People like to think that some vitamin, some drug or some other kind of treatment will "cure" diseases and alleviate symptoms. Then they can go on indulging unhealthful practices and not disturb the status quo. But there is just no getting around the fact that, if we are to have better health, we must change our eating and living practices. No so-called "cures" or other treatments can even approach "making up for" healthful living. To try to do so is a futile effort. Change is really not so difficult if more people could just accept the idea that it is necessary and beneficial to everyone, both in the long run and in the short run.

To get back to the subject of lactose intolerance, can you see why most or all people do not digest lactose? Milk is not a natural or wholesome food for humans over age three; neither are other dairy products. While not everyone exhibits the clinical symptoms of lactose intolerance, the health of everyone suffers in some way as a result of milk consumption—if they drink milk or otherwise use milk or dairy products.

As stated earlier, the problems of milk and dairy products in the diet will be discussed in much greater depth in a future lesson on the subject.

One more item might be added here before we close this subject: Texts say that milk to which the enzyme lactase has been added and fermented dairy products are tolerated by lactose intolerant people. They list foods such as yogurt, buttermilk and cottage cheese. Suffice it to say here that all dairy foods are very unhealthful, including those listed above, and many symptoms other than those of lactose intolerance result from the consumption of unwholesome foods.

## **9.2 Galactosemia**

Galactosemia is another disease condition related to milk, or lactose, consumption. This disorder, labeled "an unusual hereditary disorder," occurs in infants. Galactosemia is among the diseases that supposedly result from "inborn errors of metabolism." In this condition, a specific enzyme (p-galactose-uridyl-transferase) is lacking, so the infant cannot properly digest the sugars in milk. Specifically, the

monosaccharide galactose, which does not occur free in nature but results from the hydrolyzation of lactose from milk, cannot be converted to glucose.

Infants with this disorder vomit when they're fed milk and other dairy foods. They become lethargic and fail to gain weight. Their liver and spleen become enlarged (from overwork), cataracts develop and they become mentally retarded. In severe cases, death can occur. The solution to this problem is a milk- (and other dairy products) free diet, according to the texts. What is fed to babies instead of milk is not listed, but we would recommend freshly-made fruit juices in season, perhaps along with (at separate feedings, of course) homemade nut, seed or soy milk, depending upon the infant's tolerance to these. (The subject of care and feeding of infants and children will be treated in more depth in later lessons.)

### **9.3 Dental Caries**

Dental decay is generally attributed to the consumption of too much sugar. However, the sugars in fresh ripe fruits, even in very sweet fruits such as dates and dried fruits, will never cause dental decay. The reason for this is that it is not sugar itself that causes cavities; rather, it is the consumption of refined sugars and other refined foods, such as refined flours and white or polished rice, that results in dental caries. The consumption of meats, dairy foods and other acid-forming foods in great excess of alkaline foods (fruits and vegetables in their raw state) is also an important contributing factor to dental decay.

As mentioned earlier in this lesson, calcium is needed in the metabolism of carbohydrates. Refined foods lack minerals, including calcium. The body is forced to draw calcium from its own reserves, and these reserves are depleted rather quickly if refined foods are eaten more than "once in a blue moon." If this occurs, the body must then draw the needed calcium from its bones and teeth—hence, cavities!

Meats and dairy foods, as well as whole grains, are acid-forming in the body. Calcium is needed to neutralize the acidity and maintain the normal blood alkalinity of 7.40 pH. After the calcium available in the body is used up, this mineral is taken from the bones and teeth.

As you can see, fruits are to be preferred over grains, meats, milk or dairy foods as sources of carbohydrates. Their sugars will not cause cavities, but fragmented foods (refined products) and unnatural foods (meats, milk, dairy, grains) will! From the standpoint of maintaining body calcium, the best choices of starch foods would be the tubers—potatoes, sweet potatoes, yams, and carrots.

No one ever need fear dental decay, even on a diet of sweet fruits. The important factor here is not to eat processed or refined foods or foods that are not suited to our biological adaptations. (The subject of sugar and other sweeteners will be treated in greater depth in a future lesson.)

### **9.4 Diabetes Mellitus**

Much could be said about this disorder, but we'll treat it more thoroughly in a later lesson. At this point, suffice it to say that diabetes mellitus, defined as the insufficient production of insulin needed to metabolize sugar, has in common with dental caries the fact that it is caused by an unhealthful diet containing refined sugars, flours, grains and other unwholesome foods. Depending upon an individual's condition, special care and provision may have to be made for the diabetic who is going on the Life Science regime. Those using insulin, especially in very large amounts, should consult an experienced Hygienic professional before making very great changes in diet.

### **9.5 Hypoglycemia**

This condition is also known as low blood sugar and is often a predecessor to diabetes. It, too, will be treated in depth in a future lesson, so we will say little about it here. True hypoglycemia is caused by the same things as cause diabetes. However, people are often diagnosed as hypoglycemic when, in fact, they just have a case of body toxicity. The symptoms of hypoglycemia are many and can also occur when a person is not actually suffering from this condition—hence, the incorrect diagnoses in many cases.

Contrary to popular opinion, most hypoglycemics can fast and benefit greatly by it. Since so many people suffer with this condition, this is good news indeed!

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > 10. Questions & Answers

## 10. Questions & Answers

**I was under the impression that the primary nutrient humans need is protein—for the maintenance of body cells. You say carbohydrates are our primary nutrient need. Why this discrepancy?**

The discrepancy exists because our protein need has been overemphasized and our carbohydrate need underemphasized. In the field of nutrition, as in other fields, fads come and go. The excessive concern about obtaining adequate protein has so permeated the minds of most people that it has become a very dangerous preoccupation. It is dangerous because too much protein in the diet is very harmful and is the cause of much of the disease and suffering so many people are experiencing.

Why has our need for protein become so exaggerated? Why is our need for carbohydrates underestimated?

The meat and dairy industries, with the support of the government, are largely responsible for the "protein fashion." Their message has become a part of the public education systems—its textbooks, its universities, everything it teaches. They want us to believe that those foods which are most unhealthful, foods such as meat, fish, eggs, milk and cheese, are the most important part of our diet. Secondly, carbohydrates from grains and breads are promoted—this mostly for the benefit of the refining and baking concerns that bring us Wonder Bread, Cheerios, Pop Tarts, etc. Fruits and vegetables are given very low priority, as the money to be made from marketing these foods is much less than from the nonperishable "foods" and the animal products.

Why have carbohydrates been underemphasized? For one thing, most people, being naturally attracted to sweet things (we are natural biological fruit eaters), manage to get more than enough carbohydrates in their daily diets. This is especially so when we consider the quantity of sugar (refined sugarcane or beets) in the average diet. Desserts, breads, pastas and cereals are quite popular, though these kinds of carbohydrates cause disease because of their nutritional lack of vitamins, minerals, fiber, water, etc., and for other reasons.

Also, a large number of people in our country are weight conscious, and carbohydrates have been named as the culprit. But excessive proteins are even worse than excessive carbohydrates! While weight may be lost on a high-protein/low-carbohydrate diet, the harm being done to the organism is more than the harm from keeping the excess fat. The key is to consume natural carbohydrates in the form of fresh fruits rather than processed products. Anyone desiring to lose weight can easily do so on an all-fruit or mostly-fruit diet—and gain excellent health while doing so. It's the quality of the carbohydrates consumed that makes the difference. Fresh fruits just don't cause people to gain weight, even if large amounts are eaten.

One more note on this subject: One physiology text condones the high-protein diet, even

though it states in the same chapter that carbohydrates are the most efficient fuel foods. The reasoning for this is that "adequate nutrition is possible ... if the need for calories, essential food factors, vitamins and minerals is met." Of course, they are referring to the body's ability to utilize proteins as carbohydrates if the intake of carbohydrates is insufficient. As you know, this is an extremely inefficient, wasteful process that is also harmful. The harm caused by excess protein and animal foods will be discussed in more depth in later lessons.

**You spoke of losing weight on a fruit diet, but isn't it true that a person will gain weight on any kind of diet as long as the calories taken in are greater than the energy expended?**

Yes, it is definitely true that a person will gain weight if they consume more calories than they expend. However, anyone who is serious about losing weight must pursue an exercise program of some sort. While a person can lose weight by dieting (or fasting) alone, the loss of excess fat must be accompanied by an improvement in overall health if it is to be worthwhile—and an exercise program is essential to good health, even if it's taken up after a fast.

Because fresh fruits contain much more water than other sources of carbohydrates, they provide satisfaction and a feeling of fullness after relatively few calories are consumed. (Of course, this is not true of dates or dried fruits, which should either be excluded from a weightloss diet or taken in moderation.) It is almost impossible to consume more calories than you expend on a fresh fruit diet—assuming you are active and get daily exercise. The subject of losing weight will be discussed in depth in a later lesson, also.

**Is it possible for a person to gain weight on the diet you advocate?**

Yes. Except in rare (relatively) cases where emaciation has occurred, gaining fat is usually not desirable. Many studies have shown that exceptionally lean people have longer lifespans and fewer diseases than people we would consider of "normal" weight. As a rule, lean is best. The important factor is the building of muscle, which can be done with the use of weights, along with a well-rounded exercise program (stretching exercises and aerobic exercises) or to a lesser degree without the use of weights. Body muscle can be developed in any number of ways—from swimming or running (or both) to calisthenics or tennis. Ideally, your program should include some resistance exercises (weights, push-ups, pull-ups, sit-ups, etc.), some aerobic activities and some stretching exercises, and should work all the body muscles. A truly attractive body is not one with five or ten pounds of extra fat, but one that is firm and filled out by normal musculature.

For those people who are emaciated and do need to gain fat, this should not be rushed. In addition to obtaining generous amounts of exercise (as outlined briefly above), the excessively thin person should make sure his or her life is not too stressful. Also, he or she should consider a fast if there is a chance that adequate calories have been consumed but the body is unable to use them. A physiological rest may be needed more than tremendous amounts of food in this case.

When it comes to eating, people of all body weights should eat normal amounts of healthful foods. Weight gain or loss is a body activity that will occur naturally if we provide the normal and proper conditions of life. Gaining or losing weight is not something we do; rather, it is something the body does. We just provide our needs, and the organism will normalize itself.

**Feeding the people in the United States and in the world would not be possible without the food processing industries. There wouldn't be enough fresh fruits to feed everyone. The diet you**

**propose is totally impractical. How do you answer to this?**

I'm glad you asked that question! The food processing industries are not in business to see that a larger amount of food is available to the world's people. Rather, they are in business to make money. Everyone would be better fed, even on a diet of grains, which is very inferior to the fruit diet, if they were consumed in their whole form rather than processed. Foods are more nutritious before they are processed, so people would be healthier if it weren't for these industries.

The food processing industries do not increase the quantity of food available, either. It is the food growers (farmers and orchardists) who insure that people get enough food. The following topic will be discussed in depth in later lessons, but here we will say that fruit culture and organic gardening could feed the world's population more than adequately if the money and labor now used for food processing (destruction) was instead used for growing fruits and vegetables by organic means. This would, of course, have to happen at least somewhat gradually, but it is possible if enough people agreed to it. The whole world could become The Garden! Wouldn't orchards and vineyards of fruit and nut trees be more appealing to the senses in every way than food refining plants and factories? People's health could improve so much that the drug industry could also divert its money and labor to healthful endeavors. Hospitals could be turned into schools, hotels, gyms! As you can see, the possibilities are enormous— and exciting!

No, our natural diet is far from impractical. The earth is perfectly equipped for the growing of fruit and nut trees and vegetables. Food could also be supplied to those areas where little or no food can be grown in some seasons by using money and manpower for effective food distribution. Nuts, seeds, dates, dried fruits and seeds and beans for sprouting all ship and store relatively well.

**I and many other people have more regular bowel movements because we include bran in our diet. Would you consider this a fairly wholesome part of some people's diet because of its anti-constipation effect?**

Absolutely not! Bran is a food fragment; that is, it is only part of the whole wheat berry. It has many sharp edges which irritate and cut the delicate tissues within the gastrointestinal tract. Humans require their carbohydrate in the form of usable sugars—not in the form of indigestible cellulose.

As far as regular bowel movements go, you will definitely have them on a diet consisting primarily of the foods of our biological adaptation—fresh fruits. It is not for you, me or anyone else to decide how large or how frequent our bowel movements should be—this is strictly a body process that should remain entirely on a subconscious level. We should never have to think about it at all, let alone talk about it. And on the proper diet, you can be sure that everything is happening as it should within your body, for, as you know, the inherent intelligence of your body is great. Our only responsibility is to provide the normal needs of life—and then just live. The body will take care of its own needs.

**I'm hypoglycemic. There's no way I could ever go on the fruit diet you advocate. I can get my carbohydrates from starch foods, can't I?**

Yes, you can get your carbohydrates from starch foods. Because of the special problems of such starches as grains (phytic acid; their acid effect), beets (oxalic acid, which binds calcium) and beans (also contain much protein, which makes them digest very poorly), you should stick to lightly-steamed potatoes, yams, cauliflower, carrots and sweet potatoes rather

than using grains, beans or beets. They can also be eaten raw or juiced if you like. You may include sprouted seeds and beans, such as chick peas (garbanzos), dry peas, mung beans, alfalfa seeds, etc., as well as lots of vegetables and non-sweet fruits and some nuts, seeds and avocados in your diet. However, do not overdo on the oily foods (nuts, seeds, avocados). Rice and millet are the best of the grains, and can be used in moderation, especially with large raw vegetable salads that contain vegetables such as lettuce, broccoli, cabbage, kale, celery, etc., but that do not contain nuts, seeds, avocados, tomatoes or starch foods. (The rice or millet is sufficient starch for one meal.) Other relatively wholesome starch foods you may want to consider to insure more variety (if variety is important to you) are winter squashes, pumpkins, caladium roots, taro roots, cassava roots and Jerusalem artichokes. Rutabaga and salsify are also wholesome starch foods. (You may not be able to obtain some of the foods listed above, but keep your eyes and ears open.)

Keep in mind that starches are not ideal foods for humans, even hypoglycemic humans. Starches remain second-rate sources of carbohydrates. For best results in using them, use just one kind of starch food at a given meal and follow correct food combining rules (as briefly explained in this section, but to be discussed in greater depth in a later lesson) and chew your food well. Also, refrain from drinking anything during or within 2-3 hours after your meals. Understand that you cannot obtain optimum health on a diet consisting of cooked starches as your primary source of carbohydrates.

I recommend that, as soon as possible, you take a supervised fast. Hypoglycemics can and do fast—and with excellent results. Many can return to a normal diet that includes lots of fruits. Most or all can include fruits as a substantial part of their diet, though their intake of the very sweet fruits such as dates, dried fruits and persimmons may be restricted. Some fruits contain much less sugar than others and can be tolerated well by "recovering hypoglycemics."

Whether you fast or not, if you begin living and eating more healthfully, you will be able to eat some fruits, at least in moderation, right away or very soon. As your body begins to normalize and gets rid of stored up toxins that contribute to your problem, you will be able to consume a larger and larger proportion of fruits in your diet. A hypoglycemic does not have to remain hypoglycemic forever. Health results from healthful living—so live healthfully and you will get well.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #1: Carbohydrates by Dr. Herbert M. Shelton

### **Article #1: Carbohydrates by Dr. Herbert M. Shelton**

The following segment on carbohydrates was written by Dr. Herbert M. Shelton in his book, *Orthotrophy* in a chapter on food elements.

This is the name given to certain organic compounds of carbon that are produced by plants in the process of growth from carbon, hydrogen and oxygen, with the oxygen and hydrogen in proportions to form water. In everyday language we know the most important of these carbohydrates as starches and sugars. As will be seen later, carbohydrates are complex substances composed, in most instances, of

simpler substances, or building blocks, called sugars. Chief among the carbohydrates are:

Fruits—Bananas, all sweet fruits, hubbard squash, etc.

Nuts—A few varieties—acorns, chestnuts and coconuts.

Tubers—Potatoes, sweet potatoes, carrots, artichokes, parsnips, etc.

Legumes—Most beans, except some varieties of soybeans, all peas, peanuts.

Cereals—All grains and practically all cereal products. (Gluten bread is not a carbohydrate.)

Grains and legumes are classed both as proteins and carbohydrates. This is due to the fact that they contain enough of each of these food elements to be placed in both classes. Nuts, for the same reason, are classed both as proteins and as fats. Milk, commonly classed as a protein, is really low in protein. It may with equal justification be classed as a sugar or carbohydrate. All foods contain more or less carbohydrates, as they all contain more or less protein. Most foods contain some fats, but there is none in most fruits nor in the green leaves of vegetables.

Carbohydrates, like proteins, are composed of simpler compounds known as simple sugars or monosaccharides. According to their composition, these are classed as follows:

1. *Monosaccharides*: Sugars containing only one sugar group or radical. Among the monosaccharides are grape sugar (glucose or dextrose), fruit sugar (fructose or levulose) and galactose of honey. These are the assimilable forms of carbohydrate. Dextrose is the principle member of the glucose group and much less sweet than cane sugar. It is known as grape sugar and is found in fruits, some vegetables and honey. Glucose occurs in both plants and animals and is formed by the action of heat and the ultraviolet rays upon starch in the presence of an acid. Corn syrup is commercially known as glucose. Glucose may also be made by treating starch with sulphuric acid in the presence of heat. Fructose and levulose are derived from fruits and honey. Galactose is a crystalline glucose obtained by treating milk sugar with dilute acids.
2. *Disaccharides*: Sugars containing two simple sugars, or that can be broken into two monosaccharides. The ordinary cane sugar or sucrose of commerce is a disaccharide composed of glucose and galactose. Invert sugar found in honey is a mixture of glucose and fructose. Maltose of malt sugar is composed of galactose and glucose. Maple sugar (sucrose) and milk sugar (lactose) are also disaccharides.
3. *Trisaccharides*: Sugars containing three sugar groups or radicals. Beet sugar is the best known example of this sugar.
4. *Polysaccharides*: Colloids or noncrystalizable organic substances known as starches. There are three main groups of polysaccharides: 1) starches; 2) glycogen (animal starch) and 3) pentosans. Pentosans are numerous and include the cellulose or woody fibre of cotton, linen, walls of plant cells, etc. They are usually indigestible, although, in tender cabbage and other very tender vegetables, they are digestible. Galactose found in sugar, seeds, and algae; pectins found in unripe fruit and the gummy exudate on trees and plants are also pentosans.

Starches and sugars are well known to everyone, as they are found in all fruits and vegetables. Sugars are soluble carbohydrates with a more or less sweet taste. When heated to a high temperature they form caramel. Sugars are crystalloids; starches are insoluble and are colloids. Glycogen and milk sugar are the only carbohydrates of animal origin and even these are derived originally from the plant. Animals are incapable of extracting carbon from the air and synthesizing carbohydrates.

While the sugars are all soluble, raw starch is insoluble. Boiling will render part of it soluble. This, however, hinders its digestion. Starch is converted into a disaccharide in the mouth, and this is converted into a monosaccharide in the intestine.

The body cannot use starch. It must first be converted into sugar before it can be utilized by the cells.

This is done in the process of digestion and begins in the mouth. Disaccharides and polysaccharides are converted into monosaccharides in the process of digestion, as carbohydrates can be absorbed and assimilated only as monosaccharides. Starch must first be converted into sugar, and the complex sugars must be converted into simple sugars before they are absorbed. The body's need for sugar may easily be supplied without eating commercial sugars and syrups or any form of denatured carbohydrate. Child and adult alike should eat only natural sweets and starches.

Sugar is the most important building material in the plant world. A characteristic difference between plants and animals is that, whereas the animal is built up largely out of proteins, the plant is built up largely out of carbohydrates. Plants may be truly said to be made of sugar. They contain various minerals and some nitrogen, but practically the whole fabric of the plant or tree is composed of sugar in some form. Sugars are essential constituents of all plants without which they cannot exist. Indeed, sugars are the most important and most abundant building materials in plants. Out of the *immature* or *sap sugars*, plants build their roots, stems, flowers, fruits and seeds. The finished plant is almost literally made of sugar.

Nature produces sugars out of three gases—carbon, oxygen and hydrogen. Oxygen and hydrogen in proportions to form water are taken from the water in the soil. Carbon is taken from the carbon dioxide of the air. Out of these gases, or out of this fluid and gas, the plant synthesizes sugar, a thing the animal cannot do. The green coloring of plants is due to the presence of a pigment known as chlorophyll. This pigment takes part in a chemical process known as photosynthesis, by which carbon dioxide (or at least the carbon in the carbon dioxide), with the aid of sunlight, is united with water to form sugar. Recent experiments have shown that enzymes contained in the leaves of the plants are the chief agents in the production of this sugar. Some plants can produce sugar in the absence of light.

Not only the starches of plants, but also the pentosans, the woody fibers, cellulose and gums are made of sugar and may be reconverted into sugar. When carbohydrates are stored for long periods, they are stored as starches. When they are used, they are reconverted into sugars. Corn, peas, etc., are sweet (full of sugar) before they mature. The sap of the corn is also sweet. The sap of the cane plant is very sweet. In the matured state corn, cane seed and peas are hard starch grains. In the germinating process the starch is reconverted into sugar. As starches these seeds will keep for long periods of time; as sugars they would not keep until the following spring. It will be noticed that the enzymes in seeds do not require ultraviolet rays and acid to bring about this reversion, any more than do the enzymes in digestive juices.

Fruits are ready for immediate use and, if not used soon after ripening, tend to decompose rapidly. Grains are intended for storage. It is significant that fruits are composed of insoluble starches and are usually rich in acids before they ripen. In this state they are usually avoided by animals. The starch is reconverted into sugar in the ripening process. This arrangement protects the seed of the fruit until it is matured and ready for dispersal. Then the fruit is ripened and made ready for food.

The animal, like the plant, builds its carbohydrates out of sugar. All starch foods must be converted into sugar (in the process of digestion) before they can be taken into the body and used. Animal starch (glycogen) is made from sugar. It, like the starch of grains, is a storage product. Like the starch of grains, it must be reconverted into sugar before using. The sugar in milk may be made from starches.

*The matured fruit sugars* of plants, especially those of fruits, are particularly appropriate for food. They are never concentrated and are always well balanced with other nutrients. They are built up out of the immature sugar and impart to both fresh and dried fruits their delicious flavors. Matured sugars in flowers are collected by bees and made into honey. Fruit sugars are, in truth, export products produced by plants.

All the sugar the body requires may be obtained from fresh ripe fruits. This is especially so during the summer months. During the winter months when fresh fruits are not so abundant, dried (but un sulphured) fruits are excellent sources of sugar. These should not be cooked. Owing to the absence of water, dried fruits are more concentrated foods than fresh fruits and should not be eaten in the same

bulk.

Just as fruits are savoured with their matured sugars, so vegetable foods are savoured with the immature juices (saps) of the plants. In the plants, as in the fruits, the sugars are combined with vitamins, mineral salts, fiber and other elements of foods.

It is essential to emphasize that sugars constitute but one of the ingredients of plant life and are never put up in their pure state. In fruits and plants they are always combined with and balanced by other ingredients, particularly with salts, vitamins and water. Man, not nature, produces concentrated sugars. Man, not nature, separates the minerals from sugar. Sugars should be eaten as nature provides them.

Commercial syrups and molasses are concentrated saps. Besides being concentrated, usually by the use of heat in evaporating the water, they are deprived of their minerals and vitamins and have preservatives, artificial colors and flavors added and are often bleached with sulphur dioxide, with which they become saturated. Commercial sugars—maple, cane, beet, milk—are crystalized saps. They, too, are unbalanced, commonly bleached and thoroughly unfitted for use. So concentrated are these syrups and sugars, so denatured and so prone to speedy fermentation in the digestive tract, that it is best not to employ them at all. If they are used, they should be used very sparingly. The same rule should apply to honey. This food of the bee contains all the other nutritive elements in very minute quantities, being largely water and sugar with flavors from the flowers. If it is eaten, it should be taken sparingly.

What a difference between eating sugar cane and eating the extracted, concentrated and refined sugar of the cane! It is said that it takes a West Indian native an hour to chew eighteen inches of cane from which he derives the equivalent of one large lump of sugar—less than the average coffee-drinker puts into a single cup of his favorite poison. (The boys and girls of Texas and Louisiana can chew sugar cane faster than the West Indian native, it seems.) In thus securing his sugar, the cane eater secures the minerals and vitamins that are normally associated with sugars—he does not eat a "purified" product.

Sugar is regarded as an energy food, but it is a remarkable fact that the heavy sugar eater prefers to watch athletic games to taking part in them. We, of course, have reference to the heavy eater of commercial sugars. They seem to stimulate and then depress the muscular powers.

It has long been the Hygienic theory that the catarrhal diseases are based on carbohydrate excess—sugar excess, as all starches are converted into sugar in digestion. It is interesting to note, in this connection, that the *British Medical Journal* for June 1933 carried an article discussing "the relation of excessive carbohydrate ingestion to catarrh and other diseases," in which it was pointed out that during World War I, the incidence of catarrhal illnesses was reduced seemingly corresponding with the great eduction of sugar consumption. The writer of the article concludes that "restriction in the use of sugar would result in improvement in the national health as regards catarrhal illness, as well as in other directions."

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #2: Digestion Of Foods by Dr. Herbert M. Shelton

## **Article #2: Digestion Of Foods by Dr. Herbert M. Shelton**

Foodstuffs as we eat them constitute the raw materials of nutrition. As proteins, carbohydrates and fats, they are not usable by the body. They must first undergo a disintegrating, refining and standardizing process (more properly a series of processes) to which the term digestion has been given. Although this process of digestion is partly mechanical, as in the chewing, swallowing and "churning" of food, the physiology of digestion is very largely a study of the chemical changes foods undergo in their passage through the alimentary canal. For our present purposes, we need give but little attention to intestinal digestion but will concentrate upon mouth and stomach digestion.

## **Enzymic Limitations Necessitate the Combining of Compatible Foods**

The changes through which foods go in the processes of digestion are affected by a group of agencies known as enzymes. Due to the fact that the conditions under which these enzymes can act are sharply defined, it becomes necessary to give heed to the simple rules of correct food combining that have been carefully worked out on a basis of the chemistry of digestion.

Long and patient effort on the part of many physiologists in many parts of the world have brought to light a host of facts concerning enzymic limitations, but, unfortunately, these same physiologists have attempted to slur over their importance and to supply us with fictional reasons why we should continue to eat and drink in the conventionally haphazard manner. They have rejected every effort to make a practical application of the great fund of vital knowledge their painstaking labors have provided. Not so the Natural Hygienists. We seek to base our rules of life upon the principles of biology and physiology.

## **What Enzymes Are**

Let us briefly consider enzymes in general before we go on to a study of the enzymes of the mouth and stomach. An *enzyme* may be appropriately defined as a physiological *catalyst*. In the study of chemistry it was soon found that many substances that do not normally combine when brought into contact with each other may be made to do so by a third substance when it is brought into contact with them. This third substance does not in any way enter into the combination or share in the reaction; its mere presence seems to bring about the combination and reaction. Such a substance or agent is called a *catalyst* and the process is called *catalysis*.

Plants and animals manufacture soluble catalytic substances, colloidal in nature and but little resistant to heat, which they employ in the many processes of splitting up of compounds and the making of new ones within themselves. To these substances the term *enzyme* has been applied. Many *enzymes* are known, all of them, apparently, of protein character. The only ones that need interest us here are those involved in the digestion of foodstuffs. These are involved in the reduction of complex food substances to simpler compounds that are acceptable to the bloodstream and usable by the cells of the body in the production of new cell substance.

## **Bacterial By Products Poisonous**

As the action of enzymes in the digestion of foodstuffs closely resembles fermentation, these substances were formerly referred to as ferments. Fermentation, however, is accomplished by organized ferments—bacteria. The products of fermentation are not identical with the products of enzymic disintegration of foodstuffs and are not suitable as nutritive materials. Rather, they are poisonous. Putrefaction, also the result of bacterial action, also gives rise to poisons, some of them very virulent.

## **Digestive Enzymes Extremely Specialized**

Each enzyme is specific in its action. This is to say, it acts only upon one class of food substance. The enzymes that act upon carbohydrates do not and cannot act upon proteins nor upon salts nor fats. They are even more specific than this would indicate. For example, in the digestion of closely related substances such as the disaccharides (complex sugars), the enzyme that acts upon maltose is not capable of acting upon lactose. Each sugar seems to require its own specific enzyme. The physiologist, Howell, tells us that there is no clear proof that any single enzyme can produce more than one kind of ferment action.

## **Digestion a Step-By-Step Process**

This specific action of enzymes is of importance, as there are various states in the digestion of foodstuffs, each state requiring the action of a different enzyme and the various enzymes being capable

of performing their work only if the preceding work has been properly performed by the enzymes that also precede. If *pepsin*, for example, has not converted proteins into peptones, the enzymes that convert peptones into amino acids will not be able to act upon the proteins.

The substance upon which an enzyme acts is called a *substrate*. Thus starch is the substrate of *ptyalin*. Dr. N. Phillip Norman, Instructor in gastroenterology, New York Polyclinic Medical School and Hospital, New York City, says: "In studying the action of different enzymes, one is struck by Emil Fischer's statement that there must be a special key to each lock, the ferment being the lock and its substrate the key, and if the key does not fit exactly in the lock, no reaction is possible. In view of this fact, is it not logical to believe the admixture of different types of carbohydrates and fats and proteins in the same meal to be distinctly injurious to the digestive cells? If, since it is true that similar but not identical locks are produced by the same type of cells, it is logical to believe that this admixture taxes the physiological functions of these cells to their limit?" Fischer, who was a renowned physiologist, suggested that the specificity of the various enzymes is related to the structure of substances acted upon. Each enzyme is apparently adapted to or fitted to a certain definite structure.

## **Chewing Is First Digestive Step**

Digestion commences in the mouth. All foods are broken up into smaller particles by the process of chewing, and they are thoroughly saturated with saliva. Of the chemical part of digestion, only starch digestion begins in the mouth. The saliva of the mouth, which is normally an alkaline fluid, contains an enzyme called *ptyalin*, which acts upon starch, breaking this down into maltose, a complex sugar, which is further acted upon in the intestine by maltase and converted into the simple sugar *dextrose*.

The action of ptyalin upon starch is preparatory, as maltase cannot act upon starch. *Amylase*, the starch-splitting enzyme of the pancreatic secretion, is said to act upon starch much as does *ptyalin*, so that starch that escapes digestion in the mouth and stomach may be split into maltose and achroodextrin, providing, of course, that it has not undergone fermentation before it reaches the intestine.

## **Some Enzymes Destroyed By Acids and Alkalines**

Ptyalin is destroyed by a milk acid and also by a strong alkaline reaction. It can act only in an alkaline medium, and this must not be strongly alkaline. It is this limitation of the enzyme that renders important the manner in which we mix our starches, for if they are mixed with foods that are acid or that provide for an acid secretion in the stomach, the action of the ptyalin is brought to an end.

## **Some Factors That Inhibit Digestion**

Stomach (gastric) juice ranges all the way from nearly neutral in reaction to strongly acid, depending upon the character of the food eaten. It contains three enzymes-pepsin, which acts upon proteins; lipase, which has slight action upon fats; and rennin, which coagulates milk. The only one of these enzymes that needs concern us here is pepsin. Pepsin is capable of initiating digestion on all kinds of proteins. This is important, as it seems to be the only enzyme with such power. Different protein splitting enzymes act upon the different stages of protein digestion. It is possible that none of them can act upon protein in stages preceding the stage for which they are specifically adapted. For example, erepsin, found in the intestinal juice and in the pancreatic juice, does not act upon complex proteins, but only upon peptides and polypeptides, reducing these to amino acids. Without the prior action of pepsin in reducing the proteins to peptides, the erepsin would not act upon the protein food. Pepsin acts only in an acid medium and is destroyed by an alkali. Low temperature, as when iced drinks are taken, retards and even suspends the action of pepsin. Alcohol precipitates this enzyme.

Just as the sight, odor or thought of food may occasion a flow of saliva, a "watering of the mouth," so these same factors may cause the flow of gastric juice, that is a "watering of the stomach." The taste of food, however, is most important in occasioning a flow of saliva. The physiologist, Carlson, failed in

repeated efforts to occasion a flow of gastric juice by having his subjects chew on different substances, or by irritating the nerve endings in the mouth by substances other than those directly related to food. In other words, there is no secretory action when the substances taken into the mouth cannot be digested. There is selective action on the part of the body and, as will be seen later, there are different kinds of action for different kinds of foods.

In his experiments in studying the "conditioned reflex," Pavlov noted that it is not necessary to take the food into the mouth in order to occasion a flow of gastric juice. The mere teasing of a dog with savory food will serve. He found that even the noises or some other action associated with feeding time will occasion a flow of secretion.

It is necessary that we devote a few paragraphs to a brief study of the body's ability to adapt its secretions to the different kinds of foodstuffs that are consumed. Later we will discuss the limitations of this power. McLeod's *Physiology in Modern Medicine* says: "The observations of Pavlov on the responses of gastric pouches of dogs, to meat, bread and milk have been widely quoted. They are interesting because they constitute evidence that the operation of the gastric secretory mechanism is not without some power of adaptation to the materials to be digested."

### **Digestion Proceeds Intelligently**

This adaptation is made possible by reason of the fact that the gastric secretions are the products of about five million microscopic glands embedded in the walls of the stomach, various of which secrete different parts of the gastric juice. The varying amounts and proportions of the various elements that enter into the composition of the gastric juice give a juice of varying characters and adapted to the digestion of different kinds of foodstuffs. Thus the juice may be almost neutral in reaction or it may be weakly acid or strongly acid. There may be more or less pepsin according to need. There is also the factor of timing. The character of the juice may be very different at one stage of digestion from what it is at another, as the varying requirements of a food are met.

A similar adaptation of saliva to different foods and digestive requirements is seen to occur. For example weak acids occasion a copious flow of saliva, while weak alkalies occasion no salivary secretion. Disagreeable and noxious substances also occasion salivary secretion, in this instance to flush away the offending material. It is noted by physiologists that with at least two different types of glands in the mouth able to function, a considerable range of variation is possible with reference to the character of the mixed secretion finally discharged.

An excellent example of this ability of the body to modify and adapt its secretions to the varying needs of various kinds of foods is supplied us by the dog. Feed him flesh and there is a secretion of thick, viscous saliva, chiefly from the submaxillary gland. Feed him dried and pulverized flesh, and a very copious and watery secretion will be poured out upon it, coming from the parotid gland. The mucous secretion poured out upon flesh serves to lubricate the bolus of food and thus facilitate swallowing. The thin, watery secretion, on the other hand, poured out upon the dry powder washes the powder from the mouth. Thus, it is seen that the kind of juice poured out is determined by the purpose it must serve.

### **Humans Ate Correctly In Nature**

As we previously noted, ptyalin has no action upon sugar. When sugar is eaten there is a copious flow of saliva, but it contains no ptyalin. If soaked starches are eaten, no saliva is poured out upon these. Ptyalin is not poured out upon flesh or fat. These evidences of adaptation are but a few of the many that could be given. It seems probable that a wider range of adaptation is possible in gastric than in salivary secretion. These things are not without their significance to the person who is desirous of eating in a manner to assure most efficient digestion, although it is the custom of physiologists to gloss over or minimize them.

There are reasons for believing that man, like the lower animals, once instinctively avoided wrong

combinations of foods, and there are remnants of the old instinctive practices still extant. But having kindled the torches of intellect upon the ruins of instinct, man is compelled to seek out his way in a bewildering maze of forces and circumstances by the fool's method of trial and error. At least this is so until he has gained sufficient knowledge and a grasp of proved principles to enable him to govern his conduct in the light of principles and knowledge. Instead, then, of ignoring the great mass of laboriously accumulated physiological knowledge relating to the digestion of our foodstuffs, or glossing over them as is the practice of the professional physiologists, it behooves us, as intelligent beings, to make full and proper use of such knowledge. If the physiology of digestion can lead us to eating practices that insure better digestion, hence better nutrition, only the foolish will disregard its immense value to us, both in health and in disease.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #3: Starches Are Second-Rate Foods by Marti Fry

### **Article #3: Starches Are Second-Rate Foods by Marti Fry**

Have you noticed how often we state that fruits are the foods to which we are biologically suited? We rank them as first-class foods and we rank starchy foods such as tubers, legumes and grains as second- or third-class foods. One reason for this, as you may know, is that most starchy foods have to be cooked to make them tasty. Of course there are exceptions to this:

1. Some people like potatoes, yams, etc., raw.
2. Some mildly starchy vegetables such as carrots, peas and cauliflower are palatable in the raw state to most people.
3. Many legumes can be sprouted instead of cooked.

But despite these exceptions, starchy foods are not ideal for humans. Unlike sugars from fruits, which pass almost directly from the stomach to the small intestine for absorption, starches must be converted to sugar for the body to unlock their energy potential.

Most animals secrete starch-splitting enzymes called amylases, derived from the Latin word meaning—you guessed it—*starch-splitting*. In humans, starch digestion begins in the mouth: Our saliva contains an amylase called ptyalin, from the Greek word *ptyalon*, meaning *saliva*. Ptyalin, also called salivary amylase, changes starch chemically into maltose, a complex sugar.

Many other animals, such as pigs, birds and other starch eaters, but not humans, secrete other additional amylases to insure complete starch digestion. To be sure of adequately digesting the starch we humans consume, we must chew our food very, very thoroughly so it becomes well-mixed with saliva.

The starch that's converted to maltose by salivary enzymic action is further broken down in the small intestine by the enzyme maltase into the simple sugar, dextrose, for the bloodstream can absorb only simple sugars, never starches or complex sugars. (Dextrose is dextrorotatory glucose.)

Only 30 to 40 percent of the starch eaten can be broken down by ptyalin in the mouth. If starches are eaten with (or close in time to ingestion of) acid fruits (citrus fruits or tomatoes) or with protein foods, the ptyalin in the saliva that's swallowed with the food cannot further break down the starch into simple sugars.

This is because ptyalin can only act in an alkaline environment and the stomach environment becomes acid when proteins are consumed. The acids in fruits will also inhibit the secretion of ptyalin. Hence, you should take care to eat starchy foods (if you eat them at all) with vegetables and not with acid or protein foods to insure the best possible digestion.

We do secrete a pancreatic amylase in our intestine to digest starches not handled by salivary amylase (ptyalin). But starches, often partially decompose in the stomach before they get to the intestine.

In addition, *there's a problem relative to human starch digestion* and this is another reason why starches are usually cooked or sprouted (besides for taste):

According to *The Textbook of Medical Physiology* by Arthur C. Guyton, M.D.:

*Most starches in their natural state, unfortunately, are present in the food in small globules, each of which has a thin protective cellulose covering. Therefore, most naturally-occurring starches are digested only poorly by ptyalin unless the food is cooked to destroy the protective membrane.*

If cooking can destroy the protective membrane around the starch cells, what is it doing to the food's value? Cooking changes the minerals and proteins into unusable forms and destroys most vitamins!

Chewing only partially damages the protective covering of starch globules and so raw starches can only be partially digested. While undigested foods cause pathogenic problems in the human body, the toxins ingested when we eat cooked foods (deranged vitamins and minerals) cause even greater problems.

In light of how the human body uses starches by changing them to simple sugars through a complicated and only partially effective process, why not consider getting all your carbohydrate needs from fresh fruits which are already in the form of simple easily-digestible sugars? We don't need starches at all and can thrive more healthfully without them.

This article is reprinted from *The Health Crusader, Better Life Journal's* predecessor.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #4: The "Staff Of Life" by Marti Fry

### **Article #4: The "Staff Of Life" by Marti Fry**

We have stated many times that wheat and bread are unwholesome foods for several reasons: Wheat, the seed of cereal grass, is a starchy food that the body cannot digest properly and fully because we secrete only a limited amount of ptyalin, the enzyme that starts digestion of starches, and we secrete no enzyme to break down gluten. Also, wheat and breads are almost always eaten with sugars and/or proteins, all of which then end up in producing indigestion and pathogenic conditions inside the body.

Unless you sprout whole wheat berries, wheat must be cooked to be eaten; and cooking renders the food's nutrients mostly unusable and quite toxic. Whole wheat flour, even if freshly ground, lacks in nutritional value because of the great loss of nutrients due to oxidation of the burst food cells.

Despite these convincing reasons why we shouldn't eat bread at all let's talk about bread a bit further. The wheat bread sold in stores is likely to be only 25 percent wheat, the other 75 percent of the flour being bleached white flour. But you can't tell this by just looking at the bread, for it may be colored with caramel to make it look darker like 100 percent whole wheat bread. The label has to say "whole-wheat flour" or else it's only partly whole wheat.

This is bad enough but there's worse news: The high-fiber breads that are becoming so popular these days contain powdered cellulose, a cheap byproduct of the paper industry. Even nonhygienic minded "health" writers warn against consuming artificial fiber.

The paper mills are selling this powdered cellulose to food processors as a "bulking agent" for cookies, cakes, pastas and breakfast cereals, as well as for bread. The human body wasn't designed to digest this

waste product of the paper industry. Your best bet is still to stay away from products which contain "bulking agents," sugar or honey, salt, preservatives, colorings and wheat.

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #5: What's Wrong With Wheat by Marti Fry

### **Article #5: What's Wrong With Wheat by Marti Fry**

Most people think that whole grain breads are the "staff of life"—that we need to eat bread to be healthy. However, this has been found to be untrue. Even 100 percent whole wheat is unhealthful. Many doctors have their patients merely eliminate grain products (including whole wheat bread) from their diets because this helps many people lose weight.

Medical research has proven that wheat is one of the causes of colds. Families were asked to give up bread and grains for one year. What happened was that no one in these families suffered any colds that year. Another study has shown that wheat is a main contributor of eczema, hives, migraine headaches and various "allergies."

Of course we know wheat is an *indirect* cause of diseases; that is, it is usually cooked and otherwise processed such that it contributes to body toxicity. This starchy food is almost always combined improperly; that is, it is eaten with honey, sugar or fruit as in breads, pies, fruitcakes, cereals, etc., or with protein foods such as meat, cheese, milk, yogurt, nuts, seeds, etc.

Consequently, poisonous byproducts of indigestion are created in the stomach. The toxins resulting from fermentation (starch) or putrefaction (proteins) accumulate with other toxins and bring toxemia, the sole cause of disease.

A research undertaken by Dr. Alvarez of the Mayo Clinic states, "Bread can pass through the whole of the small intestine without being digested at all!" Also, wheat interferes with the absorption of other foods, as does salt. Life Scientists know that years of eating wrong combinations of wrong foods gradually impair the body's digestive abilities.

When people eat a lot of bread they get filled up. Thus they eat less of the fruits and vegetables that have the proper nutrient and vitamin contents. So, as J. I. Rodale says in his book, *The Complete Book of Food and Nutrition*, "This whole thing about the importance of bread as the staff of life leaves me cold. I think the average person is better off to entirely restrict the use of bread."

Mr. Rodale also stated, "What is the best program for a person who wishes to live to 120? I say don't eat bread. It is the worst form of starch ... It is not an edible starch."

[Home](#) > [Lesson 7 - Carbohydrates - Fuel For The Human Body](#) > Article #6: Fruit - The Ideal Food by Dr. Herbert M. Shelton

### **Article #6: Fruit - The Ideal Food by Dr. Herbert M. Shelton**

Tradition has it that man's original diet was fruit. While we have no written history of a period when man lived on a fruit diet, there is plenty of evidence to substantiate the view that he once did so. We do know that fruits have historically constituted an important part of man's diet in most parts of the earth

from remote times. Only within recent centuries, and then only in certain parts of the earth, has the notion that fruits have little food value come about.

Most fruits are abundantly supplied with sugar and it is quite possible to gain weight on a fruit diet. Some fruits, like the avocado and most nuts (nuts are also fruits, technically speaking) contain considerable fat. While few of the pulpy fruits are abundantly supplied with protein, some of them do contain a higher percentage of protein than mother's milk. Practically all nuts are rich in protein of high biological value. One does not have to eat animal foods in order to supply himself with an abundance of all the amino acids required.

In the last century a veritable fruitophobia arose both in Europe and America and people refrained from eating fruits because they supposedly caused disease. Fruits were accused of causing various diarrheal diseases, even typhoid and cholera. It is a fact that a large excess of fresh fruit will result in loose stools, but this is not an objection to fruit eating. One has only to cease taking the fruit in excess to have the bowel looseness cease.

The body does not have to contend with sepsis or poison when an excess of fruit is eaten as when excesses of proteins or starches are taken. Excesses of all types are harmful, but an excess of fruit is far less harmful than an excess of bread or flesh. The prejudice against fruits, however, arose not so much out of the results of excess, as out of the faulty combinations in which they were eaten. Fruits are best taken at a fruit meal and should not be combined with starches or with foods rich in protein or fats, including nuts.

In the last century the idea arose that certain diseases such as rheumatism, gout, lumbago, arthritis, etc., were acid diseases. Acid fruits were forbidden on the ground that they helped to produce these diseases. This error about fruits is as dead as are those who promoted it, and it is somewhat surprising to have it revived at a time when our knowledge of foods is so much greater than it was in the last century.

Under the promptings of this revived notion, when people are told that their gastritis, arthritis, etc., arises out of acidity, many mistake this to mean that they arise out of taking acid fruits. They especially reject oranges, grapefruit, lemons, pineapples and similar acid fruits, lest these produce arthritis in them or aggravate the arthritis from which they already suffer.

The fact is that fresh fruits and vegetables, whether burned in the air or metabolized in the body, are alkaline. On the other hand, a diet of flesh, oils, sugar and denatured starches (white flour, polished rice, etc.) provides an excess of acids—sulphuric, etc. Even such acid fruits as oranges and grapefruit are alkaline when metabolized in the body. When fruit is cooked and sugar is added, the fermentation that follows gives rise to acids that add to the acidity of the body. (All canned fruits have been cooked and most have been sugared.)

As important as water is in the processes of life you do not need to drink large quantities of it. Under the usual circumstances of life the water in fruits and salads will supply all the water needed or nearly enough, if these are eaten as they should be. The pure water of fruits and vegetables is much better for physiological purposes than the water supplied by the water systems of our cities and towns.

Fruits appeal to the eyes, the nose and the mouth. Their beauty of color, their richness of aroma, and the deliciousness of their flavors make them ideally suited to man's gustatory delight. There is a rich variety of them and they ripen at various seasons of the year, so that there is but a small part of the year in which they are not abundant. Beginning with the many varieties of delicious berries in the springtime and progressing through the varied assortments of cherries, peaches, plums, nectarines, figs and mangoes of the summer season, to the apples, pears, persimmons, oranges and grapefruit of the fall and winter season, nature provides us with a pleasing assortment of delicious foods that may be enjoyed by everyone and that are easily digested by even the most sensitive stomachs. By the exercise of a little intelligent care in selecting and combining these foods, one may be assured of better health.

## **Article #7: Are Humans Starch Eaters? by Dr. Herbert M. Shelton**

In his efforts to establish, to his complete satisfaction, the normal diet of man, Dr. Emmet Densmore pursued a line of reasoning that we may consider with profit. First, he noted that animals in their natural state live upon foods which are spontaneously produced by nature and require no cultivation. Man, on the other hand, he noted, lives upon foods that are produced by cultivation. Man does not live upon the spontaneous products of nature, but lives artificially.

The thought then occurred to him that, if nature has provided a *natural food* for all the animals below man, perhaps she has also provided a normal food for man. He assumed that nature has produced foods that are as normal to man as grasses are to the herbivore, or as flesh is to the carnivore. This was certainly no unreasonable assumption but is based on the principle of the *unity of nature*. It is based upon the fact that man, as much as the lion or the deer, is a child of nature and that, like these animals, his normal requirements are found in nature.

If man, like the other animals of nature, is constituted for a certain type of food, what is that food or what is that type? What, in other words, is the normal food of man? He sought for his answer in several directions. Scientists were agreed that man's original home was in a warm climate, either in the tropics or the subtropics. Without tools and without fire, he must have lived in a part of the world where the spontaneous productions of nature could be obtained by him with only the "tools" with which he is physiologically equipped and could eat without artificial preparation.

"If man first lived in a warm climate," he reasoned, "and, if like other animals, he subsisted on foods spontaneously produced by nature, these foods must have been those which grow wild in such a climate, quite probably such foods as are still spontaneously produced in such localities. The woods of the south, as is well known, abound in sweet fruits and nuts."

It will be seen at a glance that this line of reasoning led straight to the fruits of the trees as man's normal diet. But man does not live on a fruit diet. Indeed, the greater part of his diet has long been cereals and animal foods. Let us, then, see what Densmore found about cereals.

"It is taught by botanists that wheat is an artificial product developed from some grass plant not now known. Moreover, cereals are the product of the temperate zone, not of those regions where there is no winter, and it was, therefore a necessity of man's sustenance when he was without agriculture, without tools and without fire, and had to depend upon foods spontaneously produced by nature, that he live in a region where his natural foods were produced at all seasons of the year. This narrows or confines the inquiry to two articles of diet—fruit and nuts."

He next noted that these foods need no additions, no sweetenings, no seasonings, no preparations, to appeal to the olfactory and gustatory senses of man. "If the dishes that are set before a gourmet," he said, "those that have been prepared by the most skillful chefs, and that are the product of the most elaborate inventions and preparations, were set beside a portion of the sweet fruits and nuts as produced by nature, without addition or change, every child and most men and women would consider the fruits and nuts quite equal if not superior in gustatory excellence to the most *recherche'* dishes."

Analysis showed that these foods contain the proteins, carbohydrates, fats, and minerals that are essential to human nutrition. Subsequent analysis has shown them to be abundant in the various essential vitamins. Sugar, he noted, is the chief carbohydrate of fruits and nuts. In what way does this diet differ from the diet of civilization? Let us see how Densmore viewed this.

"Instituting a comparison between sweet fruits and nuts on the one hand, and the diet of civilization on the other, I soon detected an essential difference. I saw that bread, cereals, and vegetables are the basis of the diet of the present day and that starch is the chief element of these foods. Scrutinizing the component parts of fruits and nuts, I saw that these fruits contain very little starch, and hence I perceived that I had brought to light a fact that was not unlikely to bear an important part in the solution of the problem before me."

Thus, by a simple process of reasoning upon well-known facts of nature, he had arrived at the conclusion that, while man's normal diet as represented in the spontaneous products of nature contains little starch, the cultivated food plants of civilized man were abundant in starch. This led to the question: "What are the effects of starch upon the system?" "Wherein," he asked, "Does a diet that is without starch differ physiologically from one in which starch is the predominant element?"

Seeking a reply to this last question, he noted first of all "that the two foods (fruits and starch or cereals) involve a different process of digestion." "Sweet fruits are composed largely of glucose, with a fair proportion of nitrogen ..." cereals are composed largely of starch, with a higher proportion of nitrogen. The carbohydrate in nuts is largely sugar. If fruits and nuts constitute man's normal diet, as his reasoning had concluded, the starch diet is not his normal diet.

But he was met by one of the most convenient arguments that the evolution hypothesis has supplied its votaries. "Since man, by artificial contrivance and agriculture," it was reasoned, "has developed and employed cereals and starchy vegetables as the basis of his diet, he has reversed what appears to be the natural order." Densmore examined this contention in the light of anatomy and physiology and found that man's digestive organs have undergone no alterations in structure and function to adapt him to the starch diet. "The orangutan and the several species of long-armed apes, which have, apparently since time began, fed upon nuts and fruits to the exclusion of cereals and starchy vegetables, have today the same digestive apparatus in substantially the same proportion of parts as man, after his thousands of years of cereal eating. This fact is undeniable evidence that man's organs have not undergone essential modification or change by these centuries of unnatural diet." *Evolution just didn't evolve so readily.*

Analyzing the various mono-diets that were then popular and for which much was claimed in the way of their benefits to the patient, Densmore noted that the Salisbury meat diet, the grape diet, and the milk diet each were nonstarch diets. They were simple and, at the same time, they met another requirement of a diet—ease of digestion. "At the foundation of these diets," he said, "I was gratified to find the same basic fact that the diet is essentially nonstarch and one in which bread, cereals and starchy vegetables are reduced to a minimum." The Salisbury diet was, to quote Densmore, "entirely free from starch." He says of the Salisbury diet that it was "a uniform diet." It was usually considered that a variety of food is necessary both for the invalid and the robust. The triumphs of the mono-diets fly in the face of this commonly received axiom.

Can it be true, then, as Densmore contended, that invalids, and especially those suffering with digestive disease, are invariably benefitted by being placed on an exclusively nonstarch diet?" If man's digestive organs had undergone the modifications suggested by the defenders of the starch diet," he reasoned, "starch foods would naturally be those best adapted to man's restoration; but if, as we contend, the race has been, during all these thousands of years of cereal eating, perpetually straining and overcrowding the powers of the second stomach (the duodenum) and thus deranging the digestive apparatus—and if man is seen to be at once benefitted by discontinuing that diet, and by taking a food which is digested in the first stomach—these facts tend to confirm the view that the adoption of a nonstarch diet is in conformity with man's physiological structure and needs."

What he denominated *food fruits* consisted chiefly of sweet fruits—dates, figs, bananas, raisins, prunes, apples, nuts. Fruits and nuts, with the addition of green vegetables, constitute an adequate diet, furnishing all the food-factors needed by man's organism, and whoever eats a diet of this kind will be better off than he who eats a great variety of foods, from soup to nuts, from all the kingdoms of nature. It is not sufficient comment upon the abnormality of the modern diet that fruit is relegated to the last place

on the menu and is all too often used merely for ornamental purposes?

Prior to Sylvester Graham, the medical and conventional view of fruit was well expressed by a noted British physician thus: "for decorative purposes fruit equals flowers." Fruits were thought of, also, as relishes, but were not supposed to have any food value. "Bread and meat" were symbolic of nutriment, and those who could afford to do so often sat down to meals consisting of several types of flesh foods. Puddings, porridges and similar articles of diet were classed with bread.

"The ordinary dried figs of commerce," said Dr. Densmore, "contain about 68 percent glucose, which, when eaten, is in the identical condition that the starch of cereal food is converted into after a protracted and nerve-force-wasting digestion." He correctly observed that the sugar of fruits is predigested. Many of them require no preparation at all to render them ready to enter the bloodstream; others have to be reduced to simpler sugars, a process that takes place in the intestine. There is certainly good common sense in his thought that foods that are "predigested by nature" and are ready for absorption and assimilation upon ingestion and place less tax upon the digestive system than those foods that are prepared for assimilation only after a complicated and laborious process of digestion.

But, as man is equipped with ptyalin in the saliva and with starch-splitting enzymes in the intestine, it may be urged that starch may be thought of as constituting a normal part of his diet. It was the thought of Dr. Densmore that man's normal starch-digesting equipment is just sufficient to enable him to digest the small amounts of starch that normally exist in the fruits and nuts that constitute his normal diet. This thought is that, while man is equipped to digest a certain amount of starch, a predominantly starch diet such as is eaten in much of the world today is not normal to him, and that the best form in which he should secure his carbohydrates is sugar.

In this connection, sugar means the sweet fruits produced by old mother nature herself, not the processed sugars of commerce. Sugars, whether in the form of sugar (crystals-brown or white) or in the form of syrups that have been separated from their associated nutrients and that have been concentrated and changed, do not constitute ideal foods for man or beast. The maple sugar, cane sugar, beet sugar, milk sugar and fruit sugars of commerce and the syrups and molasses that are freely eaten, whether from cane or maple sap, do not constitute really good foods for man. Honey, even when pure and unchanged, is not a good food for man for much the same reason, and for added reasons. It is a fine food for bees.

It was believed in Densmore's day and it is still believed that toasting starch, as in toasting bread, dextrinizes it, thus rendering it more easily digested. Although the toasting of bread spoils much of the food value that remains in it after the first baking, and converts part of it into charcoal, precious little dextrinization occurs. Densmore, accepting the dextrinization of bread by toasting, said: "the sweet fruits are removed a step beyond. If there was some method by which a piece of toast could undergo a second transformation and the dextrin be converted into glucose, it would then in all probability be substantially as easy of digestion as the sweet fruits for the simple reason that it would already be glucose; in a word, no digestion would be necessary."

Certainly, as he contended, sweet foods would be far better for the weakened individual and the invalid, with lowered digestive powers, than would be a diet of starches. If there is one starch food that may be regarded as an exception to this rule, it would be the potato, as its starch is more easily and speedily converted into sugar than the starch of cereals, legumes, etc. But Densmore goes further than a consideration of the interests of the invalid when he says, "it would seem plain that a human being in apparently robust health is much more liable to remain so upon a food that is adapted to his organism and that is of easy digestion, than upon one that is a foreign body and that must undergo a protracted and difficult digestion before being of use to the system."

### 1. Introduction

The role of protein in the diet is often an emotional issue. If you wish to confirm this, try to take a steak away from a meat-eater. "But I need my *protein*" he cries. Tell your friends you are a vegetarian. They may look worried, disturbed—"Where do you get your *protein*?" they ask, as if you might drop dead at any time.

Perhaps never have so many been so confused over a subject about which they know so little. Much of the information the general public receives about protein comes from special interest groups such as the meat-packing and dairy industries. Consequently, the average person believes that eating large quantities of meat, eggs, milk, cheese, etc., is desirable. They may be full of poisons; they may cause cancer: they may cause heart disease—but, they all furnish that magical substance called protein.

If we are to separate emotion from reason, and propaganda from facts, we must educate ourselves about the true need of the body for protein. We must discover how much protein we actually need, how we can best get it and, after all, just what it is.

### 2. Why We Need Protein

Protein is needed by the body for only two reasons: 1) growth and 2) tissue repair and replacement. Protein is not necessary for muscular energy, increased activity or as a source of fuel.

## 2.1 Growth and Tissue Repair

Proteins support normal growth and maintenance of the body tissues.

## 2.2 Growth

Perhaps the role of protein in growth is best exemplified in the development of babies and newborn animals. A relatively high amount of protein is found in the milk of lactating mothers to insure healthy tissue growth in the young child. The protein needs are highest when growth is the fastest. For instance, compare the protein content in mother's milk after the first six months of birth:

<b>Time After Birth</b>	<b>Percent Protein</b>
From the 8th to 11th day	2.38
From the 20th to 40th day	1.79
From the 70th to 120th day	1.49
At the 170th day and later	1.07

Notice that the highest protein contents occur during the earliest stages of growth to allow for rapid development of the baby. As the growth of the child begins to slow, so does the protein content found in the mother's milk. It is also interesting to note that the percentage of protein found in mother's milk is approximately the same as the protein content of most fruits and vegetables. For example, grapes have a 1.3% protein content, raspberries 1.5%, dates 2.2% and so on.

We can also find a relationship between the protein content of the milk of lactating animals and the growth rate of their young by studying the following chart:

	<b>Number of Days for Newborn to Double Its Weight</b>	<b>Average Protein Percentage In Mother's Milk</b>
Man	180	1.6
Horse	60	2.0
Calf	47	3.5
Kid	19	4.3
Pig	18	5.9
Lamb	10	6.5
Dog	8	7.1

Cat	7	9.5

The highest need for protein in the diet occurs for most animals during the above periods when the newborn is doubling its birth weight. It is important that we realize the protein content in mother's milk, the optimum food nature has provided for rapid growth of the young, is far below the usual foods that are recommended because of their high protein content (such as meat, nuts, legumes, grains, etc.). Protein is indeed important for growth, but we might well question the alleged necessity for concentrated, high-protein foods.

### 2.3 Tissue Repair and Replacement

The second role of protein is in the repair of tissues or replacement of worn-out cells. After an organism reaches its full growth (usually between 18 and 22 years for humans), protein is needed only to supply the loss incidental to tissue waste. Cell degeneration and waste occur primarily because of toxicity in the body. If we adopt a lifestyle and diet that introduce a minimal amount of toxins into the body, then tissue waste will decrease significantly. As a result, actual protein needs will also diminish.

After an individual reaches adulthood, the only protein needs are for the repair and replacement of tissues that have deteriorated, due largely to body toxicity.

### 2.4 Not As A Fuel Source

Protein is not used directly as fuel for the body or for muscular activity. In muscular work, excretion of nitrogen as a result of protein usage increases only very slightly. Instead, it is the excretion of carbonic acid and absorption of oxygen that increase. These changes indicate that an expenditure of energy is derived mainly from non-nitrogenous foods (such as carbohydrates and fats) and not, from protein.

It is true that the body can use protein to generate fuel for physical activity, but it does so by breaking the protein down into a carbohydrate form. Protein is used as fuel only when there is either an excess of proteins or a lack of carbohydrates. When this occurs, the body splits off the nitrogenous matter from the protein molecule and uses the remaining carbon contents to produce fuel. This process not only involves a net loss of energy, but it also places an unnecessary strain on the liver, kidneys and other organs to eliminate the unusable nitrogenous wastes.

It is for this reason that the popular high-protein, low-carbohydrate diets result in weight loss and also why they are dangerous. Since the body has to expend so much energy in converting the excess protein into the needed carbohydrates for fuel, a net loss occurs in the body and the dieter loses weight. At the same time, he also places a heavy burden on his kidneys to eliminate all the uric acid generated by this protein breakdown and simultaneously overworks an already exhausted liver.

If more physical activity is anticipated, it is only necessary to increase the carbohydrate intake of the diet. Proteins are very poor in fuel-efficiency and do not aid directly or efficiently in muscular activity.

### **3. How Much Protein Do We Need?**

No other area of nutritional needs has been surrounded by so much controversy as the daily protein requirements. Nutritionists and scientists have made protein allowance recommendations that have varied as much as 600%. To arrive at a realistic estimate of our protein needs, we first need to understand how some of the current protein standards were derived. We then need to study the actual protein intake requirements of healthy human beings following a traditional diet that has been in effect over several generations. In this manner, we can see how many of the protein allowances today have been inflated beyond normal health needs.

#### **3.1 Background of Current Protein Recommendations**

In the late nineteenth century, Baron von Liebig was the first person to separate foods into proteins (nitrogenous substances) and carbohydrates/fats (non-nitrogenous substances). Since the muscles are composed chiefly of protein, Liebig concluded (incorrectly) that proteins supply muscular energy and the amount of protein consumed must be related to bodily activity. In fact, it is actually the non-nitrogenous foods that supply the best fuel for muscular activity.

Liebig was one of the first scientists to make a recommendation for protein intake. He determined the body's protein requirements by measuring the actual amounts of protein consumed by a group of men engaged in physical activity who ate a heavy diet. He reasoned that by measuring the protein intake of men who ate more than average and worked harder than usual, he could arrive at a safe recommended allowance of protein for all people. Such a technique for establishing a standard is somewhat akin to clocking race car drivers in order to establish a safe speed for schoolzones.

Anyway, based on this experiment Liebig determined that about 120 grams of protein daily would satisfy the needs of a moderately active adult. To obtain 120 grams of protein, a person would need to consume about 17 eggs or a pound and a half of meat or twenty ounces of almonds per day.

Following Liebig, Voit in 1881 performed a series of experiments on dogs and likewise determined that we should consume between 100 and 125 grams of protein a day. Doubtless, dogs can safely consume 125 grams of protein per day. The protein requirement for a growing puppy is five times as great as that for a growing baby. Voit, unfortunately, did not adjust his results to account for the differences between humans and dogs.

From the very beginning, we can see that protein requirements were artificially determined and excessively high. As early as 1887, experiments in Germany showed that 40 grams of protein was a sufficient daily amount about one-third of the current recommendations. The old standards of Liebig and Voit, however, were already firmly fixed in the minds of the medical establishment, and the belief persisted that a high-protein diet was conducive to health anyway, so why lower the recommendations?

After many more experiments proved that a daily protein intake of 30 to 40 grams was entirely sufficient, the establishment finally revised its recommendations down to 60 or 70 grams. Although only one-half of the early estimates, this figure is 50% too high, even by conservative nutritional standards. Today, with the support of the meat, dairy and egg industries, the protein allowances still remain around 70 grams per day. It should also be noted that a typical American meat-eater consumes about 93 grams of protein daily—more than anyone else in the world on the average.

#### **3.2 True Protein Needs**

Perhaps a more reasonable way of establishing true protein needs is to study the daily protein intake of groups of people who: 1) maintain a reasonable level of good health and 2) have followed a traditional diet over a long period of time. Even this method tells us little about what amount of protein a person

must have, but it is an interesting case study that probably has more validity than laboratory experiments on dogs, etc.

For instance, in Japan there are farming districts where dietary habits have been established for hundreds of years (unlike most Western diets which have fluctuated and changed rapidly over the past eighty years or so). In these districts, a primarily vegetarian diet was followed, consisting of many greens, plums, wild fruits, roots and occasionally fish in small amounts. These farmers were in excellent health and performed heavy manual labor all through the day. They consumed an average of 37 grams of protein per day, about half the official recommendation.

On various islands in the Pacific are tribes of people who have followed the same diet for dozens of generations—fruits, roots and tubers. They enjoy excellent health and consume about 15 grams of protein a day.

Finally, a study was done by Dr. Jaffe of the University of California at Berkeley on the effects of a non-meat diet over several generations. He studied several generations of fruitarians, ranging from young children to adults whose diet consisted principally of all raw fruits, supplemented by occasional nuts and some honey. Their diets supplied them with about 24 to 33 grams of protein a day. None exhibited any signs of protein deficiency, nor of any other nutrient deficiency. In fact, he discovered all of them to be in exceptional health.

Obviously, if large groups of people around the world are existing in good health on 15 to 35 grams of protein a day, and have done so over several generations and hundreds of years, then protein recommendations of 70 grams can only be deemed excessive.

During the last sixty years, several researchers (Rose, Boyd, Berg, et al) all independently proved that between 3.7% and 4.65% of the total food intake was all the protein necessary to maintain good health. These percentages are equivalent to about 24 to 30 grams of protein.

Careful investigations by Dr. Max Rubner, director of the Hygienic Institute of the University of Berlin, showed that only 4% of the entire caloric intake had to be in the form of protein. On a 2,500 calorie diet, this is about 100 calories of protein or about 28 grams.

Although Natural Hygiene and Life Science do not endorse gram-counting, calorie-counting or a preoccupation with minimal daily requirements, it seems that a reasonable estimate of the protein needs of an adult is probably in the 25 to 30 grams daily range — or about 1 gram per five pounds of body weight. If a person eats a varied diet of fruits, vegetables, nuts, seeds and sprouts, he is assured that he will meet this protein requirement, along with all the other nutrient needs.

### **3.3 Excessive Protein Is Harmful**

It is important that we have a realistic idea of the body's true protein needs because of the damage that may occur when we eat far beyond those needs. Almost every American consumes an excessive amount of protein, even by highly-inflated government standards. A protein-deficient diet is rare in this country, although nutrient-poor diets are the norm. Protein poisoning from an excessive amount of protein is more common than a true deficiency.

When protein is consumed in greater amounts than can be processed by the body, toxicity results from the excessive amount of nitrogen in the blood. This extra nitrogen accumulates as kinotoxin in the muscles and causes chronic fatigue.

Proteinosis, or acute protein poisoning, causes headaches and a general aching. Various symptoms of protein poisoning, such as a burning of the mouth, lips and throat, rashes, etc., are very similar to the symptoms attributed to allergies. In fact, many so-called allergies may be cases of protein poisoning instead.

A high-protein diet eventually destroys the entire glandular system. It overworks the liver and places a

heavy strain on the adrenals and kidneys to eliminate the toxins it creates. In many people, symptoms of arthritis have disappeared after they adopted a low-protein diet.

### 3.4 Protein Supplements are Harmful

It is for these and other reasons that protein supplements should never be used. Protein supplements, by supplying the body with an excessive amount of nitrogen, throw it out of balance and can actually contribute to other nutritional deficiencies. The body must try to eliminate the protein it cannot use that is found in these supplements, and an additional burden is placed on the body.

Also, protein supplements are made from fragmented foods such as soy powder, dried egg whites, powdered milk, etc. When foods are eaten in a processed and fragmented state, they tend to oversupply the body with some nutrients while creating a deficiency of other nutrients. Consequently, protein supplements, besides supplying an excessive and harmful amount of protein, also disrupt the body's nutritional balance.

Brewers yeast, a popular high-protein supplement, contributes to uric acid formation in the body. It is a waste product of the brewing industry, resulting when the barley is turned into malt. The industry then has no use for it. It is a "dead" food, because it's heated before marketing to destroy the yeast organisms. Dried egg whites result in constipation; soy powders have enzymes which actually inhibit the absorption of some of the amino acids; using powdered milk results in the formation of mucus (to aid in its removal from the body), and so on. All of these commonly-used protein supplements will be discussed in later lessons. None of them is ever necessary and they should never be included in the diet.

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > 4. What Are Proteins?

## 4. What Are Proteins?

We know now why we need protein in our diet, but what actually is protein? If you ask the average person what is the first thing that comes into his mind when you say "protein," he will most likely respond with "meat." Is protein simply meat or eggs or nuts?

Protein is one of the three categories for all foods, the other two being carbohydrates and fats. Proteins are highly complex compounds of carbon, hydrogen, nitrogen, oxygen and small amounts of sulphur or iodine. They are present in the protoplasm of every living cell and are involved in every organic activity of an organism.

### 4.1 Principal Proteins and Their Chemical Compositions

There are many different types of proteins within the bodies of animals and plants. For example, all plants have at least two different types of protein, and within the human body are over 100,000 different kinds of proteins. Although all of these proteins differ in their molecular structure, they all have approximately the same chemical composition of 53% carbon, 22% oxygen, 17% nitrogen, 7% hydrogen and 1% sulphur, iodine, etc.

The principal vegetable proteins are *albumin* (found in fruits and vegetables), *gluten* (in wheat and cereals), *legumin* (in peas and beans), *globulin* (in nuts) and *nucleo-protein* (in peas and beans), *globulin* (in nuts) and *muco-protein* (in seeds). Some of the animal proteins are *casein* (found in milk and dairy products), *gelatin* (in bones and tendons), *fibrin* (in blood) and *myosin* (in the flesh of animals).

All of these proteins are composed of amino acids. An amino acid is simply a substructure of a protein compound. You can think of protein as being chains of amino acids that are linked together to form one structure.

For example, a protein compound known as globulin exists in pumpkin seeds. It is composed of the following elements:

<b>Element</b>	<b>Number of Atoms in the Molecule</b>
Carbon	292
Hydrogen	481
Nitrogen	90
Oxygen	83
Sulphur	2

Within this globulin protein molecule are chains of amino acids that make up the compound.

In the following example, an amino acid called isoleucine is contained within this protein molecule. It is composed of the following elements:

<b>Element</b>	<b>Number of Atoms in the Amino Acid</b>
Carbon	6
Hydrogen	13
Nitrogen	1
Oxygen	2

## **4.2 Amino Acids Are the Building Blocks**

You can see that many amino acids are necessary to form one protein compound. In many cases, several different types of amino acids are in the same protein molecule. It is these amino acids that are important to the body, and this is what the body uses protein for.

When you hear the word "protein" now, you should think of "amino acids."

## 5. The Importance Of Amino Acids

Many different proteins are known, but all of them are constructed from 23 principal amino acids. These amino acids are the building blocks of all vegetable and animal protein. A molecule of protein may contain as many as several hundred or even thousands of these amino acids. These amino acids are linked together within the protein molecule in a unique fashion known as peptide linkage. A specific protein contains a variety of amino acids linked together in a sequence specific to that protein.

The body cannot use or assimilate protein in its original state as eaten. The protein must first be digested and split into its component amino acids. The body can then use these amino acids to construct the protein it needs. The ultimate value of a food protein, then, lies in its amino acid composition. It is the amino acids that are the essential nutrients. The proper study of the role of protein in nutrition can only be done with a thorough understanding of the amino acids.

### 5.1 Sources of Amino Acids

#### 5.1.1 Exogenous Protein

Amino acids are the end products of protein digestion. When protein is eaten, enzymes in the stomach and small intestine begin to break the linkages within the protein molecule and produce shorter and shorter chains of amino acids. Eventually, the amino acids are in a simplified enough chemical form so that they can pass through the intestinal walls into the bloodstream. They are then carried by the portal vein to the liver for elaboration and passed on to the blood, lymph and cells. The cells synthesize the amino acids into proteins as required.

This simplified description of the digestion and assimilation of protein applies to *exogenous protein*. Exogenous protein is the term for protein obtained through the diet or from outside of the body.

#### 5.1.2 Endogenous Protein

Protein may also be obtained from *within* the body. This is called *endogenous protein*. Endogenous protein does not come directly from the foods we eat, but from the synthesis of proteins from within the body.

Obtaining protein from the diet is common knowledge. The fact that the body can synthesize protein from its own proteinaceous wastes, however, is not widely known.

As the body's cells undergo their natural catabolic processes, they produce proteinaceous wastes in the form of spent cells and other by-products of their own metabolism. These proteinaceous products enter the lymph fluid.

Other cells in the body are able to ingest these spent proteins and to digest them in vesicles ("stomachs") of their own formation. The body's cells are thus able to break these proteinaceous wastes down into amino acids and use them to synthesize their own protein.

Endogenous protein (or protein from within the body) is an important source of amino acids that is often overlooked by conventional nutrition writers. Many times, up to two-thirds of the body's total protein needs are supplied through endogenous protein and not from exogenous dietary sources.

### 5.2 The Amino Acid Pool

From the digestion of proteins in the diet and from the recycling of proteinaceous wastes, the body has all the different amino acids circulating in the blood and lymphatic system. When cells need these amino

acids, they appropriate them from the blood or lymph. This continually-circulating available supply of amino acids is known as the *amino acid pool*.

The amino acid pool is like a bank that is open twenty-four hours. The liver and the cells are continually making deposits and withdrawals of amino acids, depending upon the concentration of amino acids in the blood.

When the number of amino acids is high, the liver absorbs and stores them until needed. As the amino acid level in the blood falls due to withdrawals by the cells, the liver deposits some of the stored amino acids back into circulation.

The cells also have the capacity to store amino acids. If the amino acid content of the blood falls or if some other cells require specific amino acids, the cells are able to release their stored amino acids into circulation. Since most of the body's cells synthesize more proteins than are necessary to support the life of the cell, the cells can reconvert their proteins into amino acids and make deposits into the amino acid pool.

Between the deposits and withdrawals by the liver and cells, there is a continual flux of amino acids in the blood and plasma. This circulating source of amino acids, as well as the potential availability of the amino acids stored within the liver and the cells, makes up the important amino acid pool. This pool of amino acids is very important in understanding why complete proteins are not necessary in the diet and will be discussed later in this lesson.

## **5.3 The Specific Amino Acids and Their Functions**

### **5.3.1 Specific Amino Acids—Descriptions and Sources**

The following descriptions of the amino acids include their most important functions and some of the food sources in which they are found.

**ALANINE** — Is a factor in regulating the adrenal glands and insuring healthy skin, particularly the scalp. It is found in almonds, alfalfa sprouts, apples, apricots, avocados, carrots, celery, cucumbers, grapes, lettuces, oranges, strawberries, sweet peppers and tomatoes.

**ARGININE** — Is used in muscle contraction and the construction of cartilage. It is essential in the functioning of the reproductive organs and in controlling the degeneration of the body cells. Arginine is found in alfalfa sprouts, beets, carrots, celery, cucumbers, lettuces, parsnips, potatoes and turnips.

**ASPARTIC ACID** — Is used in cardiovascular functions and in the retarding of tooth and bone destruction. It is found in almonds, apples, apricots, carrots, celery, cucumbers, grapefruits, lemons, pineapples, tomatoes and watermelons.

**CYSTINE** — Is used in the formation of red blood corpuscles and is involved in hair growth and the functioning of the mammary glands. It is found in alfalfa sprouts, apples, brazil nuts, beets, brussels sprouts, cabbages, carrots, currants, cauliflower, filberts, kale, pineapples and raspberries.

**GLUTAMIC ACID** — Is used in maintaining blood-sugar levels. Anemia will not occur if this and other nutrients are obtained and used. Glutamic acid is also a factor in the secretion of gastric juices. It is found in brussels sprouts cabbages, carrots, celery, green beans, lettuces and papayas

**GLYCINE** — Is a factor in forming muscle fiber and cartilage and in regulating sex hormones. It is found in alfalfa sprouts, almonds, carrots, celery, okra, oranges, potatoes, pomegranates, raspberries, turnips and water melons.

**HISTIDINE** — Is used in manufacturing glycogen and in the control of mucus. It is a component of hemoglobin and semen. It is found in alfalfa sprouts, applet, beets, carrots, celery, cucumbers, endive, papayas, pineapples and pomegranates.

**HYDROXYGLUTAMIC ACID** — Is similar to glutamic acid and is a factor in controlling digestive juices. It is found in carrots, celery, grapes, lettuces, plums, raspberries and tomatoes.

**HYDROXYPROLINE** — Aids in liver and gallbladder functions, in emulsifying fats and in the formation of red blood corpuscles. It is found in almonds, apricots, avocados, brazil nuts, beets, carrots, cherries, cucumbers, coconuts, figs, grapes, lettuces, oranges, pineapples and raisins.

**IODOGORGIC ACID** — Is a factor in all glandular functions. It is found in carrots, celery, lettuces, pineapples and tomatoes.

**ISOLEUCINE** — Aids in the regulation of the thymus, spleen, pituitary and the metabolism. It is also a factor in forming hemoglobin, Isoleucine is found in avocados, coconuts, papayas, sunflower seeds and almost all nuts.

**LEUCINE** — Counterbalances the isoleucine amino acid and is found in the same food sources.

**LYSINE** — Aids in the functions of the liver, gallbladder and pineal and mammary glands. It is also a factor in fat metabolism and in preventing cell degeneration. Lysine is found in alfalfa sprouts, apples, apricots, beets, carrots, celery, cucumbers, grapes, papayas, pears and soybean sprouts.

**METHIONINE** — Aids in the functioning of the spleen, pancreas and lymph glands. It is a constituent of hemoglobin and tissues and is found in apples, brazil nuts, cabbages, cauliflower, filberts, kale and pineapples.

**NORLEUCINE** — Balances the functions of leucine. Synthesized within the body if needed.

**PHENYLALANINE** — Is involved in the functions of the kidneys and bladder and in eliminating wastes. It is found in apples, beets, carrots, pineapples and tomatoes.

**PROLINE** — Involved in manufacturing white corpuscles and in the emulsifying of fats. It is found in apricots, avocados, almonds, beets, brazil nuts, carrots, cherries, coconuts, cucumbers, figs, grapes, oranges, pineapples and raisins.

**SERINE** — Aids in the tissue cleansing of the mucus membrane and in the lungs and bronchial. It is found in alfalfa sprouts, apples, beets, carrots, celery, cucumbers, cabbages, papayas and pineapples.

**THREONINE** — Aids in the balancing of amino acids. Threonine is found in alfalfa sprouts, carrots, green leafy vegetables and papayas.

**THYROXINE** — Involved with the activity of the thyroid, pituitary and adrenals and in metabolic functions. It is found in carrots, celery, lettuces, tomatoes and pineapples.

**TRYPTOPHANE**— Involved in the generation of cells and tissues and in the pancreatic and gastric juices. Tryptophane is also a factor in the optic system. It is found in alfalfa sprouts, beets, carrots, celery, green beans and turnips.

**TYROSINE** — Is a factor in the development of the cells and tissues and in the generation of red and white blood corpuscles. It is also found in the adrenals, pituitary, thyroid and hair. Food sources of this amino acid are alfalfa sprouts, almonds, apricots, apples, beets, carrots, cucumbers, cherries, figs, lettuces, sweet peppers, strawberries and watermelons.

**VALINE** — Involved in the functioning of the mammary glands and ovaries. It is found in apples, almonds, beets, carrots, celery, okra, pomegranates, squashes and tomatoes.

### **5.3.2 Functions of Amino Acids**

We can say that, generally, the amino acids serve five functions in the body:

1. They furnish the material from which proteins are synthesized by various cells.
2. They are used by the cells in manufacturing enzymes, hormones and other nitrogenous products.
3. They are used in constructing blood protein.

4. They may furnish a source of energy, with some of the amino acids being transformed into glucose and glycogen.
5. They aid the body in performing many functions as described in their individual descriptions.

## 5.4 Amino Acids—Essential and Non-Essential

### 5.4.1 Essential Amino Acids

Of the 23 amino acids, eight are termed essential. These are isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophane and valine. It is also said that a ninth amino acid, histidine, is essential for infants.

An "essential amino acid" is an amino acid that the body cannot produce by reduction (oxidation) from another amino acid. In other words, an essential amino acid must be found in a food source and cannot be produced within the body.

### 5.4.2 Non-Essential Amino Acids

The remaining 15 amino acids are termed "non-essential." but this term is somewhat misleading. They are essential to our health and well-being, but it is not essential that they be present in the foods we eat (provided that there is an adequate supply of the essential amino acids in our diet).

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > 6. "Complete Proteins"

## 6. "Complete Proteins"

Now that we have an understanding of the amino acids, we can intelligently discuss one of the biggest myths in nutrition—the necessity of eating complete proteins.

### 6.1 Definition

A complete protein is usually defined as\* a single or combined protein source which has all eight of the essential amino acids. Meat, for example, is said to be a complete protein, and so are eggs, dairy products, soybeans and many nuts. It has been suggested by some individuals and groups that a complete protein (or a combination of proteins that will provide certain proportionate amounts of the eight essential amino acids) be eaten at every meal to make sure that we obtain all eight of the essential amino acids, preferably in certain proportions.

### 6.2 Are Not Essential In the Diet

This idea of a "complete protein" has been so heavily advertised by special interest groups, such as the meat and dairy industries, that the average person believes he must eat meat (or at least milk and eggs if a "vegetarian") or at the very least prepare protein combinations such as grains and beans or take protein supplements in order to get enough high-quality protein. All of these beliefs are false and, in fact, may lead to practices which increase the toxicity in the body.

This is an important concept in understanding protein needs: *It is not necessary for all eight of the essential amino acids to be present in one food or even within one meal in order to obtain our full protein needs.* As we have discussed, the body has its own amino acid pool to draw from to supply

amino acids which may be missing from dietary sources. Needed amino acids may be withdrawn from those already in circulation, or the necessary amino acids may be released by the liver or other cells into the circulatory system. The amino acid pool thus acts as the supplier of the essential amino acids missing from incomplete proteins. This fact is proven by observing patients after lengthy fasts who exhibited not a protein deficiency, but a restored protein balance.

Only the carnivorous animals in nature eat "complete proteins." Most of the vegetarian animals eat grass, tubers, fruits, grains, etc. and often of a limited variety. Yet they never exhibit signs of protein deficiency. In fact, protein poisoning from eating high-protein foods is far more common among Western man than is protein deficiency.

The "complete protein" idea also falls apart if we realise that the amino acids in many of the so-called complete protein foods cannot even be fully used by the body. Meat as eaten, for example, is usually only the muscle meat of the animal, which is particularly low in some of the essential amino acids. The soybean has an anti-enzyme factor which blocks or inhibits the assimilation of some of its essential amino acids. Proteins which have been cooked or heated (such as meat, fish, eggs and most dairy products) may lose-up to 50% or more of their essential amino acids due to the creation of enzyme resistant linkages caused by the cooking. So we can see that many of the so-called "complete proteins" are not even completely used by the body.

### 6.3 Are Present In Wholesome foods

If you are truly concerned about eating a food that has all eight essential amino acids which are in a form easily used by the body, we would suggest some of these wholesome foods.

All contain the eight essential amino acids:

<b>Fruits</b>	<b>Nuts</b>	<b>Vegetables</b>
Bananas	Almonds	Alfalfa Sprouts
Tomatoes	Coconuts	Bean Sprouts
Dates	Filberts	Carrots
	Sunflower Seeds	Eggplants
	Walnuts	Sweet Potatoes
	Brazil Nuts	Broccoli
	Pecans	Cabbages
		Corn
		Okra
		Squashes

There are many other foods suitable for the human dietary which also contain all eight essential amino acids.

It should be emphasized, however, that it is *not* necessary for one food or one meal or one day's intake of food to contain all eight essential amino acids. We do not need to eat meat, cheese or soybeans to obtain complete protein, nor do we need to mix grains and beans or milk and cereals to get a complete protein in one meal.

A varied diet of fruits, vegetables, nuts, seeds and sprouts can furnish us with all the essential and non-essential amino acids, along with all the other nutrients we need. And, it can do so in the most wholesome foods suitable for the human diet and in a form most readily and efficiently used.

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > 7. Protein And The Optimum (Life Science) Diet

## **7. Protein And The Optimum (Life Science) Diet**

So far we have discussed what protein is, why we need it and how much we require. Now it is time to examine the optimum diet for obtaining all our protein needs. A diet consisting of fresh fruits, vegetables, nuts, seeds and sprouts can furnish us with the highest quality protein in a form that is readily digested and assimilated.

The protein in this diet is best for the human body for the, following reasons:

1. It is consumed in its raw state;
2. It is free from toxins and poisons that accompany many other protein sources;
3. It is present in wholesome foods along with other needed nutrients;
4. It is easily digested and assimilated by the body; and
5. It is of sufficiently high quality and quantity to meet all the body's requirements.

### **7.1 Raw Protein Is The Best**

The Hygienic or Life Science diet includes proteins only in their raw form. Fruits, vegetables, nuts, seeds and sprouts do not require cooking to increase their palatability or digestibility.

When proteins are subjected to high heat during cooking, enzyme-resistant linkages are formed between the amino acid chains. Consequently, the body cannot break these amino acids down for its use. What the body cannot use, it must eliminate. The cooked proteins then actually become a source of toxic matter within the body.

When wholesome protein foods are eaten raw, the body can make maximum use of all the amino acids without the accompanying toxins of cooked foods. It should be noted that some high-protein foods, such as soybeans and lima beans, have naturally occurring toxins which are said to be neutralized by heat. It is best not to eat these types of proteins since the cooking process does not totally remove the toxic effect these foods create.

### **7.2 Wholesome Proteins Are Non-Toxic**

Proteins consumed in the Hygienic diet are also free from the poisons and toxins that often accompany other protein sources. We have already mentioned the toxins present in many legumes (which, incidentally, are best neutralized by sprouting the legume instead of cooking it). Similarly, most grains (with the exception of young fresh corn) cannot be digested when eaten raw. The cooked grains, however, still contain the toxic by-products from inhibitory enzymes present in the grains. Although

legumes and grains are not a proper part of the Life Science diet, they are not nearly as toxic or poisonous as the other traditional protein sources: meat, milk, dairy products, fish and eggs.

Not only do meat, milk, dairy products, fish and eggs contain naturally-occurring toxins injurious to the body, but they are also often poisoned during the producing and selling of them. Since the unsuitability of these foods is discussed elsewhere in this course, only a few facts about their drawbacks as protein sources need be mentioned:

1. Meat and fish contain naturally-occurring toxins due to decaying cell nuclei in the flesh as well as toxins the animal itself releases when it is killed.
2. Meat has many pesticides and additives, including but not limited to the following: methoxychlor, chlordane, heptachlor, toxaphene, lindane, benzene, hexachloride, aldrin, dieldrin, DDT, sex hormones, stilbestrol, nitrates, nitrites, etc.
3. Meat, eggs and dairy products contain over ten times as much pesticide as commercially-sprayed fruits and vegetables.
4. Eggs are usually produced on a high chemical-hormone diet and are totally nonconsonant with the human digestive physiology.
5. Milk is poorly tolerated by the majority of the world's population and contains the hormones that are produced in the cow as a result of the artificially induced and prolonged lactation. This writer personally knows a young girl who began lactating due solely to a diet that was heavy in hormone-laden dairy products.
6. Meat, fish, eggs and dairy products are the major contributors to cholesterol problems.

### **7.3 Wholesome Protein Foods Contain A Wide Variety of Nutrients**

Proteins consumed in the Hygienic diet occur in wholesome foods which contain a wide variety of needed nutrients. Many of the traditional high-protein foods such as meat, fish, eggs, dairy products, grains, etc. are usually poor in many vital nutrients.

For example, meat is an exceedingly poor mineral source; cow's milk is so iron-poor that a growing baby must use its own stored iron supplies in the spleen for normal growth; grains are so low in sodium that people add salt to them for palatability.

On the other hand, fruits, vegetables, nuts, seeds and sprouts are rich sources of all the minerals, vitamins and enzymes we need, besides being a source of high-quality protein. The Hygienic diet provides us with a totally balanced supply of all vital nutrients as they naturally occur within whole foods. For instance, for efficient protein use, an adequate amount of carbohydrates must be present. Otherwise, the proteins are converted to carbohydrate fuel for the body and the protein is not used for its original purpose. Meat is so poor in carbohydrates that much of its protein must be used as a secondary and inefficient fuel source for the body. Fruits, vegetables and nuts, however, have a large supply of natural carbohydrates so the body can use all the protein contained within these foods for its original purpose and not create toxic byproducts through unnecessary protein conversion.

### **7.4 Wholesome Protein Is Easily Digested and Assimilated**

Protein in the Hygienic diet is easily digested and assimilated, The Life Science diet stresses the importance of eating compatible foods for ease of digestion. Since protein digestion is the most complex gastric process, it is important that protein foods be eaten in proper combinations with other foods.

For instance, naturally occurring high-protein foods such as nuts, seeds and avocados should be eaten with non-starchy and leafy green vegetables for the best results. Salad vegetables aid in the digestion of concentrated proteins and "also supply high-quality amino acids of their own.

In a typical diet, proteins are often combined with starches: meat and potatoes, grains and beans, milk and cereal, and so on. Starches and proteins require completely different digestive environments and

enzymes, and when eaten together, neither is fully digested or used by the body. As a result, most protein eaten in a conventional diet which ignores proper food combining is not fully digested by the body.

### 7.5 Protein in a Hygienic Diet Meets All Our Needs

The protein in a Hygienic diet is of sufficiently high quality to meet all the body's requirements. All essential and non-essential amino acids may be obtained from a diet of fruits, vegetables, nuts, seeds and sprouts.

A varied diet of these wholesome foods eaten in their natural state can provide all our protein requirements without concern for the exact number of grams of protein consumed. It is not necessary when eating a natural diet to be preoccupied with obtaining any specific nutrient. They are all supplied in abundance, including protein. Simply for the sake of scientific validity, and not as a regular practice, we have chosen some examples of Hygienic menus in order to analyze their protein contents.

All of these menus and suggestions have been devised to furnish 30 grams of protein to an adult weighing 150 pounds. This is equivalent to one gram per five pounds of body weight. More or less protein may be required, depending upon body weight, metabolism, body toxicity, etc.

### 7.6 Daily Menu Suggestions To Supply 30 Grams of Protein

Food	Ounces	Grams of Protein
Breakfast		
Grapefruit	14.0	2.0
Lunch		
Persimmons	7.0	1.6
Pear	3.5	0.7
Dates	7.0	4.4
Dinner		
Vegetable Salad	11.0	7.4
Kale	4.0	6.0
Squash	3.5	1.1
Avocado	9.0	6.8

Total prams of Protein		30.0
Breakfast		
Oranges	16.0	3.8
Lunch		
Almonds	3.0	14.0
Celery	8.0	2.0
Dinner		
Bananas	18.0	6.5
Dates	6.0	3.7
Total Grams of Protein		30.0
Breakfast		
Figs (fresh)	16.0	5.4
Lunch		
Avocado	9.0	6.8
Tomato	8.0	2.5
Broccoli	6.0	7.1
Lettuce	4.0	1.7
Dinner		

Apricots	12.0	3.0
Cherries	12.0	3.5
Total Grams of Protein		30.0

Of course, we do not suggest that food be weighed or eaten in ounces; nor should we eat according to predetermined menus. These are only suggestions as to what one person might desire to eat in a day. If he did so, he would obtain 30 grams of protein with all the essential amino acids.

It is better to eat according to hunger and body need and not according to grams, ounces or nutrient charts. When presented with a variety of wholesome foods, the body naturally selects the foods it needs to satisfy its particular requirements at that time.

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > 8. Questions & Answers

## 8. Questions & Answers

### **When I stop eating high-protein foods I feel weak. Doesn't this prove we need these foods?**

Actually, just the opposite. High-protein foods create an enormous amount of toxins in the body. When we stop eating those foods for a period of time, the body has an opportunity to eliminate those toxins. It is the elimination of the poisons from the body caused by a previous high-protein diet that causes this weakness—not a lack of protein. It is best to fast (for short periods of time or one longer fast) and allow the body to rid itself of these toxins. Then, you will feel quite strong eating those foods normally thought to be low in protein.

### **Is protein combining harmful. I read a good book about it.**

Unfortunately, most books on protein combining suggest eating two or more concentrated protein foods together at the same time. Different proteins require different digestive processes, and combining two heavy foods, like grains and beans for example, makes the body work too hard. Some protein combinations, like milk and cereals, for example, are so indigestible that little if any good can come from eating them. Quite simply, the ideal protein combinations are those that require the same digestive processes. Nuts and leafy greens, for example, complement each other's amino acids and at the same time are agreeable food combinations.

### **I can't digest nuts and seeds. Can I still get my protein from this diet?**

Most definitely. Nuts and seeds are concentrated proteins—all the foods in the Hygienic diet contain protein. If you eat a calorie-sufficient diet of fruits, vegetables and sprouts, you can obtain all the amino acids that you require. Avocados are sometimes better tolerated than nuts and seeds, and they too have a high concentration of protein. In time, as your health improves, you will probably gain greater digestive abilities and you will be able to eat moderate amounts of nuts and seeds.

### **Shouldn't we eat a high-protein breakfast?**

I can't imagine why. The idea behind a high-protein breakfast is that it will give us "energy" throughout the day. Actually, it has the opposite effect because protein digestion is the most complex digestive process of all. If you want energy in the morning, eat a high-carbohydrate breakfast of fruits. Better yet give your body a rest from food in the morning. Soon you will be able to function at a higher level of energy than when you ate a heavy breakfast.

### **I'm a weight lifter, and I feel that I need protein supplements. Aren't I an exception?**

Weight lifting and other strenuous physical activities primarily call for an increase in the consumption of natural carbohydrates for muscle fuel. While it is true that protein is used in building muscle tissue. I must refer you to the gorilla or the elephant. These are well-muscled animals. They eat no high-protein foods, take no protein supplements and drink no special protein drinks. In fact, they build their musculature from greens and fruits. If you feel that you need concentrated protein. I suggest seeds or nuts in moderation. Athletes who eat a very high-protein diet (as is the case with weight lifters) often develop gout later in life and experience severe kidney problems.

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > Article #1: The Question Of Proteins By Arnold DeVries

### **Article #1: The Question Of Proteins By Arnold DeVries**

The following is an excerpt from a book by Arnold DeVries called *Fountain of Youth*.

The building blocks of protein consist of 23 amino acids. Eight of these have been proven to be essential for the support of life and growth. A few others are "convenient" in the sense that animals thrive better if they get them. Proteins which contain all of the essential amino acids as well as the convenient ones, are called complete or first class. A food which contains complete protein will support life and growth if used as the sole source of protein in the diet. The foods which contain incomplete protein will not in themselves support life and growth.

It is often claimed that the difficulty of obtaining complete proteins on a fruitarian diet makes such a diet dangerous except when in the hands of an expert. But this is really not so. A child living upon the fruitarian diet could hardly keep from getting sufficient complete protein if he simply used the plant foods according to his own instinctive desires. After all, there is an abundance of plant foods which supply us with complete proteins of the highest biological value. The researches of Cajori, Van Slyke and Osborn have known conclusively that the protein of most nuts is of the very finest type and contains all of the essential and convenient amino acids. Among the nuts possessing complete proteins are butternuts, pecans, filberts, Brazil nuts, English walnuts, black walnuts, almonds, pine nuts, chestnuts and coconuts.

In addition to being complete, the protein of most nuts is of high biological quality. Investigations at Yale University and the research work of Dr. Hoobler of the Detroit Women's Hospital and Infant's Home both demonstrate the superiority of nut protein. The methods of research used by Dr. Hoobler provided a most delicate biological test of the protein of food, and it showed that the protein of nuts not only provides greater nutritive efficiency than that of meat, milk and eggs but that it is also more effective than a combination of the animal proteins.

Coconut globulin is perhaps the best of the nut proteins. Johns, Finks and Pacel of the Protein Investigation Laboratory of the U.S. Department of Agriculture found that this protein produced supernormal growth in young rats when used as the sole protein in the diet. In other words the rats grew more rapidly than when given cheese, meat, eggs, milk or any other high-protein food. McCandish and Weaver have also found that the protein of coconuts is superior to that of other foods and claim that

coconut meal is of greater value than soybean meal. As the soybean is equal in biological value to any of the animal proteins, this would mean that the coconut protein is in a class by itself and is perhaps the finest protein known.

No fruitarian need have any worries over his protein supplies. Any well-balanced selection of plant foods should meet the body's protein needs very well; in fact, it will meet them far better than the omnivorous diet, for it supplies the protein in just the right amounts.

All available evidence indicates that a low-protein diet composed of plant foods is most conducive to the best health. In the 19th century two great German scientists, Justus Freiherr von Liebig and Karl von Voit, carried out experiments to determine how much protein the body requires each day. Liebig assumed that, because muscle is composed largely of protein, we should use a diet which is very rich in this dietary factor. Later Voit carried out experiments with dogs, the result of which led him to believe that the daily human requirement is 118 grams.

It is now known that the conclusions of Liebig and Voit are not accurate. Muscles can be built from plant foods, which are relatively low in protein content better than from animal flesh. And the experiments with dogs carried out by Voit can hardly be applied to human beings, for the protein requirements of dogs and other carnivorous animals differ from those of the frugivorous animals.

The most accurate present day estimates of the body's daily protein requirement vary from about 22 to 30 grams. These estimates are based upon experiments with humans. Prof. Henry Sherman of Columbia University places the daily requirement at 30 to 50 grams, but it is probable that the other estimates, which include those of the Swedish scientist Ragner Berg, are more nearly correct. However, even 30 to 50 grams of protein is not much. It could easily be supplied by a diet of plant foods.

Dr. Mikkel Hindhede, of Denmark, made the first mass application of a diet very low in its protein content to an entire nation. During World War I this doctor was made Food Administrator of Denmark. In an effort to prevent food shortages, he greatly lowered the production of livestock and fed the plant foods to the human population rather than to the animals. As an average of only 10 percent of the value of plant foods is recovered in the milk, eggs and meat of the animals, it is obvious that this involved a great saving from the standpoint of nutrition. But Hindhede eventually discovered that the diminished use of animal foods meant far more than that. Within one year's time the death rate had decreased 40 percent. In addition, the Danish people experienced less disease. When thousands of people throughout Europe suffered influenza, Denmark was not affected. The other nations, using their high-protein diets consisting largely of animal foods, suffered greatly and their people died by the thousands.

Nuts are rich in protein, but they are not used to such an extent in the fruitarian diet that the body receives an excess of this material. The normal desires of the fruitarian call for a wide variety of plant foods with no particular dependence upon nuts. Fruits are the chief foods used and the desire for nuts is in accordance with the body's need for protein. Meat, eggs, milk and cheese are all unneeded high-protein foods. Their excessive protein acts as a burden to the body and favors the development of disease.

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > Article #2: Protein by Ralph Cinque, D.C.

## **Article #2: Protein by Ralph Cinque, D.C.**

The following article is from *The Health Crusader*.

*"Pro-teins: any of numerous naturally-occurring extremely complex combinations of amino acids that contain the elements carbon, hydrogen, nitrogen, oxygen, usually sulfur and*

*occasionally other elements (such as phosphorus or iron); an essential constituent of all living cells; is synthesized from raw materials by plants but assimilated as separate amino acids by animals."*

Most of what was in the past believed to be true about the body's need for protein has, in recent years, been shown to be false. This is true particularly in regard to the amount of protein the body requires.

The first well-publicized study of protein needs was done by the German physiologist Voit at around 1890. Voit studied healthy, young, physically active German men who were eating their conventional diet. He found that they maintained "nitrogen balance" on a diet containing 120 grams of protein daily. For years this was accepted as the standard.

Urinary nitrogen (in the form of urea, uric acid, creatinine and other substances) is derived almost wholly from protein metabolism. Voit assumed that the amount of urinary nitrogen excreted reflected the body's needs. He observed that when the German males reduced their protein intake significantly, they initially excreted more nitrogen than they consumed, a state he referred to as "negative nitrogen balance." Had he continued his experiments longer, he would have discovered that these same subjects would have re-established a nitrogen balance at the lowered intake level.

Today we know that it is not valid to determine needs on the basis of excretory levels. The body excretes the residues from materials it has merely disposed of. Whatever amount of nitrogen we consume in the form of protein must ultimately be eliminated. When an enormous excess of nitrogen enters the system, the body merely deaminizes the amino acids, converting the amino radicals into ammonia, urea and other by-products of protein breakdown. The remaining *ketogenic* or *glucogenic* acids then undergo combustion in the same manner as the fats and carbohydrates, rendering calories.

High-protein diets actually accelerate the turnover of proteins in the body, causing a metabolic bonfire that may mistakenly be regarded as a state of well-being. When one reduces the amount of protein consumed, it takes time for the body to re-adjust its metabolism, to reset its thermostat, so to speak. This is why a state of negative nitrogen balance may temporarily ensue.

During World War I the Danish government hired a physiologist by the name of M. Hindhede to study protein needs. The hardships of the war had made animal foods scarce and prohibitively expensive. A people who had been accustomed to eating lots of meats, eggs and milk were forced to rely upon grains and vegetables, especially potatoes, to sustain themselves.

Hindhede's task was to determine how little protein people could consume and still maintain health. He did extensive studies on young and old alike over a period of several years and concluded that 60 grams of protein a day was more than adequate to meet the body's needs. Even the lowly potato, Hindhede said, contained enough high-grade protein to supply body needs (assuming that total caloric intake was adequate).

The orthodox scientific community vilified Hindhede. (He is even left out of the 1963 *Encyclopaedia Britannica*, while Voit is in it and his discoveries praised.) Imagine, cutting the Voit standard for protein need in half! More recent studies, however, based upon verified patterns of enzyme synthesis, collagen turnover and muscle metabolism have drastically reduced the Hindhede figure. *Guyton's Physiology* (considered the standard in the field) maintains today that 30 grams of protein a day is fully adequate. Other respectable sources cite figures in the 20s, but even Guyton figure of 30 grams is significantly lower than the daily allowance of 70 grams recommended for active adult males by the Food and Nutrition Board of the National Research Council. This 70 grams includes a considerable "safety factor" (to allow for some degree of malabsorption).

Many if not most Americans are consuming in excess of 100 grams of protein a day despite the much lower recommendation. Eliminating the by-products of this protein overload places great stress upon the body. The liver and kidneys bear the brunt of the punishment. Fats and carbohydrates burn clean, leaving a residue of only carbon dioxide (which is relatively innocuous and is readily excreted by the lungs) and

water (which is hardly a waste product). Protein metabolism, on the other hand, leaves non-oxidizable waste products such as urea, uric acids, etc. It is a much greater burden for the body to process great surpluses of protein than to process excesses of fat or carbohydrate. It behooves all of us to consume no more protein than we need so as to prevent premature aging and the deterioration that comes from organ abuse.

Another mistaken concept regarding protein needs has to do with protein quality. For decades it was held that only animal proteins contained a full complement of all eight essential amino acids (those we cannot synthesize from other amino acids) to meet the body's needs. Although most natural foods do contain all eight essential amino acids, the claim was that the proportion of one amino acid to the others was not right. It was observed that animals grew and matured more rapidly on animal proteins than on vegetable proteins, so vegetable proteins were declared to be inadequate. Speed of development and size were considered to be a direct reflection of nutritional thoroughness.

Today we know that weight and size are not necessarily the best indicators of health and well-being, that gigantism is just as pathological when spread throughout a population as it is when it occurs in an isolated individual. We know that an individual's body is not immediately dependent upon the content of his meals in order to maintain nutrition. Referring again to *Guyton's Physiology*, radioisotopic studies have shown that at any given time protein synthesis utilizes two-thirds endogenous amino acids (from the blood circulatory pool) and one-third exogenous amino acids (as derived from meals). In other words, in regard to protein, the body is always living upon its reserves and the purpose of eating is to replenish those reserves. It matters not whether a given meal provides the exact proportion of amino acids because the body is fully capable of withdrawing from reserve sources whatever amino acids are needed to balance out the dietary supply.

Frances Moore Lappe stated in *Diet For a Small Planet* that one must combine different proteins at the same meal or otherwise preclude the possibility of utilization. Ms. Lappe said that consuming single vegetable proteins would not provide adequate nutrition. This idea, however, has been shown to be false, not only by physiological calculations, but also by the empirical evidence gained from observations of countless numbers of people around the world who live and thrive on simple vegetable diets. The experience of Hygienists in this country also provides proof of the sufficiency of simple combinations of non-animal foods.

Many common foods that we don't generally regard as sources of protein actually supply substantial amounts. The case of the potato has already been cited. Even more impressive are green leafy vegetables, which supply 3-6% protein of high-biological value, on the average slightly more than cow's milk and several times more than mother's milk. Eating a large raw vegetable salad every day can alone supply most of the protein the body needs. Eating a variety of whole natural foods that supply an adequate number of calories would, by necessity, supply an adequate amount of protein. The problem isn't how to get enough protein, but how to avoid getting too much.

Another widely-accepted but incorrect idea is that athletes and hard physical workers require more protein than less active people. Actually muscular activity entails no increase in the rate of protein catabolism (breakdown). Urinary creatinine is considered a reliable indicator of muscle breakdown, and it has been found that physical activity does not significantly increase creatinine excretion. Nor does it significantly increase the excretion of urea. What physical activity does entail, however, is a rapid utilization of muscular glycogen. It is carbohydrate replenishment that vigorous activity calls for, not protein.

The average American consumes two to four times as much protein as he needs, and cancer (which is characterized by runaway protein synthesis) is killing one person in four. Cutting down total protein in general and animal protein in particular is a desperate need. It is important to realize that all of the marvelous amino acids contained within flesh foods were derived from the animals diet. Other animals are just as powerless to synthesize the essential amino acids as we are; and we are just as capable as they of deriving our amino acids directly from the only producing source: plants.

### **Article #3: The Superiority Of Plant Foods by Ralph Cinque, D.C.**

This category could also be designated the *detrimental effects of animal foods*. All animal products (with the exception of mother's milk) have certain negative features which make their dietary use questionable. Consider, first of all, the effect that animal foods have upon protein consumption. Even modest use of meat, fish, eggs and dairy foods tends to create a protein overload, and this is one of the most dangerous dietary excesses.

Research has shown that high-protein diets actually promote aging and early degeneration. Too much protein exerts a tremendous burden upon the liver and kidneys. It also leaves acid residues in the blood and tissues which must be neutralized by sacrificing indispensable alkaline mineral reserves.

The process of aging is characterized by the transfer of calcium from the bones to the soft, tissues, that is, to the arteries (arteriosclerosis), to the optic lens (cataracts), to the ureters (kidney stones), to the skin (wrinkles), to the joints (osteoarthritis), to the valves of the heart (producing valvular stenosis and insufficiency), to the tendons and ligaments (producing frozen shoulder) and to other sites. This, of course, leaves the skeleton osteoporotic, leading to the development of stooped posture, a kyphotic spine, spontaneous fractures and other maladies that are so common to the elderly. High-protein diets (due to the accumulation of phosphoric, sulphuric, uric and other acids) accelerate this demineralization of bone and bring about calcific deposits in the soft tissues.

One could argue that nuts and seeds contain as much protein as meats, eggs, etc., and therefore they are as likely to create an excess. However, most people are easily satisfied eating a few ounces of nuts or seeds every day, whereas few people will eat just a few ounces of yogurt. Restaurants serve up to a pound of meat at a sitting, along with other foods. Cottage or ricotta cheese is eaten in huge quantities, even by many so-called vegetarians. The simple truth is that animal proteins tend to promote overeating more so than do plant proteins.

The relationship between high-protein diets and cancer has been clearly established by studying both animal and human populations. Remember that cancerous cells are characterized by runaway protein synthesis and rapid cellular division. Protein synthesis is accelerated by increased protein intake, so it is not surprising to discover that cancer bears a close tie to excess protein. There is a direct correlation between the amount of protein in the diet and the incidence of cancer on a worldwide basis. Americans, Australians and West Europeans, who ingest the largest amounts of protein, also have the greatest incidence of cancer, whereas the rural Chinese, the East Indians and native peoples of Latin America have the lowest cancer incidence. This is no casual relationship and it cannot be written off by blaming it on the "stress of modern life."

Animal products are loaded with the worst kind of fat—saturated, cholesterol-laden animal fat. A mountain of evidence has been accumulated relating high animal fat intakes with the development of cardiovascular disease (which is characterized by the deposition of saturated fat and cholesterol in the intimal layer of arteries), and many different malignancies including breast cancer, colon and rectal cancers, and cancer of the liver. Even such diverse conditions as multiple sclerosis and diabetes have been related to the consumption of animal fats. As we have already stated, heated animal fats have been shown to be even more carcinogenic, and considering that Americans take all of their flesh, milk and eggs well cooked, it's no wonder that one in four eventually succumbs to cancer. Paradoxically, those people who subsist on low-fat, low-protein, largely vegetarian, unrefined diets experience very little cancer. The incidence of cancer, cysts, tumors and heart disease among American Seventh Day Adventists is approximately half the national average. This is quite remarkable considering that only about half of this group are thought to be vegetarian.

Flesh, fish, yogurt and cheese contain various putrefactive products resulting from their bacterial

decomposition. Putting partially-spoiled food in the body can hardly be considered a Hygienic practice, despite the arguments of the fermented food enthusiasts. Flesh also contains considerable quantities of the end products of metabolism (like uric acid) which are held up in the tissues at the time of death. These wastes are poisonous, irritating and burdensome to the body. Considering also that animal products tend to be reservoirs for pesticides, herbicides and various other drugs and inorganic contaminants, there are many good reasons to avoid using them.

*Excerpt from an article by Ralph C. Cinque, D.C., entitled "Hygienic Considerations in the Selection of Foods," which was published in Dr. Shelton's Hygienic Review.*

[Home](#) > [Lesson 8 - Proteins In The Diet](#) > Article #4: The Question Of Protein by Dr. Ralph Bircher Benner

### **Article #4: The Question Of Protein by Dr. Ralph Bircher Benner**

*"Believe those who seek the truth; suspect those who have found it."  
—Andre Gide*

Gide's admonition seems to me nowhere more applicable than in the controversy over protein. In pertinent research literature, which it has been my duty to examine critically and without bias for the last 40 years. I have seen the most respectable kind of work and such a shameful pile of ignorance, much of it written by the most respected authors, as I have never seen in any other scientific field. The conclusions contradict so fantastically that the reader finds himself holding his head in despair. The textbooks, though, naturally don't reflect these contradictions. They merely repeat the results of agreements, and a lot doesn't appear in them for the simple reason that "what may not be must not be!"

First the basic question: "How much protein does a human being need to stay healthy and perform well? What is the daily requirement, the minimum, the optimum, for a standard body weight of 70 kg?"

At the turn of the century, the respected opinions were those of Rubner and Voit: we need 120-160 grams per day. But Chittenden showed in human experiments that best performance and health were possible on 50 grams, and Hindhede set the figure at 30. Forty years later. A. Fleisch, president of the Swiss Wartime Nutrition Commission, wrote in his book *Nutritional Problems in Times of Shortage* (Basel, 1947) "No quantity in the physiology of nutrition is so uncertain and finds such extreme advocates as the need of the human organism for protein." Today, after a quarter century during which mountains of pertinent research have been published every year, the situation is exactly the same. Or worse.

In Russia, Jakolev set up a minimum requirement of 141-163 grams. Kuhnau saw an optimum of 200. Kofranyi of the Max Planck Institute proved that complete nitrogen balance and performance ability could be maintained on 25 grams, and Oomen and Hipsley found a population that develops not just full health, but magnificent muscular structure and corresponding physical performance, on a mere 15-20 grams. Elvehjem insists that the optimum is near the minimum.

In the meantime, the American Research Council's Food and Nutrition Board agreed on a daily requirement for adults of 70 grams. This number is, in fact, found in their tables. Sherman, a member of the Board, described the way this figure was arrived at. The evidence pointed toward a much lower amount, somewhere a round 35 grams. But if the protein requirement had been set so low, there would have been a public outcry. And so a corresponding "margin of safety" was adopted, and "70 grams" was published. Because the scientific basis for this was non-existent, the word "recommendation" was used instead of "requirement." But who knows how this recommendation came into being? And it was

publicly interpreted as the requirement, in fact as the minimum. Thus, not long ago Stransky and Krucker in the *Therapeutische Umschau (Therapeutic Review)* expressly listed 70 grams of protein per 70 kg of body weight as the "minimum dosage ... which is indispensable for the maintenance of vital biochemical processes." Sherman had good reason for writing about the "high-protein mentality" of nutritional specialists. It's not unusual for a doctor to prescribe three eggs and yogurt for breakfast, plus meat at each meal, and patients often fear a protein deficiency if they're asked to stay away from meat for a few days.

No less confusing is the matter of evaluating protein quality and whether animal or plant protein is preferable. According to the textbooks, vegetable protein is inferior. At least a third, preferably half, of the protein intake supposedly should be from animal sources, and the public unconsciously thinks "meat" when it hears "animal," though, of course, milk and eggs are also "animal sources." The presumed inferiority of vegetable protein lacks binding scientific proof. If scientists had studied the geography and history of nutrition as well as they conducted their chemistry and animal experiments, they would never have fallen into this dogma. There have been and there are now populations numbering in the millions in various parts of the world, it is known from penetrating research, that have lived and developed enviable health and strength for centuries and even thousands of years on a purely vegan diet.

The quality and requirement of protein depend on several factors, for instance on heating, which can considerably lower the quality of the protein. The usual heating of meats results in a significant decrease in essential amino acids. The same is true of drying and preserving. It probably isn't acceptable to eat raw meat to avoid these degenerations; but eating other raw foods contributes no small amount to reducing the total need for protein.

Raw food decreases the need for protein in yet another way: the usual, everyday diet requires 6-8 grams of protein per day for the synthesis of digestive juices. But raw foods are easily digested, thanks to the enzymic content, thus economizing on digestive enzymes. Vitamin A has a "decisive relationship to protein metabolism." Protein deficiency damage is extensively conditioned by vitamin A deficiency. An everyday diet using margarine is as a rule deficient in vitamin A. It is similar to vitamin K, which like provitamin A is most richly present in fruit and is best assimilated in a raw diet with full-value oil.

We could go on, and repeatedly come back to the central question of protein economy.

Protein economy begins with the feeding of babies. In the early 50s nature failed the test of American medicine. It was found that breast milk contains 60% less protein than the infant needs. A "formula" was created with 2 1/2 to 3 times the protein plus added salt. Today we know that it wasn't nature but science that flunked: The devastating consequences soon appeared: kidney damage, hyperacidity with osteoporosis, dangerously high phenylalanine and tyrosine content in the blood, poor protein metabolism and increased acceleration with consequent stressful disparity of physical and mental growth. An attempt has been made to transfer advertising concepts of growth and weight gain rates to actual human beings—and it fell through. There was a harmful habituation to the wear and tear of a high-protein diet. The frugal use of protein was not learned. From birth on, the child was being burdened with both "stress conditioning factors" (Selye), high protein and salt. Important developmental phases were shortened by accelerated growth and this, according to Portmann, works against the development of the "super-type" (Wellek), that human type which is most needed in our timer who is not just able to analyze but also grasp the whole of a phenomenon in its form and essence.

To return to stress theory: "It is a matter of experience," wrote A. Fleisch, president of the Swiss Wartime Nutritional Commission, in his book *Nutritional Problems in Times of Shortage* (Basel, 1947) "that increased protein consumption also lowers the number of calories taken in." The stimulating qualities of protein—especially meat protein—lead to over-estimation and over-consumption, which are not justified by nutritional physiology because they lead to "luxuriant combustion"—an inefficient "burning off" of excess. There must be another, especially stimulating, irritative effect of eating meat above and beyond the irritative effects of excess protein (specific-dynamic effect) and the extractive and

general products of roasting. This irritative effect, which has since been isolated, is caused by uric acid, a very strong irritant on the sympathetic nerves. And so in meat we have a strongly hypermetabolizing three- to four-fold irritative effect.

This has contributed to its reputation as "strength food," far above its actual nutritive value. ("Meat broth" means the same as "strength broth" in German.)

Our contemporary situation demands the mobilization of our best powers to overcome the crisis of existence in our culture. I believe we have reasons for reconsidering our use of stimulants, which has become continuous and excessive. Continuous prickling of the ergotropic nervous system, which seems to be a vital necessity in these times, is no sign of strength. It stands in the way of the regenerative work of the trophotropic nervous system. This is the main reason why we renounce all stimulants including meat. Regeneration demands detoxification and metabolic economy. This is also true in athletics, where the last degree of performance must be extracted. This refers not only to alcohol, about which the French learned bitter lessons at two Olympiads, and nicotine and other stimulants—it is just as true of meat, and this is proved by the proportionally unheard-of string of international athletic records set by vegetarians. The advantages show up with special clarity in high mountain exercise. Some typical consequences of conversion to a protein-economical, full-value diet are a 10-20% reduction in oxygen requirement and a 30% lower calorie requirement with correspondingly improved performance, recovery and adaptation ability. I personally was surprised to find this out while climbing 17,343 foot high Ixtacihuatl. Indian populations living at 13,000 feet in the Andes highlands hold stubbornly to their ancient carbohydrate diet "in spite of the well-meaning advice from the!" World Health Organization Council. They race bicycles at that altitude for distances of 150 miles at an average speed of 25 mph. Similarly the Tarahumara Indians of Mexico run 90 miles at seven mph, with no heart expansion or shortness of breath. Experience has taught this highland people to stick to carbohydrates. Even rats that were taken to high altitude's suffered deficiencies in nutritional utilization on a high-protein diet, but not on lower-protein fare. The luxuriant combustion and hypermetabolizing effect of an excess-protein diet occur at sea level too, but they have immediate practical significance in the high mountains.

A further turn was taken in the protein question with the recent rise of amyloidose research. Schwarz, a professor of physiological pathology in Frankfurt, described the storing and slowly destructive effect of the penetration of tissues and organs by amyloid. This is a waxy, fatty protein mixture considered "the most important and perhaps decisive cause of decline with age," in so-called diseases of old age and specifically, atheromatosis. Katenkamp and Stiller called this amyloidosis "extraordinarily pervasive in every kind of deposited tissue."

In amyloidosis must lie the key to healing of those diseases of old age which have previously been casually unclarified. It is clear that amyloid consists exclusively of degenerate protein reduction by productions which could be the result of excess protein. Excess protein must be quickly burned, but cannot be sufficiently eliminated. Amyloid contains rich amounts of the amino acids tryptophane and tyrosine. Five to ten times as much tryptophane and five to seven times as much tyrosine are found in the dry substances of meat as that of vegetable protein sources. It remains to be investigated whether other sulphurous amino acids play a similar role, and what the amyloid situation is among populations living on protein-frugal diets. All the essential amino acids, especially the sulphurous, can cause damage in overdoses, through creation of poisonous substances or other disturbances. On 70 grams of protein a day containing all the essential amino acids, there can be excessive intake of some amino acids. The connection between amyloidosis and excess protein is easily proved by animal experiments. It is produced with special ease in case of high cholesterol intake and intestinal poisoning (pathological microorganisms in the intestines create amyloid-dissolving antigens). Amyloid is created, according to Katenkamp and Stiller, in wrongly nourished mesenchyme cells with increased protein production and formation of "pathologically fine fibrillary sclero-protein"; here we should remember that regeneration of the mesenchyme as well as that of pathological intestinal flora are best accomplished by raw diet.

In this connection it should be mentioned that in investigations at Harvard, an excessive amount of the aromatic amino acid methionine was discovered to favor the formation of nearly insoluble protein

bodies, and hardening of the inner surface of the arteries. The human need for methionine, which is found most abundantly in meat, egg and cheese protein, and which is three times as abundant in cow's milk as in breast milk, has been set much too high (at 930 mg/day) by the F.A.O. according to Kofranyl and is actually just 273 mg/day. Excesses of the amino acid tryptophane—which, as mentioned, is seven to ten times more richly present in meat and eggs than in plant sources—are, as proved on radioactive molecules, eagerly, consumed by cancer cells, which produce serotonin from it, block tryptophane metabolism and have been demonstrated to lead to a strong increase in cancer-producing ortho-aminophenols.

Bone atrophy (osteoporosis) is extraordinarily widespread among us; it begins in childhood, is almost considered a normal accompaniment of aging and is conceived as quickly increasing. Extensive scientific literature deals with the possible causes. Wachmann and Bernstein of the Department of Nutrition at Harvard University investigated all previous research results in the *Lancet* and arrived at the considered conclusion that a protein-rich, and especially meat-heavy diet plays the strongest role in the genesis of osteoporosis, more so even than denatured carbohydrates and fats. It is caused when the function of the bone system as a reservoir of basic minerals is continually overstrained. This corresponds to the fact that athletes who eat much meat are especially susceptible to arthrosis. Helas found among 20 professional football players who were observed for 18 years, 100% incidence of ankle arthrosis and 97.5% incidence of knee arthrosis. A negative lime balance is easily produced in experimental animals by increased protein supply, and they then die of disease associated with lime deficiency. The Walker group found in investigation among the Bantu tribe, that on an almost purely plant-source, low-protein diet there were no signs of calcium deficiency and no weakening of the bones.

Further work during recent years makes Ragnar Berg's acid-base theory, once set aside, again pertinent. The eminent importance of potassium and magnesium is emphasized by several authors. These two basic mineral substances are known to be deficient in an everyday diet rich in meat, eggs, cheese, fat, sugar and grains, but richly present in a full-value diet rich in vegetables and raw foods. One-sided chemical fertilization and refinement detract from these good effects. Also, animal protein-rich diet and alcohol consumption both hinder the absorption of magnesium from the intestine and correspondingly raise the magnesium requirement. The "magnesium deficiency syndrome," which has been prevalent now for 20 years, includes arteriosclerosis, high blood pressure, migraine, eclampsia, the leaching of calcium from teeth and bones, liver damage and disturbance of the neuro-muscular vessel system (Holtmeyer).

Strangely enough, the old Haig uric acid theory is also making a comeback. It seemed at one time to have been rendered invalid when no raised uric acid level was found in the diseases listed by Haig, except for gout. But now it has turned out that the reason for this was simply the introduction of new medicines for rheumatism, and that the evaluation of all uric acid tests on blood must be preceded by at least eight days during which anti-rheumatism medicines have been omitted. Uric acid has again assumed a position among the chief factors causing arterial blockage diseases—including rheumatism, kidney disease and cancer, as well as the amyloid formation, discussed above.

Naturally, the kidneys are deeply involved in all the above factors from birth on in the child, and this has been especially true since the early '50s, when protein and salt-enriched baby foods were introduced. No wonder athletic medicine services in the U.S.A have had to treat an extraordinary number of kidney injuries and kidney breakdowns after athletic competitions and that the American Heart Association arrived at the conclusion that "almost all instances of these diseases"—arteriosclerosis, high blood pressure and coronary disease "are significantly related to the kidneys," and that, therefore, "more than half of the population die of kidney disease."

Only two more subjects still deserve a short mention, since they make the protein question particularly topical at this time.

First, environmental pollution. The individual has no or insufficient, effect on changing this situation. But what he can do is to put the defense and detoxification organs of his own organism in the best

possible condition first by detoxifying his body, and then by making it more powerfully reactive by dietary economy and raw food. Not everyone can supply himself with unsprayed and rationally fertilized food, but he can and must consider that meat and eggs have been far more contaminated since the 1960s than plant products—a result of conversion to industrial production. Anyone who fully understands the extent to which, for example, meal is treated will certainly forego these products. Besides pesticides, meat is treated with tetracycline, chloramphenicol, estrogen, tranquilizers, preservatives, plus metabolic toxins of the fattening process.

Second, and finally, what Sherman wrote two decades ago now applies to a much greater extent. "Feeding grain and potatoes to animals represents an enormous waste of nutritional production potential; and more than that, every person with a social and international sense of justice must become most deeply conscious of the fact that our excessive meat and egg consumption is a leftover from the times of colonial exploitation habits. If we ourselves do not see the provocative injustice in this situation for poorer classes and peoples, they themselves will certainly feel it with increasing intensity."

*This article is reprinted from Dr. Shelton's Hygienic Review. The Review, in turn, reproduced it from The Hygienic Practitioner, the Journal of the British Natural Hygiene Society. Winter, 1974.*

### 1. Prologue

#### 1.1 The Role Of Vitamins In Human Nutrition: A Hygienic View

##### 1.1.1 Misconceptions About Vitamins

The role of vitamins in nutrition is one of the most widely misunderstood subjects in a study of nutritional science. Today, in this age of technology, industry, food products, pills, powders and potions, vitamin supplementation is considered essential for good health in most circles—from the medical circles to the holistic groups and naturopaths. Some advocate a multiple vitamin each day from the drug store; others promote several bottles of a variety of vitamin tablets from the natural foods stores or distributors. Some say we also need to get a balanced variety of minerals in our supplementation program, and others say we also need a protein powder supplement. Both of the latter emphasize the need for a "complete" nutritional supplementation program and not just vitamins alone.

The cons of using food supplements and why they are harmful and unnecessary will be treated in greater depth in a later lesson. Here we will only note that the current preoccupation with vitamins is totally inappropriate and that, while vitamins are necessary, they are amply supplied in natural raw foods of our biological adaptation.

Keep in mind, also, that foods are not to be prescribed in place of supplements as "cures" for symptoms that people often interpret as vitamin and other nutrient deficiencies. Foods should be consumed as much for their carbohydrate (calorie) content as for their vitamin, mineral or protein content. Also, the importance of the water and the undiscovered nutrients in whole fresh foods should not be

underestimated. At all times foods should be considered in their entirety and not as specific sources of specific vitamins and other nutrients.

In the following lesson, foods particularly rich in each vitamin will be listed, but this is not so you or your clients can eat certain foods to obtain certain vitamins; rather, it is just to show you how the foods of our biological adaptation (fresh fruits, vegetables, nuts and seeds) provide adequate amounts of all the known vitamins that we need.

### **1.1.2 The Quantity of Vitamins We Need Is Small**

In a national bestseller, *Everything You Always Wanted To Know About Nutrition*, Dr. David Reuben pooh poohs our preoccupation with vitamins by pointing out that if we took all the vitamins we need in the quantities recommended (which is much higher than actually required), a whole year's supply would not fill a thimble!

For further perspective as to the minuteness of our quantitative needs, let's look at vitamin A. It is recommended that the average adult get 5,000 international units daily to meet needs. One IU weighs one microgram, or one-millionth of a gram, and there are 28 1/2 grams in an ounce. Therefore, 5,000 IUs of vitamin A equal one 5700th of an ounce. If 5,000 IUs were supplied in the diet every day, it would be more than fifteen years before we would have consumed a single ounce!

Or look at vitamin D. This vitamin is formed by the interaction of sunlight and ergosterol in the skin. Our needs are met by so little sunlight that Dr. Reuben has pointed out that while a vitamin D deficiency could occur to a black nun living in Norway, it is an unlikely occurrence in most cases.

Dr. Reuben has observed that, despite the atrociousness of most diets, it is difficult to keep from getting enough vitamins. We can't avoid repleteness of some vitamins even if we try. Let's examine vitamins B-12 and K as examples. Scientists who tried to test for these deficiencies could not create them. Why? Because bacteria in the gut formed an ample supply of these vitamins.

Or examine vitamin C. A single ounce will meet our needs for about 2 years. Despite a denatured diet of deranged and depleted foods, most Americans get enough vitamin C from vegetable salads, slaws and fruits to meet needs. Scurvy hasn't been observed in ages, though some symptoms of vitamin C deficiency have been noted in smokers.

Americans think in terms of deficiencies when, as Dr. Reuben says, almost no American physician has ever witnessed a case of beriberi, pellagra, rickets, scurvy or other disease due to vitamin deficiency.

### **1.1.3 Toxemia, Not Deficiencies, Causes Most Diseases**

We Hygienists recognize that deficiency is not the problem nearly so much as is toxemia. The reason why toxemia and not deficiency is the cause of symptoms is twofold. First, some vitamins are depleted because they play a role in the body's detoxification of harmful substances within. Vitamin C is a notable example of this. Secondly, drugs and drug-like substances, such as coffee, teas, colas, aspirin, medications, junky foods, sugar, alcohol, birth control pills and, in fact, all non-food substances, interfere with the body's absorption and/or utilization of vitamins and other nutrients. Also, certain foods contain toxic substances and should not be consumed. Notable examples of this are foods containing mustard oil—onions and garlic.

The causes of symptoms of ill health that are blamed on vitamin and mineral deficiencies are really drugs and drug-like (toxic) substances ingested—and not vitamin or mineral deficiencies at all! This is a key fact to keep in mind. So, instead of prescribing food supplements or recommending certain foods containing large amounts of certain vitamins (or minerals), which is legally outside the purview of non-physicians anyway, the Hygienic practitioner will simply have the client eliminate the causes of toxemia and consume a wholesome natural diet that contains no toxic substances. Not only will the real causes of disease symptoms be removed and health be regained, but also a natural diet of all or mostly raw foods

of our biological adaptation will supply ample amounts of all the vitamins we need—without the expense or harmfulness of supplements.

Let's look at vitamin B-12 as an example. Its insufficiency results in pernicious anemia. Most sufferers are meat-eaters who obtain B-12 from their diets. So what gives?

Toxemia has impaired the body's ability to absorb vitamin B-12. The body has numerous substances that are engaged in active transport of nutrients from one medium to another through separating membranes. The transport mechanism for vitamin B-12 is called *intrinsic factor*. It is loss of this factor that accounts for B-12 deficiency and anemia. Pernicious anemia is due to toxemia, not deficiency. A fast will restore the lost faculty in almost all cases, and the anemia disappears even before the end of a fast! Such are the powers of the body when liberated from the baneful influences of toxicity.

Vitamins are absolutely essential in our diet—make no mistake about that. But, if we're on a proper diet of mostly fruits with some vegetables, nuts and seeds, we do not have to worry any more about vitamins or other nutrients than we have to worry about each heartbeat, the secretion of bile, or millions of other physiological processes.

## **1.2 Hygienic Perspectives On Vitamins Compared With Medical Perspectives — Marti Fry**

As this is a course not just in nutritional science, but also in Natural Hygiene, or Life Science, it is appropriate that we point out how the Hygienic perspective on the subject of vitamins differs from the generally accepted conventional perspective.

### **1.2.1 Attempts To Be Scientific**

Thanks to scientific research and experimentation, we have learned a great deal about vitamins (and other nutrients). In fact, thanks to the efforts of "science," we have "discovered" the existence of vitamins. We are now able to make a large variety of statements about vitamins—their functions in the body, approximate amounts needed and many other interesting facts.

However, it should be kept in mind that "science" or technology is also responsible for the refining and processing of foods that led to the discovery of vitamins. What the texts fail to note overtly is that many humans (and animals) have suffered (and, in some cases, still suffer) because of the tampering with foods by food industries, who are usually in intimate association with the scientific laboratories. Oftentimes the scientific studies done relative to nutrition are done in laboratories and research centers owned, operated and/or supported by the food processing and refining firms.

The point is that "science" does not always do the favors for humanity that they lead most of us to believe they do. Much suffering has stemmed from "scientific meddling" in the regular order of nature. This is not to condemn the efforts of scientists as much as it is to enlighten students of nutritional science of certain realities. We are not saying that scientists should stop studying phenomena, but that their approach and motives ought to be changed so that humans are truly benefitted by their efforts instead of allowed to believe they are benefitted while much suffering and harm is done. A shockingly high portion of scientific study is done to discover new drugs (poisons) to "cure" diseases, when, in fact, diseases cannot be "cured." The causes of disease must be removed and then the body will spontaneously heal without interference by drugs, medications, herbs, colonies or anything else.

### **1.2.2 The Scientific Approach to Vitamin Study**

A look in physiology and nutrition texts shows that, while many facts about vitamins have been discovered, much more is unknown than is known. Not only that, but much of what is "known" is based on studies in which many animals and some humans have had to suffer. The rationale is that, in the long run, a greater number of living creatures, especially humans, will suffer less due to the greater store of

knowledge.

However, this rationale is to be seriously questioned because the reality is that humans suffered less disease before "science" became so advanced and before technology started refining rice and flour and sugar and marketing these products, along with milk and other unwholesome foods, to the people of the world. In other words, humans, in their pristine state, do not need the supposed benefits of so-called "science" to maintain radiant, sickness-free health. Fresh, untampered-with raw foods of our biological adaptation, not from the food industries, but from the garden and trees, will amply provide all our needs without the need for scientific studies. We certainly do not object to studies that uncover interesting information for our entertainment and use, but we do object to the thinking that we are dependent on and forever grateful to "science" for making it possible for us to live healthfully. We can live much more healthfully without science—at least the way science's priorities stand today.

This is the basis of Natural Hygiene. It involves a simple, wholesome lifestyle and diet that is in full harmony with our needs. Diseases will not occur if the simple, basic laws of life are not violated. If orchards predominated our lands instead of cattle, drug industries, food industries, chicken farms and dairy farms, etc., it would be a lovely and healthful world!

Life Science is, however, scientific. The basic laws of life and principles of Life Science are all provable in scientific laboratories. Many have already been proved. There is absolutely nothing unscientific about Hygiene. In fact, the attempts of so-called "scientists" to discover drugs to "cure" diseases is unscientific in that these efforts are not based on the laws of life. As stated earlier, the ingestion of drugs and medications can result in only harm and can never, under any circumstances, bring about true health.

As stated in Lesson 5, a tiny cell has more intelligence than a team of scientists seeking "cures."

### **1.2.3 The Deficiency Approach to Vitamin Study**

Perhaps the most revolting aspect of the medical/scientific approach to vitamin study is the preoccupation with deficiencies, and especially with deficiency diseases. The grotesque photos in texts of people suffering with various "deficiency diseases" graphically illustrate the distorted perception the medical scientists have of the role of vitamins—"to prevent horrible deficiency diseases." That whole concept of "prevention" is erroneous, as has been stated in earlier lessons. Deficiency diseases are not normal or natural and do not have to be "prevented." We have only to live in accord with the laws of life and nature, and we will be healthy—as nature intended.

A conventional/medical study of vitamins, as presented in textbooks, leads people to think in terms of deficiencies when they think about vitamins. But the study of vitamins should not be a study of deficiency diseases; it should be primarily a study of their role in human nutrition. In fact, identifying individual vitamins and naming the deficiency, disease connected with the lack of each is totally unnecessary. All we really need to know is that they are present in sufficient quantities in natural foods and that we will meet our needs for them on a natural diet of fruits, vegetables, nuts, sprouts and seeds. It is also well to realize that food processing, storage and preservation destroy Vitamins in foods and that drugs and drug-like substances deplete vitamins in the body and interfere with their absorption and utilization.

## **2. Introduction**

### **2.1 Definition of Vitamins**

Vitamins are organic compounds which the body needs to function normally. They cannot be manufactured by the body (with few exceptions); therefore, they must be supplied by food. In their absence, disease will develop.

### **2.2 Discovery of Vitamins**

The first vitamin was discovered in 1897 by a Dutch biologist named Eijkman. He found that when bran was removed from rice, people consuming the refined rice developed beriberi, a serious disease. Eijkman also observed that when people ate the rice with the bran intact, no beriberi resulted. This finding directed Eijkman and other scientists to chemically analyze rice for the substance which, when not present in adequate amounts, resulted in the development of beriberi. Thiamine, named vitamin B1, was discovered to be this mystery substance.

In the following years, scientists found that there are many chemicals in food which are necessary for maintenance of health. One by one, as they were discovered, names were given to these chemicals. As a group, they were named "vitamins."

### **2.3 Sources of Vitamins**

It is crucial to understand that scientists have not isolated every substance in food that is essential for normal functioning of the body. Thus, we must depend on food, not vitamin pills, for good nutrition. There is no vitamin pill that contains all the vitamins the body needs.

### **2.4 Function of Vitamins**

Vitamins function in the body as coenzymes. To understand this function, consider an analogy. Suppose you were trying to build a house. The size of the house is strictly limited by your budget. You begin the process by buying the major raw materials: cement, wood and outdoor siding material. Once you have laid the foundation and framed the walls, you go to the store and buy all the windows you need. The number of windows is obviously limited by the spaces you have built in the walls for windows. For proper function of the house, you need windows.

Vitamins are like the windows in the house. Your body has a need for vitamins (windows) when it is trying to manufacture something: new tissue, energy, etc. (a house). Your body determines the exact amount it wishes to produce and brings together just enough raw materials for the purpose of construction (cement, wood, etc.). The body manufactures the necessary amount of apoenzyme (window frame) to combine with the vitamin coenzyme (window) to form an active enzyme. The active enzyme then makes a chemical reaction progress quickly (it catalyzes the reaction) leading to the formation of the desired end-product.

### **2.5 Vitamins Are Inert**

"Vitamin function" is a commonly used phrase, as is "vitamin action." Yet these expressions convey a misconception. Vitamins cannot act, since they are inert chemical substances. In any and all physiological processes, it is the body that acts. Vitamins are used by the body for many purposes. Usually, vitamins combine chemically with other substances, thereby fulfilling the mandate of the body. It is crucial to remember that it is the body that acts on the vitamin, not the vitamin that acts on the body.

## 2.6 Vitamins Work Together and With Other Nutrients

Although this lesson discusses vitamins exclusively, it is important to realize that vitamins do not function alone or in a vacuum within the body. Vitamins work together; for instance, production of energy by the body when food is burned in the cells depends not only on vitamin B1, but also on vitamins B2 and niacin.

Furthermore, vitamins work together with all other nutrients such as fats, carbohydrates and proteins. For instance, vitamin B6 is needed for the normal metabolism of protein. So, even though this is a lesson on vitamins, don't think of vitamins alone when you consider the functioning of the body. Vitamins are only one small part of the metabolic machinery of the body.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > 3. A Study Of Each Individual Vitamin

## 3. A Study Of Each Individual Vitamin

The discovered vitamins will be studied one by one. You will learn about their discovery, measurement, chemistry, physiology, functions, requirements, sources, effects of deficiency and effects of excess.

### 3.1 The Fat-Soluble Vitamins

Vitamins can be categorized according to their properties. The two basic groupings of vitamins are the fat-soluble vitamins (A, D, E and K) and the water-soluble vitamins (vitamin C and the B-complex vitamins).

Certain common characteristics distinguish the fat-soluble vitamins from the water-soluble vitamins:

1. Fat-soluble vitamins are absorbed into the body as fat and with fat and are soluble in fat solvents (alcohol and ether), whereas water-soluble vitamins are soluble in water.
2. Fat-soluble vitamins are excreted mainly by the fecal pathway, whereas water-soluble vitamins are excreted via the urinary pathway.
3. A text which states that the fat-soluble vitamins are stored in the body but that water-soluble vitamins are not goes on to state in a later chapter that vitamin C, a water-soluble vitamin, can be stored. They state, "It has been shown that human beings are able to store some vitamin C; healthy, well-fed subjects store about 1500 mg. On vitamin C deprivation diets, these stores are used at an average rate of three percent of the existing reserve (pool) per day and supply the body with vitamin C for a period of about three months." As you can see, significant amounts of this vitamin can be stored in the body.

#### 3.1.1 Vitamin A

- a. *Discovery.* This fat-soluble vitamin was discovered by McCollum and Davis of the University of Wisconsin and by Osborne and Mendel of Yale University in 1913. They found that rats on a diet with lard as the only source of fat developed eye problems and failed to grow. It was later found that a shortage of carotene, the yellow pigment of plants, led to the development of these problems. Carotene is converted into vitamin A within the organism.
- b. *Measurement.* Vitamin A is measured in international units. A complicated formula exists whereby micro-grams (1/millionth gram) of vitamins are converted into international units (IUs). Amounts of vitamin A in foods and requirements for this vitamin are expressed as IUs.

- c. *Chemistry.* Vitamin A is relatively stable to heat but is easily destroyed by ultraviolet radiation (as in sunlight). Chemically, it occurs in many forms: retinal, retinol and retinoic acid.
- d. *Physiology.* Most dietary vitamin A is in the form of carotene, the yellow pigment of plants. About half of the carotene consumed is converted into vitamin A in the body and the other half is utilized as a hydrocarbon. Because vitamin A is fat-soluble, if the diet is devoid of fat, or if too little bile is secreted by the liver (bile is needed to digest fat), or if too little thyroid hormone is secreted, there will be poor absorption of vitamin A in the intestines. This vitamin is stored in the liver.
- e. *Functions.* Vitamin A is used by the body in many important ways. The body needs it to maintain normal vision in dim light. Vitamin A is also needed for synthesis of mucus, a secretion the body uses to maintain the health of membranes lining the eyes, mouth and gastrointestinal, respiratory and genitourinary tracts. When enough vitamin A is present, when other nutrients are sufficient, and when the body is not toxic, these membranes will be in a high state of health. However, if there is not a vitamin A deficiency, taking more of this vitamin will not protect the body from diseases nor "cure" diseases. This is a myth that has been scientifically disproven many times. Vitamin A is also needed for normal skeletal and tooth development, for formation of sperm, for the normal progression of the reproductive cycle of the female, for formation of the adrenal hormone cortisone from cholesterol, and for maintenance of the stability of all cell membranes.
- f. *Requirements.* Male adults need 5000 IUs, female adults 4000 IUs, pregnant or lactating females 5000 IUs and infants about 1/10th the adult requirement of vitamin A per day. Infant needs are easily supplied by breast milk.
- g. *Sources.* Healthful sources of vitamin A include dark green leafy vegetables (lettuce and other greens), green stem vegetables (broccoli, asparagus), yellow or orange vegetables (carrots, etc.) and yellow or orange fruits (peaches, cantaloupe, etc.).
- h. *Effects of deficiency.* A deficiency of vitamin A is rare in the U.S. and is usually only seen in chronic diarrhea from colitis and other such diseases, liver disease or use of mineral oil. A deficient person manifests night blindness and degeneration of membranes (eye, nose, sinuses, middle ear, lungs, genitourinary tract).
- i. *Effects of Excess.* Intake of excess vitamin A results in toxicity (poisoning), causing a loss of appetite, increased irritability, drying and flaking of skin, loss of hair, bone and joint pain, bone fragility, headaches and enlargement of liver and spleen. An overdose of this vitamin is about 50,000 IUs per day in adults and 20,000 IUs in infants.

### 3.1.2 Vitamin D

- a. *Discovery.* Vitamin D was chemically isolated in food in 1930. For hundreds of years previous to the 20th century, people had used cod liver oil to supply, a factor which the body needed to maintain normal bone structure. Scientists in the 1900s were able to identify vitamin D as the necessary substance.
- b. *Measurement.* Vitamin D requirements and the amounts present in foods are expressed in international units. One international unit (IU) of vitamin D is equal to 0.025 meg (a meg is one millionth of a gram) of vitamin D.
- c. *Chemistry.* Chemically, vitamin D is very stable. Neither heat nor oxygen will destroy this substance. Vitamin D is produced when the skin (or flesh) of animals is exposed to ultraviolet light.
- d. *Physiology.* Like vitamin A, vitamin D is fat-soluble. Therefore, bile salts are needed for absorption. Vitamin D is stored mainly in the liver. Significant amounts of this vitamin are formed by the skin of human beings exposed to sunlight.
- e. *Functions.* The body needs vitamin D to maintain normal calcium and phosphorus metabolism in the body and to maintain the health of bones and teeth. With adequate D, the body is able to regulate the absorption of calcium and phosphorus from the intestines and the amount of phosphorus eliminated through the kidneys.

- f. *Requirements.* Men, women and children need approximately 400 IUs of vitamin D per day. Moderate exposure to sunlight allows the body to produce all the vitamin D it needs. In the summer the body produces excess vitamin D and stores it in the liver. In the winter, when there is less sunlight, the body draws upon the stores of D in the liver to maintain normal vitamin D metabolism.
- g. *Sources.* Clothing prevents formation of D in the skin with sunlight exposure, and window glass, fog and smog may also interfere. There is no scientific evidence, however, that sunlight exposure will not allow the body to produce sufficient vitamin D if the skin is exposed to light for enough time. One-half hour per day in the warm months should suffice.
- h. *Effects of deficiency.* A deficiency of vitamin D will, result in rickets in infants and osteomalacia in adults. The body cannot maintain normal bone structure when too little vitamin D is present. Rickets is characterized by soft and fragile bones, especially in the legs; curvature of the spine; enlargement of certain joints; poor development of many muscles; irritability and restlessness; poor dental structure; and abnormality of the blood. Osteomalacia also is characterized by soft bones, plus leg and lower back pain, general weakness, and fractures that occur without significant trauma.
- i. *Effects of excess.* Excess vitamin D results in nausea, diarrhea, loss of weight, frequent urination, all in mild cases; kidney damage, calcium deposits with damage to the heart, blood vessels and other tissue, in severe cases. A dose of vitamin D approximately 100 times the amount needed will cause poisoning and the above symptoms.

### 3.1.3 Vitamin E

- a. *Discovery.* Shortage of another organic compound which dissolves in fat solvents was discovered in 1922 to result in destruction of the fetus in the uterus of animals. In 1936 vitamin E was chemically isolated as this substance.
- b. *Measurement.* Amounts of vitamin E are expressed as international units (IUs). One IU is equal to 1 mg (1/1000th gram) of vitamin E.
- c. *Chemistry.* Vitamin E is relatively stable but will break down on exposure to ultraviolet light and when exposed to rancid fats, lead or iron.
- d. *Physiology.* Since vitamin E is a fat-soluble vitamin, bile salts are needed for absorption (see under vitamin A). Most vitamin E is stored in muscle and fat tissue.
- e. *Functions.* The body uses vitamin E mainly as an antioxidant. It chemically combines with oxygen, and, as a result of this, other organic compounds are not destroyed by oxygen. Scientists think that vitamin E is also needed for production of certain essential tissues, especially red blood cells.
- f. *Requirements.* The amount of vitamin E needed for normal body function is about 15 IUs per day. Fortunately, one of the richest sources of E in nature is un-saturated fats (oils, as found in seeds and nuts). This vitamin is also found in fruits, vegetables, sprouted grains and sprouted legumes.
- g. *Effects of deficiency.* Symptoms of deficiency in animals continue to baffle scientists. When E is in extremely short supply, disease in many areas of the body results. There is breakdown of the reproductive system, muscular system, nervous system and vascular (blood vessel) system. But the conditions needed to produce such destruction in animals involve such extreme deficiency that scientists think no such problems develop in human beings from a dietary deficiency of vitamin E. Therefore, impotence, infertility, heart disease and other such problems in people are not from vitamin E deficiency and will not be helped by taking excess vitamin E.
- h. *Effects of excess.* Excess intake of vitamin E, long thought to be harmless, has now been implicated in the causation of cholesterol deposits in blood vessels, elevated blood fat levels, interference in the blood-clotting process, enhanced growth of lung tumors, interference with vitamin A and iron, disturbances of the gastrointestinal tract, skin rashes, interference with thyroid gland function and damage to muscles. Megadoses of vitamin E are certainly not to be

considered harmless.

### 3.1.4 Vitamin K

- a. *Discovery.* Vitamin K was discovered in 1935. A doctor in Scandinavia found that this substance was necessary for normal clotting of the blood.
- b. *Measurement.* Amounts of vitamin K are expressed as micrograms, one millionth of a gram.
- c. *Chemistry.* Vitamin K is the fourth of the fat-soluble vitamins (others are A, D and E). It is easily destroyed by light but is stable to heat.
- d. *Physiology.* Vitamin K is a vitamin that does not need to be supplied in food. Bacteria which live in the human intestine are fully capable of producing the vitamin K needed for normal functioning of the bloodclotting apparatus. Vitamin K, being fat-soluble, is absorbed with fat and as a fat and therefore requires the presence of bile salts.
- e. *Functions.* The liver produces certain organic compounds needed for the bloodclotting process. Vitamin K is required by the liver for production of these compounds.
- f. *Requirements.* A dietary requirement has never been set for vitamin K because it is supplied by intestinal bacteria. A deficiency of vitamin K is unknown.
- g. *Sources.* Dietary sources of vitamin K are kale and other green leafy vegetables, cabbage and cauliflower.
- h. *Effects of deficiency.* A deficiency of vitamin K results in failure of the bloodclotting system, resulting in hemorrhage. This is found only in premature infants of mothers taking anti-bloodclotting drugs, in people with intestinal malabsorption and patients on sulfa drugs and antibiotics (which kill the intestinal bacteria that produce vitamin K). Intestinal malabsorption can occur as a result of liver or gallbladder disease, severe diarrhea, colitis and some other conditions; it can result in deficiency of any essential nutrient.
- i. *Effects of excess.* The effects of excess vitamin K are unknown.

## 3.2 The Water-Soluble Vitamins

### 3.2.1 Vitamin C

- a. *Discovery.* Vitamin C, also known as *ascorbic acid*, was isolated chemically in 1932 at the University of Pittsburgh. Feeding this organic compound was found to prevent scurvy. Almost 200 years previous to the chemical identification of vitamin C, Dr. James Lind, a British physician, found that scurvy would not occur if citrus fruits were consumed.
- b. *Measurement.* Amounts of vitamin C are expressed in milligrams, 1/1000th of a gram.
- c. *Chemistry.* Vitamin C and all the B vitamins dissolve in water but not in fat as with A, D, E and K. Vitamin C is more easily destroyed than any of the other vitamins. Heat, light, copper, and iron are especially destructive.
- d. *Physiology.* Most forms of life synthesize the vitamin C they need and thus do not need a dietary source. However, humans do not synthesize this vitamin. When vitamin C is supplied to the body, the tissues quickly become saturated and excesses are eliminated in the urine.
- e. *Functions.* The body uses vitamin C in many important ways. The main one is in the formation of connective tissue, the underlying structure of bone, cartilage, blood vessel walls and most other tissues. Without vitamin C, the body cannot rebuild injured tissue.  
There are many other important roles of vitamin C: It is needed for normal cellular metabolism and enzyme function, for the normal metabolism of iron and folic acid (a B vitamin) and for the formation of adrenal gland hormones.
- f. *Requirements.* There is much controversy about the requirement for vitamin C. The recommended dietary allowance is no more than 1/10th of a gram, yet Linus Pauling states that we need 100 times that amount. Scientific evidence clearly states that 1/10th of a gram, 100

milligrams, is more than enough. Some evidence indicates that slightly more than this amount may be desirable. On a Hygienic diet, with its great abundance of raw fruits and vegetables, it is easy to get over 500 milligrams per day. There is certainly no need for supplements, despite the allegations of Dr. Pauling.

- g. *Sources.* Vitamin C is supplied in fruits and vegetables, especially citrus fruits, tomatoes and bell peppers. Other foods also contain small amounts of this vitamin.
- h. *Effects of deficiency.* A deficiency of vitamin C results in poor connective tissue structure. Symptoms include joint pain, irritability, growth retardation, anemia, shortness of breath, poor wound healing, bleeding of gums and pinpoint hemorrhages. If the diet contains enough vitamin C and these symptoms still develop, causes other than vitamin C deficiency must be searched for. Taking large amounts of vitamin C for diseases which are not the result of a vitamin C deficiency may alleviate symptoms but will not remove the cause of the problem.
- i. *Effects of excess.* Excess vitamin C, even though water-soluble and so not stored in large amounts in the body, can be harmful to your health. Problems include destruction of red blood cells; irritation of the intestinal lining; kidney stone formation; interference with iron, copper, vitamin A and bone mineral metabolism; interference with the reproductive tract, causing infertility and fetal death; diabetes; and, believe it or not, scurvy. Intake of excess amounts of vitamin C, as with most vitamins, is only possible when pills or crystals are taken.

### 3.2.2 Vitamin B1

- a. *Discovery.* The existence of vitamin B1, also known as *thiamine*, was first theorized in 1897 by a Dutch doctor who found that eating polished rice would result in a serious disease called beriberi. When unpolished and unrefined rice was eaten, however, *beriberi* did not develop. In the 1920s and 1930s, thiamine was chemically isolated from rice bran.
- b. *Measurement.* Amounts of vitamin B1 are expressed in milligrams (mg), 1/1000th of a gram, or micro-grams (meg), 1/millionth of a gram.
- c. *Chemistry.* Vitamin B1 is readily destroyed in the cooking process.
- d. *Physiology and functions.* This important vitamin plays a crucial role in the body's energy-producing processes. In the body, when glucose is burned in the cells, energy is produced. This energy is stored when an organic substance named ATP is produced. Vitamin B1 is needed for the formation of ATP.
- e. *Requirements.* The requirement for vitamin B1 is approximately 1/2 mg daily for infants and children, 1-1.5 mg daily for adults.
- f. *Sources.* If mainly fruits and vegetables are eaten, as we recommend, significant amounts of vitamin B1 will be supplied. Other sources are nuts, seeds, sprouted legumes and sprouted grains. When grains are refined, much of the vitamin B1 (and other vitamins) is lost.
- g. *Effects of Deficiency.* A deficiency of vitamin B1 results in serious breakdown of cellular metabolism. Manifestations of this breakdown include fatigue, emotional upsets, appetite loss, weakness, vomiting and abdominal pain, heart failure and nervous system destruction (generalized weakness and/or paralysis occur). Again, it is essential to note that there are many other causes of these problems. If the diet contains enough vitamin B1, these problems will not be helped by getting more of this vitamin.
- h. *Effects of excess.* The problems which develop when excess vitamin B1 is consumed have not been investigated. We can be sure, however, that problems will result when "megadoses" are ingested.

### 3.2.3 Vitamin B2

- a. *Discovery.* In the late 1920s and early 1930s, scientists discovered a substance in food which the body needed for normal nervous system function. This substance was chemically identified and named *riboflavin*, also called vitamin B2.

- b. *Measurement.* As with thiamine, amounts of riboflavin are expressed as milligrams or micrograms.
- c. *Chemistry.* Vitamin B2 is more stable to heat than vitamin B1, but it is easily destroyed by light.
- d. *Physiology and functions.* The function of vitamin B2 is much the same as B1, although neither vitamin can substitute for the other. Riboflavin is needed for the synthesis of ATP.
- e. *Requirements.* The requirement for riboflavin is about the same as for thiamine. About 1/2 mg daily is needed by infants, and 1-1.5 mg per day is needed for older children and adults.
- f. *Sources.* Riboflavin is supplied by green leafy vegetables, seeds and nuts.
- g. *Effects of deficiency.* Symptoms of a vitamin B2 deficiency include the eyes becoming sensitive to light, easy fatigue of the eyes, blurred vision, itching and soreness of the eyes, cracks in the skin at the corners of the mouth, purplish red appearance of the lips and tongue, and eczema.
- h. *Effects of excess.* Symptoms of excess intake of riboflavin have not been clearly elucidated.

### 3.2.4 Niacin

- a. *Discovery.* Niacin deficiency disease, called *pellagra*, was written about hundreds of years ago. It was not until the 20th century, however, that this disease was related to a dietary deficiency. This took place when a researcher placed subjects on a diet identical to that which caused pellagra-type symptoms in certain groups of people in the South. When these symptoms occurred in the experimental subjects, the researcher concluded that pellagra is a deficiency disease. Soon after, other scientists found that niacin was the missing link.
- b. *Measurement.* Amounts of niacin are expressed in milligrams.
- c. *Chemistry.* This important B vitamin (called B3 by some nutritionists) is more stable than most other B vitamins; it is not easily destroyed by heat, light or exposure to oxygen.
- d. *Physiology.* Not all the niacin needed by the body need be supplied as niacin. Tryptophan, an amino acid (subunit of protein), is easily converted by the body into niacin. Therefore, to have a niacin deficiency, the diet must be deficient in both niacin and tryptophan.
- e. *Functions.* Niacin is intimately involved in cellular metabolic reactions which release energy from the oxidation ("burning") of fats, carbohydrates and proteins. In this function it is quite similar to vitamins B1 and B2, but niacin cannot substitute for or be replaced by other B vitamins.
- f. *Requirements.* The requirements for niacin are about 5-10 mg per day for infants and children and 15-20 mg per day for adults.
- g. *Sources.* There are many sources of niacin in the diet: green leafy vegetables, potatoes, nuts and seeds, to name a few.
- h. *Effects of deficiency.* Deficiency of niacin leads to development of pellagra. This disease involves the gastrointestinal tract, skin and nervous system. Common symptoms include fatigue; headache; weight loss; backache; appetite loss; poor general health; red sore tongue; sore throat and mouth; lack of hydrochloric acid in the stomach (which results in anemia from vitamin B12 deficiency); nausea; vomiting; diarrhea; red, swollen and cracked skin; confusion; dizziness; poor memory and, in advanced cases, severe mental illness.  
If the diet contains sufficient amounts of niacin, and if a person suffers from any of the aforementioned symptoms, taking extra niacin will have no beneficial effect.
- i. *Effects of excess.* Intake of excess niacin has been found to cause liver damage, high levels of blood sugar, unsafe levels of uric acid in the bloodstream, and gastrointestinal distress ("stomachache").

### 3.2.5 Vitamin B6

- a. *Discovery.* A deficiency of vitamin B6, or *pyridoxine*, was first produced in animals in 1926. In 1938, this vitamin was isolated from food and identified. In 1939, scientists synthesized it in the laboratory.
- b. *Measurement.* Amounts of vitamin B6 are expressed in micrograms or milligrams.

- c. *Chemistry.* Vitamin B6 is easily destroyed by light but is somewhat stable to heat.
- d. *Physiology and functions.* Vitamin B6, sometimes referred to as pyridoxine, is deeply involved in the metabolism of protein. When amino acids (subunits of protein) are converted into other substances (such as tryptophan to niacin), vitamin B6 is often needed. Also, when non-protein substances are converted into amino acids, vitamin B6 is often needed.
- e. *Requirements.* Infants and children require about .5-1 mg of vitamin B6 per day. Adults need about 2 mg per day.
- f. *Sources.* Vegetables are the main source of vitamin B6 in the diet.
- g. *Effects of deficiency.* Deficiency of vitamin B6 leads to problems in the skin, nervous system and blood in animals. It has been difficult for researchers to produce any deficiency in adult humans. In extreme experimental situations, skin disease has resulted in adults from a vitamin B6 deficiency.
- h. *Effects of excess.* Generalized symptoms of toxicity (poisoning) have been recorded in rats upon intake of excess vitamin B6. Future research will certainly find damage in human beings from intake of excess vitamin B6.

### 3.2.6 Pantothenic Acid

- a. *Discovery.* Pantothenic acid was first isolated in 1938. Two years later researchers synthesized this vitamin in the laboratory.
- b. *Measurement.* Pantothenic acid is measured in milligrams.
- c. *Chemistry.* It is relatively stable, yet significant amounts are lost in cooking.
- d. *Physiology and functions.* Pantothenic acid is part of coenzyme A, an organic substance which plays a critical role in many cellular metabolic pathways.
- e. *Requirements.* Four to seven mg of pantothenic acid per day will fulfill the body's needs in both adults and children.
- f. *Sources.* Sources of pantothenic acid include fruits, vegetables, sprouted legumes and grains.
- g. *Effects of deficiency.* A deficiency of pantothenic acid has been observed only in laboratory animals. This vitamin is widely available in common foods so that deficiency outside of the laboratory is unlikely. Symptoms of deficiency include vomiting, fatigue, a feeling of generalized sickness, pain in the abdomen, burning cramps, personality changes and blood abnormalities.
- h. *Effects of excess.* Diarrhea is the only symptom thus far shown to result when excess pantothenic acid is taken.

### 3.2.7 Biotin

- a. *Discovery.* The discovery of biotin was made when large quantities of raw eggs were fed to animals before World War II. Scientists found that raw egg whites contain avidin, a substance that inactivates biotin. The diet high in raw eggs therefore led to development of deficiency symptoms in animals.
- b. *Measurement.* Amounts of biotin are expressed in micrograms.
- c. *Chemistry.* This vitamin is stable to heat and light but is sensitive to oxygen.
- d. *Physiology and functions.* The body uses biotin as coenzymes needed for normal metabolism of protein, carbohydrate and fat.
- e. *Requirements.* The requirement for biotin is about 150 micrograms per day for adults.
- f. *Sources.* Nuts and seeds are high in biotin. Another excellent source is sprouted legumes.
- g. *Effects of deficiency.* Biotin deficiency is produced only when many raw eggs are consumed. Symptoms which develop include skin problems, fatigue, muscle pain, lack of appetite, nausea and blood abnormalities.
- h. *Effects of excess.* The effects of excess biotin have not yet been described.

### 3.2.8 Vitamin B12

- a. *Discovery.* Vitamin B12 was not identified until 1955. Long before, in the early 1920s, foods high in this vitamin (such as liver) were used in cases of *pernicious anemia*.
- b. *Measurement.* Amounts of this vitamin are expressed in micrograms.
- c. *Chemistry.* Vitamin B12 is not damaged by heat, but it is inactivated by light. Very little is lost in cooking.
- d. *Physiology.* The physiology of vitamin B12 is complex. To be absorbed into the bloodstream, vitamin B12 must combine with an organic substance secreted by the stomach called *intrinsic factor*. The resultant complex can then be absorbed only at the far end of the small intestine, the terminal ileum. Disease of the stomach often results in deficiency of intrinsic factor. This condition, not a dietary deficiency of vitamin B12, is called pernicious anemia.
- e. *Functions.* All cells in the body need vitamin B12 to function normally, but certain tissues need more of this vitamin than do others. These include the gastrointestinal tract, nervous system and bone marrow (where blood cells are produced).
- f. *Requirements.* Infants and children need about .5-2 meg of vitamin B12 per day, with the larger amounts needed in later years. Adults need about 3 meg per day; 1 meg additional is recommended for pregnant and lactating women.
- g. *Sources.* Vitamin B12 should perhaps be called the "vegetarian's nemesis," since standard nutrition teaches that it is only present in animal foods (meats, eggs, dairy products) and that none is found in vegetables, fruits, seeds, nuts, sprouted legumes or sprouted grains. Yet vitamin B12 is produced by bacteria that are so widely prevalent in nature that many or most vegetarian foods contain small amounts of vitamin B12. Also, scientific evidence has shown that bacteria in the human intestine can produce vitamin B12. Although vegetarians often have low blood levels of vitamin B12, there has almost never been a well-documented case of a vegetarian who was sick from a dietary vitamin B12 deficiency. Therefore, there is no need for the subject of vitamin B12 to be a "vegetarian's nemesis."
- h. *Effects of deficiency.* When the body has a poor supply of vitamin B12, pernicious anemia will result. Fewer red blood cells are formed in the bone marrow. Advanced cases of vitamin B12 deficiency show nervous system disease characterized by "pins and needles" sensations in the hands and feet, poor balance and mental depression.
- i. *Effects of excess.* The effect of taking too much vitamin B12 has not been described.

### 3.2.9 Folic Acid

- a. *Discovery.* An unknown organic substance, distinct from all other vitamins, was found in the early 20th century to be necessary for animal health. In the 1940s the chemical structure of folic acid was described. The name comes from *folium*, Latin for leaf, since folic acid is present in such great amounts in green leaves.
- b. *Measurement.* Amounts of folic acid are expressed in micrograms.
- c. *Chemistry.* Folic acid is not stable to light and heat so that large amounts are lost in cooking.
- d. *Physiology and functions.* Folic acid is needed for the normal functioning of the genetic material in cells (DNA), for metabolism of protein and some other organic substances.
- e. *Requirements.* Adults need about 400 micrograms of folic acid per day. In pregnancy, an additional 400 meg are needed, while in lactation, an additional 200 meg will suffice: Needs in infancy, as with all vitamins, are much lower, about 50 mcg per day.
- f. *Sources.* Folic acid is best derived from green leafy vegetables and sprouted grains.
- g. *Effects of deficiency.* A deficiency of folic acid will lead to anemia. If anemia is from vitamin B12 deficiency and folic acid is given, the body will be able to correct the anemia. The nervous system disease from vitamin B12 deficiency, however, will not be affected by giving folic acid.
- h. *Effects of excess.* Effects of excess folic acid intake have not been described.

## 4. Questions & Answers

**Is the conventional American diet generally deficient in vitamins, and is this the major health-destroying aspect of this diet?**

No. While the conventional American diet has been shown to be deficient in vitamins in many cases, this is not the major problem with this diet. The major problems result from excess intake of toxins, calories, fat, protein and sugar. Taking vitamin pills will have no beneficial effect on the problems resulting from the excesses in the American diet.

**Should I take vitamin pills?**

A person eating a diet of whole, unrefined foods, mostly uncooked, has no need for supplements.

**When the necessary amount of vitamins is supplied in the diet, will additional vitamins help?**

Definitely not. The body can use only a limited amount of vitamins as supplied in food. Excess vitamins often cause damage to the body.

**Are extra vitamins needed because of stress, smoking and pollution?**

Yes, and the extra amounts are easily supplied from food.

**A deficiency of a vitamin will lead to development of a certain disease, for instance night blindness and vitamin A. If the diet contains enough vitamin A and a person still develops eye disease, will additional vitamin A solve the problem?**

No. Taking vitamin A will only correct a vitamin A deficiency and the problems associated with such a deficiency. There are multiple causes of eye problems and all the other symptoms that develop when there is a vitamin deficiency.

**I know that too much of vitamins A and D can be harmful, but I heard that you cannot take too much of the water-soluble vitamins like vitamins C and B. Is this true?**

No. Although excesses of vitamins C and B will be eliminated rapidly from the body, there will be damage to the body before and during their elimination.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Caution: Megavitamins May Be Dangerous To Your Health by Dr. Alan Immerman, D.C.

**Caution: Megavitamins May Be Dangerous To Your Health by Dr. Alan Immerman, D.C.**

Surprising as it may sound, vitamins—especially the fat-soluble ones—when taken in unnaturally large quantities, can be dangerous to your health. In fact, megavitamin therapy carries risks similar to those of other drugs. Just as with other medications, the taking of large amounts of vitamins can cause side effects and other more serious health problems.

For years I took large daily doses of many vitamins. I read many of the magazines which are sold in

health food stores and I believed what I read. I was convinced that large doses of vitamin C would "prevent" and "cure" colds and that some of the B-complex vitamins would calm my emotions "naturally" with no side effects. I believed that large amounts of vitamin E would prevent heart disease and delay the aging process. Fortified daily as I was, I was certain that I was doing myself a world of good, even though I didn't feel better while I was taking the supplements in such large doses.

Then it happened: I put down my health food store paperbacks long enough to read a few scientific textbooks and journal articles. I studied the biochemistry of vitamins (I have a B.S. in chemistry) and I read scientific studies which investigated the possibility of side effects from taking vitamins. I was more than a little surprised by what I found.

First, what is a "megavitamin"? I consider it to be a level of dosage that one could never get from food. For example, if you ate a large amount of fruits and vegetables, you could get 500 to 1,000 milligrams (.5 to 1 gram) of vitamin C per day from food. Although the RDA (recommended dietary allowance) is only 60 milligrams, it is possible to get ten, even 20 times this amount from foods. Therefore, in the case of vitamin C, I would use the term megavitamin to describe something in the neighborhood of 2 grams per day. While this may seem extraordinarily large, bear in mind that some self-appointed authorities recommend that we take 5-10 grams of vitamin C per day.

In large doses, vitamins act like drugs, not nutrients. If you eat more than the amount required, your body won't be able to use them. In its wisdom, the body will try to eliminate the excess, but too much of an overload may cause the excess to remain in the bloodstream, causing drug-like effects.

Megavitamin proponents argue that the requirement for vitamins differs from one person to another (biochemical individuality). This is true. But the conclusion that some people must, therefore, take megadoses of vitamins is false. Taking the recommended dietary allowances of vitamins fulfills the body's needs since the RDAs have been formulated with full awareness of biochemical individuality. The RDA compensates so well for the fact that some people need more of a certain vitamin that it has even been occasionally criticized for being too generous, for instance in the RDA for vitamin E.

Megavitamin proponents claim that large amounts of vitamins are used as nutrients. A nutrient is a substance that is used in normal physiological processes and causes no harm to the system. Other chemicals, such as drugs, are not used by the body and do cause harm. Scientific studies have shown that megavitamins can cause harm to the body. Therefore, I classify them as drugs.

Our bodies are capable of using nutrients supplied in the proper amounts. But when a nutrient is supplied in too great an amount, havoc is the result. We have all heard of the rare cases where someone has drunk too much water and died. The same is true with vitamins: too much of a good thing is harmful.

Experiments such as the following have often been repeated. Megadoses of vitamin B3 (niacin) were given to large groups of experimentees for a number of weeks at a time. Before and after the dosage period, blood was drawn from the subjects and analyzed for many chemicals. At the end of the experiment, scientists found that up to 45% of the subjects had liver damage, 50-66% had abnormally high levels of blood sugar, 62-78% had unsafe levels of uric acid and 20-40% had "gastrointestinal distress" (stomachaches). Though it may be hard to swallow that our old friend niacin is harmful in large doses, swallow it we must if we want to align our beliefs with reality.

Niacin has been recommended in large doses to lower blood cholesterol levels and to control schizophrenic symptoms. I suggest that better ways be found to deal with these problems (such as eating less meat and eggs to lower cholesterol).

Megadoses of vitamin C are also potentially harmful. Consider the following side effects: destruction of red blood cells; irritation of the intestinal lining; kidney stone formation; interference with iron, copper, vitamin A and bone mineral metabolism; interference with the reproductive tract, causing infertility and fetal death; diabetes; and something called rebound scurvy. Scurvy is vitamin C deficiency disease. If you take large amounts of vitamin C for a long time (many months, at the least), your body will increase

its level of elimination of vitamin C (more evidence that your body doesn't want it around). If you then decide suddenly to stop taking vitamin C cold-turkey you will become deficient in this vitamin because it takes a period of time (many weeks sometimes) for your body to adjust downward its level of elimination of vitamin C. Does this sound safe? I would rather have a cold any day than the possibility of the side effects of megadoses of vitamin C. Besides, a cold is actually a detoxification process that shouldn't be interfered with by use of anything, even it is a supposedly friendly vitamin.

The third vitamin that has been investigated in depth is vitamin E. Megadoses of this vitamin (over about 100 IU per day) have been found to cause deposits of cholesterol in blood vessels; elevations of blood fat levels; interference with the bloodclotting process; enhanced growth of lung tumors; interference with absorption of vitamin A and iron; gastrointestinal disturbances; skin rashes; interference with thyroid gland function; and damage to muscles. Thus, megadoses of vitamin E also function as drugs, complete with side effects.

All nutritionists recognize the hazards from large doses of vitamins A and D: Megadoses of vitamin A have been known to cause the following negative effects: fatigue; generalized feeling of sickness; stomach discomfort; bone and/or joint pain; severe headaches; insomnia and restlessness; night sweating; loss of body hair; brittle nails; constipation; irregular menstruation; emotional instability; dry scaly and rough skin and other effects. Megadoses of vitamin D can cause nausea, diarrhea, weight loss, kidney damage and other problems.

I have no argument with those who claim that megadoses of vitamins will change the way you feel. They may, although in most cases there is no solid scientific proof that they will. But the way you feel is not in itself a valid criteria with which to judge megavitamins. If it were, then we could endorse drugs as completely beneficial. Both drugs and megavitamins may change symptom patterns. If you take vitamin C, there is a slim chance that you may experience a reduction in cold symptoms due to an antihistamine (not nutritional) effect. If you have arthritis and take cortisone, you will experience a reduction in joint pain. But both these substances have side effects; and neither of these substances are getting at the cause of the health problem, just the symptoms. In fact, both are causes of other problems!

And there is even more: By treating yourself with vitamins, you may mask a serious disease until it has progressed to the point of no return. For instance, if you are anemic from vitamin B12 deficiency and you take folic acid, the folic acid will correct the anemia but you will have continuing subtle nervous system damage from the B12 deficiency.

Megadoses of vitamin C interfere with tests for sugar in the urine (a common indicator of severity of diabetes) and for blood in the stool (a test for cancer of the large intestine, among other things).

Once you find out what your problem is, I have one bit of advice: Don't try megavitamins for a solution. If they give you any relief, it will only be symptomatic: the cause of your problem will remain untouched. And the megavitamins may cause even further disruption of your health because of the many harmful side effects they can have.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #2: Vitamins And Disease Causation By Marti Fry

## **Article #2: Vitamins And Disease Causation By Marti Fry**

Conventional medical practice attributes disease causation to: 1) bacteria or viruses; 2) hereditary or genetic disorders; or 3) deficiencies of vitamins or other nutrients. They do not blame disease causation on the habits and lifestyles of people who get diseases—except in the cases of deficiency diseases. Food

supplements are supposed to solve the problems ("cure" the diseases) resulting from nutrient deficiencies. Sometimes nutrient-rich foods are also or instead recommended. For example, oranges or tomatoes may be recommended in cases of vitamin C deficiency or carrots or other orange foods for vitamin A deficiency, etc. However, with the popularity of food supplements today, especially among "alternative health groups," but also among conventional practitioners, pills are more often prescribed or recommended.

The error made by conventional medical and "health" practitioners is even worse than prescribing or recommending vitamin pills. They do not recognize that the true cause of diseases in most cases is not bacteria, viruses, hereditary or genetic disorders or nutrient deficiencies—rather, diseases result from enervation and toxemia; that is, lowered nerve energy, retention of toxic metabolic wastes, and consumption of toxic substances (wrong foods, drugs, etc.).

Even the "alternative healers," though many recognize that diseases are body-created processes for elimination of toxins, think more in terms of nutrient deficiencies and food supplements than of removing the true causes of most diseases—body toxicity. Supplying the normal needs of life as recommended by the Life Science health system while simultaneously removing the causes of diseases is the only way health can be restored effectively and permanently.

The idea of getting more vitamins, protein or other nutrients to prevent or overcome diseases is erroneous. Most diseases are not deficiency diseases as so many people believe today. Also, vitamins are not specific detoxifying substances that assist the body in eliminating its pathogenic toxic load. In massive amounts they are like drugs that add to the body's toxic load and must be expelled. In normal amounts as supplied in wholesome, raw foods, they play many varied roles. It is really foolish to tamper with normal body functioning in any way, including the use of vitamin supplements which do not go to the root—do not deal with the cause—of disease any more than do drugs or medications.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #3: Why RDAs Are Too High by T.C. Fry

### **Article #3: Why RDAs Are Too High by T.C. Fry**

Before entering into a discussion of how RDAs are set, it is appropriate to distinguish between Recommended Dietary Allowance (RDA) and Minimum Daily Requirement (MDR). These are not the same, though MDRs are usually set unduly high, as are the RDAs.

RDAs are set by the Food and Nutrition Board of the National Research Council. Minimum Daily Requirements are mandatory on labelling of processed foods. They are required by the FDA, who has published the MDRs. MDRs generally closely parallel the RDAs. Supposedly the minimum requirement is the least amount you can ingest and adequately meet need. RDAs are recommended as intake to be on the safe side. RDAs are, therefore, higher than MDRs.

In setting RDAs, the NRC has criteria for each nutrient, vitamin or mineral. For instance, it figures vitamin C need based on what is required as a minimum. Say this minimum is set at 15 milligrams daily, which is the generally recognized minimum in much of the world. The NRC figures there is perhaps a 30% difference between individuals in their vitamin assimilation abilities. Thus they add on 30% to this minimum.

Further, the NRC gives a biologic value of about 2/3 to dietary vitamin C (could this be due to cooking or due to synthetic C or both, making 1/3 not available?) Instead of 19.5 mg, we now have 30 mg. As a margin of safety, the recommendation allows an extra 100%.

Thus, a man of say 154 pounds is said to need 60 mg of vitamin C daily. This is the RDA when, in point of fact, the needs of a healthy person are amply met on an intake of 15 to 20 mg daily. But, as this water-soluble vitamin in its natural form is easily excreted, there is no great danger in an intake of 60 mg daily. In fact, a natural diet furnishes 200 to 500 mg daily.

While establishing an RDA some four times in excess of what a healthy individual really needs is not harmful in the case of natural vitamin C, in other cases the RDA is positively pathogenic! This "generosity" amounts to recommended overfeeding. In people's minds the RDA becomes a mandatory minimum and they add on perhaps another 100% just to be sure! In the case of protein this is a great contributing cause of widespread disease!

As a Hygienist, be ever cognizant of those principles that go like this: The healthier you are, the more efficient your body becomes up and down the line. On a proper diet the biological value of nutrients is at or near 100%! The food will not be deranged by cooking or processing. Further, it will be 100% in accord with human digestive adaptations and capabilities. The healthy person will have about 100% uptake of dietary intake up to an optimum point and nearly 100% usage. Hence most RDAs are some 200% to 1,000% too high at the least!

Why get into a meaningless numbers game when all that we need in nutrients to repleteness is amply furnished with a great margin of safety by a modest diet consisting mostly of fresh fruits with some vegetables, nuts, seeds and perhaps some dried fruit. All, of course, must be eaten in the raw or live state to assure nutrient integrity on the one hand and non-toxicity on the other.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #4: Vitamin B-12 And Your Diet By Dr. Alan Immerman

### **Article #4: Vitamin B-12 And Your Diet By Dr. Alan Immerman**

*If you do not eat animal foods of any kind your fears about dietary deficiency in this highly publicized vitamin will be allayed by this report.*

Do we get enough vitamin B12? This is a major concern to people who consume no animal foods (vegans). Much of their worry arises from the wide publicity given to statements like the following which appeared in the prestigious journal, *Nutrition Reviews*: "Strict vegetarianism in western countries is a form of food faddism which can have serious consequences" due to the possibility of a vitamin B12 deficiency. What are the facts?

First of all, it cannot be said that vegans consume too little vitamin B12 unless it can be shown they have a definite deficiency of this vitamin. Therefore, in order to understand the facts, we must decide how we will determine who is deficient. To be diagnosed as having a dietary deficiency of vitamin B12, all the following five criteria must be fulfilled:

1. Intake of less than the minimum daily requirement of vitamin B12.
2. Abnormally low blood vitamin B12 level.
3. Normal absorption of vitamin B12.
4. Presence of sickness specifically associated with a vitamin B12 deficiency; a specific type of anemia (megaloblastic) and/or nervous system degeneration.
5. Elimination of the signs and symptoms of such sickness following consumption of a small amount of vitamin B12-containing food.

The finding of a vitamin B12-deficient state without fulfillment of every one of these criteria cannot be blamed solely on the diet. This is because all of the following can also cause a vitamin B12 deficiency:

stomach disease (interferes with production of intrinsic factor, a chemical necessary for normal absorption of vitamin B12), intestinal disease (may interfere with normal absorption), kidney or liver disease (may increase loss of vitamin B12 from the body), use of alcohol or tobacco, use of some drugs such as neomycin and oral contraceptives and a multitude of other problems. Unless these problems are ruled out by fulfillment of the five criteria, a dietary cause of a vitamin B12 deficiency cannot be diagnosed.

Let's take a few examples. Say a 58-year-old man on a vegan diet goes to his doctor with signs of nervous system disease. It comes out in the history that this person is a vegan so the doctor presumes that the disease is from dietary vitamin B12 deficiency and prescribes large doses of vitamin B12 supplements. But, without investigation of this person's ability to absorb vitamin B12, his disease cannot be said to come from dietary deficiency alone. He could have pernicious anemia—deficiency of the intrinsic factor needed for absorption.

Or consider the vegan who has routine blood analysis done and it is found that his vitamin B12 level is low compared to the standard American range. The doctor would probably warn this individual of the grave consequences of continuing on his diet, even though this person feels fine. This individual cannot be classified as vitamin B12-deficient, however, because he has no symptoms of the diseases associated with a vitamin B12 deficiency.

As a third example, let's consider the most complex case: a vegan with a vitamin B12 deficiency-associated illness, normal absorption as reflected by use of routine absorption testing (the Schilling test) and disappearance of symptoms after ingestion of vitamin B12 supplements of routine dosage. Wouldn't this be a clear case of dietary vitamin B12 deficiency? Not necessarily—it could be a case of poor absorption not revealed by routine testing. A case like this occurred where the fault in absorption was not detected until sophisticated methods were used.

Short of sophisticated testing available only in research centers, the only way this fault in absorption, and probably many other similar faults, would be discovered is by experimental oral administration of small amounts of vitamin B12, as opposed to the large amounts routinely used. For this reason, fulfillment of criterion No. 5 (positive response to consumption of small amounts of vitamin B12) is essential for a diagnosis of dietary B12 deficiency.

As simple and full of common sense as are these five criteria, we see many cases in the medical literature in which one or more of them have not been fulfilled. For example, Smith in 1962 investigated twelve vegans and found vitamin B12-associated illness in three of them.

He did not, however, check to see if they were able to absorb vitamin B12 efficiently; thus his diagnosis of dietary vitamin B12 deficiency is unconvincing. There are even cases presented as dietary vitamin B12 deficiency in which no accurate diet history is reported to show that no vitamin B12-containing foods have been eaten.

Verjaal, et al., in 1967, presented the case of a vegan with nervous system disease which the researcher attributed to the diet without checking absorption or the response to small amounts of oral vitamin B12. Connor, et al., in 1963, discussed two cases in which he also failed to investigate absorption.

In preparing this article, I have reviewed every article discussing cases of reported dietary vitamin B12 deficiency, and I can say that lack of fulfillment of all five criteria, as in the articles just described, is the rule, not the exception.

On the other hand, many studies have reported vegans with normal vitamin B12 status and complete health. Hardinge, et al., in 1954, studied 26 vegans and found them to be healthy. Ellis, et al., in 1970, studied 26 vegans and found the same.

Roberts, et al., in 1973, investigated 322 Indian vegans during pregnancy. All but one were perfectly healthy and this one was not studied to determine whether she could normally absorb vitamin B12. Sanders, et al., in 1978, studied 34 vegans and found no sickness.

The conclusion must be that the vast majority of the studies which have reported abnormal vitamin B12 status in vegans have not been thorough enough to prove the problem was from the diet only, and that, on the other hand, many studies have found normal vitamin B12 status in vegans. Though this is hard for a western nutritionist to accept, no Indian doctor would have the slightest problem with it.

Indians, for the most part, are not pure vegans, as they consume small amounts of dairy foods. These amounts, however, fall far below the amounts that would be needed to supply adequate amounts of vitamin B12 if western dogma is valid.

Yet, in India, vegetarians have lived for ages and have begotten and reared healthy children who, in turn, have never eaten fish, fowl or meat. There is no evidence to suggest that such a vegetarian population consuming adequate lactovegetarian food is any way different from the non-vegetarians.

As Dr. David Reuben points out, the news that an almost-vegan diet is dangerous "will come as a surprise to 500,000,000 Hindus, most of whom don't eat any meat or animal products at all from the moment they are born until the moment they die (with the exception of mother's milk for a while). The Hindu religion has been around for over 10,000 years, or about 98 centuries longer than modern American medicine.

But how do vegans get their vitamin B12? Since it is produced only by bacteria, and vegans don't eat the animals that had the bacteria growing in their second stomach (rumen), what is the source of this vitamin B12?

There are no definite answers to this question, but the fact that most vegans are healthy shows one of the following answers must be applicable: Absorption of the vitamin B12 routinely produced by bacteria living in the intestine (supposedly they live in a area where the vitamin cannot be absorbed, but an adaptation may occur in vegans); no loss of vitamin B12 from the body, thus no need for additional dietary vitamin B12; ingestion of vitamin B12 in water (from the well or the distiller) due to bacterial contamination; accidental ingestion of insects or bacteria containing vitamin B12; presence of vitamin B12 in root vegetables due to absorption of vitamin B12 from the soil where it was produced by bacteria; presence of vitamin B12 in soil on poorly washed root vegetables; presence of vitamin B12 in seaweed (all but green) and/or contamination of plant foods with vitamin B12 produced by bacteria.

It is true that vitamin B12 is produced only by bacteria, but these bacteria are almost everywhere, and for this reason vitamin B12 has been found in some samples of many vegetables.

A vegan diet, therefore, does not have "serious consequences" as threatened by *Nutrition Reviews*; it is quite the reverse, as contrariwise it has such "beneficial consequences" as vegans not having to fear any risk of ever suffering cardiovascular disorders or colon and breast cancer. The low fat intake of vegans minimizes the chance of these diseases. The threat of a vitamin B12 deficiency is more often than not hypothetical rather than actual.

It is important to emphasize that deficiency may be present only if a person has low blood vitamin B12 levels plus illness associated with vitamin B12 deficiency. Indications of a low vitamin B12 level by itself will not interfere with attaining a long and healthy life with full capacity for normal reproduction. The contrary has never been proven to be so, unless the deficiency is accompanied by illness as discussed above.

## **Article #5: Do We Need To Take Vitamins? By Alan M. Immerman, D.C.**

A few months ago I picked up a copy of a promotional magazine in a health food store. This magazine, *Better Nutrition*, contained an article entitled "The Care and Feeding of Vitamins," which addressed itself to the need for taking daily vitamin supplements. Since this is a subject about which I get many questions, I thought I would discuss this issue. The article on vitamins was in a question and answer form; I will give an alternative opinion in the same form.

### **I eat a good diet, why should I take vitamins or other supplements?**

ANSWER: The *Better Nutrition* article (to be referred to as BN) stated that "your idea of a 'good diet' may not include all the essential nutrients" and that with pollution, stress, chronic illness, drugs and food of low nutritional value (presumably from conventional farming methods), it is reasonable that "a number of distinguished nutrition experts" believe that we should take supplements.

MY ANSWER: It is no doubt true that many peoples' idea of a "good diet" is inadequate. The nutritional orthodoxy believes that enriched flour is entirely adequate even though many nutrients are removed by processing and only a few are replaced by enriching. But this does not mean that supplements should be taken, but rather that proper foods should be chosen! Also, there is no proof that pollution and stress increase vitamin needs. If drugs increase vitamin need, the obvious answer is to discontinue their use if at all possible. Drugs have many harmful side effects besides increasing vitamin needs.

Also, the mention of nutritional values of foods grown with today's conventional farming methods brings up an important point. Plants synthesize all the vitamins they need from carbon dioxide, water and sunlight. Therefore, foods grown conventionally will have the same amounts of vitamins as those grown organically.

Finally, in all respect for the "distinguished nutrition experts" who believe that supplements are needed, it would be far preferable to choose the proper foods; many equally distinguished experts support this position.

### **How much do I need of vitamins and minerals?**

ANSWER: (BN) Official recommended dietary allowances (RDAs) ... are for perfectly healthy 22-year-old men and women ... anyone not perfectly healthy and not 22 years of age may need more.

MY ANSWER: This statement in BN poorly reflects the intent of the National Research Council in establishing the RDAs. The RDAs are for the vast majority of people, not for a small group. In setting these figures, the National Research Council estimated the requirements of the nutrients and then established recommended intakes in excess of requirements so as to "exceed the requirements of most individuals." The RDAs have even been criticized as too high in some cases! In any case, it is quite easy on a properly chosen diet to far exceed the recommended intake of vitamins. There is no need for nutrients in pill form.

### **Isn't it possible to get too much of vitamins or minerals?**

ANSWER: (BN) Not if you take reasonable amounts ... there is no record of any damage

from large amounts of vitamin E. Vitamin C and the B vitamins, being water soluble, are excreted harmlessly if you happen to take more than you need.

MY ANSWER: False again. Although there probably is no direct harm from taking small amounts of vitamins, there is indirect harm. For one, many who take supplements tend to be less cautious with their diet because they feel protected by the pills. This is false security, as there are many substances needed by humans which are not yet in vitamin/mineral tablets. Some substances known at the present time include vanadium, nickel, tin and silicon; also, as any research biochemist will admit, there are probably many vitamin-like substances which will be discovered to be essential as the years go by, and they are not yet in supplements, even the supposedly "natural" supplements from food sources. So the threat of deficiency remains unless care is exercised in choice of foods.

Also, to state that there is no danger from large doses of vitamins E, C and the B complex is to display ignorance of present scientific knowledge. Megadoses of niacin (B3) may damage the liver, raise the blood sugar and uric-acid levels and cause other problems. Megadoses of vitamin C may cause: irritation (leading to diarrhea), kidney stones, problems with mineral metabolism (iron, copper, calcium and phosphorus), and possibly infertility and fetal death. Large doses of vitamin E may elevate the blood fats (high blood fat levels are associated with heart disease), interfere with vitamin A and iron metabolism, interfere with thyroid gland function and cause severe fatigue, perhaps due to muscle damage.

**I have heard that some vitamins are incompatible with others and will cancel out their good effects, so they should not be taken together.**

ANSWER: (BN) Basically, take your supplements and don't worry about it.

MY ANSWER: When one tries to provide proper nutrition by extracting nutrients from food and taking them in various proportions and quantities, there is indeed a risk of creating imbalances. The best way to supply vitamins to the body is to eat them as nature provided them: in foods.

**Should old people and children take vitamins?**

ANSWER: (BN) "To produce strong bones, teeth, muscles and perfectly functioning organs," children should take vitamins. "Old age is stress ... so taking supplements is even more important."

MY ANSWER: Both groups definitely need vitamins. But is it too old-fashioned to suggest that they get their vitamins from food at 1/1000 the cost and in a preferable form?

To conclude, then, a proper diet, consisting of mainly raw fruits and vegetables, will supply amounts of vitamins far in excess of the recommended daily allowances. Pollution and stress should be avoided, but their effects are not compensated for by taking supplements. Fruits and vegetables available in the supermarket have enough vitamins to support health in its highest state.

Also, there are many possible sources of harm from megadoses of vitamins, even the water soluble ones such as vitamin C and the B complex. Therefore, avoid these.

## **Article #6: Antivitamins And Vitamin Antagonists By Marti Fry**

### **Definition**

An antivitamin is simply "a substance that makes a vitamin ineffective." A vitamin antagonist is essentially the same thing as an antivitamin. It is a substance that lessens or negates the chemical action of a vitamin in the body.

Following are some examples of antivitamins, or vitamin antagonists.

### **Some Antagonists of a Few Specific Vitamins**

#### **Vitamin A Antagonists**

Blood-thinning medications and other drugs, including aspirin, phenobarbital, arsenicals and dicumarol (a drug used medically to retard bloodclotting), destroy vitamin A in the body.

Vitamin A is also depleted when nitrosamines are formed in the stomach from the union of nitrites with secondary amines and when the mucous membranes of our respiratory passages are exposed to air pollutants (carbon monoxide, ozone, sulphur dioxide, nitrogen dioxide, lead, hydrocarbons, etc.) In addition, mineral oil used as a laxative absorbs vitamin A and carotene (a naturally-occurring substance in foods which is used by the body to make vitamin A), thereby destroying it.

#### **Vitamin K Antagonists**

The amount of vitamin K needed by humans is very small, and a deficiency is highly unlikely because this vitamin is in a wide variety of commonly eaten plant foods and is synthesized by bacteria in the intestinal tract. However, antibiotic therapy (the taking of any antibiotics such as penicillin, streptomycin, tetracyclin, Chloromycin, Terramycin, etc.) suppresses bacterial growth and, consequently, the synthesis of vitamin K.

Other vitamin K antagonists include the drugs dicumarol and hydrocoumarol, which are used by medical people to relieve thrombosis (abnormal formation of blood clots in the blood vessels). Because the chemical structure of these antivitamins is similar to that of vitamin K, they act as anticoagulants by interfering with the synthesis of pro-thrombin and the other natural clotting factors.

#### **Vitamin C Antagonists**

It is well known that cigarette smokers have lower vitamin C levels than nonsmokers. A Canadian physician, Dr. W. J. McCormick, tested the blood levels of vitamin C in nearly 6,000 smokers. All had below normal readings. The March 9, 1963, issue of *Lancet*, similar findings are revealed by a group of three researchers. Frederick Klenner, M.D., has been quoted for many years as saying that a single cigarette can deplete as much as thirty-five milligrams of vitamin C from the body. (Calcium and phosphorus, both minerals, are also depleted in cigarette smokers.)

Because vitamin C reacts with any alien substance in the bloodstream, all drugs and pollutants can be considered to be vitamin C antagonists. Some of the foremost vitamin C antagonists include ammonium chloride, sribesterol, thiouracil, atropine, barbituates and antihistamines. Alcoholic beverages are also vitamin C antagonists, as are all stresses (surgery, emotional outbursts and upsets, acute pressures, extremes of heat and cold and all drugs).

## **B Vitamin Antagonists**

Cortisone is an antagonist of vitamin B6 (pyridoxine). Since the body needs B vitamins to metabolize sugars, B vitamins are depleted when refined sugar or flour is consumed because refined sugar and flour, are devoid of B vitamins that existed in the beet, cane or grain before refining. Specifically, the body's supply of vitamin B1, vitamin B2, biotin, choline, niacin and the mineral magnesium are depleted when refined sugar and flour are consumed.

Alcoholic beverages are antagonists of thiamin and the other B-complex vitamins, and coffee is another popular beverage that is a B vitamin antagonist—because it contains caffeine and other noxious substances, one of which is chlorogenic acid. Inositol deficits may occur among coffee drinkers, too, as well as deficits of biotin and thiamin.

Raw fish and raw shellfish, including oysters, are also B-complex antagonists. This is one of many reasons not to eat the Japanese dish, sashime (raw fish) or any other raw seafoods.

Birth control pills are antivitamins, especially of the B vitamins riboflavin, vitamin B6, vitamin B12 and folic acid. Two Indian physicians discovered that women taking oral contraceptives had much lower levels of riboflavin than a control group who used no oral contraceptives. These contraceptives are especially damaging to vitamin B12 and folic acid. (The estrogen in oral contraceptives is also an antagonist of vitamin E.)

The most potent folacin (folic acid) antagonist is aminopterin. This substance has been used in the medical treatment of leukemia, a disease in which there is a marked increase in the production of leucocytes (white blood cells). Though aminopterin has, in some cases, resulted in a temporary relief (remission) of leukemia, it does not "cure" this disease. This is because there are no "cures;" there is only body healing—and antivitamins interfere with body healing but never help it.

## **A Mineral Antagonist**

Most, if not all, vitamin antagonists (all drugs and other stresses) are also mineral antagonists. A specific mineral antagonist is oxalic acid, which is present in too-large amounts in spinach, rhubarb, beets and beet greens, Swiss chard and chocolate. Oxalic acid is a calcium antagonist. Calcium binds the oxalic acid in the body in order to render this toxic acid harmless. In doing so, the calcium is unavailable for its normal uses in the body.

## **Some Specific Antivitamins**

### **Stresses Are Antivitamins**

All kinds of stresses are vitamin antagonists. Drugs are serious stress producers in the body because the body must exercise great effort in expelling them as quickly as possible, lest they damage tissues and cells and interfere too much with normal functioning. In addition, surgery, accidents, overly exhausting work or exercise, exposure to extreme's of heat or cold, and emotions such as fear, hatred, anger, worry and grief all produce great stress on the body. The B vitamins (thiamin, niacin, folic acid, pantothenic acid and vitamin B12) and vitamin C, as well as proteins and minerals, are all depleted and/or unassimilable as a result of stresses on the body. But don't think for a minute that the other vitamins can be properly or fully utilized when the body is under stress—they can't!

### **Aspirin Is An Antivitamin**

Aspirin interferes with digestive processes and can result in stomach bleeding. It interferes with blood-clotting and lessens the ability of cells to absorb glucose for heat and energy. It depletes most, if not all, nutrients and results in especially high losses of vitamin C and the B vitamins plus the minerals calcium

and potassium.

### **Antibiotics Are Antivitamins**

Besides being a vitamin K antagonist, the antibiotic penicillin is also an antivitamin of vitamin B6. The antibiotic streptomycin is a folic acid antagonist and the antibiotic streptomycin inactivates manganese, a mineral which is needed for the functioning of many enzyme systems.

### **Diuretics Are Antivitamins**

Diuretics are drugs prescribed medically to promote weight reduction or to relieve pressure of retained fluids. Even so-called "natural" diuretics, including herbal types, are harmful, for all diuretics result in great losses of B vitamins, vitamin C, other vitamins, and the minerals potassium and magnesium. Diuretics would never be prescribed to anyone on a natural diet containing no rock salt or sea salt, as these salts are poisonous and cause the body to retain fluids to hold the salt in suspension so it doesn't harm cells and tissues.

### **Laxatives Are Antivitamins**

All laxatives, including the herbal types, are vitamin antagonists. Mineral oil is perhaps the most devastating laxative. It absorbs vitamin A and carotene, as well as the other fat-soluble vitamins (vitamin D, vitamin E and vitamin K). It also absorbs calcium and phosphorus, carrying them out of the body. (Hospitals today still use mineral oil as a laxative for their patients, one of thousands of reasons why hospitals are antivital places.) Laxatives will never be used by people on a natural all-raw diet of fruits, vegetables, sprouts, nuts and seeds.

### **Soil, Air and Water Pollutants Are Antivitamins**

Most people regard soil, air and water pollutants as "unavoidable" antivitamins that necessitate the use of vitamin supplementation. However, not only are the vitamins from fresh whole foods more than adequate to meet our needs when our diet is all or mainly raw foods of our biological adaptation (as described in the Life Science health system), but they will also meet our needs adequately despite our polluted air and water.

Besides this argument against food supplementation, we can control completely the water we drink by drinking only pure distilled water. To some extent we can also control the quality of the air we breathe by keeping the pollutants out of our homes and/or by locating away from the pollution of cities and other highly-populated or polluted centers. Foods not grown organically are "fed" (via their soil) synthetic chemical fertilizers which contain excessive nitrogen. This excessive nitrogen increases the crop yield, but the ultimate health costs are high—too high. Nitrates and nitrites are formed, and these pollutants are potent antivitamins.

Dr. E. E. Hatfield revealed, from his results in an animal research project, that nitrates and nitrites systematically and subtly reduce the vitamin A stored in the liver. They also prevent formation of this vitamin in our body from its precursor, carotene, which is present in much produce. Also, according to Dr. W. M. Beeson of Purdue University's Department of Animal Sciences, fruits picked green contain far higher amounts of nitrates and far less carotene than tree and vine-ripened fruits.

Nitrites join with amines in the stomach, forming nitrosamines. Nitrosamines are highly carcinogenic, though not necessarily more so than other pollutants and drugs. As often and as much as possible, purchase organically-grown produce and/or produce that has been fully ripened on the tree or vine.

Keep in mind, too, that buying organically-grown foods and then cooking them, seasoning them, or taking any kind of drugs or medications whatsoever makes little sense. You are far better off not to

concern yourself with whether or not your food is or isn't organically grown and just discontinue use of any and all drugs and medications. The ideal, however, is to both discontinue drugs and to purchase organically-grown foods when possible.

Nitrites, chlorine, flourides, inorganic minerals and many other harmful substances found in city, spring, well and other nondistilled waters are all antivitamin. Therefore, only distilled water should be drunk.

Antivitamins found in polluted air, especially city air, are carbon monoxide, hydrocarbons, lead, ozone, sulphur dioxide and nitrogen dioxide. Vitamin A and vitamin C are both depleted when the body is exposed to air containing these pollutants, as is vitamin E. Arsenic dust, found on commercially-grown produce, is an antagonist of the B vitamin PABA (para-aminobenzoic acid). This vitamin is important for the growth of valuable bacteria in the intestines, for the metabolism of proteins, for manufacture of red blood cells and for healthy skin and hair.

## Conclusion

This has been only a partial listing of a few specific vitamin antagonists or antivitamin. In reality, any substance that is not food of our biological adaptation and any living practice that is not in accord with our physiological needs is a vitamin antagonist—in fact, a nutrient antagonist. All substances and practices not normal (physiologically, not in the commonly-used meaning of what is widely practiced) to humans interferes with normal functioning, including the normal use of vitamins in the body.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #7: What To Do About Vitamin Antagonists By Marti Fry

## Article #7: What To Do About Vitamin Antagonists By Marti Fry

If you've read any popular health books or magazines, you've no doubt heard about vitamin antagonists, or anti-vitamins. They are portrayed as "thieves out for the highest stakes: your health and well-being." They are described as criminals. However, while these descriptions may make for colorful writing, they do not point to the real culprits. Even worse, they point their readers to harmful and ineffective solutions to the problem.

Drugs, medicines, pollutants, stresses, refined sugar and flour, coffee, alcohol, the Pill, etc. are inert, lifeless substances, and they are not anxiously waiting to get into human bodies where they can ravage and plunder and make off with booty. People are the real culprits, the thieves. From the consumer or user to the manufacturer, inventor and promoter, people are the living beings who are responsible for depleting their own vitamin supplies and rendering vitamins consumed nonusable. Humans are responsible for the living practices that so enervate their bodies that assimilation of nutrients is impaired. We are responsible for informing ourselves (and others) of a healthful lifestyle.

Popular health magazines make statements such as the following from *Bestways* (September 1981): "Drugs are antagonists in many ways. They destroy nutrients, cause them to be used up quickly, keep them from being absorbed, rush them through the system before they can do the most good, and sometimes replace them chemically."

What they're saying is that drugs interfere with normal body functioning. Drugs are vitamin antagonists, however, only if humans consume them. We humans do not have to consume any drugs. Therefore, we need not deplete our vitamin stores, etc. We need only avoid drugs and eat wholesome foods in appropriate amounts. Pollutants that are unavoidable (such as soil and air pollutants) cannot deplete our vitamin stores and intake to the extent that we need concern ourselves about deficiencies or consider

using vitamin supplements.

The best way (and the only healthy way) to deal with the problem of vitamin antagonists is to stay away from the physicians, hospitals, pharmacies, etc. that prescribe and sell drugs and medications. We should also do the best we can to live in a healthful environment and lead a stress-free lifestyle. The idea that we can counteract the harmful effects of drugs and other stresses with the use of vitamin and/or mineral supplements is entirely erroneous. A proper diet and lifestyle will simultaneously supply the nutrients we need and include no vitamin antagonists or anti-vitamins. Health results from healthful living—that's a fact to keep in mind at all times!

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #8: Factors That Lower Vitamin Needs By T. C. Fry

### **Article #8: Factors That Lower Vitamin Needs By T. C. Fry**

Healthy people require less of all nutrients because their bodies make more efficient use of them. Not only that, but healthy people eat wholesome foods that furnish more nutrients. Thus, their needs are lower and their supplies are simultaneously higher than that of unhealthy people.

Certain societies of the world, notably some West Indian and Carib tribes of the world, have been thriving on 15 to 20 grams of daily protein intake, far less than is considered necessary. These people live on foods such as cassava, manioc and other starchy roots that contain only .2 to .3 percent protein. Just as they thrive on an "abnormally" low protein intake, they also thrive on a vitamin intake that would quickly result in deficiencies in our stressful and self-poisoned people.

For the reasons that other societies can thrive on diets that would make ours deficient, there are those within our society who so live as to parallel the healthful groups in other lands. Thus, a raw food fruitarian within our society that has a highly efficient body requires but a fraction of the vitamins as his counterpart who eats meats; dairy and poultry products; cooked foods; condiments and seasonings; refined, processed and preserved foods, and who may have one or several drug habits such as tobacco, alcohol, coffee, medications, etc.

The seeming unfairness of this situation is that, though raw food fruitarians eat less than half as much as their perverted cousins, their intake of usable vitamins, minerals and other nutrients are usually much greater though their needs are much lower.

The healthier our lifestyles, the less vitamins we need in the face of greater supply, whereas the less wholesome our lifestyles, the greater our needs in the face of lowered supply and lowered ability to utilize.

### **Exercise and Vitamin Utilization**

Vigorous exercise activity on a regular basis slightly increases our need for vitamins on the one hand but, on the other, so fine-tunes our system that they vastly increase their efficiency in uptake, assimilation and usage. With all other life factors properly observed, including a proper diet of mostly fruits with some vegetables, nuts and seeds, body toxicity is very low. All other needs are correspondingly lower due to the higher efficiency of the organism.

### **Emotional Poise Necessary to Optimum Vitamin Usage**

Being emotionally balanced is normal. Abnormal emotional conditions vitiate and drain our resources

and heighten our need for vitamins while at the same time impairing our ability to utilize them. Thus can be seen the enormous benefit of establishing self-mastery and a becalming philosophical outlook.

## **Raw Foods and Vitamin Usage**

A proper diet of mostly ripe raw fruits and some raw vegetables with raw nuts and seeds not only furnishes us with problem-free eating, but it also heightens body efficiency, thus lowering need. On the other hand, the nutrient values obtained from this proper diet are greater by far than conventional diets, even in the face of intake amounting to less than half that of conventional feeders.

## **Correct Foods and Feeding Practices**

Vitamin utilization is more efficient if intake is of those foods to which we are biologically adapted. Our digestive expenditures are lowered and body energy needs are likewise lowered. More nerve and chemical energy are available for the regular pursuits of life. Less sleep is required to restore "our fund of nerve energy in view of decreased need and increased efficiency of generation when faculties are operating better.

Vitamin intake is greater on a proper diet, while vitamin need decreases on several accounts. The big bonus is increased body efficiency that makes better use of nutrients.

[Home](#) > [Lesson 9 - Vitamins: The Metabolic Wizards Of Life Processes](#) > Article #9: Factors That Interfere With Vitamin Utilization And The Applicable Principles By T.C. Fry

## **Article #9: Factors That Interfere With Vitamin Utilization And The Applicable Principles By T.C. Fry**

You can read much in conventional health magazines about smokers requiring more vitamin C, about alcoholics requiring more B-Complex vitamins and so on. Peddlers of vitamins highlight greater need for vitamins by those on drugs, both habitual and medical, in order to induce drug users to purchase vitamin supplements. However, vitamin utilization is the least of the ill effects of drug habits, whether they be alcohol, tobacco, coffee, condiments and seasonings, medicinal, recreational or internally created drugs from the toxicity of retained metabolic wastes.

## **Factors That Interfere With Usage Also Destroy Health**

There would be no argument against drugs if the destruction of vitamins within the body were their only evil because our natural foods would more than compensate for the loss. But vitamin depletion is only one of the minor effects of drugs. They are far more destructive to the organism itself!

Drugs are a three-edged sword! For practical purposes we must classify sugar, white flour, processed and refined foods, cooked foods, meats and animal products, coffee, condiments and seasonings, tobacco, alcohol, marijuana, herbs, inorganic minerals, prescribed and over-the-counter drugs, synthetic foods and supplements, etc. as drugs.

The first bad effect of so-called "foods" that have drug effects is less vitamin intake, even if they are "enriched." The second effect is that the body requires extra vitamins in order to deal with the toxicity. Thirdly, and even worse, these substances impair our ability to utilize vitamins.

Some by-products of drug use are loss of sex potency; interference with vitamin utilization; loss of vital

senses such as taste, smell, eyesight, hearing and touch; increasing ugliness of both appearance and disposition; and loss of mental faculties.

### **Stress and Vitamin Depletion**

Stress might be likened, in its effects upon the body and its fund of nerve energy, as crossing the wires to a battery. The battery shorts out and is quickly drained. Stress thusly requires more body resources on one hand, while impairing body functions on the other hand. When the body is bereft of a normal fund of nerve energy and other faculties, there is a great increase in uneliminated body wastes. Toxemia arises and problems proliferate.

Emotional upsets are perhaps the most stressful experiences of all. Cultivating self-mastery and a philosophical attitude lowers our liability in the face of stress.

### **Toxemia and Decreased Vitamin Usage**

Toxins within the body have drug effects. They interfere with vitamin uptake and usage while simultaneously increasing need for vitamins in order to cope. Further, they impair the faculties involved with vitamin assimilation and usage.

### **Principles That Apply**

A theme that runs through the observations of vitamin antagonists can be expressed as principles that are highly instructive:

1. The less wholesome our food and practices, the fewer usable vitamins we will get.
2. The less wholesome our food and practices, the more vitamins we'll require.
3. The less wholesome our food and practices, the less able we are to make use of vitamins.

Thus, again, we can see demonstrated that bad practices proliferate bad results.

## Lesson 10 - The Role Of Minerals In Human Nutrition

- [1. Introduction](#)
- [2. The Minerals In The Body](#)
- [3. Organic And Inorganic Minerals](#)
- [4. Mineral Deficiencies](#)
- [5. Obtaining The Minerals We Need](#)
- [6. Questions & Answers](#)
- [Article #1: The Minerals Of Life By Dr. Herbert M. Shelton](#)

### 1. Introduction

#### 1.1 The Study of Minerals Is a Fragmentary View

*"We have become so accustomed to the practice of dividing foodstuffs into their various nutritive factors—proteins, carbohydrates, fats, minerals, vitamins, etc.— that we often miss the importance of the whole food." —Dr. Herbert M. Shelton*

As we begin our lesson on minerals, it is important to keep Dr. Shelton's observation in mind. Phrases like "iron deficiency" and "calcium-rich foods" are all too common in the study of minerals, and they represent a fragmented view of our diet and nutritional well-being.

A mineral deficiency rarely exists by itself in a vacuum, nor can a single food be recommended exclusively because of a particular mineral content. The study of minerals by themselves necessarily leads to a fragmented view of nutrition, and the student should not be quick to attribute conditions in the body solely to a mineral deficiency, nor should he choose certain foods entirely because of their mineral content.

Instead, it is more important to realize that minerals have an interdependence between many other various elements of food and with the complex actions of the organism itself. Minerals are not isolated food factors, but parts of the nutritional whole.

#### 1.2 What Are Minerals?

The broadest definition of a mineral is that it is something that is "neither vegetable nor animal." It has also been defined as a "solid homogeneous crystalline chemical element or compound" such as iron, copper, carbon, aluminium and so forth. For this lesson, we define a mineral as follows: A naturally occurring inorganic element in the soil which is transformed into an organic compound for use and assimilation by the human body.

Notice that there are two parts to the definition: 1) We are concerned only with those minerals that are directly usable by the human organism and that are vital to the healthy functioning of the body. 2) We make a very important distinction between the inorganic form of the mineral as it occurs in the soil and

the organic form of the mineral as it is used by the human body. This difference between organic and inorganic mineral forms is the crucial point in understanding mineral nutrition, and is discussed at length later in this lesson.

[Home](#) > [Lesson 10 - The Role Of Minerals In Human Nutrition](#) > 2. The Minerals In The Body

## 2. The Minerals In The Body

### 2.1 A List of Major and Trace Minerals

We still do not know all the minerals that are present and utilized within the body. We do, however, recognize twenty-eight minerals that have definite uses in the body, and twelve other minerals whose uses are not fully understood.

The following thirteen minerals are found in appreciable quantities within the body and are listed in the order of their total percentages of the body's composition:

<b>Mineral</b>	<b>Percentage of total body weight</b>
Calcium	2.00%
Phosphorus	1.00%
Potassium	0.40%
Sulfur	0.25%
Chlorine	0.25%
Sodium	0.25%
Fluorine	0.20%
Magnesium	0.05%
Iron	0.008%
Manganese	0.003%
Silicon	0.002%

Copper	0.00015%
Iodine	0.00004%

The other following minerals are sometimes referred to as "trace minerals" because of the minute amounts present in the body:

<b>Trace Minerals</b>		
Zinc	Titanium	Argon
Cobalt	Tin	Beryllium
Molybdenum	Silver	Boron
Aluminium	Rubidium	Cerium
Chromium	Nickel	Helium
Lead	Mercury	Lanthanum
Neodymium	Neon	Scandium
Selenium	Strontium	Vanadium

## 2.2 Traditional Approach to Mineral Nutrition

Of the twenty-eight recognized minerals, recommended dietary allowances have been determined for only six: Calcium, phosphorous, iodine, iron, zinc and magnesium. The rest of the minerals are also important to the functioning of the body, but the exact body needs are too indeterminate to list.

We will discuss all the major minerals and some of the trace minerals as to their uses in the body, the recommended daily allowance (if known), the deficiencies caused by their absence and the Food Sources of these minerals.

This is the traditional approach to studying minerals and is a basis for understanding some of the other facts in this lesson. However, this approach does have some shortcomings, and we should note them.

*First, their use in the body:* No mineral is used in isolation within the body. All minerals interact with other minerals, vitamins, enzymes and so on. It is overly simplistic to say that "iron builds rich blood" or "calcium makes strong bones." For instance, copper must also be present for the iron to be used in blood-building. Likewise, a certain amount of phosphorus must also be present along with the calcium to build bones. However, it is also a fact that certain minerals are utilized by the body as nutrients for specific organs more so than other organs. Also, the body uses certain minerals in performing certain body functions. Nonetheless, in studying an individual mineral, keep in mind that it is only a part of a whole complex process.

*Next, the effect of a mineral deficiency:* A mineral deficiency rarely exists in a vacuum and is seldom the only cause for a condition exhibited by the body. Often, a mineral deficiency occurs even when there is

an abundance of the needed mineral in the diet, but the body cannot digest nor assimilate the mineral. Mineral deficiencies are discussed at length later in this lesson.

*The recommended allowance of a mineral:* This can be almost meaningless. Mineral requirements depend upon individual constitution, climate, type of work, personality, age, sex, body weight, level of health and hundreds of other factors. There can never be one recommended allowance of a mineral that applies to everyone. All given Recommended Allowances may vary considerably and they should not be considered as "law."

*Finally, Food Sources of a mineral:* Minerals are abundantly supplied in all foods natural to man's diet (fruit, vegetables, seeds, nuts and sprouts). There are certain mineral-rich foods such as calf liver, clams, milk, etc. that are not suitable for the human organism, and any mineral content they may have is negated by the harmful effects they have on the body. Only suitable foods for man are listed in this lesson as sources of a particular mineral. Note also that the mineral contents of foods are calculated upon a fixed size portion (e.g., 100 grams, 4 ounces, etc.). This type of calculation unfairly favors the concentrated foods such as dried fruits, seaweed, nuts, seeds, etc. When choosing such foods keep in mind that ounce for ounce, a person normally eats a larger amount of the less-concentrated foods.

## 2.3 The Major Minerals in the Body

### 2.3.1 Calcium

*Use in the Body:* Calcium is the most abundant mineral in the body. Almost 99% of the body's calcium is in the skeletal structure and the teeth. Calcium is essential for the clotting of blood, the action of certain enzymes and the control of the passage of fluids through the cell walls. It is also essential to normal heart action and muscle contraction.

*Effect of deficiency:* Calcium deficiency results in retarded bone and tooth development and a fragile skeletal structure. Nervous irritability and muscle sensitivity are, also signs of calcium deficiency. Since calcium is needed for bone and tooth growth, children especially need an adequate calcium intake.

*Recommended Allowances:* The National Academy of Sciences has made the following recommendations for daily calcium intake:

Men and Women	800 milligrams
Children	800 milligrams
Teenagers	1200 milligrams
Infants	500 milligrams
Pregnant and Nursing Mothers	1200 milligrams

*Food Sources:* The following foods are high in calcium content:

<i>Sesame seeds</i>	<i>Oranges</i>
<i>Green vegetable leaves</i>	<i>Strawberries</i>

<i>Almonds</i>	<i>Papayas</i>
<i>Figs</i>	<i>Most nuts</i>
<i>Sunflower seeds</i>	<i>Most seeds</i>
<i>Broccoli</i>	<i>Most green vegetables</i>
<i>Apricots</i>	<i>Most fruits</i>
<i>Dates</i>	

### 2.3.2 Phosphorus

*Use in the Body:* Phosphorus occurs in the protoplasm and nucleus of every cell. It is used in more functions than any other mineral in the body. Phosphorus is necessary to metabolize fats, carbohydrates and proteins. It is used with calcium in the building of bones and teeth. The building of nerve tissue and brain cells requires phosphorus. Like calcium, the largest amount of phosphorus is found in the bones.

*Effect of deficiency:* A deficiency of phosphorus affects the skeletal structure similarly to a calcium deficiency. A lack of this mineral may also result in mental fatigue and a feeling of depression resulting from exhausted nerve energy.

*Recommended Allowances:* The following are the official Recommended Allowances for daily phosphorus intake (revised 1974):

Infants	400 milligrams
Children	800 milligrams
Teenagers	1200 milligrams
Adults	800 milligrams
Pregnant and Nursing Mothers	1200 milligrams

*Food Sources:* All seeds and nuts are excellent sources of phosphorus. In addition, the following foods contain a high percentage of phosphorus:

<i>Coconuts</i>	<i>Apples</i>
<i>Peaches</i>	<i>Pears</i>
<i>Apricots</i>	<i>Avocados</i>

<i>Broccoli</i>	<i>Green vegetable leaves</i>
<i>Figs</i>	<i>Carrots</i>
<i>Dates</i>	<i>Mung bean sprouts</i>
<i>Cabbage</i>	<i>Beets</i>
<i>Squash</i>	<i>Persimmons</i>

### 2.3.3 Potassium

*Use in the Body:* Potassium is a factor in tissue elasticity, healing injuries in the body, liver functioning, normal bowel activity and regular heart rhythm. It is used in regulation of nerve and muscle action and is needed for intercellular fluid balance.

*Effect of deficiency:* A lack of potassium often results in liver ailments, pimping of the skin and the slow healing of sores. Weak muscular control and incomplete digestion also accompany a potassium deficiency.

*Recommended Allowances:* No official recommendations exist for potassium, but unofficial sources estimate the body's daily potassium needs at about 3000 milligrams for adults and 1500 milligrams for children.

*Food Sources:* Potassium is abundantly supplied in a proper diet, and non-meat eaters should never have a problem in obtaining sufficient potassium. The following foods are especially rich in potassium:

<i>Apricots</i>	<i>Green vegetable leaves</i>
<i>Sunflower seeds</i>	<i>Tomatoes</i>
<i>Peaches</i>	<i>Bananas</i>
<i>Almonds</i>	<i>Carrots</i>
<i>Raisins</i>	<i>Beets</i>
<i>Dates</i>	<i>Nectarines</i>
<i>Figs</i>	<i>Cabbage</i>
<i>Avocados</i>	<i>Lettuce</i>
<i>Pecans</i>	<i>Almost all fresh fruits</i>
<i>Papayas</i>	<i>Almost all fresh vegetables</i>

Melons	
--------	--

### 2.3.4 Sulfur

*Use in the Body:* Sulfur is found in the hair, nails, cartilage and blood. It is essential in digestion and elimination, bile secretion, and the purification and toning of the system.

*Effect of deficiency:* The lack of sulfur may result in inhibition of functioning. It also results in restricted growth, eczema and poor growth of the nails and hair.

*Recommended Allowances:* No official recommendations are made for sulfur. Almost all diets contain adequate amounts of this mineral.

*Food Sources:* The following foods are rich in sulfur:

All cabbage family members	Cucumbers
Lettuce	Pineapples
Avocadoes	Peaches
Tomatoes	Watermelon
Carrots	Strawberries
Apples	Oranges

### 2.3.5 Chlorine

*Use in the Body:* Chlorine is required for digestion and elimination. It is needed for normal heart activity and osmotic pressure in the blood and tissues.

*Effect of deficiency:* A lack of chlorine results in disturbed digestion and in waste retention. Also, a chlorine deficiency may manifest in pyorrhea.

*Recommended Allowances:* Unofficial estimates place daily chlorine needs at about 500 milligrams.

*Food Sources:* Sodium chloride (salt) and chlorinated drinking water are not sources of organic chlorine and are poisonous to the body. The following foods are good sources of organic chlorine:

Tomatoes	Coconuts
Celery	Bananas
Kale	Pineapples
Turnips	Raisins

<i>Lettuce</i>	<i>Mangoes</i>
<i>Avocados</i>	<i>Strawberries</i>
<i>Watermelon</i>	

### 2.3.6 Sodium

*Use in the Body:* Sodium is utilized in the formation of digestive juices and in the elimination of carbon dioxide. It is needed in the osmotic pressure, maintenance of water balance and proper nerve function. Sodium is also necessary for the utilization of iron.

*Effect of deficiency:* A sodium deficiency can result in indigestion, arthritis, rheumatism and in gallbladder and kidney stones. Muscle cramps and nausea also accompany a lack of sodium.

*Recommended Allowances:* Sodium is usually plentiful in most diets. No official recommendations are made, but unofficial estimates of the body's daily sodium needs are about 500 milligrams.

*Food Sources:* Sodium chloride (table salt) is not a source of organic sodium and is poisonous to the body. The following foods are good sources of organic sodium:

<i>Strawberries</i>	<i>Sunflower seeds</i>
<i>Celery</i>	<i>Broccoli</i>
<i>Carrots</i>	<i>Melons</i>
<i>Raisins</i>	<i>Cabbage</i>
<i>Kale</i>	<i>Lettuce</i>
<i>Beets</i>	<i>Peaches</i>
<i>Sesame seeds</i>	

### 2.3.7 Flourine

*Use in the Body:* Flourine is found in the bones, teeth, blood, skin, nails and hair. It is essential to the body's healing processes.

*Effect of deficiency:* A lack of flourine in the diet can result in tooth decay, weakened eyesight and spinal curvature.

*Recommended Allowances:* No recommended, allowances exist for flourine.

*Food Sources:* Flouridated water is not a source of organic flourine; it is injurious to the health. The following foods contain high amounts of organic flourine:

<i>Almonds</i>	<i>Carrots</i>
----------------	----------------

Vegetable greens	Exists in some quantities in all plants
------------------	---

### 2.3.8 Magnesium

*Use in the Body:* Magnesium is found in the blood albumen, bones and teeth. It is employed in carbohydrate metabolism and elimination. Magnesium is necessary for strengthening the nerves and muscles and in conditioning the liver and glands.

*Effect of deficiency:* A lack of magnesium contributes to nervous conditions and irritability. A poor complexion, heartbeat acceleration, digestive disorders and soft bones may also indicate a magnesium deficiency.

*Recommended Allowances:* The following recommendations are made by the National Academy of Sciences:

Infants	60-70 milligrams
Children (1-4 years)	150 milligrams
Children (4-6 years)	200 milligrams
Children (7-10 years)	250 milligrams
Males (11-14 years)	350 milligrams
Males (15-18 years)	400 milligrams
Males (19 older)	350 milligrams
All females	300 milligrams
Pregnant and Nursing Mothers	450 milligrams

*Food Sources:* The following are good sources of magnesium:

Almonds	Cherries
Dates	Green vegetable leaves
Bananas	Beets
Walnuts	Avocados
Raisins	Pears

Raspberries	Broccoli
Mangoes	Canteloupe

### 2.3.9 Iron

*Use in the Body:* Iron is found primarily in the hemoglobin of the body and is closely connected with the quality of blood. About two-thirds of all the body's iron is in the bloodstream, with the remainder distributed in the marrow of the bone, the liver and the spleen. Iron is also used in the building of bones, brain and muscle and in the carrying of oxygen throughout the body.

*Effect of deficiency:* The most dramatic sign of an iron deficiency is anemia and paleness of complexion. A lack of sufficient iron also results in limited growth and a low vitality level.

*Recommended Allowances:* The Official recommended daily allowances for iron (revised 1974) are:

Children (1-3 years)	15 milligrams
Children (4-10 years)	10 milligrams
Males (11-18)	18 milligrams
Males, Adult	10 milligrams
Females (11-50 years)	18 milligrams
Females (51 and over)	10 milligrams

*Food Sources:* The following are good sources of organic iron:

<i>Sesame seeds</i>	<i>Figs</i>
<i>Peaches</i>	<i>Green vegetable leaves</i>
<i>Apricots</i>	<i>Lettuce</i>
<i>Raisins</i>	<i>Mung bean sprouts</i>
<i>Walnuts</i>	<i>Broccoli</i>
<i>Almonds</i>	<i>Berries</i>
<i>Dates</i>	<i>Cherries</i>

### 2.3.10 Manganese

*Use in the Body:* Manganese is chiefly found in the liver, kidneys, pancreas, lungs, prostate gland, adrenals, brain and bones. It is used in the metabolism of carbohydrates, and in strengthening tissue and bone. Manganese, like iodine, is used in thyroxine formation in the thyroid. It also seems to be connected with regulation of the blood sugar level.

*Effect of deficiency:* It should be noted that the National Academy of Sciences has officially stated that no one has observed a manganese deficiency in humans. In laboratory experiments with animals, an induced manganese deficiency produced restricted growth, glandular disorders and defective reproductive functions.

*Recommended Allowances:* No official recommendations are made for manganese. Unofficial sources place the body's daily manganese needs at about 15-25 milligrams for adults and 2-15 milligrams for children.

*Food Sources:* Manganese is found in significant quantities in the following foods:

Bananas	Leafy vegetables
Beets	Carrots
Celery	Squash
Cucumbers	Nuts

### 2.3.11 Silicon

*Use in the Body:* Silicon is found in the blood, muscles, skin, nerves, nails, hair, connective tissue and teeth. The pancreas is especially rich in silicon. Silicon is also noted for its use in antiseptic action.

*Effect of deficiency:* Insufficient silicon in the body may result in baldness or the graying of hair. Skin irritations and rashes may develop easily. Hearing and vision may also be affected, and the teeth may decay.

*Recommended Allowances:* No official daily allowance has been determined for silicon.

*Food Sources:* Silicon is often concentrated in the skins and outer layers of vegetables and fruits. The following are good sources of silicon:

<i>Lettuce</i>	<i>Beets</i>
<i>Strawberries</i>	<i>Carrots</i>
<i>Cucumbers</i>	<i>Tomatoes</i>
<i>Sunflower seeds</i>	<i>Cabbage</i>
<i>Celery</i>	<i>Watermelon</i>
<i>Cherries</i>	<i>Apples</i>

<i>Apricots</i>	<i>Bananas</i>
<i>Figs</i>	<i>Grapes</i>
<i>Pears</i>	

### 2.3.12 Copper

*Use in the Body:* Copper is found in the liver, gallbladder, lungs and heart. It is essential primarily for the absorption and metabolism of iron.

*Effect of deficiency:* A deficiency in copper results in the same effects as an iron deficiency, such as retarded hemoglobin production, general debility, limited growth, etc.

*Recommended Allowances:* No official recommendations are made for copper allowances. Some sources have estimated about 2 milligrams per day. Very few cases of copper depletion have been observed in humans.

*Food Sources:* All of the following foods contain a significant amount of copper:

Nuts	Sunflower seeds
Raisins	Sesame seeds
Leafy vegetables	

### 2.3.13 Iodine

*Use in the Body:* Iodine is found mainly in the thyroid gland. It is essential for the formation of an organic iodine compound called thyroxine which regulates some of the metabolic functions. Iodine is required in the oxidation of fats and proteins and for circulatory functioning.

*Effect of deficiency:* An iodine deficiency is partially responsible for goiter (the enlargement of the thyroid gland) and cretinism (a subnormal metabolism). A lack of iodine also leads to sensitivity to toxic accumulations, low physical and mental activity and a susceptibility to nervous disorders.

*Recommended Allowances:* Daily iodine needs are very small. The following are the Daily Dietary Allowances (revised 1974):

Infants (0-5months)	.035 milligrams
Infants (5-12 months)	.045 milligrams
Children (1-3 years)	.060 milligrams
Children (4-6 years)	.080 milligrams
Children (7-10 years)	.110 milligrams

Males (11-14 years)	.130 milligrams
Males (15-18 years)	.150 milligrams
Males (19-22 years)	.140 milligrams
Males (23-50 years)	.130 milligrams
Males (51 over)	.110 milligrams
Females (11-18 years)	.115 milligrams
Females (19-50 years)	.100 milligrams
Pregnant & nursing mothers	.125-.150 milligrams

*Food Sources:* Iodine is found in high amounts in all sea vegetation. The following are also good sources of iodine:

Swiss chard	Kale
Turnip greens	Strawberries
Squash	Peaches
Mustard greens	Lettuce
Watermelon	Bananas
Cucumbers	Carrots
Spinach	Tomatoes
Pineapples	Grapes

### **2.3.14 Zinc**

*Use in the Body:* Zinc is found in the brain, genital organs, thyroid, liver and kidneys. It is needed in the healing of wounds and in the transfer of carbon dioxide from the tissue to the lungs. Zinc is also required in the manufacture of insulin and in the regulation of blood sugar.

*Effect of deficiency:* A lack of zinc may result in mental depression, prostrate troubles and absence of taste. A zinc deficiency may also result in defective intestinal absorption and restricted growth.

*Recommended Allowances:* The allowances for zinc as recommended by the National Academy of Sciences in 1974 are:

Infants (0-5 months)	3 milligrams
Infants (5-12 months)	5 milligrams
Children (1-10 years)	10 milligrams
Adults	15 milligrams
Pregnant and Nursing Mothers	20-25 milligrams

*Food Sources:* Zinc is found in the following foods:

All seeds and nuts, especially pumpkin seeds
Sprouted wheat
Most green and yellow vegetables

### 2.3.15 Other Minerals

The functions and daily allowances of the other minerals in the body have not yet been fully understood. All are important to the health of the human organism, however, and should not be disregarded.

These minerals, often called "trace minerals," will usually be found in sufficient quantities in diets which contain adequate amounts of the major minerals. Like the major minerals, all requirements of the trace minerals are supplied in a varied diet of fruits, vegetables, nuts, seeds and sprouts.

[Home](#) > [Lesson 10 - The Role Of Minerals In Human Nutrition](#) > 3. Organic And Inorganic Minerals

## 3. Organic And Inorganic Minerals

### 3.1 The Differences in Mineral Forms

Most knowledgeable people today recognize that the body must have certain minerals to accomplish its work and preserve its health. However, only a few realize that these minerals must be in their organic state to do us any good at all.

Please understand these facts:

1. Minerals are inorganic as they exist naturally in the soil and water.
2. Minerals are organic as they exist in plants and animals.
3. Only plants can transform inorganic minerals into organic minerals.
4. Animals must eat plants or plant-eating animals to obtain their organic minerals.
5. Inorganic minerals are useless and injurious to the animal organism.

### 3.2 How the Confusion Began

Because inorganic minerals and organic minerals have the same chemical compositions, they were confused by the early nutritionists. The mineral, iron, in the bloodstream has the same chemical composition as the mineral, iron, in a nail—iron is iron, after all. However, these nutritionists incorrectly reasoned that there were no other differences between these two forms of iron. As a consequence, there actually were iron mineral supplements that consisted of surplus powdered nails.

Perhaps you have heard the expression, "mad enough to chew nails." In this case, mad or unbalanced is certainly the correct word.

These nutritionists made an error in reasoning by assuming that a chemical similarity in minerals also meant there was a nutritive similarity between organic and inorganic minerals. While it is true that the same minerals found in the human body are also found in the soil and water it is wrong to assume that the minerals in the soil are food for man. We are not soil eaters—we are plant eaters.

It is necessary that the minerals in the soil be elaborated into organic compounds by the plant before they can be assimilated by the body. The various mineral compounds produced by the chemist differ in their structure and in the relative positions of their component molecules than those produced in the plant.

Over sixty years ago a German scientist named Abderhalden conducted a series of experiments comparing how several species absorbed different forms of iron. He found that animals fed with food poor in iron, plus in addition of inorganic iron, were unable in the long run to produce as much hemoglobin as those, receiving a natural iron-sufficient diet.

While the inorganic iron may be absorbed into the body, it is not utilized in the formation of hemoglobin, but remains unused within the tissues. Abderhalden also concluded that any apparent benefit of the inorganic iron resulted from its stimulating effect.

Chemically, it is true that iron in the bloodstream and iron in nails are the same and that calcium in rocks (known as dolomite) is identical to calcium in the bones.

However, it is a grave error to believe that the body can digest and assimilate and utilize powdered nails and crushed rocks.

### 3.3 Mineral Supplements

The idea of administering inorganic minerals as foods and remedies for man started with the German scientist Hensel in the early twentieth century. Later the homeopaths expanded upon his idea and made numerous artificial mineral preparations called cell salts, which are still sold today as popular "cures" for mineral deficiencies. Today mineral supplements exist in many forms and come from many sources. They are all useless.

Mineral supplements are of no benefit to the body because they are: 1) inorganic and 2) fragmented.

Because mineral supplements are inorganic, the body cannot assimilate or use them. In fact, the body must work harder to compensate for the imbalance created by ingesting these supplements. The body accelerates its eliminative activities and works hard to expel these foreign substances. This stimulation is often mistaken for the "beneficial action" of the supplement. Actually, the supplements are not beneficial—they are harmful—and they are inanimate and therefore incapable of acting (except chemically).

As health consumers have grown more aware of the differences between organic and inorganic minerals, so have producers of these supplements. Consequently, there are now mineral supplements which are advertised as coming from "organic" sources. These are equally useless because they exist in a fragmented state, extracted from the sources within which they naturally occur.

Minerals do not work in isolation. When they are extracted from their natural sources, the other co-

existing vitamins, minerals, enzymes, etc., are not also extracted. Even if they were, the process of laboratory extraction destroys any vital benefits that may have been associated with the minerals.

Minerals must be consumed in their natural, unfragmented and organic state to be of any use to the body. The best mineral supplements are those naturally occurring in mineral-rich foods in their unprocessed state—fresh fruits, vegetables, nuts, seeds and sprouts.

### **3.4 Mineral Waters**

Like mineral supplements, mineral waters cannot provide any beneficial minerals to the body. Any minerals contained in such waters are inorganic and must be expelled by the body. Should an excess of these inorganic minerals be consumed in the water, the body cannot rid itself of them fast enough and they are deposited within the body.

These inorganic mineral deposits lead to kidney and gallstone formation, hardening of the arteries, arthritis, heart trouble, ossification of the brain and other serious diseases. The unexpelled mineral matter from mineral-containing waters combines with cholesterol to form plaques. These plaques lead to cardiovascular problems, and they join with uric acid to cause arthritic and rheumatic complaints.

The body cells can use only pure (distilled) water—such as that found in fruits and plants—and they reject all inorganic minerals consumed in mineral-laden waters.

When mineralized waters are drunk, a condition known as leukocytosis occurs within the body in thirty minutes to three hours after drinking. Leukocytosis is the proliferation of white blood cells which are the body's first line of defense against foreign and harmful body substances—in this case, the inorganic minerals in the water.

Mineral waters cannot furnish the body with any needed elements other than the water itself. The remaining inorganic minerals are either eliminated through the skin, kidneys, etc., or they are deposited within the body where they may cause eventual harm.

Sea water is our "richest" mineral water, yet it is poisonous. Similarly, all other mineralized waters are simply dirty waters, contaminated with inorganic matter which is pathogenic to the body.

### **3.5 How Inorganic Minerals Are Transformed**

Even plants, when in their embryonic state, cannot use inorganic minerals in the soil, but instead feed on the organic compounds contained within its seed. Not until its roots and leaves are grown can a plant utilize the inorganic minerals of the soil.

The changing of inorganic matter into organic matter takes place principally in the green leaves of the plant by means of photosynthesis. Only by the presence of chlorophyll is the plant able to utilize the inorganic carbon molecule and convert it with hydrogen and oxygen into the organic combinations of starch and sugar. And, ultimately, the plant combines nitrogen and other mineral elements from the soil into more complex organic combinations. Only the chlorophyll-bearing plants have the ability to assimilate iron, calcium and other minerals from the soil and to use the resulting combinations to construct nucleo-proteins.

Vital changes occur in all minerals as they pass into the structure of plants. These changes cannot be isolated by normal chemical laboratory processes which destroy living plant tissues to analyze them. Such crude methods of studying the role of organic minerals in an organism is somewhat akin to the old medical practice of dissecting cadavers to look for evidence of the human soul.

## 4. Mineral Deficiencies

So far we have discussed the differences between organic and inorganic minerals and how inorganic minerals cannot be used by the body. Such inorganic mineral forms as supplements and mineral waters are therefore useless in correcting mineral deficiencies. We might now ask what causes a mineral deficiency in the first place.

A mineral deficiency only occurs for two reasons: 1) improper diet and 2) inability of the organism to assimilate and use the mineral.

### 4.1 Improper Diet as a Cause

An improper diet can be defined as the habitual consumption of foods that are incompatible with our biological heritage, or the eating of usually wholesome foods in a processed state.

For example, we are not biologically adapted to meat-eating because our digestive juices are not strong enough to digest the bones and cartilage of the animal along with its flesh. Consequently, meat-eating humans only get the flesh of the animal and neglect the bones, blood and cartilage—unlike naturally carnivorous animals. It is the bones, blood, cartilage, etc. that contain many of the minerals that are needed by carnivorous animals. Humans who eat only the flesh of animals thus receive a diet very poor in sodium, calcium, sulfur, magnesium and iron.

This is not an argument for eating animals in their whole state—blood, bones, and all—but a serious question of the value of flesh-eating as practiced by humans.

Like meat, grains are also very poor in sodium. Because of these sodium deficiencies, people salt grains and meats to make them more palatable. They add an inorganic chemical, sodium chloride (salt), in an effort to correct the inherent sodium deficiency within these unnatural foods. Of course, the body cannot use sodium in this inorganic form, and it must try to eliminate it. Grains, then, being minerally unbalanced, are not a good food for the human diet.

Foods that are usually regarded as wholesome and mineral-rich can also be rendered minerally unbalanced by processing them. For example, the potato, while not an optimum food, is an acceptable addition to the diet in its whole state. It, too, is somewhat sodium deficient, but its skin is a storehouse of many other minerals. When peeled, boiled or fried, the potato loses much of its mineral content and becomes an unfit food.

A truly mineral-rich diet, then, should consist of food best suited and natural to the human diet which are consumed as they are found in nature with a minimum of processing or preparation.

### 4.2 Metabolic Deficiencies

Although an improper diet is usually viewed as the main cause of a mineral deficiency, it is also important to realize that a mineral deficiency can occur even when there is an excess of minerals in the diet. Although the minerals may be present, the body, for some reason or other, is unable to digest and assimilate them. In this case, a metabolic deficiency occurs.

For example, in cases of pernicious anemia, which is often viewed as a serious iron deficiency, there is often an excessive amount of iron-containing pigment in all the organs. Post-mortem diagnosis of several anemic patients showed that there was enough iron stored in the spleen to correct the deficiency in the body. The mineral was present, it just was not being metabolized.

Also, in cases with fasting anemic patients, it has been discovered that their number of red blood cells improve and iron is utilized more efficiently while on a fast. It is interesting to note that this occurs

when the patient is not receiving any iron at all in his diet. The fasting condition enables the patients to metabolize the iron already stored within their system.

Similarly, in cases of patients with rickets, a condition often associated with a calcium deficiency, improvements were noted in their conditions after they had fasted for a length of time. They were allowed exposure to sunshine in sufficient amounts to develop Vitamin D within their bodies. The presence of Vitamin D then allowed them to use the calcium within the body more effectively. These patients were suffering more from a "sunshine deficiency" than from lack of a certain mineral.

Many factors may cause an individual to be unable to assimilate and use the minerals present in his diet. Personal habits, working environment, state of mind, manner of cooking, overworked emotions, lack of sleep, overeating, worry, grief and so on are all causes of impairment of the metabolic process.

To allow the body to assimilate and use the minerals in the diet, the individual may need to correct his habits of living. He may need a physical or mental rest or even a complete physiological rest which can only happen while fasting.

### 4.3 Minerally Deficient Soils

One last cause of a mineral deficiency should be noted—not because it is a common cause, but because it may be an important consideration for those people who are attempting to grow all their food for self-sufficiency. That cause is: The exclusive consumption of foods which are grown on minerally poor soils.

If the soil itself is minerally deficient, it will be difficult to obtain the minerals we need from the plants grown on that soil. The mineral content of soils in certain locales may be deficient in one or two important minerals. As a result, there can be a wide range of mineral contents in the same variety of food, depending upon the soil in which it was grown. Consider, for example, the variations in these minerals as found in grapes grown in different soils:

<b>Percent of total Mineral Matter Grapes Grown on different Soils</b>	
Sodium	From 0.29 to 10.54 percent
Calcium	From 1.70 to 22.60 percent
Iron	From 0.05 to 1.68 percent

In this one example you can see how the mineral content of a food can vary up to 35 times, depending upon the soil in which it is grown.

Proper mineral nutrition begins with proper agriculture, and the commercial fertilizing methods of adding chemical nitrogen, potash and phosphoric acid ignore the many other mineral elements required to grow healthy plants.

People who eat fruits, vegetables, nuts and seeds grown in a wide variety of soils rarely have to worry about developing a mineral deficiency because of a single soil deficiency. Those people who do grow and eat all their foods from a single soil source should make compost to insure that their soil contains all the essential minerals needed for good health.

## 5. Obtaining The Minerals We Need

### 5.1 All Minerals Present in a Natural Diet

All mineral needs may be supplied to the body by eating a varied diet of fruits, vegetables, nuts, seeds and sprouts as they are found in their natural unprocessed state.

Before these minerals can be efficiently used, it may be necessary to give the body a complete physiological rest through fasting. A fast will enable the body to increase its metabolic powers.

Given that we lead our lives in a healthy manner, free from undue emotional and mental stress, we should have no trouble at all satisfying all our mineral and other nutritive needs from a simple Hygienic diet.

The efficiency of a Hygienic diet in supplying all of our mineral needs can best be illustrated by analyzing the mineral contents of two typical daily menus. These menus were taken at random from Herbert Shelton's book Superior Nutrition, and the reader is referred to this source for more examples of the Hygienic dietary.

The first menu is a summer menu and the second is a fall-winter menu. The amounts of each food below were chosen to be the similar amounts an adult woman or man might eat. For increased mineral or nutritive content, the amounts of food eaten could also be increased in accordance with environment, type of work done, physical constitution, etc. All mineral content estimates were made on the conservative side.

### 5.2 Examples of Mineral Contents of Meals

#### SUMMER MENU

<i>Meal</i>	<i>Food</i>
Breakfast	Watermelon
Lunch	Bibb lettuce
	Yellow squash
	Sunflower seeds
Dinner	Cherries
	Nectarines
	Bananas

#### MINERAL CONTENT OF FIVE ESSENTIAL MINERALS

CALCIUM	400 milligrams
---------	----------------

IRON	18.2 milligrams
MAGNESIUM	16 milligrams
PHOSPHOROUS	1150 milligrams
IODINE	.245 milligrams

FALL/WINTER MENU

<i>Meal</i>	<i>Food</i>
Breakfast	Oranges
	Grapefruit
Lunch	Lettuce
	Asparagus
	Chard
	Almonds
Dinner	Persimmons
	Apples
	Grapes

MINERAL CONTENT OF FIVE ESSENTIAL MINERALS

CALCIUM	600 milligrams
IRON	18.9 milligrams
MAGNESIUM	458 milligrams
PHOSPHOROUS	800 milligrams
IODINE	.235 milligrams

Looking over the mineral contents of these two daily menus, we discover that they usually supply anywhere from 100 to 180 percent of the officially recommended allowances, except for calcium, which

totals 70 - 90% of our daily requirements.

It should be noted that calcium needs on a vegetarian diet (such as this one) are significantly less than the calcium requirements for a carnivorous diet, upon which the official recommendations were based. Consumption of flesh causes the body to excrete calcium to neutralize the toxins within the meat and the uric acid formed. Calcium needs are less on a vegetarian diet.

By adhering to a diet of fresh fruits, vegetables, nuts, seeds and sprouts, a person need never worry about obtaining sufficient minerals in the diet. In fact, this is the most mineral-rich and efficiently utilized diet for humans.

[Home](#) > [Lesson 10 - The Role Of Minerals In Human Nutrition](#) > 6. Questions & Answers

## 6. Questions & Answers

**You said that even mineral supplements from organic sources are fragmented and therefore not wholesome. Isn't there sometimes a need for a megadose of a particular nutrient when there is a severe deficiency?**

First, remember that a deficiency of an individual mineral rarely exists in isolation. If a person, for instance, has a "calcium deficiency," it may be because there is not enough phosphorous in the diet which is used by the body together with calcium, or a Vitamin D deficiency may be responsible for the exhibited calcium deficiency. By supplying a large amount of a specific mineral, you ignore the other accompanying needs of the body.

Finally, along with this idea is the concept of the "law of minimum." This law states that the body is able to use a certain nutrient only to the extent that other necessary nutrients are available. If, for example, you had only enough copper in the body to aid in assimilation of 10 milligrams of iron, taking 30 extra milligrams of iron would do the body no good. Nature provides the minerals and other nutrients we need in a perfectly balanced combination within foods. When we introduce large amounts of minerals, vitamins, etc. in a fragmented form, we throw the body out of balance.

**But I've taken dolomite for years and no longer suffer from the signs of calcium deficiency I had before. Why is that?**

When mineral supplements, etc. are added to the diet, it usually is a sign that an individual has become aware of problems within the body. Consequently, along with the taking of supplements, a person often improves his diet, his exercise program or whatever. These changes are what improve a condition, not the supplements.

Supplements and pills of all forms often have a placebo effect upon the individual. That is, you believe you are getting better by taking an external agent—a supplement. Dolomite's chief effect is to cause the formation of stones in the body from the inorganic calcium it contains.

**If we get all the calcium we need from fruits, vegetables, nuts, seeds and sprouts, why does the National Dairy Council say we need milk and milk products? Other health organizations say the same thing.**

Milk is such an inappropriate food for humans that some reason has to be given for drinking

it. Since calcium is its most abundant mineral, the National Dairy Council has based its campaign on this fact. First, the calcium in dairy products, and especially in pasteurized products, is not completely assimilable by the body. The calcium in chocolate-flavored milk quickly forms stones of calcium oxalate within the kidneys. Cows' milk cannot even be digested by over 80% of the world's population because they lack the necessary enzyme. Within the milk itself are so many other harmful items (casein—used in glue making, artificial hormones to induce lactation, etc.) that any value obtained from the calcium is completely negated.

**Almost the entire health community advocates the use of food supplements, including minerals, because they realize that most people will not eat the strict diet you advocate. How can people who don't eat the most healthful diet still get the minerals they need?**

I believe that even people on a typical "junk food" diet can be convinced to eat one or two pieces of fruit a day or a small raw salad or a handful of raisins. There are more usable minerals in a single apple than in a whole bottle of mineral supplements. You simply cannot get the minerals you need from a bottle or a drugstore. Only the diet can supply needed minerals. If a person is unwilling to adopt a healthy diet, then at least let him eat a small amount of "real" food each day. The body will work hard to make do with any minerals in their natural food form, no matter how small the amount.

[Home](#) > [Lesson 10 - The Role Of Minerals In Human Nutrition](#) > Article #1: The Minerals Of Life By Dr. Herbert M. Shelton

### **Article #1: The Minerals Of Life By Dr. Herbert M. Shelton**

It seems quite clear that the vital importance of the organic salts of foods was established by men who were outside the regular folds. The older physiologists and physiological chemists gave no attention to them. In the tables of food analysis they were relegated to the "ash" column and ignored.

At the present day their importance is everywhere recognized. It is no longer thought that only the "nutritive values"—proteins, carbohydrates, fats—are important.

Animals fed on foods deprived of their salts (minerals) soon die. In the same manner, they die if, to these demineralized foods, are added inorganic salts in the same quantities and proportions as are found in the ashes of milk. The salts must come to the body in the organic form. These inorganic salts are not used except in the presence of vitamins.

Berg has pointed out that there does not exist one single complete analysis, either of the human organism or its excretions or of our foodstuffs. Not everything is known about the function of minerals in the body and of some of them almost nothing is known. Some of them, such as zinc and nickel, apparently perform functions similar to those of vitamins. Prof. E. V. McCollum showed that animals deprived of manganese lose the maternal instinct, refuse to suckle their young, do not build a nest for them, and even eat their young. Their mammary glands do not develop properly and they are unable to secrete proper milk for their young. Here are effects commonly attributed to vitamin deficiency.

This "ash" enters into the composition of every fluid and tissue in the plant and animal body and without even one of these minerals, life could not go on. They are of the utmost importance. They serve a number of purposes. They form an essential part of every tissue in the body and predominate in the harder structures such as bones, teeth, hair, nails, etc. The bones consist largely of calcium phosphate.

They are the chief factors in maintaining the normal alkalinity of the blood as well as its normal specific gravity. They are also abundant in the body's secretions, and a lack of them in the diet produces a lack of secretions. They are also used as detoxifying agents, by being combined with the acid waste from the cells. The wastes are thus neutralized and prepared for elimination. Their presence in the food eaten also aids in preventing it from decomposing. Acidosis produced by the fermentation of proteins and carbohydrates often comes because the mineral salts have been taken from the food, thus favoring fermentation.

In a simplified sense we may consider the blood and lymph as liquids in which solids are held in solution—much as salt is dissolved in water. The cells, which are bathed at all times in lymph, are also semi-fluid with dissolved matter in them. If the lymph outside the cells contains much dissolved solid, as compared to that within the cells, the cells shrink in size. If there is more dissolved solid within the cell than without, the cell expands and sometimes bursts. In either case the result is pathological.

If the amount of dissolved solids within and without the cell are equal, so that internal and external pressure are equalized, the cell remains normal. It falls very largely to the minerals of the food to maintain this state of osmotic equilibrium.

The waste formed in the body, due to its normal activities, is acid in reaction. The greater part of the work of neutralizing these acids is done by the mineral elements—the "ash."

These minerals enter into the composition of the secretions of the body. The hydrochloric acid in the gastric juice, for example, contains chlorine. Clotting of the blood does not take place without the aid of calcium or lime.

The mineral matters in food undergo no change in the process of digestion, prior to absorption, as do proteins, fats and carbohydrates. They are separated from these other elements in the process of digestion and pass directly into the blood.

If our foods do not contain enough of the right kinds of mineral salts we simply starve to death. It does not matter how much "good nourishing food," as this is commonly understood, that we consume, if these salts are not present in sufficient quantities we suffer from slow starvation, with glandular imbalance or disfunction, more disease and other evidences of decay. McCarrison showed, definitely, that foods and combinations of foods that are inadequate and unsatisfactory in feeding animals are equally as inadequate and unsatisfactory in feeding man.

Life and health are so directly related to these salts, of which little enough is known, that we can never have satisfactory health without an adequate supply of them. We may be sure that each salt has its own separate function to serve, while certain combinations of them have long been known to serve vital services in the body.

No drug salts can be made to take the place of those found in food. As Dr. William H. Hay, says: Nature provides all her chemicals for restoration of the body in the form of colloids, organic forms, and man has for a long time sought to imitate her in this, but he has not been so very successful that we are now able to insure the recouping of the mineral losses of the body by any artificial means, and must still depend on nature's colloids as found in plant and fruit." Well or sick, no compound of the chemist, druggist or "biochemist" can recoup your mineral losses.

### 1. Introduction

Fat makes up a larger caloric portion of the American diet than any other foodstuff. The average American's food intake is 40% fat. He eats animal foods rich in fat; he tosses his salads in fat; and he spreads his bread with fat. When he eats out, he patronizes fast food restaurants that deep-fry and grill-fry most of their food in fat.

He lives off the "fat of the land" and "high on the hog," and he suffers from some of the most serious health problems in the world. His arteries become clogged with cholesterol, his breathing becomes short and he dies in what should be his prime years.

Fat is not the only culprit in the American diet, and indeed fat is not "bad," just as proteins and carbohydrates are neither good nor bad. Fat is needed in the diet. It is present in every food we eat—even cucumbers, watermelons and apples have fat.

It is the particular sources from which people get their fat and the way in which fat is utilized in the diet that is "bad," or at least unhealthy.

What you will learn in this lesson is what fats are, how the body uses them, how they are digested and how they should be obtained in the diet. This is the type of understanding we need to evaluate intelligently the role of fats in the human diet.

## 2. What Are Fats?

### 2.1 Basic Composition

Fats, or hydrocarbons, are one of three food categories, the other two being proteins and carbohydrates.

Fats are composed of the same three elements as carbohydrates—carbon, oxygen and hydrogen. However, they are much poorer in oxygen and richer in carbon and hydrogen than are carbohydrates. Because of this higher carbon and hydrogen content, fats have a greater heat or energy equivalent than carbohydrates.

The fats found in plants are manufactured from water and carbon dioxide with the aid of chlorophyll, much in the same manner that the carbohydrates in a plant are produced. The fats found in humans and animals come from two sources: 1) from the fats in the diet and 2) from the metabolism of excess carbohydrates into fat. The greatest amount of fat in the body usually comes from carbohydrate metabolism.

As far as the human digestive process is concerned, fats are composed of two components: 1) glycerin (or glycerol) and 2) fatty acids.

Glycerin is the energy source of fats and is metabolized much in the same manner as are the carbohydrates. The glycerin is broken down into sugars which may be used by the body for fuel.

The fatty acids are often spoken of as chains of hydrogen, carbon and oxygen atoms. Simplistically speaking, the fatty acids are to fat what the amino acids are to protein. These chains of fatty acids have links within them where additional hydrogen, oxygen or carbon atoms may be attached to the chain.

If hydrogen is attached to these links, the fat becomes it more solid. This is called *hydrogenated* fat.

All the solid vegetable fats, such as Crisco, margarines, etc., are hydrogenated. If oxygen is attached to one of, these fatty acid links, the fat becomes rancid. Thus, fats left exposed to the air begin to oxidize and become rancid rapidly.

### 2.2 Unsaturated, Saturated and Hydrogenated Fats

Fat that is unsaturated is composed of fatty acids in which one or more of the carbon atoms in the chain do not have all of their accompanying hydrogen atoms. In other words, unsaturated fatty acids have open available links in their chains.

These open links in fatty acid chains are important. The body is able to combine various nutrients with the fatty acid chains through these open links. This combination of nutrients and fatty acids allows both of them to be transported through the body where they can be used in building cell structure.

Animal fats contain very little unsaturated fats. The chief sources of unsaturated fatty acids are nuts and seeds. Almost all vegetable fats in their natural state have a high proportion of unsaturated fatty acids.

The term *polyunsaturated* means that there is a large number of fatty acids which have two or more open links in their chains. These vegetable polyunsaturated fats are used in making margarine and shortening. This is done by the process of *hydrogenation*.

Hydrogenation causes liquid fats to become solidified by introducing hydrogen atoms into the open links of the fatty acid chains. If a fat becomes completely hydrogenated, it is rock-hard. The process is controlled, however, so that varying consistencies of hydrogenated fats can be produced.

The hydrogenation process consists of heating the fats and oils to a temperature of 212 to 400 degrees. Hydrogen is then mixed in, along with Some catalytic agents, such as nickel or platinum. The fatty acids

then take on the hydrogen atoms and begin to solidify.

The heating of the oils during this process destroys any vitamins that might be present. The addition of the hydrogen atoms fills the open links in the fatty acid chains and thus prevents nutrients from binding with the acids. As a result, hydrogenated fats can supply only empty calories and no nutritive value.

Since hydrogenated fats cannot become rancid (nor can they support life), they are manufactured extensively. Margarine, cooking fats, processed cheeses, lard and peanut butter are but a few products subjected to hydrogenation.

The *saturated* fats are found chiefly in animal fats. Saturated fats are solid at room temperature, unlike the liquid unsaturated fats. Saturated fats are found in animal flesh, dairy products, eggs and coconuts. It should be noted that the saturated fats in coconuts have a different chemical structure.

Like hydrogenated fats, the saturated fats cannot enter into a nutrient bonding within the body. Consequently, they cannot be used effectively by the body in cellular composition than the saturated animal fats metabolism. The saturated fats are usually empty calories that contribute to a fat build-up within the body. They serve no useful function.

### **2.3 Cholesterol: Villain or Hero?**

Accompanying the saturated animal fats is cholesterol, which can be considered a "cousin" to the fat family. Since cholesterol is generally discussed in terms of fats in the diet, this is an appropriate place for its inclusion.

Cholesterol is not a harmful substance as such. The body uses it in all of its tissues. It occurs in the brain, spinal column and skin. Cholesterol is part of the raw materials from which bile salts, sex and adrenal hormones and vitamin D are made. It combines with proteins to enable fats to be carried to the cells.

*The liver produces all the cholesterol the body needs for its functions.* In an average adult, about 3,000 milligrams of cholesterol are produced each day, regardless if cholesterol is present in the foods eaten or not.

When additional cholesterol enters the body through diet, an excess occurs. Typically, a person consuming animal products ingests about 800 milligrams of cholesterol a day. This extra cholesterol is deposited along the walls of the arteries throughout the body.

As these deposits grow, a condition known as atherosclerosis or "hardening of the arteries" occurs. The arteries become constricted and circulation is seriously impaired. This impaired circulation contributes to a wide variety of problems, including loss of hearing, baldness, shortness of breath, dizziness and heart attacks. All tissues the body are harmed since a reduced amount of oxygen and nutrients reach the cells.

Atherosclerosis now affects a majority of Americans, regardless of age. Autopsies of infants less than one year old, many of them fed commercially prepared baby formulas, revealed large amounts of cholesterol already deposited within their arteries.

There is absolutely no need for saturated fats or cholesterol in the diet. The body manufactures all of its cholesterol needs. The consumption of additional amounts in the form of saturated animal fats destroys the health of the body at the cellular level.

### **3. Fat Digestion**

Fat digestion takes much longer than the digestion of carbohydrates and somewhat longer than the digestion of proteins. A raw salad consisting of nonstarchy vegetables can be digested within two to three hours. When free fats such as corn, sesame, peanut or other oils are added to the salad, digestion is delayed for another two or three hours.

Coating our food with free oils inhibits the natural digestive processes by preventing digestive juices access to these foods until the oils are digested. Consequently, by the time the oils or fats surrounding the other food particles are digested, the elementary carbohydrates or proteins in the vegetables have begun to ferment (carbohydrates) or putrefy (proteins) in the stomach.

#### **3.1 Fats Require Special Digestion**

Free fats, unlike carbohydrates, require special digestive action before absorption. This is because the end products of all digestion are carried in a water medium (that is, the blood and lymph). Free fats are not soluble or transportable in these water mediums until they undergo special changes.

#### **3.2 Tracing Fat Digestion**

After fats leave the stomach, they enter the duodenum of the small intestine. Their presence causes the stimulation of the gallbladder, which forces bile down into the small intestine. The bile emulsifies, all the fats in the intestines.

The emulsified fats are then split by enzymes into fatty acids and glycerol. At this point, the fats can be absorbed through the intestinal mucosa. During absorption, the fatty acids and glycerol recombine with a small amount of protein to form microscopic particles of fat called chylomicrons.

The fats in the form of chylomicrons are now soluble enough to enter lymph circulation. The fatty acids are converted to the liver to acetate or ketone bodies as an energy source for the cells.

The fat which is not used immediately for the body's energy needs is stored primarily in adipose tissue. Adipose tissue is a special kind of tissue (found mainly around the stomach, thighs and buttocks) which contains the necessary enzymes to continually produce and release new fat to meet the body's needs.

### **4. How The Body Uses Fat**

Fat is used in the body in four main ways:

1. As a source of heat and energy;
2. As padding and insulation for the organs and nerves;
3. As a regulator for the fat soluble vitamins (A, D, E and K); and
4. As a source of the essential fatty acids.

#### **4.1 Fats Supply Heat and Energy**

Each gram of fat supplies nine calories. This is more than twice the amount of energy supplied by a

gram of carbohydrates. The body uses fat in much the same way as it uses carbohydrates. That is, fat is used mainly as an energy food.

Fats are converted to energy by being split into fatty acids and glycerol. Glycerol is then converted to either glucose or glycogen. At this point, the usual processes of carbohydrate metabolism take over to produce needed energy from the glucose and glycogen.

While fats may supply twice the caloric energy of carbohydrates, we find that they must undergo a longer digestive process before they are ready for an essentially carbohydrate metabolism. In general, carbohydrates do a more efficient job of providing the body with readily usable fuel. Fats are valuable in that they may provide a form of stored energy, but strictly speaking, they are not a necessity in the diet as far as a fuel source goes.

Fats, however, are usually more extensively stored within the body than are carbohydrates and may be converted into fuel when the body's carbohydrate reserves are depleted. In fact, this is exactly what occurs when a person goes on a diet, fasts, or is exposed to extremely cold weather. As the stored carbohydrate reserves in the liver are exhausted, the body's fat reserves are metabolized for a new supply.

It should be understood that these fat reserves in the body do not simply come from the fat that is eaten in the diet. When an excess of carbohydrates is eaten, it is converted by the body into fat and stored.

In this way, the body can store and use fat without having a large amount of fat in the diet. The fat deposits could be viewed as a carbohydrate bank, where deposits and withdrawals are made as necessary.

We can see that fat within the body is an important energy and heat source, but strictly speaking, fat in the diet is not an essential outside source for this fuel.

## **4.2 Fats Provide Padding and Insulation**

Within the body, fat deposits provide padding and support for the organs and insulate the body from cold.

For instance, a certain amount of fat is necessary in the buttocks. A loss of most of the fat in this body area actually makes sitting down uncomfortable. Fat tissue is also a special type of connective tissue that aids in the support of certain organs, such as the liver.

Most animals in nature experience an increase in their fatty tissues with the advent of the cold weather. This fat may be used as a fuel source during the winter months when food is naturally scarce and help in the insulating of the body.

This function of fat in the body should not be confused with the role of fat in the diet. Fat reserves in the body do not necessarily come from fat intake in the diet but may instead be developed from the carbohydrates consumed.

## **4.3 Fats Aid in Absorption of Fat-Soluble Vitamins**

Some of the vitamins are termed "fat-soluble." This means that fatty compounds must be present in the intestines for these vitamins to be absorbed. The fat soluble vitamins are A, D, E and K. The other vitamins (B, C, etc.) are termed "water-soluble."

If these fat-soluble vitamins are obtained from the foods in which they naturally occur and eaten in an unprocessed state, they will be readily absorbed by the body. The wholesome foods which contain these vitamins also contain the necessary fatty compounds for their absorption.

If these vitamins, however, are extracted (as in supplements) or occur in foods which have been fragmented, processed or subjected to heat, then their absorption will be impaired. Heating fatty foods,

for example, renders almost all of the fat-soluble vitamins useless.

#### 4.4 Fats Are Sources of the Essential Fatty Acids: Vitamin F

Even if no fat is eaten, the body can manufacture most of its fatty acids from fruit and vegetable sugars. There are three fatty acids, however, that the body is said to be unable to synthesize. These are called the essential fatty acids.

The three essential fatty acids are linoleic acid, arachidonic acid and linolenic acid. The linoleic acid is generally thought to be the most important and has been termed absolutely essential to life by some nutritional researchers. The arachidonic acid can act as a fairly good substitute for linoleic acid. The third acid, linolenic, is said to be only a partially satisfactory substitute for linoleic acid in that it can support growth but cannot aid in the other functions that linoleic acid performs.

#### 4.5 Functions

Collectively, these essential fatty acids are sometimes referred to as vitamin F. The fatty acids or vitamin F are considered necessary for normal glandular activity, especially the adrenal glands. The adrenal and sex hormones seem to require the presence of these fatty acids for their manufacture.

The essential fatty acids are thought to be involved in many of the body's metabolic processes. They promote the availability of calcium and phosphorous to the cells and help form the fat-containing portion of every cell's structure. They are also considered a factor in growth and in reproduction.

#### 4.6 Effect of Deficiency

A lack of vitamin F (the fatty acids) is said to contribute to skin disorders, gallstones, loss of hair, impaired growth and reproductive functions, kidney and prostate disorders and menstrual disturbances.

Since the fatty acids are also said to aid in the growth of intestinal bacteria which help produce the B vitamins, the symptoms of a B-vitamin deficiency may be related to a lack of fatty acids in the diet.

#### 4.7 Requirement

No minimum requirement for vitamin F or the essential fatty acids has been established. The National Research Council has stated that about 1% of the total daily calories of about 2200-2800 per day should consist of unsaturated fats to provide a margin of safety for the intake of essential fatty acids.

The following wholesome foods contain the shown percentages of linoleic acid, the major fatty acid. In general, if the intake of linoleic acid in the diet is adequate, then all other fatty acid needs are also well satisfied.

Food	% Linoleic Acid
English walnuts	40
Sunflower seeds	30
Black walnuts	28
Sesame seeds	22

Pumpkin/squash seeds	20
Brazil nuts	17
Pecans	14
Almonds	11
Filberts	10
Pistachios	10
Cashew nuts	3
Avocados	2
Coconuts	1
Raw sweet corn	Trace

It is interesting to determine how much of the above foods would supply the 1% caloric intake of unsaturated fatty acids (in this case, linoleic acid). This is not to suggest that we accept this "1%" figure as an absolute or even as a necessity at all.

However, for the sake of argument, let's assume a daily intake of 2500 calories. At this level, official figures tell us we should have 25 calories of unsaturated fatty acids. By examining the total amount of linoleic acid available in the nuts and seeds in our previous chart and knowing their calorie contents per ounce, we discover that anywhere from one-half to an ounce and a half of these nuts and seeds would give us 25 food calories of linoleic acid.

That is not the sum total of all the unsaturated fatty acids in these foods, nor is it the total of all the other fats we get in our daily diet. It is merely a statement that even if one-half to an ounce and a half of these nuts and seeds were consumed each day, and nothing else, we would still surpass all official recommendations for essential fatty acid intake.

This does not mean that we must eat this small amount of nuts or seeds each day. We should always eat only what the body needs or requires and not become involved with calorie counting or food weighing.

All fresh fruits, for example, contain between 0.5% and 1% unsaturated fat. Some fruits are higher in fat (particularly the avocado which may be 15% to 22% fat). If fruits alone were consumed, we would still have no difficulty meeting the government suggestion that we make 1% of our diet unsaturated fats.

## **5. Harmful Fats**

### **5.1 Free Oils**

The term free oils refers to those fats and oils which are separated from the foodstuffs in which they naturally occur. For instance, peanut oil is a free oil and likewise we can say that lard is a free oil (although somewhat solid).

Free oils in the diet are of vegetable, animal or chemical origin. Some of the free oils are definitely poisonous to the body. The others, while less harmful, have no place in the human diet.

### **5.2 Vegetable**

Some examples of free vegetable oils are corn oil, olive oil, safflower oil, almond oil and the generic cooking oils which may be a mixture of vegetable oils and added chemicals. These are the most commonly used oils in the typical vegetarian diet which excludes all animal fats.

The fat content of these extracted oils is 100%. No proteins or carbohydrates are contained in these oils. Actually, very few minerals are present and only vitamins E and F are present in any amount. We see that these extracted oils are very lopsided nutritionally—they supply oil, but little else. They may be likened to white sugar or white flour as refined products.

In addition, these extracted oils are very susceptible to pesticide residues. Many of the free vegetable oils have chemicals added to them to prevent them from becoming cloudy or going rancid. Unfortunately, however, almost all free oil undergoes a certain amount of oxidation and becomes rancid regardless of the preservative methods used.

The great majority of all vegetable oils are heat-extracted. That is, they are raised to high temperatures in their manufacturing process in order to expel the oils from their vegetable sources. This heat causes a breakdown in the oil's original composition which renders it nutritionally unfit.

Even most of the so-called "cold-pressed" oils sold in health food stores have had a certain amount of heat applied. Although the amount of heat used in these "expeller-pressed" oils (which is really what they are instead of "cold-pressed"), is somewhat lower than conventional methods, it is still high enough to destroy the oil's original composition. Usually, only olive oil and avocado oil have any chance of being extracted without heating methods of some kind.

All free vegetable oils, with the exception of olive oil, have been added to the human diet only in the past hundred years. The human constitution is simply not adapted to handle these large quantities of free oils. .

Even olive oil, the traditional favorite of many health enthusiasts, cannot be recommended. Unless obtained from strictly organic sources, most, olive oil is mixed with other oils and petroleum products. These additives are considered normal by the government and no labeling of their presence is required.

No free oil, not even vegetable oils, should be included in a healthy diet.

### **5.3 Animal**

The most common free animal oils are lard and butter. Strictly speaking, these are not pure oils or fats. Butter is about 87% fat, while lard is 94% fat. Because of their high fat content and their use outside of their naturally occurring sources (milk and meat), they will be discussed as examples of free animal oils.

The reasons for abstaining from animal free oils (or any animal fats) are basically the same as those for avoiding all animal products in the diet.

Like human beings, animals tend to store the accumulated pesticides, chemicals and additives from their diet in their fatty tissues. Consequently, lard and all animal fats are a concentrated reservoir of environmental poisons.

The animal fats are usually superheated during their extraction and tend toward rapid rancidity almost immediately.

Butter is usually colored and salted and is suspect to the hormonal and additive contamination from the cow.

Like all animal fats, the animal free oils are high in cholesterol which may eventually result in destruction of the cardiovascular system.

No free oil, and certainly not free animal fats, should be included in a healthy diet.

## **5.4 Chemical**

This is a new one. Thanks to the synthetic food industries and the availability of petroleum by-products, free oils made from chemicals are being introduced into the diet. These chemical oils appear in ice cream, artificial coffee creams, artificial butter, etc.

Strangely enough, the people who consume these chemical oils often do so out of a concern for their health. They seek to avoid cholesterol and instead eat chemicals produced by the petroleum industries.

The plastic margarine and imitation coffee cream and ice cream that people eat may have a worse effect than the animal products they purport to replace. At least butter and cream have been a regular part of some people's diet for hundreds of years. Most of these chemical oils have been on the market for less than ten years. No one has any idea as to the eventual harm they may cause.

The eating of these chemical oils is done to satisfy a purely psychological need. They are devoid of nutrition and undermine the body's health.

No free oil, and absolutely never any chemical oils, should be included in a healthy diet.

## **5.5 Fats In Cooking**

Although a lot of fat is consumed in the typical American diet in the form of free oils, the largest amounts of fat are consumed from eating those foods which have been cooked with fat.

French fries, potato chips, doughnuts, cakes, snack foods—almost all the "convenience" foods and junk foods eaten—contain high percentages of heated fats.

When fats and oils are heated to a high degree as in cooking or frying, they become carcinogenic—capable of causing cancer. Healthy cells may become cancerous, that is, "go wild" if the diet is high in heated oils because heated oils are extremely toxic.

The digestive processes for the assimilation of fats require that the fats be emulsified. Fats that have been heated in cooking cannot be emulsified or digested. Since they cannot be used by the body, these overheated fats must be eliminated. Fats which have been subjected to a high degree of heat are difficult for the body to break down and expel. If the body has no use for a substance and cannot effectively eliminate it from the system, then the body stores the substance where it can do the least harm or walls it off by creating a tumor around it.

Besides the heated fats themselves, the foods that are saturated with these cooked fats are also indigestible and poisonous. Starches such as potatoes, pastries, breads, etc. that are soaked in hot fat become impossible for the body to convert to sugar—the essential part of starch digestion. These foods then are worse than nutritionally useless since they also place a strain upon the body to eliminate them.

Any food values associated with oils or fats are lost when they are heated. As fats reach 350 degree

temperatures, the standard range for frying and cooking, they begin to decompose totally and lose all their vitamins and minerals. They also prevent the absorption of any other fat-soluble vitamins and so contribute to the nutrient starvation of the body.

[Home](#) > [Lesson 11 - Fats In The Diet](#) > 6. The Use Of Fats In The Optimum Diet

## 6. The Use Of Fats In The Optimum Diet

Now that we have discussed the harmful effects of animal fats, free oils and heated fats, we should examine the wholesome sources of fat in the diet. First, there are no such things as "fat-free foods." All foods that are part of the human dietary contain fat. Every cell of every living plant and animal contains fat.

### 6.1 Fat Contents of Wholesome Foods

There are, of course, different fat contents in different foods. The following chart shows the fat content of foods natural to the human diet:

Food	% of Fat (by Calories)
Fruits (Apple)	3
Vegetables (Spinach)	15
Mother's milk	55
Avocados	77
Seeds (Sesame)	70
Coconut (Mature)	79
Nuts (Hazelnut)	81

data from [nutritiondata.com](http://nutritiondata.com)

### 6.2 Nuts, Seeds and Avocados As High-Fat Sources

Nuts and seeds that are fresh, unroasted and unsalted are acceptable high-fat foods. If digestion permits, these should be eaten fresh in their whole state. If used as a nut butter or dressing, they should be made at home immediately before eating. All manufactured nut and seed butters, even those labeled as "raw," undergo some degree of oxidation and become somewhat rancid.

When eaten, nuts and seeds should be masticated thoroughly. For ease of digestion, only a single variety of a nut or seed should be eaten at one meal. These high-fat foods combine best with leafy green vegetables and other non-starchy vegetables. They should not be eaten with starchy vegetables, fruits or

avocados.

Coconuts, although rich in saturated fats, may be added to the diet in small quantities and also combined with leafy green vegetables. Coconuts should not be combined with fruits, as is sometimes done, to avoid fermentation of the fruits.

Avocados are another wholesome high-fat food. They are best eaten with nonstarchy vegetables. The nutritive value of an avocado and nuts is quite similar; the avocado simply has a higher water content.

### **6.3 Olives as food**

Olives are the only other fruit besides avocados that have a high fat content. They are a wholesome food only if eaten in their natural dried state. Unfortunately, sundried natural olives are very difficult to locate. Olives that are canned, bottled or pickled are indigestible and should not be eaten. Olive oil, while perhaps the potentially less harmful of all the free oils, has no place in the optimum diet.

### **6.4 Recommendations**

Although no specific amounts of these foods are recommended, it should be noted that many practitioners of Natural Hygiene suggest that no more than three to four ounces of nuts or seeds be eaten daily or no more than one avocado. The body appears to have difficulty in handling much larger amounts. Of course, this also means that one may certainly eat less than these amounts or no amount whatsoever. These are not recommendations for eating these foods daily, but suggestions that these foods should be consumed in limited amounts.

[Home](#) > [Lesson 11 - Fats In The Diet](#) > 7. Questions & Answers

## **7. Questions & Answers**

### **Just how necessary is fat? Can we live without it?**

First, we must make an important distinction between fat in the body and fat in the diet. Fat in the body is absolutely necessary for our health. It exists in every cell and performs a vital role in our metabolic functions. We could not live without it. Now fat in the diet is a somewhat different matter. It is also omnipresent. It is in every food we eat. The fat needed in the body can also be formed from the carbohydrates in the diet. Fat in the body does not have to come from high-fat foods.

### **I like salads, but I couldn't make a meal out of them unless I add salad dressings. Aren't there some acceptable salad oils?**

The only acceptable oil for a salad is the oil as it naturally occurs in the complete wholesome food. When you use extracted vegetable oils, you are coating all your foods with a layer of rancid fat. Free oils are simply too unstable and fragmented to be used safely.

There are, however, some acceptable alternatives. I would first suggest eating a small amount of nuts or seeds or avocado along with your salad. By adding a small amount of these high-fat foods, a salad can give you the "full feeling" which is caused by the slow digestion of the accompanying fats. The second alternative, while not as good, is to blend a few nuts or seeds or avocado with a tomato and/or a small amount of distilled water. This

makes an acceptable salad dressing substitute if used immediately after making.

### **Nuts and seeds are hard for me to digest. How can I get my fats?**

By eating a calorie-sufficient diet of wholesome foods. It is not necessary to eat high-fat foods to obtain fat in your diet, nor should we feel obligated to eat any foods, even wholesome foods, because of some particular nutrient value. Eat only what you can relish and digest. Many Life Scientists go for months without eating high-fat foods, especially during the warmer seasons.

### **I'm underweight. Shouldn't I eat high-fat foods to gain weight?**

Many underweight problems arise from metabolic instead of dietic problems. Fats are difficult to digest. If your powers of digestion and assimilation are somewhat weak, as is often the case with underweight people, fats are not good foods to eat. The best foods for weight gain are not the high-fat foods, but the high-carbohydrate foods. Sweet fruits such as bananas, dates, figs, grapes, raisins, etc. are the best high-carbohydrate foods for weight gain.

Fats play a variety of roles in the health of the body. Most diets today have an excess of fats, which contributes to a number of diseases and problems. The fat intake in a diet should be limited as much as possible.

A deficiency of fats in the diet is a nutritional rarity. Usually this can only occur after a period of nutrient starvation or from a metabolic impairment. Fats are present in every food we eat.

High-fat foods are difficult to digest and should be consumed in small quantities. Only wholesome high-fat foods should be eaten at all. This means that no animal fats, free oils or heated fats should ever be included in the diet.

A diet consisting chiefly of fruits and vegetables eaten in their natural state, possibly supplemented by moderate amounts of seeds and nuts (at separate meals) can supply us with all the fats we need and optimally meet our other nutritive needs as well.

[Home](#) > [Lesson 11 - Fats In The Diet](#) > Article #1: A Natural Diet And Sunlight Could Save Your Life  
By Dr. Zane R. Kime, M.D.

### **Article #1: A Natural Diet And Sunlight Could Save Your Life By Dr. Zane R. Kime, M.D.**

*A leading physician with a degree in nutrition offers some guidelines for the optimal diet—a diet which can actually reverse some of the ailments associated with aging.*

Several research centers here in the United States have been developing a diet that can reverse hardening of the arteries (atherosclerosis). Some authorities now believe that this same diet may dramatically aid in prevention and treatment of heart disease, appendicitis, diverticular disease, gallstones, hypertension, varicose veins, deep vein thrombosis, pulmonary embolism, hiatus hernia, hemorrhoids, certain types of cancer, colitis and obesity.

This diet is a very natural diet. It is a vegetarian diet. It is low in fat and protein and high in complex

carbohydrates such as potatoes, beans, corn, fresh fruit and most other unprocessed foods. Refined foods should be eliminated.

A natural food is one that comes with all its bulk and all its fiber plus all the vitamins and minerals. The vitamins and minerals are there to help metabolize and digest the natural food. Nature intended that we take in the bulk and the fiber plus the vitamins and the minerals and other nutrients all together to have a harmonious nutritional balance.

Foods that are not natural and not included in the diet include those that have been processed or have passed through a chemical factory. Examples abound. A walk through any supermarket will reveal aisle upon aisle of highly refined, overprocessed foods which, unfortunately, are the mainstay of the American public's diet. The most prevalent, of course, are white sugar and refined (white) flour.

Once part of a natural food, sugar cane or sugar beets, refined sugar is almost universally used in processed foods. The health consequences of sugar consumption are well known. But while less visible, its more subtle effects are equally insidious.

## **Protein**

The Standard American Diet (SAD) also contains too much refined protein. Meat, as a "prime" example, contains lots of protein, but little else. It is a concentrated food, but not a particularly good one in terms of overall balance. Many other products advertised as "high in protein" would also fall into this category of overly refined foods. This includes all protein supplements.

Quite simply, a diet of complex carbohydrates—beans, grains, fruits and vegetables—will provide sufficient protein (and indeed superior nutrition) for an adult. The protein scare is a lot of hype. It is not necessary to supplement a natural foods, vegetarian diet, as it is virtually impossible to get a protein deficiency if one is eating enough calories. It is not necessary to complement amino acids in every meal if one is eating a variety of whole natural foods in a day's time.

Oil is another example of food that is refined no matter what its process of extraction is, since it no longer is a whole food. The oil is an extract of a vegetable or animal product in which all the bulk and fiber are removed, plus many of the vitamins and minerals. All that is left is a pure chemical that is classified as a triglyceride. Numerous diseases now are being recognized as associated with too much oil in the diet, and this includes sesame, safflower, soy, olive and other commonly used oils. It takes many ears of corn to produce one tablespoon of corn oil. Essential fatty acids are needed in the diet but can be adequately supplied by whole grains, nuts, seeds and legumes where they are in a water-soluble form. The oil in a nut, for example, is water-soluble; the extracted oil from a nut, no matter how it is processed, is no longer water-soluble. The body seems better able to utilize properly the oil in its water-soluble form, but seems to have serious complications with the non water-soluble, extracted, refined form. The association of a diet high in oil—whether saturated or polyunsaturated—and disease is actually well documented, though this is not well known to the public.

## **Heart Disease**

The average American has a cholesterol level somewhere between 150 and 300 mgm. percent. The average American also has a very high rate of heart attack, stroke and other chronic degenerative diseases. The World Health Organization, in studying many developing countries, has found that their cholesterol levels are much lower than this American average. Many developing countries have cholesterol in the area of 90 to 120 mgm. percent. It is the feeling of some authorities that cholesterol levels of about 140 can begin to produce hardening of the arteries.

To reverse or prevent hardening of the arteries, a low-fat diet is necessary. A diet low in fat means that it is low in all fats—saturated, unsaturated and polyunsaturated. This would eliminate from the diet many of the products that are highly advertised and can be bought in most any supermarket, such as margarine,

mayonnaise, oils, most of the salad dressings, butter fat as found in most of the dairy products, and egg yolks.

Meat is very high in fat, at least 44%. Commercially processed nut butters should be minimized in the diet, as they have been so finely ground that the oil has separated from the original nut and therefore is no longer in its original water-soluble form. It would be acceptable to eat nut butters if one were able to grind them less finely in order that there be no separation of the oil from the nut being used, whether almond, sesame, cashew or peanut (a legume).

Many of the harmful effects of saturated fats also appear when polyunsaturated fats are used. In addition, the polyunsaturated fats have many of their own harmful effects. Some people still believe that polyunsaturated oil is good because it lowers the cholesterol level in the blood. Indeed, many doctors even prescribe tablespoons of corn oil or other types of oil every day to help lower blood cholesterol. Polyunsaturated fats will indeed lower the serum cholesterol. According to research done by Dr. Scoll Grundy, it moves the cholesterol from the bloodstream into the tissues, where it's more harmful.

Dr. R.A. Swank from the University of Oregon has published a number of studies showing the effects of fat in causing the red blood cells to stick together. After feeding some hamsters a meal of cream, he noticed that the little red blood cells started sticking together. They would not pass through the capillaries, but would block them off. Since the red blood cells carry oxygen to the tissues, he also found there to be a great decrease in oxygen in the tissues. Following a high-fat meal, the oxygen content of the tissues of the brain was measured and found to be markedly decreased.

Dr. Meyer Freedman found that both saturated and unsaturated fats caused this sledging or sticking together of red blood cells. His article in the *JAMA* stated that substitution of the unsaturated for the relatively saturated fats did not lessen the interference in capillary blood flow. If such interference in the flow also occurs in the critically important collateral vessels of the coronary circulation in cardiac patients, then the ingestion of unsaturated fats could lead to disaster as readily as ingestion of saturated fats.

In another article in *JAMA*, Dr. Peter Kuo described a study he had conducted on patients who had angina pectoris. This is a pain in the chest that is caused by a lack of blood supply to the heart. He took fourteen patients and fed them a high-fat meal. All of his patients had angina, but it was an intermittent thing and was easily controlled by their heart medications. However, after the high-fat meal, these patients all experienced a tremendous increase in chest pain, and they actually had changes in the electrocardiograms and their ballistocardiograms.

Some have recommended unsaturated oil as a treatment for heart disease. Dr. G.A. Rose of England studied a large group of people in which he added corn oil to their diets to see if this would protect them from developing heart disease. His study concluded that corn oil cannot be recommended as a treatment of ischemic heart disease and that it is possibly harmful.

Supporting this theory was an article in the *American Heart Journal* stating that polyunsaturates have increased in the average American diet almost threefold over the past three decades without the slightest decrease in heart disease mortality.

The National Heart and Lung Institute admits that any difference in the effects of saturated versus polyunsaturated fats in heart disease is strictly intuitive, and based only on personal impressions and fragmentary conclusions with unscientific proof.

The Food and Drug Administration has gone on record saying, "It is a violation of the law to make any claim that polyunsaturates could prevent or treat heart disease." Several researchers have shown that polyunsaturated fat will inhibit the white blood cells.

Other researchers have observed native people who drank lots of milk which contained its own butterfat in the form of cream (although it rises to the top, it still is water-soluble); they nevertheless had low cholesterol counts. Another group of people were subsequently studied substituting a cube of butter each

day for its equivalent in milk ' (one cube of butter for two quarts of milk). The result was a rise in cholesterol. The solid form of the butter was no longer water-soluble.

In November 1977 Dr. Howard of the University of Cambridge published his studies on cholesterol and dairy products in *Lancet*. He concluded that of all the dairy products only butter raised the cholesterol levels when ingested.

The theory then might be formulated, based on Dr. Howard's study, that cholesterol in its water-soluble form does not raise cholesterol levels. In order to check this, a series of experiments was performed at a small college. Following are the tests and results:

Eighteen young men on a natural vegetarian diet of vegetables, fruits, legumes, nuts, seeds, avocados and whole grain were checked for their cholesterol level which was 120 to 300.

They were then divided into three groups.

- Group I continued their natural vegetarian diet.
- Group II continued their natural vegetarian diet and added two eggs (hard or poached).
- Group III continued their natural vegetarian diet and added two eggs (hard or poached) and margarine.

Five weeks later, the results were:

- Group I cholesterol same.
- Group II lower, but no difference statistically.
- Group III cholesterol rose to 170, with some over 200.

As mentioned before, some authorities feel that cholesterol above 140 can begin to produce hardening of the arteries. The above study may therefore be significant in explaining why lacto-ovo vegetarians may develop hardening of the arteries.

Although lacto-ovo vegetarians have lessened their risks of heart diseases and hardening of the arteries due to omitting meat in their diet, they nevertheless would improve their risks by eliminating or at least minimizing some of the dairy products such as butter, as the fat is no longer in its soluble form.

On the other hand, neither is milk desirable, especially regular commercial milk, because it has been pasteurized and homogenized at high heat and enriched with vitamin D (which is really a hormone, like a steroid). Protein-fortified milk is especially undesirable, as it has been fortified with dry milk, and even nonfat milk contains cholesterol.

Cholesterol oxidizes when dried, and it may actually produce cholesterol. Dried milk or any dried animal product should be omitted from the diet.

## **Gallstones**

Prairie dogs have been used to study the effects of different types of fats and cholesterol in producing gallstones. On a high-fat diet, the prairie dogs seemed to develop gallstones easily. When they were placed on a diet that was low in fat and cholesterol, the gallstones dissolved.

Gallstones in humans do not seem to be limited to high saturated fat content in the diet. Dr. R. A. L. Sturdevant reported a significant increase in gallstones in men fed a diet that was rich in safflower oil. Dr. T. Osuga wrote that corn oil alone, without cholesterol in the diet, produced gallstones.

## **Cancer**

According to Dr. R. K. Boutwell, the stimulating effect of fat on the rate of formation of certain types of tumors is well established. Dr. Pickney, previously mentioned in regard to polyunsaturates in the diet and its relation to heart disease, also wrote about the epidemiologic association between a diet high in

polyunsaturates and the increased incidence of cancer, especially gastric, in humans. He discussed his research in the *American Health Journal* showing that 78% of the people who used more polyunsaturated fat also showed marked clinical signs of premature aging. In addition, they looked much older than their chronological age. In the same group, 60% reported that they had had at least one or more skin lesions removed because of suspected malignancy after having altered their dietary fat.

Dr. Ernest Winder of the American Health Foundation states that both epidemiologic and animal data suggests that colon cancer is due largely to high fat consumption. (Refined foods lacking in bulk and fiber also have been linked to bowel cancer, and studies made in Japan have correlated high fat diets with cancer of the breast in women—Veg. Times Ed.)

Dr. Bauman, in the *American Journal of Cancer*, showed that an increase in the fat content of the diet accelerated the appearance of tumors caused by ultraviolet radiation. Dr. Bausch repeated the study using corn oil and got the same results. Ultraviolet light is found in sunlight. The current understanding is that excessive exposure to ultraviolet light is responsible for skin cancer, when in fact, as these studies show, the true culprit may be a high-fat diet in combination with ultraviolet light.

Fats turn rancid in the tissue. Fats that are oxidizing damage the tissues, thus stimulating cancer (and aging of the skin). Oxidation is prevented in nature with vitamin E in its natural state: in nuts, whole wheat, seeds, legumes, etc. Vitamin C, carotene and selenium also help.

Unsaturated fats eventually turn rancid due to air, heat and sun. All the elements are present when refined polyunsaturated oils are in the tissues: the heat and oxygen are provided by the body and the sun's ultraviolet rays accelerate the oxidation of the fat in the body. Without the oxidation of rancid fat in the tissues, the sun is beneficial for a healthy body.

Exposure of the body to the sun is vital for optimum health. It is a natural source of vitamin D (which is different from that artificially ingested as an additive in milk). Most times of the year as little as about fifteen minutes exposure on the face will give more than the recommended daily amount. Contrary to popular belief, vitamin D can be stored in the body. Even on cloudy or foggy days, 80% of the ultraviolet rays come through; however, the rays are blocked entirely by glass windows. Nevertheless, special glass can be ordered called UV-Passing Plexiglass that is very good.

## **Obesity**

In a natural diet where no sugar or fat of any kind is added, obese people will lose weight even though they are eating all they want. They are allowed to have potatoes, rice, bread, fresh fruit and any other natural food in any quantity that they want. However, they should restrict the amount of avocados, olives and nuts that they eat on this diet. There are built-in safety factors in the natural food provided for us that prevent us from becoming obese.

Our bodies are designed to eat a low-fat diet. When we add extra fat to the natural diet, we start to gum up the beautiful machinery we were given. There is an abundance of natural fat in the unrefined grains, legumes and other vegetables that more than meets our need for fat in the diet. It is impossible to get a fatty acid deficiency if whole grains, legumes and other vegetables are included in the diet; it is not necessary to add any extracted oil to provide the fat that is needed in the diet. Because our bodies were designed to eat a low-fat diet, a high-fat diet will cause nothing but trouble, whether the fat is of animal or vegetable origin. Probably the biggest proof we have that a low-fat diet is essential is the miracle that happens in patients' lives when they are placed on a diet free from margarine, mayonnaise, grease and oil of all kinds.

Diseases that are caused by arteriosclerosis are markedly proved. The world of medical research is only now discovering the tremendous power in a natural vegetarian diet.

*Editorial Note: Grains and legumes are not needed in the diet to assure enough fat and essential fatty acids. Fruits, nuts, seeds and avocados all contain plenty.*

## **Article #2: Fats In The Diet By Marti Fry**

The subject of fats in the diet is one that receives little attention, especially compared to the attention it should receive! Along with refined sugar and flour chemicals, all of which are very antivital and disease-causing, fats should be listed. This is not to say that all fats are very toxic. But it is to say that the only ones that aren't are those contained in raw (uncooked, unheated) natural foods to which humans are biologically adapted to eating—avocados, nuts and seeds plus all fruits and vegetables recommended in the Life Science diet.

When considering toxic substances that are eaten, the reason most fats should be included as toxic is because all fats become highly carcinogenic when heated. Even rancid fats, as in stale nuts or seeds, are harmful and should not be eaten. Nuts or seeds should never be eaten roasted, either.

Atherosclerosis, heart disease, cancer, senility and arthritis are just a few of the most serious diseases with which many Americans (and people the world over) are plagued. These diseases would not have become a problem to anyone if our people had not eaten heated fats and oils. Frying is the worst way to cook foods, though all cooked foods are pathogenic. Remember: All foods contain some fat. Therefore, any food that is cooked, even if it's not fried, contains a carcinogen—heated fat. This is one of the most serious of the many problems with cooked foods.

### **High-Fat Foods In The Diet**

A question not raised by most Life Scientists is whether we really need high-fat foods such as nuts, seeds or avocados in our diet at all. Our need for fats is so low, and the presence of fats in all foods so ubiquitous, that it is likely that we would fare better if we would not include nuts, seeds or avocados in our diet.

Yet, Hygienists recommend up to four ounces of nuts or seeds or one avocado per day in the diet.

### **Why?**

For one thing, they are delicious raw. Secondly, and most important, they are very satisfying, keeping the sensation of hunger away for a longer time than other fruits or vegetables.

Many people, including some Hygienists, have difficulty digesting nuts and seeds. Most have little or no trouble with avocados. This could be, as one professional Hygienist has stated, because most of us have weakened digestive capabilities as a result of so many years of wrong eating and living practices. In any event, no conclusive statements can be made at this time. More research would perhaps be in order.

It is certain that humans can fare well without high-fat foods in their diet. But is it practical? Can people feel satisfied without including either oils (fats) or starches in their diet? Can a diet of nonfat and nonstarchy foods satisfy? If it can meet our needs—which there is no doubt it can and does—then it follows that it should satisfy. Perhaps it would take months or years for a person to become accustomed to this type of ideal diet.

This is an area that will warrant further study by professionals in the field. One thing you can be sure of, however, is that the amount of fat needed in the diet is extremely small and should be met only from raw foods. No foods should be eaten that will leave an oily film on a plate or bowl that will not wash off with water and a cloth or sponge—without any kind of soap or detergent. That is to say that only water-soluble oils should be consumed. These are the only oils that will not cause diseases in the human body.

For a long and healthy life, keep your fat consumption to a minimum; consume only water-soluble fats; and stay away from free oils and nut butters except those you make fresh yourself without adding free oils. You'll be many times further ahead healthwise than the lacto or lacto-ovo vegetarians who still

consume many foods that are in many ways as harmful or almost as harmful as animal flesh. You will become healthier than you've ever been in your entire life!

[Home](#) > [Lesson 11 - Fats In The Diet](#) > Article #3: Are We Oil And Fat Eaters By T.C. Fry

### **Article #3: Are We Oil And Fat Eaters By T.C. Fry**

It is well known that most meat eaters trim the fat off meats because they have an aversion to it. This is not without a sound physiological basis.

However we witness millions eating foods fried in oils and fats. Millions eat foods smothered in oils, butter, margarine and other fats. Oils and fats constitute about 40% of the American caloric intake.

For this heavy indulgence Americans pay dearly. Indigestion is an American institution. Pathogenic effects are rife. It is said that 50% of all American meals result in indigestion. Antacids are a multi-billion dollar business. At the door of oils and fats can be placed much of the blame.

Humans are constitutionally frugivores. All the fats needed in the human system are self-created from the raw materials furnished by carbohydrate foods just as cattle elaborate their fats from a grass diet. It is not necessary that humans eat oils or fats of any kind to have the body oils and fats necessary for great well-being. One of the chief complaints of many who eat sugar and wheat products is that it turns into unwanted fat, thus indicating how efficiently our organisms convert carbohydrates to the oils and fats we need.

Fruits we digest with dispatch, efficiency and comfort. Most are discharged from the stomach in from 10 to 30 minutes, whereas oils and fats lay heavy on the stomach for hours before digestion really begins.

To be sure, our diet can profit from certain foods with an oil content. From nuts and seeds we can obtain the linoleic and linolenic acids that we need. But if nuts, seeds and avocados constitute a mere 1 1/2% to 2% of our diet, that is ample.

Professional Hygienists point out that the body's needs for oil are very small. All condemn free oils, that is, oils out of context with the food in which nature developed them.

Most Americans eat oils and fats with foods that are of a differing digestive character than oils. In the combination of bread and butter or bread and margarine or bread and peanut butter—quite common combinations, the bread requires an alkaline medium for its digestion. Within two or three hours starches are usually ready to pass into the intestinal tract for appropriation. Fats and oils usually do not begin to digest until about the fourth hour.

Hence, when oils and fats are eaten with other foods such as starches they coat the food particles such that little or no digestion results, but indigestion does! By the time the oils or fats surrounding the other food particles are digested, the starches and sugars are food for bacteria instead of us. Bacteria convert carbohydrates into poisonous acids (especially acetic) and alcohol. Our stomachs become a fermenting mess. Caustic bicarbonates end the process by killing off the bacteria and neutralizing the acids.

But this is merely a first step in a chain of problems. Indigestion is bad enough, and employing antacids begets yet other problems. Fats degenerate into butyric and other acids. This begins a long train of pathology that can exhibit as inflammations, ulcers and eventually cancer. Rashes, pimples, biliousness, a "tired feeling" and other complaints are often a direct result of a heavy oil or fat meal.

Fats are often in association with cholesterol, another form of alcohol. We create this in our bodies for our own needs, but we cannot handle foreign cholesterols as true meat-eating animals do. To be sure, cholesterols are found only in animal fats such as cheeses, butter, eggs, meat and animal products such

as milk, ice cream, etc. When the cells reject alien cholesterol, it combines with blood contents, especially wastes and inorganic minerals, and forms plaque in the circulatory system.

Free oils and fats are a disaster in the human digestive tract no matter how eaten. Oils on salads, popcorn, bread and other foods (most of them unwholesome in themselves) interfere with digestion as heretofore stated.

When we eat fried foods, we are invariably inviting disaster. Even before eating such foods, the heat of cooking has converted some of the fats or oils to acroleic acid (or it has become acrolein) which is deadly poisonous and carcinogenic in humans. Fats in animal foods are always bad for us. Oils in vegetable and fruit foods should be eaten rarely, say not more than once every two or three days. We handle nuts, seeds and avocados fairly well, but our need for them is small. Further, great caution must be employed in eating such foods. Always eat them with vegetables, never with foods that contain a carbohydrate complement. Tomatoes, cucumbers, celery, cabbage family members and green leafy foods such as lettuce combine best with these oil-bearing foods.

It is noteworthy that legumes are heavy in oil but, once beans and pulses are sprouted, their fat content is converted into easily digestible vegetable matter.

There is no truth to the widely circulated belief that oils are good for dry skin. In digesting oils and fats, the body converts them to sugars anyway. Then it reconstitutes them to its specific needs in the body's own chemical factories. Thus dry skin is the result of impaired function of the sebaceous glands, not a lack of oil in the diet.

Oily foods should not be used as fuel foods. Carbohydrate foods serve us amply in this regard. Loading up on oily foods will not enhance the performance of athletes or manual workers. Their need for the oils and proteins of concentrated foods such as nuts, seeds and legumes are no greater than for sedentary people. It is well to repeat again that carbohydrate foods supply this best, and fruits are our most wholesome and efficient sources of carbohydrates.

Only one meal in any given day should contain a heavy oil-bearing food. And only one concentrated oil-bearing food should be eaten at a meal. Thus, if you eat an avocado with a salad, your oil license for the day has run out. If you eat two to four ounces of nuts or seeds with a salad, your oil license has expired, not only for the meal, but for the day.

Studies have shown that peanut oil is more "atherogenic" than even cream from cow's milk in inducing arteriosclerosis in monkeys. It has been suggested that free oils actually promote the deposition of cholesterol and other lipids in the arterial walls.

Proceed with caution with oils. Never eat them outside of their natural context and then eat them in restriction as above noted.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 1. Acid-Base Balance

### 1. Acid-Base Balance

When we talk about acid-base balance, we are referring to the pH balance (degree of acidity or alkalinity) of substances or of the body. The symbol pH is used after numbers that measure the degree of the acidity or alkalinity of solutions. The acidity or the alkalinity of a solution is determined by the number of *hydrogen ions* ( $H^+$ ) it contains. The smaller the pH value of a solution; that is, the smaller the number preceding the symbol *pH* is, the greater is the acidity of that solution. Likewise, the larger the number in front of the symbol *pH* is, the greater is the alkalinity of the solution.

Any neutral solution, such as water, will have a pH value of 7.0. Solutions which have a pH value below 7.0 are acidic in nature. Solutions which have a pH value above 7.0 are considered to be alkaline, or basic.

The human body must continuously deal with many different substances in the bloodstream. Each substance has a range of concentration which can vary within certain limits without creating an imbalance of normal bodily functions. Certain substances, such as blood glucose, can vary up to 200%, while certain other substances, such as blood calcium, are constricted to a much narrower range of deviation.

The balance in the blood of acidic and alkaline components can be only moderately altered without creating a very serious physiological instability. Therefore, it is crucial that the body, while controlling degrees of pH in organs, glands and other areas of the body, simultaneously maintain this strict range of balance in the pH of the blood. The following chart best illustrates the pH ranges of different areas of the body:

Body Area	pH Value
Gastric Juice	0.9

Gallbladder Bile	5.4-6.9
Urine	6.0
Saliva	6.3-6.8
Feces	7.0-7.5
Intestinal Juices	7.0-8.0
Pancreatic Juices	8.0

The blood is slightly alkaline, with a pH of 7.35 to 7.4. Many of the enzymes that facilitate metabolic reactions operate optimally only in solutions of specific alkalinity. When there is a deviation from this level of alkalinity, whether higher (referred to as alkalosis), or lower (referred to as acidosis), severe malfunctions can occur. These malfunctions are manifested by slower enzymatic reactions, and thus a decrease in synthesis of specialized molecules, such as vitamins, proteins, etc. There is also an impairment of the production of ATP molecules that are needed for energy and are made from glucose.

The major effect of acidosis is disorientation due to the depression of the central nervous system. Inversely, the major effect of alkalosis is extreme nervousness, eventually leading to convulsive reactions, namely tonic spasm. This spasm is referred to as *tetany*, and usually develops primarily in the musculature of the forearm and face, then spreads over the muscular system of the entire body. Tetany results from over-excitability of the central and peripheral nervous systems due to alkalosis.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 2. Body Maintenance Of Normal pH

## 2. Body Maintenance Of Normal pH

In order to maintain a proper pH in the bodily fluids, and so that acidosis or alkalosis will not manifest, three major physiological control systems exist within the body. The first mechanism involves a buffer system for the hydrogen ion fluctuations. All bodily fluids are supplied with acid-base buffers which combine with any acid or alkaline substance and prevent excessive change in the hydrogen ion concentration.

Another mechanism the body uses to maintain normal pH is within the respiratory system. When the hydrogen ion concentration ( $H^+$ ) changes measurably, the respiratory system is immediately stimulated to alter the rate of pulmonary ventilation. This brings about a change in the quantity of carbon dioxide ( $CO_2$ ) within the system. High levels of carbon dioxide in the system, as created when holding the breath or due to physiological impairments of respiration, increase the acidity of the bloodstream. Any disease that interferes with normal breathing, such as emphysema or asthma, will impede the release of  $CO_2$  from the lungs and, subsequently, this  $CO_2$  will combine with water to form carbonic acid. This increases the concentration of hydrogen ions, and thus the acidity of the blood is simultaneously increased.

The last of the three major physiological control systems of the body to maintain normal pH involves the

kidneys. When the (H + ) (hydrogen concentration) deviates from a normal value, the kidneys excrete either an acid or alkaline urine. This serves to help readjust the (H + ) of the bodily fluids back toward the normal value.

The key point to keep in mind when you are trying to understand the terms acidosis and alkalosis is that, as was previously mentioned, when the hydrogen ion concentration (H + ) is above normal, there is a state of acidosis and when the (H + ) falls below normal, we have alkalosis. If either acidosis or alkalosis occur within the bodily fluids, the buffer systems; namely, the lungs and kidneys, the organs that influence the acceptance or excretion of hydrogen ions, will attempt to regulate the imbalance. In a normal, healthy individual, any increase or decrease in (H + ) will be modified so that the pH of the blood does not fluctuate from its normal range of 7.35 to 7.45. If, however, either the lungs or kidneys fail to function properly, the end result is often acidosis or alkalosis.

Acidosis and alkalosis both have numerous causes. As mentioned above, one or more of the body's buffer systems may be impaired in some way. Thus, acidosis or alkalosis may occur. Also, acidosis or alkalosis may result because of improper respiration (breathing), improper diet or both.

An example of respiratory alkalosis is when a person ascends to a very high altitude and proceeds to overbreathe because he is aware of the low oxygen content in the air. This overbreathing results in an excessive loss of CO<sub>2</sub>, referred to as a mild state of respiratory alkalosis. If such a situation persists and the individual fails to acclimate, eventually the balance of acid and alkalinity in the blood may be altered.

Both diarrhea and vomiting are considered to be some common causes of metabolic acidosis. During diarrhea, large amounts of sodium bicarbonate, an alkaline substance, are secreted from the gastrointestinal tract; and during vomiting, there is a loss of alkaline substances deep within the gastrointestinal tract.

However, diarrhea and vomiting are processes the body uses to speedily eliminate highly toxic materials from the body so these toxins cannot harm the tissues. Diarrhea and vomiting are not themselves causes of acidosis. Rather, they result from the same offending substance(s) that the acidosis results from.

It is important that you understand that body actions to expel toxic materials (acute illnesses, so-called "infections," fevers, etc.) are not harmful processes. What is harmful is what occasioned the body to perform in such an expedient manner.

As students of Natural Hygiene, you must realize that the pH balance within the body is a result of the entire physiology of the body working in harmony. So, while this lesson will deal primarily with dietary influences on pH, be aware that you must utilize all areas of Natural Hygiene. This includes not only diet, but also pure water, fasting, exercise, fresh air, sunshine and mental poise. All of these must be integrated to form a lifestyle which can allow the body to carry out its physiological duties as effectively and efficiently as possible.

To sum up what we have discussed in this section, the pH in the blood and tissues is directly related to the concentration of (H + ) within the body. This range and balance of pH in the bodily fluids is quite narrow and delicate. Even slight deviations from these values can lead to major physiological complications. Several mechanisms, as expressed by *McNutt's Nutrition and Food Choices*, regulate this intricate balance.

1. Excretion or retention of ions by the kidneys.
2. Exhalation or retention of CO<sub>2</sub> by the lungs.
3. Metabolic production of acids by the tissues.
4. Concentration of proteins in the blood.

We have already discussed briefly these first two mechanisms. In order to understand the latter two, we must begin our study of dietary influences upon the body's acidity and alkalinity.

### 3. Acid And Alkaline In The Diet

When nutritionists talk about acid- or alkaline-forming foods, they are referring to the condition of the food after ingestion. There are many food substances which are acidic in their natural form that become alkaline when broken down within the body.

A physical description of an acidic substance would be "sour or sharp to the taste buds." Litmus paper is a simple means to determine whether a substance is acidic. Acidic substances such as vinegar, lemon juice, grapefruit juice, tomato juice, tea, coffee or sour milk will all turn blue litmus paper red. The red coloration is an indication of the substances acidic characteristics. Alkaline substances, on the other hand, will cause red litmus paper to turn blue. However, when acid and alkaline substances are mixed together, they neutralize each other, forming water and salt.

Generally speaking, the metabolic processes of the breakdown of foods from the vegetable kingdom change in character from acidic to alkaline, while the foods from the animal world change from alkaline to acid during metabolism.

All foods contain within them a combination of both acid-forming and alkaline-forming elements. The particular influence a food will have on pH will be determined simply by which elements are dominant, the acid elements or the alkaline elements. These elements, when broken down, will either release (H<sup>+</sup>) ions, and thus create an acidic medium, or they will accept and combine with (H<sup>+</sup>) ions, creating an alkaline medium.

Keep in mind the following basic concepts:

1. Organic matter is taken into the body in the form of food.
2. This organic matter is broken down into simple compounds (monosaccharides, amino acids, lipids etc).
3. After metabolism, these compounds leave an acidic or alkaline residue in the body.
4. The simple compounds contain elements such as sulphur, potassium, sodium, magnesium and calcium. These minerals determine the H<sup>+</sup> concentration and thus the acidity or alkalinity of the body.

These elements are either acid-forming elements or alkaline-forming elements. The acid-forming substances are sulphur, phosphorus and chlorine, while the alkaline formers are sodium, potassium, calcium, magnesium and iron.

Most proteins contain sulphur, as well as phosphorus, within their chemical structures. When metabolized, these substances are broken down into phosphoric acid and sulphuric acid, which must then be neutralized through various chemical reactions. Another by-product of protein metabolism is uric acid. (Uric acid has been found to have a major influence on the development of arthritis; in particular, gouty arthritis.) Uric acid must be neutralized and excreted from the kidneys. Because of these toxic by-products of protein metabolism (phosphoric, sulphuric and uric acids), and for many other reasons not mentioned here, protein foods, and especially animal products, are acid-forming. Most grains and dairy products, also high in protein, are, like meats acid-forming.

Within the plant kingdom, the organic acids found in fruits and vegetables are metabolized and eventually become carbon dioxide and water. The alkaline elements such as potassium, calcium, sodium and magnesium remain. Although many fruits are acidic in nature, when broken down into their constituent elements, the acids are rendered neutral and the alkaline elements are dominant. Therefore,

the end result of the organic breakdown and digestion of fruits and vegetables is alkaline in nature.

Since we are constantly supplying acids and alkalies to our bodies through the various foods we eat, it is very important that we consider the balance between these two extremes. If we consume excessive amounts of acid-forming foods, such as animal and dairy products, the body must tap its alkaline reserves (buffer salts) in order to maintain the proper pH. The kidneys, lungs and entire physiology is overworked in the process of excreting the neutralized acids from the body. This strain eventually leads to a depletion of buffer salts and the breakdown in the physiological functions of various organs, including the kidneys. Many different organ malfunctions are referred to as "disease," while the underlying cause, acidosis (due largely to faulty diet), has been overlooked. The point to keep in mind is that any food, drug or condiment that is extremely acidic in nature utilizes alkaline reserves and overworks the various organs. This type of dietary abuse may be tolerated for a period of time, but eventually the body will no longer be capable of handling this overload and will slowly begin to break down.

Following is a reference list categorizing some common foods as being either acidic or alkaline within the body.

*ACID FORMERS*

Most Grains	Fish*
Beef*	Cheese*
Poultry*	Eggs*
Most nuts (walnuts, pecans, brazils)	
Most legumes (peanuts, lentils)	

(\* Not wholesome foods)

*ALKALINE FORMERS*

Vegetables	Fruits
Greens (lettuce, spinach, etc.)	Citrus fruits
Carrots	Bananas
Tomatoes	Melons
Potatoes	Strawberries
Celery	Apples
Cabbage	Apricots

Broccoli	Figs
Beets	Dates
Sprouts	Plums
Peaches	Pears

Foods that are beneficial in maintaining body pH are fruits and vegetables (preferably in their raw form), plus unprocessed nuts and seeds.

I have refrained from giving you a complete list of all the specific acid and alkaline-forming foods, because this author feels that it is most important for you, as a student of Natural Hygiene, to grasp the major concepts and apply them to your life. Please refer to *Composition and Facts About Foods* by Ford Heritage for more specific details.

The following rules will supply a conceptual basis from which to apply the dietary philosophy of Natural Hygiene.

#### *FOODS TO AVOID*

- a. All animal foods.
- b. Dairy products, including milk, yogurt and cheese.
- c. Vinegar and various condiments.
- d. Drugs (acidic and alkaline).
- e. Refined and processed foods. (Many alkaline elements have been removed.)
- f. Fats. (found in both meat and dairy products.)
- g. Teas, coffee, cocoa and chocolate.

#### *FOODS TO EAT*

These should be fresh and unprocessed.

- a. Uncooked vegetables.
- b. Fresh fruits.
- c. Unroasted nuts and seeds.

If you simply follow these rules, your body will benefit from a diet rich in all the essential proteins, fats, carbohydrates, vitamins and minerals. It will do this without having to deal with foods that deplete alkaline reserves and simultaneously overwork the buffer systems and organs of the body. These simple rules, combined with all the other areas of Natural Hygiene, will insure a condition in which your body can maintain a balanced state of health and well-being.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 4. Acute Conditions Involving Acid Alkaline Imbalances

## **4. Acute Conditions Involving Acid Alkaline Imbalances**

Every year the number of prescriptions written for acid-alkaline imbalances continues to increase. Antiacids, alkalizers, specific digestive enzymes, etc. remain popular as household "remedies" for many acute digestive disorders. The temporary relief experienced by these so-called remedies is interpreted by

the majority of sufferers as being a cure for the problem. Nothing could be further from the truth. These drugs work in much the same way as a lazy housecleaner sweeps the dust under the rug; that is, covering up the symptom, but not eliminating the cause.

Our bodies are like the rug in that they will only allow the drugs to cover up the problem for so long. Eventually, these acute digestive disorders will become chronic, resulting in a more difficult condition for the body to deal with. So, what was once simply a minor case of acid indigestion or heartburn becomes a major digestive ailment. The stomach, liver, small and large intestines, kidneys and pancreas can all be seriously impaired, both from consumption of an improper diet and from the use of drugs that cover up an overly-acidic diet and the, consequent indigestion.

Almost anyone who has been eating the standard diet of meat, dairy foods and refined and processed foods will suffer in varying degrees from an acid-alkaline imbalance. Add to this fare: alcohol, cigarettes, drugs and condiments, and the percentages will rise even higher. As a Hygienic practitioner, you will begin to witness miraculous results when working with people suffering from these acute imbalances.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 5. Case Histories Of Acid Indigestion Due To Improper Diet

## **5. Case Histories Of Acid Indigestion Due To Improper Diet**

### **5.1 Case #1**

A young female, age 26, came to my office complaining of a dull, aching stomach pain. This pain seemed to manifest whenever she ate a large meal. At times this pain would work its way up the esophagus, causing discomfort under the ribs and around the heart.

These symptoms, along with lack of vitality, occasional constipation and mood fluctuations, had been plaguing the patient for about eight months. Investigation into her diet indicated that she was consuming a great deal of dairy products and sweets. After placing the client on a short fast, her diet was changed to include mostly fruits, vegetables, nuts and seeds. I also put her on an exercise program. After three weeks, the client's pain had completely subsided and her vitality, mood swings and constipation had improved dramatically.

### **5.2 Case #2**

A male client, age 31, entered my office complaining of severe gas whenever he ate. He was also passing pieces of food in his stools, indicating an imbalance in the digestive juices. This condition has been going on for about three years and was gradually becoming worse. A case history showed that the client was consuming dairy products, refined sugar and some meats in excess, as well as combining his foods improperly.

The client was placed on a fast and then placed on a Hygienic diet with proper food combining. Gradually, over the next month-and-a-half, the client's condition improved to the point where his stools were normal and he was no longer experiencing his gas problem.

### **5.3 Case #3**

A 32-year-old female came to me complaining of multiple problems. She had been suffering from

bladder infections for over eight years. Along with this, she was taking allergy shots twice weekly and digestive enzymes to aid in her sluggish digestion. The client was unable to eat food without experiencing an "allergic" reaction and a flair-up in her bladder region. Her mood swings were radical, depending upon what she ate, and she periodically lost her ability to concentrate.

Her case history showed that she was eating a very inconsistent diet, rotating her foods to reduce allergic sensitivity to them. After a five-day fast the client was placed on a Hygienic diet and on an exercise program, and she began fasting one day a week. Within a month she was off her allergy shots and digestive enzymes. Her bladder was feeling much better, and within two months her symptoms had completely disappeared.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 6. The Acid-Alkaline Ratio In The Diet

## **6. The Acid-Alkaline Ratio In The Diet**

The body will maintain a proper pH balance at all times because it must do so for proper functioning. The organism is designed that way. In order to make the body's job easy—and so expend less energy and have more energy for other activities, the diet should consist of foods that have an appropriate acid-alkaline ratio, at least 80% alkali and not more than 20% acid.

This balance is maintained by the lungs, kidneys and buffer salts. However, to limit the wear and tear on the lungs and kidneys, and so as not to deplete the body's buffer salts, our diet should consist of foods that best match our organism's acid-alkaline ratio. A diet of fresh ripe fruits, along with raw vegetables and nuts and seeds, is optimum. The amount of nuts and seeds in the diet should, of course, be rather small relative to the less concentrated foods—fruits and vegetables. Also, the amount of vegetables should be smaller than the amount of fruits because fruits provide the calories we need, whereas vegetables do not.

Fruits should be eaten alone or with each other at a meal, and vegetables can be eaten at a meal with either nuts, seeds or avocados. An example of a menu that insures a good acid-alkaline balance is as follows:

*Breakfast:* Melon

*Lunch:* Grapes, bananas and dates

*Dinner:* Large vegetable salad of lettuce, tomatoes, avocados, broccoli and sprouts

The important point to keep in mind is that the alkaline-forming foods are the most natural and beneficial foods for humans. As a Hygienic practitioner, it is important to understand that even if some people will not completely adhere to a totally Hygienic regime, any improvement in the acid-alkaline ratio will be an improvement of their well-being.

## 7. Considerations When Working With pH Imbalances

When a client comes to you complaining of fatigue, nervousness, insomnia, hyperactivity, emotional swings, lethargy, frequent colds, abdominal discomfort, etc., it's fairly certain that part of their problem is an acid-alkaline imbalance. If this is the case, you, the Hygienic practitioner, must educate your client and help him to eliminate the causes of his problem. You should start out by explaining that the two major reasons for their particular problem are:

1. Too many concentrated proteins in the diet; that is, meat, eggs, milk, fish and cheese;
2. Overconsumption of foods that have been processed and refined and are thus deficient in alkaline elements.

It is important to explain the benefits of a more alkaline diet and how it is truly the only way to eliminate the cause of their problems.

The Hygienic practitioner should also take into consideration the client's overall vitality. If their digestive systems are in a weakened state, a fast may be in order. This will allow the organism to rest, get rid of toxins that interfere with normal functioning and to regain normal functioning abilities.

If a client complains that he or she suffers indigestion when he or she eats acid fruits such as oranges, grapefruits, pineapples, etc., he or she will benefit by fasting. People who have this difficulty have impaired digestive abilities due to past practices and diet. Again, a fast will enable the organism to regain normal functioning abilities.

Even if a client is unable or unwilling to fast for any reasons, he will still improve by staying on a healthful diet of fruits, vegetables, nuts and seeds. However, improvement will occur more slowly than if the client fasts. Nonetheless, as the client's condition improves, he will find it easier and easier to eat and enjoy these wholesome and delicious fruits.

If your clients will adhere to the basic Hygienic format, they will experience major transformations in their health and well-being. Not only will the major symptoms clear, but your clients will become increasingly disease-free and will find that the quality of their lives will dramatically improve. It is necessary that we preserve our pH at a level of maximum physiological efficiency, and this can be achieved easily through the Hygienic program.

The following is a sample of a basic three-day plan:

### DAY ONE

*Breakfast*

Oranges

*Lunch* A fresh green salad with romaine lettuce, broccoli, cabbage and tomatoes Dressing: either lemon juice or an avocado mixed with lemon

*Dinner* Fresh fruit salad of bananas, apples, pears and chopped pitted dates

### DAY 2

*Breakfast* Citrus fruit(s) or pineapple

*Lunch* Assorted sliced fresh fruits: bananas, peaches, apples, pears

*Dinner* 3-4 oz. Pecans Vegetable salad with tomatoes sprouts, celery, and lettuce

### DAY 3

*Breakfast* Grapes

*Lunch* Green salad with vegetables: romaine lettuce, cauliflower, broccoli, cucumbers and avocado with

lemon juice

*Dinner* Assorted sliced fruits: Apples bananas, cherries, mangos, nectarines, etc.

Eating raw foods can be fun! People forget what an assortment of delicious raw foods there are.

Keep in mind that you should always eat melons alone. There are so many different kinds of delicious melons: honeydew, cantaloupe, crenshaw, sharlyn, cassaba, watermelon. The body digests melons very rapidly, and thus many people find them to be the ideal breakfast food.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > 8. Questions & Answers

## 8. Questions & Answers

**I got the impression that the "acid-forming elements" and the "alkaline-forming elements" you refer to are particular minerals, the acid-forming ones being sulphur, phosphorus and chlorine and the alkaline-forming ones being potassium, sodium, calcium, magnesium and iron. Why is the study of acid and alkaline separate from the study of minerals?**

Your impression is correct. Also, your question is a good one. It is important to remember that the human organism is a whole entity, even though it is composed of various glands, systems, etc. Also, foods are whole, even though they are composed of carbohydrates, fats, proteins, vitamins and minerals. Yet, it is customary and convenient to study the various parts of the whole, always keeping in mind that the whole is greater than the total of all its parts.

The subject of acid and alkaline should have been at least briefly discussed in the lesson on minerals. But is an important and large subject that also warranted a lesson in itself. Hence, this lesson!

**You said to avoid refined and processed foods because these foods are lacking in alkaline minerals. Does this mean that refined and processed foods are acid-forming?**

No. Refined and processed foods are usually devoid of both the alkaline minerals and the acid minerals. This means they are more likely to be neutral than acid-forming in the diet. However, like the acid-forming foods, foods devoid of most minerals upset the acid-alkaline ratio of the body, but in a different way: Vitamins and minerals are needed for the metabolism and consequent efficient use of foods eaten. When carbohydrates are eaten, but the nutrients needed in their metabolism and utilization are not supplied in the way that nature intended, the body must draw upon its reserve supplies and then on the minerals in the bones and teeth. Since the body's reserve supplies are quite limited, consumption of refined and processed foods results in minerals being drawn from bones and teeth and in a myriad of health problems, from hypoglycemia and diabetes, to dental caries, osteoporosis, nervousness and depression.

The reason why the body does not keep a larger reserve of vitamins, minerals, etc. for metabolism of refined and processed foods is obvious: We are not naturally designed for eating fragmented foods; that is, foods that have had some components removed in processing or refining.

**People who advocate a macrobiotic diet claim that rice is the perfect food in that it best harmonizes with the body's needs as regards acid and alkaline. Yet the macrobiotic diet is entirely different from the Hygienic diet—and you do not advocate the use of rice in the diet at all! Please explain.**

In a diet based on grains, rice is one of the best of the grains as regards the acid-alkaline. Indeed, it is far less harmful in the diet than is wheat, the Western world's staple grain. In that regard, the macrobiotic diet is less harmful than the conventional American diet. In fact, the macrobiotic even has a few things in common with the Life Science (natural) diet: For one, neither dietary regime, in its pure interpretation, advocates sweeteners of any kind. Nor does either dietary school advocate dairy foods, eggs or meats (except fish, in the case of macrobiotics).

However, it must be understood that macrobiotics is based on tradition, economic lack and many false premises, whereas the Life Science regime is based on science and nature and not upon economic considerations or tradition. Sea salt is advocated by the macrobiotic school. However, scientific fact is that all salt in inorganic form, which sea salt and rock salt both are, is poisonous and is responsible for many diseases and health problems. This is why soy sauces and miso, both containing salt, are very harmful foods. Rice is rather bland without soy sauce or other flavorings. Also, it has to be cooked, a distinct health disadvantage. Rice is deficient in water and in the wide variety of vitamins and minerals that can be found in fresh raw fruits and vegetables. Rice also lacks the flavor and the attractiveness of fresh fruits and vegetables. Just looking at a few of the facts, you can readily see which foods nature intended for humans and which came to be used by humans as a result of lack, ignorance and tradition.

**Macrobiotic cooking also uses oils for sauteeing foods and for making tempuras.**

That's correct. As you have learned in previous lessons, heated oils are very toxic within the human organism and lead to many serious diseases, including cancer.

**Will including grains in the diet disturb the body's acid-alkaline balance?**

First, we should repeat that the body has built-in buffer systems for maintaining its normal pH balance. Most foods will stimulate these systems to maintain normal pH. However, some foods cause the body's buffer systems to work extra hard because certain foods (those not normal and correct to the human dietary) render too many acids upon metabolism, most notably, meats, dairy products, eggs, etc.

Grains are also acid-forming, as a rule. Therefore, if you eat them, eat them in extreme moderation (not more than once every two or three days). We recommend that you have your grain portion in place of a portion of nuts, seeds or avocados, since grains are very poor combinations with these foods. Grains, if eaten, should be consumed with raw nonstarchy vegetables and not with fruits or sweeteners. Nor should they be salted because, as stated earlier, salt is poisonous in the human organism and leads to health problems.

**Isn't it okay to use a little baking soda (sodium bicarbonate) mixed with distilled water in case of indigestion that may occur even if foods are correctly combined or in cases where incorrect combinations cannot be avoided, like when you're a guest at someone else's house?**

Absolutely not! Baking soda and all commercially-sold antacid preparations are very harmful when taken often, for they cause alkalosis by depleting the body's acid-forming minerals. Remedies of any kind should never be used! The law of dual effects says that a secondary effect follows on the heels of the primary effect of any drug (baking soda is one).

What this means in this case is that a worse case of indigestion will occur in the next meal after the baking soda was used.

You should always avoid incorrect combinations, even when you are a guest at someone else's house. Correct combinations are usually possible or can be politely requested. You may have to pass up certain dishes or pass up invitations if you really want to become and/or remain healthy.

If you get indigestion despite correct food combining, you would benefit by a fast. A fast will give your digestive system a chance to rest and heal so that it can better do its job. It is also advisable to eat smaller meals, to chew your food well, to eat easy-to-digest foods such as raw fruits and vegetables and to be sure you are relaxed during mealtime. Your food will digest best if you do not exercise very vigorously immediately before or after a meal and if you are not overly stressed or anxious before, during or after your meal.

[Home](#) > [Lesson 12 - The Role Of Acid And Alkaline Substances Within The Body](#) > Article #1: Alkalinity And Acidity Of Foods In Metabolic Reaction

### **Article #1: Alkalinity And Acidity Of Foods In Metabolic Reaction**

When foods are eaten, they are oxidized in the body resulting in the formation of residue or ash. In this residue if the minerals sodium, potassium, calcium and magnesium predominate over sulfur, phosphorus, chlorine and uncombusted organic acid radicals, they are designated as alkaline ash foods. The converse of this is true for foods designated as acid ash.

Numerical values of alkalinity or acidity are determined in long, painstaking analytical laboratory work. The concentrations of the various elements are determined separately and then computed in terms of equivalents. The excess of one group of minerals over the other is expressed as cubic centimeters of normal acid or base (alkaline) per 100 grams edible food. The values obtained are called degrees of acidity or alkalinity.

(most alkaline reaction)	
43.7	Fig, dried
41.6	Lima bean, dried
36.6	Apricot, dried
25.3	Raisin
20.4	Swiss chard
20.3	Prune, dried

17.5	Dandelion greens
16.4	Soybean sprouts
15.8	Spinach
15.0	Taro corms & tubers
14.2	Cucumber
14.0	Lima bean, fresh

4.2	Horseradish, raw
3.2	Brazilnut
3.8	Oliver, green pickled
4.3	Artichoke globe
4.3	White bean, dried
7.8	White rice
8.5	English walnut
10.3	Jerusalem artichoke
10.5	Lentil
10.6	Peanut
10.9	Wheat grain
11.3	Rye grain
	(most acid reaction)

*From Composition and Facts About Foods*

## **Article #2: Acid/Alkaline: Clearing Up The Confusion By Marti Fry**

The purpose of this article is to clearly and simply explain the meaning of *acid* and *alkaline* and to explain why a study of the acid-alkaline balance, or pH balance, is important in the study of health and healthful living.

Acid and alkaline are words used to differentiate two classes of minerals with differing chemical compositions. One class of minerals contains a relatively large number of hydrogen ions. These minerals are the acid-forming minerals. They include sulphur, phosphorus and chlorine. The other of these two classifications of minerals contains a relatively small number of hydrogen ions. These minerals are the alkaline-forming minerals. They include potassium, sodium, calcium, magnesium and iron.

Substances contain both acid-forming and alkaline-forming minerals. Whether a substance is classed as acid or alkaline depends upon which type of minerals predominate in the substance. Substances that have approximately equal amounts of acid and alkaline (base) minerals are neutral. Water is neutral.

Foods may be acid before ingestion but alkaline after metabolism, or they may be alkaline before ingestion but acid after metabolism. The former is generally true for fruits and vegetables, while the latter is generally true for animal foods.

The human body is maintained slightly alkaline, and alkaline foods are our normal diet and therefore a healthful diet. When we refer to alkaline foods, we mean foods that leave an alkaline "ash" after metabolism—fresh fruits and vegetables, primarily, as well as some nuts and seeds. Ingestion of animal foods results in many acids, most notably uric acid, sulphuric acid and phosphoric acid. The presence of these acids causes the body's buffer systems (those organs that maintain normal body pH) to work extra hard, whereas the consumption of fresh fruits, vegetables, nuts and seeds does not overwork the body.

The body's major buffer organs are the kidneys and the lungs. If either of these organs is impaired for any reason, or if a diet containing an excess of acid-forming foods is consumed, acidosis may occur. Acidosis is by far more common than alkalosis. An excess of acid-forming foods does not directly result in acidosis, however. Rather, this practice results in overworking the kidneys and lungs and depleting the body's supply of buffer salts. Then the body's ability to neutralize excess acids from acid-forming foods becomes impaired.

Alkalosis may result from lung or kidney impairment or from overbreathing, but it does not result from consumption of too many alkaline-forming foods, as there is no such thing as too many alkaline-forming foods. These foods are our normal dietary and they always contain a proper balance of base (alkaline) and acid minerals. Alkalosis may occur, however, if antacid preparations are frequently taken.

Acidosis and alkalosis are both pathological conditions that need never occur. However, acidosis is rather common because so many people consume a diet heavy in acid-forming foods such as meats, milk, cheese, eggs, etc. and because so many refined foods are consumed (sugar, flour, rice, wheat, etc.).

Acidosis is the predecessor to almost all, if not all, diseases. This is not because acidosis causes diseases, but the same unhealthful practices that result in acidosis also are the causes of diseases. Illnesses are body processes to set a wrong internal situation right. They are carried on by the body in order to eliminate harmful toxins and to correct imbalances, including over-acidity in the body. Therefore, no "cures" should be sought. The body should be left alone to carry out the cleansing process without interference from drugs, foods, etc.

If you suspect that your body is overly acidic, all you need do is fast one to five, days and/or consume

only fresh fruits and vegetables, uncooked and without seasonings of any kind. The body is fully capable of correcting all internal imbalances and will automatically do so as soon as the causes of the problem are removed (and, in some cases, before the causes of the problem are removed, as a matter of life or death).

From a practical standpoint, you need not concern yourself with the degree of acidity or alkalinity of the foods you eat. Just eat a wholesome diet of uncooked fruits, vegetables, nuts and seeds, and you will be providing your body with exactly the kind of nourishment it needs and was designed to handle.

## **Lesson 13 - Air, Sunshine, And Natural Light Essential To Health**

- [1. Sunshine And Its Role In Human Health](#)
- [2. Natural Light Versus Artificial Light](#)
- [3. Air And Breathing](#)
- [4. Questions & Answers](#)
- [Article #1: Sunlight And Air By Otto Carque](#)

### **1. Sunshine And Its Role In Human Health**

#### **1.1 History of Sunbathing**

Throughout recorded and unrecorded time (history and prehistory), humans have made use of the beneficial effects of the sun. Playing and/or relaxing in its illuminating rays have been as much a part of natural living as the procuring of food and water or any other necessity of human life. Indeed, humans originally existed without clothing on any part of their body and were sun-kissed throughout the years of their lifespan.

Positive evidence of the use of the sunbath is offered to us by many of the ancient civilizations. It is known that the Babylonians, Egyptians, Assyrians, Greeks and Romans all were aware of the hygienic use of the sun and equipped their cities with sun gardens for this purpose. Akhenaton of Egypt, Zoraster of Persia and Hippocrates of Greece all looked upon the sun as a great force and worshipped it as a god. An example of this worship is given to us by the Egyptians, whose first temple was erected in honor of their sun god. It was located in a city called On, east of the Nile, and its name was later changed to Heliopolis—City of the Sun.

The ancients knew of the effects the sun had on strengthening the body, including the muscles and nerves, and extensive instructions were given in this regard by Herodotus. The Romans applied this knowledge in the training of their gladiators, giving them regular sunbaths. It is also known from the writing of Philostratus that the Olympian athletes were required to take sunbaths.

In the old German epic poem, the Edda, we learn of the hygienic use the Germans made of the sunshine, carrying their sick to the sunny mountain slopes for exposure to its rays. An account has also been recorded regarding the Incas of Peru using the sunbath in the treatment of syphilis.

In the third century, A.D., Mithraism, or sun worship, came very close to being accepted as the universal religion. It was very similar to Christianity in many essential respects. The final triumph of Christianity practically ended the sunbath, even though it was so widely employed by the peoples of that time. The sunbath was viewed by Christians as a "pagan" ritual. This condemnation of the sunbath could be considered the beginning of an era known as the Middle Ages, or the Dark Ages, where and when many of the desirable features of ancient civilization were destroyed and replaced by an antinatural philosophy and culture. During this thousand-year reign, only the Jewish and Arabian physicians preserved the sunbath in their care of the sick.

Regarding the modern phase of sunbathing, there was a dual origin—one of these in Europe, the Other in the United States. First we shall discuss the European phase: Waldvogel, of Bohemia, advocated sunbathing as far back as 1755, but he had few, if any, followers. Madame Duhamel, in 1857, believed in the use of the sunbath to aid children in their recovery from tuberculosis. Dr. Lahmann of Germany employed the "Sun and Air Cure" in his institution, as did Bilz in his world-famous sanitarium, as early as 1872-73. But the person who is given credit as the originator of the modern practice of sunbathing is Arnold Rikli, who prescribed sunbaths to his patients at his institution, established at Weldes Krai on the Adriatic Sea in 1855. He wrote seven books describing his methods, the principal ones being translated into the Spanish, French and Italian languages.

The first series of observations relating to the effects of sunlight on disease were made by Dr. Loncet of Lyons, France, about 1890-1900. In 1911, Dr. Rollier, a Swiss physician, also did some work in this area. Both of these people enjoyed favorable results, and, as a result, sunbathing has continued to grow in popularity in all parts of Europe.

One last name should be mentioned, that of Dr. Finsen of Denmark, whose comparative experiments with the rays of both sunlight and artificial light became largely responsible for the vast array of artificial lighting apparatus used in the treatment of disease.

In the United States, the first advocate of sunbathing was Sylvester Graham, a pioneer hygienist, who not only discussed the importance of sunshine, but also the detrimental effects of clothing. He presented his ideas in his masterful work, "Lectures on the Science of Human Life," first published in 1843, stressing the benefits of sunshine on bone growth and development.

Another hygienist, Dr. Russell Trall, placed great emphasis upon the power of sunlight in both health and disease. His writings, published around the mid-nineteenth century, clearly show a deep awareness and understanding of the need for sunlight and its value in cases of rickets, scrofula and anemia.

Although credit is generally given to Huldshinsky, who in 1919 proved the definite value of sunshine in overcoming rickets, Dr. Trail was actually about seventy years ahead of him in making this discovery. Additionally, Dr. James C. Jackson and Dr. Dio Lewis both used the sunbath in caring for their patients at around the same time as Dr. Trail. These facts point out that these individuals were using the sunbath previous to Dr. Loncet's observations as to the effects of sunlight in disease between 1890-1900. Actually, the sunbath has been employed in this country for over a hundred years, especially among the pioneer hygienists who have not received their due recognition.

## 1.2 The Use Of Sunshine

Both plants and animals make use of the catalytic powers of sunlight, attaining the highest form of their development in the neighborhood of the equator, where the sun's rays are most abundant. At the equator, life exists in greatest profusion, but as we approach the higher latitudes, where nights are longest throughout the many winter months, we notice life consists of poorly-developed forms or is absent altogether.

Sunlight is an essential nutritive factor to both plant and animal life. Under its influence, plants both excrete and absorb oxygen. Their leaves are able to absorb *carbon dioxide* from the air and convert it into plant substances by transforming the carbon dioxide into formaldehyde. This in turn is polymerized to sugar, thus forming a carbohydrate. This is the process of *photosynthesis*, and both chlorophyll and xanthophyll are associated with this process, making the green color of plant life.

Additionally, the conversion of starch into sugar during the ripening process of fruits requires the action of both the heat and light of the sun for perfection. The beautiful coloring of the flowers, stems, leaves and fruits of plants are all dependent on sunlight for their production. When deprived of it, the result is an inferior plant, pale or colorless, that is said to be *etiolated*.

The colors of butterflies, birds and animals are also determined by light, as is their complete

development. An example of this was given by Dr. Trail. He pointed out that in the tadpole the process of *metamorphosis* is arrested if it is deprived of sunlight. It is unable to develop into a frog; rather, it continues to grow as a tadpole. Complete absence of light results in blindness and even eyelessness.

Sunlight also enables the animal body to assimilate calcium, and it is because of this that it is of great value in the prevention of *rickets* and tuberculosis. A lack of calcium is associated with both of these conditions. This assimilation of calcium may be observed by comparing chicken eggs of various birds. Those raised in the sunlight produce harder and thicker shells than those not so exposed.

The influence of sunlight is also intimately related to the number of red cells and hemoglobin in the blood. An insufficiency of light will cause an increase in the serum or watery portion of the blood and a corresponding decrease in the quantity of blood fibrin and red Corpuscles, resulting in anemia. But with sufficient sunlight, the oxygen-carrying power of the blood is increased, the circulation of the blood is improved, and consequently the blood's power to repair and build tissue is increased. Sunlight's influence on the muscles is to add to their size and quality and to enhance their contractile powers by improving the condition of the entire body, including the nerves that control the muscles. In addition, by improving the overall health and vitality of the body, sunshine is the finest cosmetic, helping the body to smooth away wrinkles, to strengthen and tone the skin, and, at the same time, to insure a soft, delicate texture and overall beauty. It may also be said that, in general, the pigmented skin is stronger, contributes to the health of the entire organism and, therefore, is subject to fewer diseases, and is less sensitive to heat and cold.

Regarding the pregnant mother and her unborn child, it must be noted that the benefits to be derived from sunlight are greatest during periods of development and rapid gains in flesh. Sunshine, again, by improving overall health and vitality, aids in, the skeletal development of the baby and helps preserve the normal alkalinity of his/her blood. Additionally, its influence on the unborn will aid in promoting sounder sleep; deeper, slower breathing; diminished blood pressure; and an increase in urinary excretion. Sunbaths before and after childbirth will increase the mother's ability to nurse her child, with an improvement in the quality of the milk. It will produce better general health in the mother and prevent the loss of blood, making for a more painless delivery. Another benefit is that pregnant mothers who get sunlight will not experience tiredness, backaches and loss of appetite.

### **1.3 Sunshine in Sickness**

It has been shown that after a fast or a wasting illness, obtaining sufficient sunshine will enable the body to build higher quality flesh. It will also enable the body to most efficiently digest and assimilate food. This is not to imply that we should wait to become sick to make use of the sun's rays. The sun is not a therapeutic agent; it is an essential of good health and nutrition. Sunlight is of value in all states and conditions of the body and in all stages of development. Its importance must be relegated to that of hygiene, and it should not be thought of as a specific "cure" for a disease condition.

We spoke earlier of the great importance sunlight plays in proper bone development. This is due to the fact that only through the aid of sunlight, particularly the ultraviolet rays, may the laying down and fixation of the calcium and phosphorus salts be accomplished in an ideal fashion as to make for the transformation of cartilage into bone. On the other hand, when insufficient sunlight is obtained, the result is defective, misshapen, brittle and easily broken bones, a condition known as rickets.

Sunlight also proves invaluable in cases of glandular inactivity, favorably affecting irregularities of ovulation, pubertal difficulties and impotency. Acne, a condition representing a glandular disturbance of the skin, is also noticeably aided by sunlight, as is the condition of psoriasis. Also, as sunshine aids in increasing the coagulating power of the blood, it is of inestimable value to sufferers from uterine hemorrhage. Additionally, if cautiously applied, the sunbath can be very valuable in some nervous affections.

## 1.4 Suntan and Sunburn

Suntanning is the bronzing or browning of the skin due to a deposit of pigment or melanin granules around the nuclei of the epidermal and basal cells. This process of pigmentation is the most important protecting mechanism against sunburn because it prevents the overabsorption of ultraviolet rays.

Just as chlorophyll is formed as a light screen in plants, humans deposit a brown pigment, called melanin, when in the presence of sunlight. This pigment deposit absorbs the visible and ultraviolet rays, converts them into rays of less energy and lower vibration, and then passes them onto the deeper cells of the epidermis. A combination of the infrared and ultraviolet rays will result in the deepest pigmentation.

It must be understood in this context that the sun's rays do not produce pigment; rather, they occasion its formation. Pigmentation is a physiological process, pigment being manufactured within the body from the elements of food and deposited in the skin by the processes of life. The tanning process is totally dependent upon the body's ability to make use of the sun. A lack of response may commonly be seen in cases of leukoderma, where the white patches of skin fail to produce pigment.

The second protective mechanism the body uses against too much sunshine is a thickening of the corneum, the uppermost layer of skin. This process is undesirable, as it results in harsh, dry, coarse skin. It is largely to avoid this dryness that olive oil and other commercial preparations are used on the skin, but it is far wiser to avoid excessive exposure by retreating to the shade.

We must distinguish between suntan and sunburn. This latter is a true burn and injures the skin just as if it was fire or scalding water. An inflammatory process results and may be accompanied by severe blisters, general discomfort, and later a peeling of the dead tissue. As in other burns, there are three degrees of sunburn. A first degree burn produces redness due to an excess of blood in the skin, causing much or little discomfort, depending upon the severity of the burn. In second-degree burns, the skin becomes intensely red and painful to the touch and may be accompanied by diarrhea, fever and/or vomiting. Blisters may develop and then burst, discharging their fluid contents over the body. There is also much itching and finally peeling of the skin. A third-degree burn results in a sloughing dermatitis and may end in death. Complications may develop, such as inflammation of the brain, stomach and intestines; blood poisoning; and hemorrhages.

## 1.5 The Sunbath

Sunbaths play a vital role in the life processes of human nutrition, the tanning process being coincident with them. There is a tendency to overexpose the skin to acquire a "good tan," and this should be avoided, as it will enervate the body, lessening the value of the sunbath.

The untanned body should begin with exposure to the solar rays of about ten minutes a day and increase gradually until an hour or more may be taken without harm. Too much sun will result in restlessness and decreased nerve tone. Additional precaution must be taken by blond and red-haired people, as they do not pigment as readily as dark-haired people. Heliophobes, those individuals who redden and blister and are cautioned to stay out of the sun, should still take sunbaths but do so for short periods during the early morning or late afternoon hours to avoid large amounts of ultraviolet rays.

The sunbath should be taken in an entirely nude state or with scanty attire, preferably without glasses or hats, as the eyes and hair also benefit. Sunglasses render the eyes more sensitive to the sunlight and ultimately impair the vision, whereas it has been found that gazing directly into the sun greatly benefits weak eyesight. It is also known that sunlight accelerates the growth of hair.

Suntan lotion or olive oil on the skin is unnecessary and should not be used. These will prevent all the ultraviolet rays from being absorbed and will inhibit the oil-secreting glands of the body from working properly. They will not prevent the injurious effects of excessive sunbathing, nor will they provide for a uniform tan. Remember, it is not mere tanning that we seek, but a general revitalizing of the entire organism, not confined to the skin alone.

Suntan lotion or olive oil on the skin are unnecessary and should not be used. These will prevent all the ultraviolet rays from being absorbed and will inhibit the oil-secreting glands of the body from working properly. They will not prevent the injurious effects of excessive sunbathing, nor will they provide for a uniform tan. Remember, it is not mere tanning that we seek, but a general revitalizing of the entire organism, not confined to the skin alone.

If the sunbath is taken at the beach, additional caution must be exercised, as the reflection from the sand and water cause more sun rays to strike the body. Thus, burning will result more quickly. Neither a thin haze over the sun nor a cool breeze will prevent the ultraviolet rays from reaching us. It is important to understand in this context that it is not the sun's heat from which we benefit (except secondarily on a cold day), but rather its light. The hot sun is very exhausting and should be avoided, and like other animals we should instinctively seek the shade at these times.

Those people living in colder climates must take advantage of the warmer months to secure an ample supply of sun-made reserves to carry them through sunless periods. This is not to say that the body stores up sunshine, but rather it stores up substances produced with the aid of sunshine to be used in times of stringency. Along with vitamin D, other materials are synthesized in the body with the aid of the sun's rays. These body reserves will be adequate as long as the general mode of living throughout the year is not enervating. All forms of excesses, dissipation of the emotions, lack of rest and sleep, sexual excesses, overwork and/or an improper diet will waste these reserves.

Some additional precautions should be noted in the case of invalids or generally weak individuals. If the sunbath leaves the person feeling weak or depressed or with an increase in any of his/her symptoms, then it has been overdone. Fever, headache, weariness, loss of appetite and sleeplessness may all be considered signs of excess. In those individuals suffering from asthma or tuberculosis, a difficulty in breathing may be experienced. Nervous patients may not be able to sleep due to a stimulating effect caused by too much sun. The end result for securing the sunbath should be to produce a better feeling in the individual, not worse. A person's need for sunlight is dependent upon their ability to make use of these light rays. Overindulgence of the sunbath will lend to additional enervation and serves no useful purpose.

[Home](#) > [Lesson 13 - Air, Sunshine, And Natural Light Essential To Health](#) > 2. Natural Light Versus Artificial Light

## **2. Natural Light Versus Artificial Light**

Sunlight, when broken up by means of a prism, is found to be composed of the color bands of the spectrum—red, orange, yellow, green, blue, indigo and violet. These different colors represent different rates of vibration, increasing as we go from red to violet, while their wavelengths decrease. These visible rays give us sensations of light, color and heat. In addition to these color rays, sunlight also contains other rays not perceptible to our ocular sense and therefore invisible. The wavelengths immediately shorter than visible violet and those immediately longer than visible red are both invisible to humans and are called ultraviolet and infrared, respectively.

Regarding the heating power of sunlight, it is found to be greatest at the red end of the spectrum where it blends with the infrared rays, while the greatest chemical activity takes place at the violet end, blending with the ultraviolet rays. These invisible rays of the sun are the most beneficial ones. However, the complete color spectrum, blended in perfect proportion so as to produce white light, is needed for ideal growth and development of both plants and animals.

Artificial light does not radiate a complete spectrum but instead produces a light with an excess of one

or more of the color rays. In the case of incandescent lighting, most of its light is yellow, orange and red, whereas the standard "cool white" fluorescent light emits mostly yellow-green light. The various so-called "sunlamps" produce either too much ultraviolet or too much infrared radiation and are definitely harmful. They may cause headaches, third-degree burns and severe conjunctivitis.

The effects of artificial lighting have been noticed in both plants and animals. John Ott, of the Time Lapse Research Laboratory, discovered that the apples on a branch of a tree under artificial light grew larger than those growing under natural light, but they did not mature or ripen. Despite the addition of many chemical products to produce more color in the fruit, the fruit never acquired color until exposed to ultraviolet rays from the sun.

Further observations made by Ott revealed that the ratio of the sexes of plants was affected by different wavelengths of the spectrum. Experimenting on a pumpkin vine raised in a basement under a skylight and a cool, pinkish, white fluorescent light, it was noticed that the female pumpkin-producing flower turned yellow, then black and finally dried up and dropped off the vine. Consequently, the vine did not produce fruit. When these lights were replaced with tubes containing more blue in them, the female buds developed bountifully, while the male buds dried up, turned black and dropped off the vine at an early stage. The usual ratio of male to female buds on a pumpkin vine is seven to one respectively; however, in these artificially-lighted plants, normal reproduction could not take place.

In general, it has been observed that plants grown in artificial light lack the rugged constitution of plants grown under natural lighting conditions. Their growth may be stimulated by subjecting them to longer hours of light, as compared to the natural light cycle of the revolving earth. But this forced growth produces plants bearing flowers and fruit of lesser quality and color appeal than those grown in sunlight.

The animal world is also adversely affected by variance of light wavelengths. In an experiment conducted to determine the effects of different light on animals, 1000 mice were used and divided among three different light environments: Those receiving natural daylight produced an equal amount of male and female offspring; those under white fluorescent bulbs produced 70% females and 30% males; and those under pink fluorescent bulbs produced 30% females and 70% males. This latter group did not thrive as well as either of the two other groups. All those exposed to the pink light quit breeding two months earlier and died one month earlier than those exposed to the white light.

As these experiments were made with a strain of mice in which malignancy develops in 98% of them, almost all the mice did succumb to cancer. However, those mice under natural daylight developed cancer two months later than those under the white fluorescent bulbs, and three months later than those under the pink fluorescent bulbs. An additional effect was noticed: Those mice receiving the pink light gave birth to young which were smaller in number and size than those mice receiving natural light.

Other investigations have shown that light definitely affects the pituitary gland, as well as other areas in the midbrain and hypothalamic regions. In the early 1920's, William Rowan demonstrated that the varying seasonal lengths of the daylight was responsible for the migration of birds. In other studies conducted by Bochenek, Marburg and Gudden, it was shown that light may occasion reaction on the entire endocrine system of an animal via nerve impulses originating in the retina and reaching other areas of the brain by way of accessory optic pathways. Thus, artificial light, not being of the same quality as natural light, can play havoc with the endocrine system via the nerves.

A study was conducted involving some elderly men at a nursing home who spent most of their time indoors under the influence of unnatural lighting. They found that these men suffered a severely diminished ability to absorb calcium; yet when the lights were replaced with special bulbs designed to simulate sunlight, their calcium absorption was increased by 15% within a month. Even more disturbing research conducted by scientists has indicated that fluorescent lighting can cause genetic mutations, cancer and death in the cells of many life forms, including humans.

Aside from the facts concerning the direct negative effects of unnatural lighting; we must also consider their more indirect effect on our body rhythms. Their presence, by turning night into day, tend to

imbalance the circadian rhythms—the regular cycles of rising and falling body temperature, variations in body chemicals, etc., that naturally occur approximately once every 24 hours. The result may be what three West German photobiologists have called "light stress."

All plants and animals require alternating periods of light and dark so that some vital processes may rest while others become activated. The anabolic activities during the night can take place efficiently only when not interfered with by lighting, which will continue to occasion activity in the living cells. The result is that the processes of growth and repair are interrupted, resulting in the necessity for disease, and the body is robbed of a certain degree of life force.

Experiments testing the influence of artificial light on fish revealed that, when exposed to too many hours of light, the fish ceased to reproduce. When time exposed to light was cut down gradually over a period of weeks, the fish resumed reproduction if exposed to pink light, but not under the slightly bluish white light. Also, under the pink light, the ratio of female to male offspring was 80 to 20 respectively and the development of the secondary sex characteristics of the male offspring was retarded.

Regarding humans, some scientists suspect that the age at which girls reach sexual maturity might be influenced by the artificial illumination of nighttime. It has been noticed that in countries experiencing long winter nights, girls are now reaching sexual maturity months or years younger than their grandmothers did. Apparently, their normal maturation cycle is being interfered with by the introduction of artificial lighting into their lives, thereby increasing the rate at which they mature.

From this information, we may understand the importance lighting plays in our daily lives and we may also suspect that all the effects of artificial lighting have yet to be uncovered. A true science of health must endeavor to ascertain all aspects of life and living and their ultimate effects on human health.

[Home](#) > [Lesson 13 - Air, Sunshine, And Natural Light Essential To Health](#) > 3. Air And Breathing

### **3. Air And Breathing**

Air is the gaseous substance that makes up the atmosphere of the earth and provides every living thing with its breath of life. Plants receive oxygen through their leaves; insects breathe through tiny openings in their bodies; frogs breathe partly through their skin; fish absorb oxygen out of the water as it passes over their gills; and humans receive their supply of oxygen partly through the skin, but largely through the lungs. The independent life of a body does not begin until it takes its first breath and this function of breathing continues until the end of life. This is the process of respiration, and it must be considered the primary function of the living organism. We can live many weeks without food and some days without water, but if the function of breathing is interfered with for only a few minutes, our life quickly ends.

Respiration is an automatic, involuntary process, being regulated according to the body's internal needs. With healthy lungs, we breathe normally and rhythmically, yet unconsciously, as the process is beyond our conscious control. At rest we breathe slowly and less deeply. As activity is increased, breathing becomes more rapid, with greater excursions of the diaphragm and chest to allow for increased oxygen intake.

But the respiratory movements are not confined to the chest alone; they are systemic motions pervading the whole trunk. It is known that the rhythmic pulsations of the heart synchronize with the movements of the chest in respiration. These breathing movements also constitute an important factor in the circulation of the blood, as we may experience in the case of a drowned person being resuscitated by artificial respiration, by which circulation and heart action are restored.

By far, the largest organs in the body are the lungs, designed and adapted to their work of receiving air

and nothing else. They fill the thorax from the collarbone to the lowermost ribs and from the sternum in front to the spine in back. When the chest wall is raised through the action of the muscles of the chest, and when the diaphragm is depressed, the chest cavity expands, this forms a vacuum, and the air rushes into it. Conversely, when the chest wall contracts and the diaphragm is raised, the air is forced out of the lungs. Coincidentally with this process, the blood flows through the lungs, picking up oxygen, carrying it to the cells and giving off carbon dioxide that it has brought from the cells. This whole process is automatic and is regulated by the body's need for oxygen.

A normal pair of lungs contain approximately a billion tiny air cells. If these cells were all spread out on a flat surface, they would cover an area 40 x 50 feet. The average man inhales daily approximately 777,000 cubic inches of air, and in this same time 125 barrels of blood are purified in the lungs. Here the poisons and impurities of the body are brought by the blood and cast off. Also, the blood absorbs a fresh supply of oxygen, nitrogen, hydrogen and the essence of sunlight to be conveyed to all parts of the body to furnish the trillions of cells with the normal stimulation to activate its various functions. This is a continuous process, and if it is interfered with, the result could be fatal. When respiration is obstructed, the lips quickly turn bluish-purple due to the rapid collection of carbon dioxide gas in the blood. In only a few seconds, if respiration is impeded the blood will turn almost black in color, signifying a great increase in poisons.

Carbon dioxide is composed of one part carbon and two parts oxygen and is not easily detected, as it is colorless, odorless and tasteless. For every 2,500 parts of atmospheric air, there is one part of carbon dioxide. When the air we breathe contains 3% carbon dioxide, a drowsy feeling occurs, and when it is present in larger quantities, death quickly results. If the organism does not promptly eliminate carbon dioxide, every cell becomes weakened and the entire body suffers. Carbon dioxide gas is present in all charged drinks, in beer and fermented liquids, in baking powder cookery, in self-rising flour products, in yeast bread and in all fermenting products.

At each exhalation the lungs discard enough gases, consisting of carbonic, lactic, hydrochloric, phosphoric and other acids, to poison a barrelful of air. In every 24-hour period, the amount of carbon dioxide eliminated by the lungs is equal to a lump of charcoal weighing eight ounces.

With this in mind, consider also that every person in a room needs 3,000 cubic feet of fresh air an hour to insure purity. In the case where several occupy a room not adequately ventilated, we inhale the exhalations of others and ourselves, and the amount of carbon dioxide contained in the air increases, making it more dangerous to breathe. This is the principal reason why patients in hospitals develop diseases of the lungs such as influenza and pneumonia. The early symptoms of mild carbon dioxide poisoning are sensations of uneasiness and oppression, drowsiness, sneezing, headache and coughing.

Under the laws of accommodation, our bodies are equipped with powers to enable it to tolerate for a time an atmosphere so poisonous that it could cause a vital person to pass out if it were suddenly entered into. This principal was illustrated by an experiment by Claude Bernard in which he used a bird placed under a bell-glass, providing it with enough oxygen for three hours, but then removing it at the end of the second hour and replacing this bird with a fresh, healthy one. It was shown that the latter died instantly, as it did not have sufficient time to accommodate itself to the vitiated environment of the bell-glass.

In addition to carbon dioxide, our bodies also must deal with the poisonous fumes of modern industrial cities. City air contains such chemicals as carbon monoxide, sulphuric acid, hydrochloric acid, nitric acid, hydrocyanic acid, benzene, methane, etc. The *Cincinnati Post* of April 1946 stated that in the month of March the amount of soot and ash that fell on that city was equal to 2725 tons or 227 railway carloads. It amounted to enough to cover a 40 x 150 foot, 75 foot deep lot.

Another interesting fact: A professor H. H. Sheldon of New York University once erected an apparatus in the Times Square theatrical district that drew in air at roof level. In one week, the apparatus cleaned 341,250,000 cubic feet of air, removing from it 12 cubic feet of solid matter composed of dust, soot and tar and weighing 37 pounds.

All the protection one has against polluted air is to exhale it through deeper breaths, but this should be done actively through movement. Ernest T. Seaton, in his story of the coyote, tells of this animal's protective instincts after ingesting some poisonous bait. It instinctively knows there is but one way it can overcome the poison, and that is by vigorous exhalation. If it can run long enough and fast enough before the poison does its deadly work, the lungs will eliminate the poison and the animal will survive.

H. B. Meller of the Mellon Institute of Industrial Research said: "When it is known that one takes about 30 cubic inches of air into one's lungs in each inhalation, or about seven times the weight of food and water consumed, it can be understood why more people are weakened, devitalized and poisoned by the pollution in the air they suck into their lungs than by all the ingredients in the food they eat and the water they drink." When the air we breathe is fresh and pure, it brings life into the body, but when it is filled with poisonous gases from industrial waste, etc., it leads us to ill-health and premature death.

The press of August 19, 1939, stated that these poisonous gases and acids in the air of the city of Paris were "eating away and disintegrating the historic monuments of that city. The rapid decay of \ these stone monuments dates from about 1900. Since that time, the smoke and fumes from factories, river tugs, motor cars and trucks and heating plants have steadily increased. The smoke, mixed with the exhaust of motor cars, trucks and buses, produces a compound of sulphuric acid gas that chemically attacks everything that it strikes."

Until about seventy five years ago, fresh air was considered by physicians as being dangerous to the sick, especially during the night, and all windows were kept closed and all air holes were plugged up to prevent any air from entering. Thanks to the work of the early pioneers of hygiene such as Graham, Trall, Densmore, Page, Oswald and others, most people of today are aware of the importance of adequate ventilation at all times.

Although the Greeks and Romans were able to manufacture glass, they did not use it to obstruct their windows. Instead, they allowed the free passage of light and fresh air to enter their dwelling houses. It was not until later periods, called the Middle Ages, that the fear of night air and of other natural instincts including a fear of eating uncooked foods became predominant, and habitual indoor life between closed walls became customary. This grew out of the philosophies and religions of the day that preached anti-natural doctrines.

Oxygen is essential to the highest physical and mental development of humans. This may be provided through free ventilation and exercise in the open air. Although there seems to be more need for fresh air during the daytime while we are active than during the night when we are inactive, this is hardly an argument for sleeping in unventilated rooms. In sleep, nature seeks complete rest and reduced oxygenation. This is provided for by decreased breathing, and should not be accomplished by the breathing of foul air.

Regular and continuous breathing is essential to meet the needs of life, and it is for this reason that we should live, dress and carry ourselves in ways that do not interfere with the process of breathing. Five minutes of deep breathing twice a day will not compensate for inadequate breathing the rest of the day. It is what we habitually do all day that counts in the long run, rather than any five-minute breathing sessions. Proper and sufficient breathing depends upon a number of factors, including health of nose, throat, chest, lungs and abdomen; proper body posture; freedom of movement of the chest and abdomen (lack of restrictive clothing); well-ventilated homes, bedrooms, etc. and ample exercise in the out-of-doors.

In this light, mention should be made that exercises to develop the chest and to increase its capacity for oxygen are well advised. Modern life generally does not adequately develop the musculature and framework of the chest, and it is for this reason that the modern man or woman's breathing reserve is small compared to that of wild animals and those people of more primitive societies. Regarding our breathing apparatus, the normal nose permits adequate amounts of air to enter the lungs through but one nostril under ordinary conditions. When under great stress, as when running, the additional nostril should provide for the ingress of sufficient air, providing both nostrils are normal. Generally, mouth

breathing is a symptom of disease, as in adenoids, polyps, nasal catarrh, a cold, etc. Every day we should take advantage of the cleanest air available in the particular vicinity in which we live. It is important that we do some exercises that will promote greater oxygen intake. This will also enable us to throw out additional poisons from our lungs and help to keep our breathing functions in a healthier condition.

[Home](#) > [Lesson 13 - Air, Sunshine, And Natural Light Essential To Health](#) > 4. Questions & Answers

## 4. Questions & Answers

### **Are specific deep breathing exercises recommended for greater intake of oxygen?**

If you are referring to a passive form of deep breathing not associated with total bodily movement, then the answer is no, they are not recommended. We must understand that the rate of breath is automatically controlled through the respiratory center in the medulla of the brain. The more carbon dioxide that is contained in the blood, the more this center is stimulated, with a corresponding increase in the rate of breathing. Conversely, oxygen inhibits this center so that the more oxygen the blood possesses, the slower we breathe. Thus the breath rate and the volume of oxygen are always automatically adjusted to the body's true needs. Deep breathing "exercises" that do not involve great muscular exertion will not provide for any more air into the body than the blood can take up according to its needs. Passive deep breathing "exercises" do not force anything out of the body, nor do they "feed" the nerves or regenerate the body in any way. Such activities may result in mental confusion and various other symptoms and are best discarded. Active deep breathing, that which is coincident with various bodily movements such as hiking, running, swimming, etc., occasion a greater need for oxygen and are beneficial. The body's normal response to this need is met through an increase of breath rate and volume of oxygen intake.

### **Do all forms of artificial lighting produce detrimental effects upon our health and, if so, what can we do to minimize these effects?**

Yes, all forms of artificial lighting negatively affect our health, but most of us must spend some time under their influence in order to live in this society. A few things may be done with regard to fluorescent light bulbs that will lessen the potential hazards associated with their use. First, we may use solid plastic covers over the lighting fixtures to help filter out excessive ultraviolet light rays. Secondly, and more importantly, we may use and encourage others to use some of the more recently developed broad-spectrum fluorescent lamps instead of the more commonly used "cool white" fluorescent bulbs. The former more closely simulate the full spectrum that is offered us by sunlight, and they should prove to be less harmful.

### **How may one obtain sufficient sunlight during the cold winter months of the temperate zones?**

Humans originally came into existence when the conditions of the environment harmoniously agreed with their constitution. This was in such a climate as to allow for living without clothing, so as to be sun-kissed throughout the years of their existence. Nowadays, many of us inhabit less comfortable areas of the world and may only experience these life-giving rays part of the year. A possible solution during the winter is to construct a solarium or close off an area in such a way as to keep the wind out but the solar rays in. Through the use of reflecting the rays, we may additionally produce more heat in this specialized area, thereby making it more comfortable for the sunbath. We may also secure some sunlight

through an open window if conditions permit. But probably the most important consideration is that we live healthfully throughout the months so as to secure adequate nutritive reserves, and not dissipate our nerve energy through food and/or sexual indulgences or lack of adequate rest and sleep. This will prove to be of paramount importance for maintaining good health during those months not as suitable to humans.

Lesson 13 has discussed many reasons why humans need sunshine on a regular basis. Sunshine has been described as one of the basic essentials of life and a valuable factor-influence in all states and conditions of the human body. It is needed for assimilation of calcium and phosphorus salts and for the production of vitamin D in the skin.

While sunshine and other nutritive factors obtained on a regular basis result in fewer diseases, especially rickets, tuberculosis, anemia, insomnia, acne, psoriasis, leukemia, high blood pressure and reproductive disorders (irregular ovulation, pubertal difficulties, impotency, uterine hemorrhage, etc.), it cannot be considered a specific "cure" for any disease condition, and it will not protect us from other destructive habits we may indulge.

Excessive sunshine, especially under the sun's most intense rays, is not healthful and should be avoided. It may result in sunburn, dry, coarse skin and nervousness. In short, too much heat and sunlight is enervating. Tanning should not be considered the primary objective of sunbathing, and suntan lotions or oils should not be used because they will clog the body's skin pores and inhibit the oil-secreting glands of the body from working properly.

Lesson 13 also gave a history of sunbathing and the use of sunshine for improved health, nerves and muscles. The practice of sunbathing was just about lost during the Middle Ages, however, and its revival was brought about in large part as a result of the efforts of Hygienic pioneers, including Graham and Trail.

Lesson 13 explained that artificial lights do not produce a complete spectrum of light, and they upset natural body rhythms that are tuned to the light of nature. Artificial lights produce an excess of one or more of the color rays, and they interfere with normal reproduction in plants and animals...

The anabolic activities that take place efficiently only at night when not interfered with by artificial lighting are disturbed by the use of artificial lights. Therefore, the processes of growth and repair of cells and tissues are hindered and the body is robbed of some of its life force. Additionally, Lesson 13 stated that sunlamps are harmful and should not be used.

Air as a primary, and the most immediate, need of life, was discussed in this lesson. It must be obtained in ample amounts and it must be free from pollutants, including the exhalations of ourselves and others. This means that good ventilation is necessary inside buildings, and we should refrain from using polluting substances in our homes and offices. The fact that we consume more weight in air than in food and water combined makes it evident why people are so devitalized by air pollutants.

Lesson 13 described the lungs and how they work to take in oxygen and eliminate carbon dioxide and other toxins. It was explained that the heart works in harmony with the lungs. The symptoms of carbon dioxide poisoning were described, and the body's process of accommodation was explained and illustrated. Also, some of the major air pollutants in cities were listed and their damages described.

The need for adequate ventilation during sleep was discussed, and the need for outdoor exercise was highlighted. Lesson 13 also explained why passive deep breathing "exercises" should not be indulged but vigorous exercise should be obtained. Suggestions were made on how to avoid the harmful effects of artificial lighting and on how to obtain adequate sunlight during the cold winter months of the temperate zones.

### **Article #1: Sunlight And Air By Otto Carque**

Most important for the preservation of health and vitality are sunlight and air. They are just as necessary for growth and perpetuation of life as are liquid and solid food. "When the sun does not enter, thy physician enters," says an old proverb. It has been found that the greatest mortality occurs in the narrow streets of cities and in houses having northern exposure. The inhabitants of southern mountain slopes are stronger and healthier than those living on the northern sides. Inhabitants of secluded valleys where the sun rises late and sets early are generally afflicted with peculiar diseases, chiefly due to a lack of direct sunlight and its salutary power to dissipate and decompose noxious vapors that accumulate in dark and low places.

The sun indeed is the great and ultimate source of all power that manifests itself in the inorganic as well as in the organic formations of matter. Plants require sunlight above all for the completion of their complicated organic combinations. While the lowest species of organic life, such as fungi, are capable of developing darkness, the higher plants, which principally support animal life always depend upon the rays of the sun for the processes of assimilating the elements of soil and atmosphere. They require especially the non-illuminating ultraviolet rays, which we know to be most active in the production of electrochemical effects.

Likewise, the animal body is to a large extent directly dependent upon sunlight for its growth and healthy development. It is a well-established fact that, as the result of an insufficiency of light, the fibrine and red blood corpuscles become diminished in quantity, while the serum or watery portion of the blood is increased, inducing leukemia, a sickness characterized by a great increase in the number of white blood corpuscles. A total exclusion of the sunlight induces the severer forms of anemic diseases, originating from an impoverished and disordered state of the blood.

Of the many experiments that have been made so far to demonstrate the beneficial effects of sunlight, the one conducted by John Blaytonis is the most remarkable and significant. In order to determine whether the indirect or diffused daylight, perhaps during a longer period of time, has the same effect as the direct sunlight, he selected twelve bean plants of the same variety and in the same stage of development. Then he planted them near one another in such a way that six always had full direct sunlight, while the others received only the diffused daylight. In October, the pods were harvested, and the weight of those grown in the shade or diffused light compared with that of those exposed to the sun rays was found to be in the proportion of 29:99; that of the dried beans 1:3.

This result was expected, but in the following year, when all the plants grown from the same seed received the full amount of the direct sunlight, the surprising fact was ascertained that those which had been raised in the shade yielded only half the amount of the previous year's harvest, while in the fourth year they blossomed but did not mature. The deprivation of direct sunlight during *one* summer weakened the stock to such a degree that the species became extinct after four years.

The lesson of this experiment may be applied with great benefit to humans and their daily habits. The highly beneficial effect of sunbaths, if judiciously taken, is demonstrated by the above example in the best possible manner. A dwelling place that admits the sunlight during all hours of the day is, therefore, one of the first conditions for the preservation of health.

Statistics show that the tenement house districts of the large cities to which sunlight has very slight access have the greatest infant mortality and have many cases of rickets and tuberculosis. If it were not for the constant renewal of the population from the rural districts, the city dwellers, especially the poorer classes, would die out in the course of a few generations. All mothers should realize the importance and benefits of sunlight and use every opportunity to admit the direct rays of sun to their living and sleeping rooms whenever and wherever this is possible. Sunlight and fresh air are primal factors on which the normal development and health of the child depend.

Frequent exposures of the naked body to the sunlight will greatly assist the system in the performance of all physiological functions. It will especially insure an even distribution of the blood. Such an adjustment of the circulation is necessary for the normal functioning of all organs. People should make it a practice to expose their nude bodies frequently to sunlight and fresh air in order to keep in the best possible physical condition. Public parks should have enclosures where sunbaths and airbaths can be taken, and these should become an adjunct of every modern progressive city.

Sunlight can kill cells in our bodies if the cells are exposed too much to the very intense rays of the sun. Moderation and discrimination should always be exercised. Sunbaths are best taken in the morning, and an eastern exposure should be selected for the purpose.

Equal attention should be paid to a continuous supply of fresh air during day and night. Not many persons seem to realise the absolute necessity of the electrifying, life-giving oxygen for the maintenance of vitality and health. It has been only a century and a half ago (1774) since the English scientist, Priestly, and the French scientist, Lavoisier, discovered that we live by means of a chemical process of combustion in which the blood unites with the inhaled air, yielding the products of combustion that we exhale as aqueous vapor and carbonic acid gas. This chemical action corresponds to that which we find in the case of a burning candle or a lamp fed with oil. If the supply of air is cut off, we will be suffocated, just as the flame of a lamp is extinguished if the air is prevented from passing to it. A person may live more than sixty days without food and a few days without water, but when deprived of air or oxygen, they die within a few minutes. This proves that pure air is the most necessary of all the essentials of life.

Atmospheric air consists of two gases, viz.: nitrogen and oxygen; the former serves only to dilute the oxygen. Besides these two elements, the air always contains some aqueous vapor, carbon dioxide and ammonia. On an average, 100 volumes of air contain: 78.35 vol. of nitrogen (N); 20.77 vol. of oxygen (O); 0.84 vol. of water vapor ( $H_2O$ ); 0.04 vol. of carbon dioxide ( $CO_2$ ); 0.0001 vol. of ammonia ( $NH_3$ ); and traces of other gases (ozone, etc.).

There are also various kinds of microbes in the air, according to moisture and temperature, causing fermentation and chemical disintegration of organic substances. The composition of air, i.e., its proportions of nitrogen and oxygen, is the same all over the surface of the earth. The degree of moisture or humidity in the air varies according to location and temperature. Carbon dioxide is always present, even in mid-ocean and forests, but its quantity is very small, ranging from three to four parts per ten thousand by volume.

In closed rooms, however, where numbers of persons are present and at the same time gas and coal are burned, the percentage of carbon dioxide rapidly increases. At the same time, the air is filled with other more poisonous gases, such as ammonia and albuminoid ammonia, while the amount of oxygen is gradually lowered. All these facts should be seriously considered in the proper ventilation of living rooms, schoolrooms, etc. The following table gives the average amount of carbon dioxide in 10,000 parts found in the air of different localities:

Ocean and forests	0.3
Cities, open streets	0.4 to 0.5
Bedroom during night, Window partly open	0.8
Bedroom during night, Window closed	1.2
School-rooms	1.5 to 3.0
Hospitals	2.8
School-room, 70 occupants at close of school hrs.	7.2
Churches, during services	3.5 to 7.0
Churches, if heated by furnaces	20.0 to 30.0
Theatres, crowded meeting rooms	25.0
Workshops, ill-ventilated	30.0

These figures show how little attention is paid to proper ventilation, and they explain the constant increase of pneumonia and similar diseases. The importance of pure air becomes still more obvious if we consider the wonderful anatomical structure of the respiratory organs. The lungs, into which the air is drawn, consist of two rounded, oblong, somewhat flattened masses of cellular substance. They are situated in the cavity of the chest, which communicates with the atmosphere through the windpipe (trachea). The trachea, as it descends from the throat, branches off into large tubes, and these branch again and again into smaller and still smaller ones and finally into hairlike vessels.

Through these the air penetrates into the remotest parts of the cellular substance. Around each visible extremity nearly 18,000 cells are clustered, each of which is connected through these minute tubes with the external air. The cells vary in size. They have an average diameter of about one one-hundredth inch. Their total number has been estimated at about six hundred million. The wall of these cells is very thin; they are mere air vesicles.

The internal surfaces of all these cells together form an area of about one hundred sixty square yards of thin cell-wall. Over the whole of this surface, minute blood vessels branch out, almost entirely covering it. Along these tiny vessels the blood continually flows and, in its course, absorbs through their walls the oxygen of the inhaled air.

It is in the delicate membrane of these blood vessels that the change from venous into arterial blood is effected. The venous blood must be changed continually because it is an impure fluid containing matter

that has already served for the support of life in the various parts of the body. Carbon dioxide and other gases are given off, and the oxygen of the air enters, the cells of the lungs and is absorbed by the minute vessels that spread over the cell walls. Within these vessels the oxygen combines directly with the hemoglobin of the blood, and by means of the action of the heart, proceeds with it in ceaseless currents through the arteries and veins.

To a certain extent the skin also absorbs oxygen and exhales carbon dioxide, the amount being about one-thirtieth of that excreted by the lungs. Besides, the skin gives off other gases, water and solid matter, amounting to from one to two pounds during the day. In summer people perspire more than in winter. During exercise or exertion more water is lost than at rest. All parts of the skin should be brought frequently in immediate contact with the external air. There are several million pores in the skin acting as little sewers through which various waste products of the system are constantly excreted. The clothing and particularly the underwear should be porous to permit free circulation of the air. Closely woven linen or cotton shirts, if covered with heavy woolen clothes, cause the retention of waste matter that is partly reabsorbed by the system and thrown back on the lungs and kidneys, overworking and weakening these organs.

As has been shown that in ill-ventilated and often tobacco-laden public halls, churches, schoolrooms, theatres and workshops, the air thrown off from the lungs is rendered still more noxious by the emanations of the skin. People, on leaving such places, feel the contrast between the inside and outside air and erroneously blame the fresh air as being responsible for their "colds," which are but the result of the inhaled poisonous gases and their unsanitary methods of living in general.

Many persons sleep with closed windows because they cherish the old delusion that "night air is dangerous." After a few hours they begin to breathe the exhaled air over again. In the morning they get up with a "tired feeling" and have to resort to "eye-openers" which make their condition still worse. It is during the night when we are at rest that the lungs redouble their efforts to inhale the life-giving oxygen to recharge the human dynamo. It is therefore even more essential to insure an adequate supply of pure air during the night than in the daytime. There is absolutely no danger of "catching cold" from cold, fresh air. On the contrary, the bodily heat, which results from combustion, is increased by an abundant supply of oxygen. A "cold" is really but an effort of the system to cast out impurities, chiefly through the mucous membranes of the throat and nose. Few persons realize that the amount of air taken up by the system daily outweighs that of the solid food.

The changes that have taken place in the composition of the exhaled air are indicated by the following table:

<b>Constituent</b>	<b>Inhaled Air</b>	<b>Exhaled Air</b>
	<b>Volumes percent</b>	
Nitrogen	78.35	78.85
Oxygen	20.77	16.00
Carbon dioxide	00.04	04.35

Exhaled air is also saturated with water vapor and contains traces of ammonia and organic matter varying with the diet, climate and occupation of the individual. Under normal conditions, if the blood is rich in the essential organic salts, the lungs absorb through the medium of the red blood corpuscles twenty-four and one-half ounces of oxygen during twenty-four hours, while they give off twenty-eight ounces of carbon dioxide retained in the lungs. Children need relatively more oxygen than adults, as the

tissue changes are more active during the growth of the organism.

The adult man of average weight at each inhalation draws in about one pint of air, and during twenty-four hours he averages fifteen respirations a minute. Thus he takes in two gallons of air a minute or 120 gallons an hour, amounting to about 2,880 gallons or 384 cubic feet a day. This volume of air would fill a room measuring a little over seven square feet. The weight of this volume is about thirty pounds and contains about seven pounds of oxygen, as the latter forms 23.2 percent of weight of the atmosphere. Of the total amount of inhaled air, the human body takes up oxygen at the rate of 4.78% by volume or 5.25% by weight, while exhaled air contains 4.34% of carbon dioxide by volume or 6.5%, by weight.

Of the total amount of oxygen inhaled, the body generally absorbs from eight to ten ounces (one-third) during the activities of daytime, while during sleep in the open air or in well-ventilated rooms, the quantity may be doubled to sixteen ounces. It may be noted here, incidentally, that the absorption of oxygen depends largely upon the number of red blood corpuscles in a given quantity of blood. During severe muscular exertion, respiration is also increased in frequency and in depth, and the volume of air exchanged may be from five to seven times greater than during a period of rest.

Experiments have been made by German scientists showing the effect on oxygen consumption of walking on a level and climbing. The following figures give the quantities of oxygen consumed during one minute, the subject being a man of 125 pounds weight:

<b>Form of Exercise</b>	<b>Oxygen Consumption</b>
Standing at rest	16 cubic inches
Walking on a level	48 cubic inches
Climbing	78 cubic inches

It appears that walking increases the consumption of oxygen threefold and climbing nearly fivefold over that consumed at rest. These facts illustrate the influence of muscular activity upon the bodily metabolism and the incidental purification of the system from waste matter. Regular exercise in the open air during all seasons of the year is one of the most important factors for the preservation of health and the prolongation of life.

## Lesson 14 - Water Transports Nutrients To All The Body Cells

### 1. Water Is The Essence Of Life

Water is the prime essence of life! The functioning of our planet is dependent upon its massive reservoirs of water and its complex system of atmospheric water dispensation. In our oceans, rivers, underground aquifers, and streams, water prevails and abounds. No one would argue with the statement that without water, life as we know it would be impossible. Even if life were possible without water, most of the beauty of life would be lost in its absence. Dull, barren rocky landscapes devoid of vegetation would be prevalent everywhere. The clouds that color rosy and multi-hued in our sunrises and sunsets would be nonexistent.

The fact is that water is a major need of all forms of life. Fortunately for us, in most places on Earth, water is abundant. There's water in all of the foods we eat. Even dry foods like nuts and seeds have water content. Fruits possess plenty of pure water which is ideal for human functioning.

How does our body use water? What is the best kind of water for its functioning? These are questions this lesson addresses.

### 2. Water's Role In The Body

#### 2.1 How Body Water Is Obtained

The average adult is composed of almost 60% fluid. That's more water than the total of all other substances in the body! Our body's water is obtained from the fluids we drink and from the water content of the foods we eat. It is also obtained from the body's internal oxidation reactions. The

oxidation process occurs in the combining of hydrogen in the food we eat with the oxygen we breathe. Some animals are dependent on the oxidative water they produce for their very existence.

## 2.2 Minerals In the Body Fluids

The water within our body contains many materials in solution; that is, it contains many substances dissolved in it. The complement of minerals dissolved in the body fluid are referred to as salts. These salts include sodium, calcium, magnesium, potassium, chlorine, phosphorus and other elements. They possess electric charges and are thereby referred to as *electrolytes*.

Some salts possess positive electrical charges and others possess negative charges. These charges, inherent in the salts, are part of the regulatory process in the movement of fluids within the body. The positively and negatively charged particles exist in equally balanced amounts in the body. The resultant charge between the particles is therefore neutral.

It is true that the balance of salts is crucial to the proper functioning of the human organism. It is, however, not necessary that we add substances such as table salt, baking soda, mineral supplements or mineralized waters to our diet in order to assure ourselves of the proper complement of salts. Our bodies, as you will remember from Lesson 10 on minerals, can assimilate and utilize only organic minerals as are found in foods. Adding table salt to the diet is literally adding a poison. We'll discuss this in more detail later in the lesson.

## 2.3 Cellular Fluids

About three-fourths of the body's fluid is stored within the cells and is known as *cellular fluid*. The extracellular fluid is composed of *plasma and interstitial fluid*.

Blood plasma, a clear, yellow-colored fluid, is approximately 92% water. The plasma carries within it a huge volume of substances. It transports mineral salts and carries carbohydrates, proteins, gases, enzymes, fats and hormones. There are certain plasma proteins that are always present in the plasma. Other materials are in a constant state of change. The amounts of food materials (such as glucose), carbon dioxide and nitrogen wastes are constantly changing in the plasma.

Interstitial fluid is similar to plasma except it does not contain the plasma's complement of proteins. However, interstitial fluid does contain glucose, minerals and urea and it continually bathes the cells. Through this bathing, the cell is supplied with all its needs for existence.

In addition to the circulatory system formed by the blood, yet another system exists and flows through the lymph vessels. The lymph circulation, along with the blood, is responsible for the flow and mixing of the extracellular fluid. One of the major functions of the lymph vessels is the return of the proteins to the circulation after they leave the bloodstream. The lymph provides the only routing whereby these "plasma proteins" can be restored to the circulation. Another part of the lymphatic system consists of small filtering organs called lymph nodes, which filter the lymph fluid as it passes through.

## 2.4 The Inner Sea and Its Movements

The fluids in our body are true life-keepers and can be likened unto an ocean in which literally trillions of cells, themselves largely water, are immersed. Within this "ocean" the materials we need for our survival are carried. In addition, the same system is responsible for carrying away our wastes, such as nitrogen, unusable minerals and other toxic substances.

The nutrients our body needs are broken down from foodstuffs in the digestive system. After they are broken down they are water-soluble. This means they can be mixed with water and dissolved in it. When the nutrients are put into solution, they pass through the capillaries (small tubes) within the intestinal wall. The blood flowing in these walls picks up the tiny particles of nutrients. Through the circulatory

system, the nutrients are finally distributed by the extracellular fluid bathing the cells.

When the nutrients are finally distributed by the circulatory system to the cells, how do they make themselves available for use by the cells themselves?

It is the responsibility of the circulatory system to distribute the nutrients and bathe the cells with them. The process by which needed materials are absorbed (and also by which wastes leave the cell) are known by the names *diffusion*, *osmosis* and *active transport*.

*Diffusion* is merely the arbitrary movement of particles through the cell walls. The movement of the particles is limited by the size of the pores of the cell wall (cellular membrane). The cellular membrane is a semipermeable membrane—it allows only certain substances in particular forms to pass through it. This factor is very crucial to the cell's existence. If the cellular membrane did not have the capacity to keep some substances outside of the cell and others permanently inside, the cell would be no different in composition from the fluid surrounding it, and it would not be able to maintain its distinct life.

*Osmosis* refers to the particular process in which the balance of salts takes place. Water tends to go where the greater concentration of salt lies; in other words, water will pass through the semipermeable membrane from a lesser concentrated salt solution to a greater concentrated solution. The result is that the proportion of positive and negative electrolytes is balanced. An easy way to remember the term osmosis is that it's a fancy way of saying that in cellular metabolism, water goes where the salt is.

At this point, mention should be made that this action of water is not an intelligent one done by the water. Water is utilized by the body; it is itself an inert substance and does not act upon the body.

In addition to osmosis and diffusion, a process called *active transport* occurs, in which electrolytes move across the cellular membrane from an area of lesser salt concentration to an area of great salt concentration.

Fluids constantly flow through the cellular membranes in both directions—both into and out of the cell—through these processes of diffusion, osmosis and active transport. However, the total amount of cellular fluid and the total amount of extracellular fluid remain at a constant balance during this interchange. There is a real need for this precisely balanced flow of fluids between the cellular fluid and the extracellular fluid, so that the cells within the body do not continually shrink and expand.

An example illustrates the importance of this balance of fluids. If the cells were immersed in distilled water, they would grow to the point of bursting because distilled water is so much less dense than the fluid in the cells! Conversely, if the cells were surrounded by a strong salt solution, the cells would lose their water and shrivel up. These examples are an impossibility in the functioning of our organism, but they do point to the need for the proper balancing of both the amounts and types of fluids to which our cells are exposed.

Now let's see what happens when the processes of diffusion, osmosis and active transport occur within the body. Glucose, or blood sugar, is a primary nutritive factor derived from foods. It is the immediate fuel of the cells of the body and is distributed by the extracellular fluids. The liver is responsible, among other things, for regulating the amount of blood sugar that reaches the cells. It also forms proteins from amino acids, which are then dissolved in the plasma. These plasma proteins float in the watery part of the blood and are easily absorbed by the individual cells, which break it down again into its component amino acids.

Minerals can be directly absorbed from the small intestine and put into the bloodstream without undergoing chemical change.

## **2.3 Waste Removal**

Thus far we have been discussing water's role in delivering nutrients to the body's cells. Water plays an equally significant role in removing the wastes of the body.

One of the more persistently produced wastes by humans and animals alike is carbon dioxide. The body has uses for a small amount of carbon dioxide, but would expire could it not expel its excesses! In the process of carbon dioxide expulsion, the cells firstly allow their excess carbon dioxide to diffuse into the extracellular fluid. Later the lungs exhale the unneeded carbon dioxide. Blood is able to carry carbon dioxide because carbon dioxide is easily dissolved in the blood's water.

Another waste that the body continually produces is nitrogen. Nitrogen is basically a by-product of protein metabolism. The elimination of nitrogen is not as simple as that of carbon dioxide; it cannot merely be discharged as nitrogen gas. Our organism has not developed the capacity to discharge nitrogen. If nitrogen were combined with hydrogen in the bloodstream, it would form the extremely toxic substance ammonia. The ammonia would then itself poison the body. Therefore, nitrogen must be expelled in a form that is not itself toxic to the human body. Ammonia combines with carbon dioxide, itself a waste product of humans, to form *urea*. Urea itself is a solid, but it is easily dissolved in the water within the bloodstream.

Urea would quickly reach a toxic level within the body were it not for the functioning of the kidneys. It is the job of the kidneys to filter the blood. They also return to the bloodstream the substances in blood that the body needs. The waste products, including urea, are not reabsorbed but are mixed with water to form urine, which is afterwards expelled through the bladder.

As stated earlier, nitrogen is a by-product of protein metabolism. It costs the body energy to expel this substance in the form of urea. A person following the Life Science regime and eating a diet of raw fruits, vegetables, nuts and seeds will not have as many proteinaceous wastes as someone eating a conventional diet of processed foods, meats and dairy products and thereby will expend less energy in expelling these wastes. The urine of a person who is eating a conventional diet high in protein is apt to be darker and thicker than the urine of a person who eats Hygienically.

## **2.4 Water Cools the Body**

One of the major reasons the water balance in the body is so crucial to our health is water's direct relationship to the temperature regulation of the body. Some animals, such as the camel, actually undergo large differences in body temperature dependent on the air temperature around them. Yet an internal temperature change of even a very few degrees can mean death to a human being.

A "normal" human adult gains about two and one-half quarts of water daily. To maintain bodily balance, one also loses approximately the same amount. This water is gained from food and liquid sources, and also, from oxidative sources. Oxidative water is merely water that is formed by the chemical reaction of hydrogen combining with oxygen within the body.

The body loses water through the kidneys and bowels. It also loses water through the lungs, and through the skin as perspiration. Perspiration cools the skin when it evaporates, which helps to maintain body temperature, but it can be dangerous or even fatal if the body loses too much water. On an extremely hot day we may lose as much as a quart of water per hour through perspiration. Losing eight quarts by this method would mean death.

When water is lost by the blood, the blood becomes denser. When this happens, water is drawn into the capillaries from the intercellular fluid so that the blood can maintain its flow and carry away unneeded heat in the body.

The skin stops the evaporation of the water in the body. It is the structure from which 85% of the body's heat is lost. Sweat is a clear fluid, mostly water, and it may contain toxins. Sweat is excreted through the pores of the skin. Heat is lost by radiation and the evaporation of sweat from the skin. Typically we may lose a pint of water daily due to sweat.

### **3. Other Body Uses Of Water**

The body needs water for the proper functioning of its glandular systems. The salivary glands in the mouth and the glands in the tongue help prepare food for digestion and keep the mouth moist.

The hypothalamus, located within the brain, regulates the conservation, replenishment, and elimination of water. It can be affected by the type of water you drink, since inorganic mineral deposits can impair its functioning. Also easily damaged by impure water are the thyroid, the adrenals and the pituitary glands.

The pancreas has as its function the manufacture of digestive juices and insulin, and it utilizes water in their manufacturing.

The uses of water in the body are so multifarious that we can't begin to list them all here!

### **4. Water In Our Diet**

Since water is so important to the proper functioning of our organism, it's crucial that we come to an understanding of when to drink, how much to drink and what kind of water is best fit to drink.

#### **4.1 Natural Diet Is Water Sufficient**

Firstly, we should stress that there are no hard and fast rules as to how much water a person needs. Those people eating of man's natural dietary—raw fruits, vegetables, nuts and seeds—will certainly need less water than a person eating a conventional diet of meats, breads, cooked foods, etc. A person accustomed to the Hygienic diet partakes of a diet that is basically water-sufficient. Under most circumstances, the foods themselves contain enough water for optimum functioning. The naturally ripened fruits that we eat typically contain upwards of 80% of the purest distilled water. Such water is ideal for human consumption.

#### **4.2 How Much Water Should Be Drunk**

There are instances, nevertheless, in which a person subsisting on the Hygienic dietary might need additional water. Such times would include days of heavy toxin elimination and during a fast. We also may need additional water when exerting ourselves in the hot sun. The body will determine its particular water needs and manifest this need as thirst. We should readily accommodate our thirst with water of the purest kind.

A person who eats a typical American diet containing processed junk foods, salt and seasonings, cooked foods, etc., must drink a great deal more water than someone partaking of a Hygienic diet. This is true because the typical American diet is far from being water-sufficient. The high salt content in most of these "foods" requires the body to demand a large amount of additional water to hold the salt in solution so that it won't harm body tissues. The same is true of many of the condiments and spices such as pepper and garlic, commonplace in processed foods.

More insidious food additives such as monosodium glutamate must also be kept away from the cells in a

highly diluted form so that they are not immediately toxic. Even a moment's thought will reveal that the body considers such substances as toxic; or else why keep them in diluted solution? Even in such a diluted solution, some of the toxic materials may cause damage. It would seem sensible to avoid such toxic material, thereby saving the energy needed for their elimination.

Some health advocates prescribe that we drink anywhere from three to eight, or even more, glasses of water daily. My suggestion is: Listen to your body! Partake of a diet that is basically water-sufficient in itself. If you find that you need water in addition to the water you get from foods, let your thirst guide you as to how much you should drink.

### **4.3 When We Should Drink Water**

Now we must consider when to drink. Drink only when really thirsty, and never drink during a meal or directly afterwards. If you must drink near mealtime, it is suggested that you drink at least thirty minutes before eating or two hours after eating. When drinking with meals, we often have the tendency to swallow food that is only partially masticated. In addition, the water will hinder the process of digestion by diluting the digestive juices. Of course undigested or partially digested food is toxic and cannot be assimilated.

[Home](#) > [Lesson 14 - Water Transports Nutrients To All The Body Cells](#) > 5. Water: Is It Fit To Drink?

## **5. Water: Is It Fit To Drink?**

The importance of water in our diet has been well established. Although it is best for us to obtain our water from food sources, sometimes we need additional water.

For example, when a person works in the sun for several hours on a hot day, his need for water will be proportionately greater than the water content of most foods. When the need for additional water exists, what kind of water should be taken?

### **5.1 Tap Water and Its Processing**

Most folks in this country drink the water that is easily available to them. Commercial "purified" tap water is easily available and is used for drinking water by the majority of people. Nevertheless, few of those drinking such water are aware of exactly what constitutes the water they are drinking. At least in the United States, most people drink their tap water without giving it a second thought.

Any person who carefully considers the nature of tap water and its constituents will be unlikely to continue to drink it. Besides the barrage of chemicals added to the water at the "purification plant" (which we'll go into later), in most cases the water must travel through an intricate web of pipelines before reaching its destination. These pipes pose the additional danger of adding even more unneeded materials to the water.

Through man's continual disregard for the purity of his environment, almost all of the natural waters of the earth are contaminated by chemical pollutants. For instance DDT has been found in the far reaches of the North Pole area. Among the pollutants of our natural water are: soap, wood pulp, oil, sulfuric acid, copper, arsenic, paint, pesticides and even radioactive wastes! Among the most prevalent inorganic minerals in our waters, which are unusable by and toxic to the body, are calcium, magnesium, sodium, chlorine and sulfur.

It is unfortunate that so many pollutants are in our natural waters. What is even more unfortunate for the tap water drinker is that still more chemical pollutants are added to the commercially available water

supplies. These chemicals are added supposedly in a effort to purify the water and kill its "disease-producing bacteria." The chemicals are more harmful, though, than the bacteria they're supposed to rid the water of!

Let's take a closer look at the major methods commonly used in water treatment.

1. *Sedimentation*: When water is allowed to stand still, its heaviest particles will naturally settle to the bottom. This principle can be easily illustrated by stirring some standing water. If you stir up the bottom and watch for awhile, its murkiness will dissipate and it will become relatively clear again in time. Particles that tend to sediment include sand, rocks and heavy particles that are not chemically bonded with the water itself.
2. *Filtration*: Filtration is a process that strains out particles in the water that do not settle. Commonly, the water is allowed to pass through some kind of porous material, such as sand or diatomaceous earth. The porous material acts like a net and captures the particles in the water mixture. Water is sometimes put under pressure in the filtration process.
3. *Coagulation*: Coagulation is a process that involves the use of jelly-like binding materials. These materials can include aluminium hydroxide, aluminium sulfate and activated silica. The theory goes that these chemicals will bind with impurities and cause them to settle out. However, there's a great likelihood that at least trace amounts of these toxins remain in the water after this process.
4. *"Softening"*: Many of the waters used for commercial water supplies in this country are originally "hard," mineral-laden waters. In water treatment facilities, chemicals such as calcium hydroxide and sodium carbonate are added to the water. These substances form chemical bonds with the "hardening" minerals, particularly calcium and magnesium. The resultant chemicals from the reaction are then filtered as much as possible.

Sometimes this filtering is done by a process called reverse osmosis, whereby the purer water is transported towards the area of least salt (mineral) concentration. This process is literally the reverse of normal osmosis and is done by artificial means of transport such as water pumps.

The idea of removing hardening minerals from the water we drink is in accordance with Hygiene. But we just can't agree with this methodology. Anytime unnatural substances are added to the water, our chances of ingesting these chemicals substances are increased. Since it is true that our body can use only the water content of the water we drink, it is best to avoid water that has been chemically softened.

5. *Chlorination*: With few exceptions, chlorine is added to the water supply of every large city in the United States. It is added at the rate of approximately one-half to one part per million. Theoretically, chlorine is added to the water in order to poison and kill the germs contained therein. However, we must only remember World War I to imagine the deadly effects chlorine produces in the body. Chlorine has, for instance, been found to be a contributing factor in atherosclerosis. From my own childhood experience, I can remember swimming in a large chlorinated pool, and to my chagrin, a bucketfull of chlorine was added to the water in which I was swimming! Fortunately, I was not seriously injured— it probably was not a strong chlorine solution. However, I can still remember the stinging of my skin and the feelings of nausea and disorientation I experienced from even such a short exposure. From this experience, I must question the advisability of taking any amount of a deadly toxin such as chlorine into the body! Even such a small amount as one part per million, which is considered "safe" by the scientific community, is actually harmful.
6. *Bromine and iodine addition*: In lieu of chlorine, which is by far the most widely used germ killer added to commercial water supplies, bromine and iodine are sometimes added. Both of these substances are deadly poisons to humans and are best avoided.
7. *Fluoridation*: Probably there is no more controversial additive to water than fluorine. These major reason usually cited in favor of fluoridation is its supposed value in the protection of teeth. Some studies have shown that, at best, fluoridation only delays decay. Others have shown no improvement at all in "dental health" from the use of this poison.

Reasons aplenty exist, however, for the avoidance of fluoride. If excessive fluoride consumption persists, teeth stains and mottling of the teeth, eventually resulting in brittleness, can ensue. The Mayo Clinic department of Orthopaedics wrote that, although fluoride administration has been shown to stimulate new bone formation, the bone formed thereby is poorly mineralized.

Fluoride is mainly stored in bones, and it increases skeletal mineralization. In tests with animals, it has been found that abnormal amounts of bone formation occurred in those animals to which fluorine was administered. Fluoride can contribute to the calcification of ligaments and tendons—even eventually contributing to the spine become a solid column of bone.

In addition to bone storage, fluorine can be stored virtually anywhere in the body, including the aorta, the main bloodflow artery of the heart. There is considerable evidence that fluorine impairs kidney function. In some studies, fluorine has been linked to genetic damage, birth defects and cancer. Fluorine can even react with the hydrochloric acid in the stomach and turn to highly corrosive hydrofluoric acid. This acid can lead to hemorrhaging in the upper gastrointestinal tract!

Clearly, the harmfulness of fluorine in our waters is abundant! Surely the dubious benefit of "protection of the teeth" cannot compare to the known health detriments of fluoridation.

Fluoride, as it is added to water, is in an inorganic, unassimilable form. Although fluoride can be found in the bodies of people with healthy teeth, it is also sometimes found to be absent. What has been stated above is ample cause for the avoidance of fluoride and its concurrent pathological effects.

We've not even discussed all the possible problems to be found in tap water. Its toxins include lime, soda ash, fluorine, chlorine and sulfur. Some city water supplies have been found to contain many other substances thought to be carcinogenic. Perhaps the most important thing to remember about tap water is this: It's more than just water! The chemicals added to the water are unusable poisons; the inorganic minerals in that water are little better! Let's relegate our tap water to uses other than for drinking, and our health will benefit immeasurably.

It is our hope that this discussion of tap water has convinced you of the merits of its avoidance! Let's continue our discussion of other types of water you might consider drinking.

## **5.2 Salt Water**

Lots of folks are proclaiming the health benefits of sea water and sea salt. They say the complement of minerals in sea water is similar to our blood. Yet sea water is not a food; its drinking occasions vomiting and can produce death. Sailors will die of thirst before drinking it. All its elements are in an inorganic form (see the next section on mineral waters) and are unusable by and toxic to the body. Its salt content requires extra pure water to keep the salt in solution away from body tissues. We're best off avoiding sea water as well!

## **5.3 Mineral Water**

A huge controversy exists concerning the beneficence of mineralized water in the diet. This subject is fully discussed in the book *The Great Water Controversy* by T.C. Fry, Herbert M. Shelton and others. Some of the most important things to remember about mineralized waters are:

1. As was discussed in Lesson 10, minerals cannot be used by the body unless they are in their organic unfragmented form. The body must expend considerable energy to expel these unneeded materials from the body before the water itself can be cured.

Let's go into this subject a bit more fully. Minerals are only usable to the body as they are found in organic forms of life such as plants. Only plants form the link between the earth-minerals and animal life! We cannot digest rocks. Although inorganic minerals may have the same chemical

composition as the organic minerals, they differ in structure and in the relative position of the component molecules. This difference is crucial, for it determines the usability of the substance by the body.

How does a plant transform earth's inorganic minerals into usable forms? First, the plant takes in sunlight, carbon dioxide, water and elements from the earth. By the process of photosynthesis, the plant's chlorophyll captures the sunlight and forms carbohydrates from water and carbon dioxide. In the process of the growth of the plant, the minerals from the earth become organically part of the plant itself. Then, and only then, can the minerals be considered assimilable by the body.

2. The inorganic minerals found in mineral water are deposited by the body in tissue structures and bones. Mineral deposits can lead to kidney stone and gallstone formation, hardening of the arteries, ossification of the brain, arthritis and heart disease. Inorganic minerals excreted through the skin can cause tissue degeneration.
3. When harmful substances enter the body, they are encountered by the white blood cells, which are a part of the body's inherent defense mechanism. Continued ingestion of harmful substances, including inorganic minerals, can result in an over-proliferation of the white blood cells. This condition is called leukocytosis.
4. It has been suggested that the different stages of life—from infancy to old age—are just differences in the state of ossification of the body parts. The major difference in body tissues between youth and old age is the greater rigidity and toughness of tissues in advanced age.

## **5.4 Rainwater**

What can be more refreshing than a soothing summer shower? Rainwater was once a prime choice for drinking. However, we must begrudgingly recognize that the "waste products" of all the technological boons of mankind have befuddled our waters. Our atmosphere is polluted badly, and rainwater tends to absorb and wash these toxins out of the air. Although that's great for the air, it makes rainwater drinking unfeasible in most circumstances. If you have a heavy rainstorm and begin collecting water several hours into it, chances are the water will be good (unless you live in an area where the air is severely polluted). Otherwise, rainwater is best avoided for drinking.

## **5.5 Wellwater**

Most well waters are heavily laden with inorganic minerals. When this is the case, well water is best left in the ground or used only for cleaning, swimming and bathing.

## **5.6 Spring Water**

Some spring waters are heavily mineralized; others are fresh and soft. When you buy spring water from the store, there's little way of knowing just what you're getting. Soft pure spring water can be good to drink—but unless you know it's soft and pure, pass it up!

## **5.7 Distilled Water**

Distilled water is the purest water available. Nothing but water is in it. When the need for additional water other than what we get from our diet exists, distilled water is unequivocally the best choice for drinking.

Perhaps the most prominent objection to the use of distilled water, is that distillers are not to be found anywhere in nature, although the process is a natural one. For great health, it is necessary that we partake of foods, air and sunshine as they are found in nature. To the great discredit of exploitative humankind, our natural waters have been fouled to the point of toxicity with the waste matter of our so-

called "advanced" civilization. It is for this reason that it's dangerous to drink even rainwater! Distilling water is perhaps our only real choice in insuring the purity of our drinking water. Nevertheless, it is a shame that we must use unnatural mechanical procedures to make pure water available to our bodies once more.

The proponents of hard water drinking have claimed that distilled water is dangerous to drink because it leeches out minerals from the body. There is some truth in this statement, but not the way they mean it. Distilled water does aid the body in removing harmful, disease-producing inorganic minerals from the tissues and bones where those not eliminated are stored. However, distilled water does not leech out the organic minerals that have become part of our cellular structures. We must remember that the body chooses what it does with the water that is ingested. The water does not act upon the body. It is the body that acts upon the water! The body will relegate the proper usage of the pure distilled water it receives.

[Home](#) > [Lesson 14 - Water Transports Nutrients To All The Body Cells](#) > 6. Sources Of Pure Water

## 6. Sources Of Pure Water

Fresh raw fruits are our best source of pure water. The plant itself has already done the distilling! There are no intermediate steps needed.

Our body is about 60-70% water; fruits are typically 80-90% water! Vegetables are high in water content, too. If we eat an abundance of fresh raw fruits, including melons in the hot seasons, little or no water for drinking will be needed!

There are no "dry" foods. Sunflower seeds are approximately 5% water. At the other end of the scale, watermelon is around 92% water. It's sweet and delicious, too!

Here are some typical water contents of easily available fruits and vegetables:

<b>Food</b>	<b>Percentage Water Content</b>
Avocados	73%
Grapes	81%
Bananas	75%
Oranges, Peeled	86%
Peaches	89%
Strawberries	90%
Celery	94%

Broccoli	89%
Lettuce	95%
Tomatoes	93%
Cucumbers	95%
Carrots	88%

Even "dry" vegetables have high water content. Potatoes are almost 80% water.

If nuts and seeds are eaten, the possibility of need for additional water increases. Pecans are about 3% water, cashews 5%, almonds about 5%, and brazil nuts are about 4% water.

The water in raw fruits is preferable to that found in vegetables. The water in vegetables, especially the water in the leaves, has not been distilled by the plant to as great an extent as in the case of fruits.

When you need water, such as when you're fasting, working in the sun, or if you've deviated from a water-sufficient diet (heaven forbid!) then you need pure distilled water. Distilled water may be purchased commercially. However you should be careful in its purchase and usage. If it has any odor, color or taste, it should not be used.

The best way to ensure your pure distilled water is truly pure and distilled is to do your own distillation. However, you should take care to purchase the proper noncontaminating distilling equipment.

Distilled water is obtained by a mechanical method in which water is first heated to boiling. Then the resulting vapor, which has separated from the boiling water, is collected. In the process, the chemicals and sediments in the water are removed, leaving only the water.

Since distilled water has a fantastic ability to dissolve metals and minerals, it should only be stored in glass or stainless steel. We suggest you store it in a narrow-necked container so it will have as little contact with the air as possible; also, keep distilled water from air contact by keeping the container closed.

High-quality steam distillers, using stainless steel and glass components, should be used in distilling water.

[Home](#) > [Lesson 14 - Water Transports Nutrients To All The Body Cells](#) > 7. The Choice Is Yours

## 7. The Choice Is Yours

Now you have done a good deal of thinking about what type of water is best fit to drink. As a less burdensome (and hopefully more fun) way of reviewing some of these ideas, let's now listen to a group of drinkers and see what they have to say about the virtues and vices of drinking their respective beverages.

The setting for the following conversation is in the living room of a home shared by three young men. It's Friday evening, and some friends and neighbors have come by to celebrate the beginning of the weekend.

*Frank:* Ahhhh! There's nothing like a refreshing cold beer to start the weekend right!

*Ted:* I don't believe it. (*disgusted voice*) No matter how much I tell you that beer is bad for you, you still guzzle the stuff. Man, that alcohol goes right into your stomach lining! Not to mention it'll raise havoc in your whole digestive tract.

*Frank:* Aw, I've been drinking beer for years and I'm never sick.

*Julie:* C'mon Frank, I'll go to the sink and get you some water. Maybe that'll please your worried friend.

*Ted:* With, all the chemicals in that stuff, you might be better off with the beer! (*At this point John and Amy enter the room.*)

*John:* I couldn't help overhearing your little discussion. I started drinking spring water a couple of years ago. It's full of minerals which I'm sure we need. You want some, Frank?

*Frank:* Nope. You just don't get that good feeling from water that you get from beer. Besides, this beer is made from spring water. Does that make you feel better, Ted?

*Ted:* No way. Mineralized waters, including spring water, are full of inorganic minerals. Those minerals are poison to your body. And, oh yes, Frank, just because you're never showing the symptoms of illness doesn't prove you're not sick. Maybe your beer drinking proves that you are sick though (*laughs*).

*Julie:* Ted, you're just never satisfied. I went to the faucet to get a drink. I suppose I'm going to die because of that?

*Ted:* Well, you might. All the toxic chemicals in tap water are best avoided. How many miles of pipeline did that have to go through?

*Ann:* Well, I'm drinking some distilled water.

*Julie:* Let me have a taste (*Sips the water*) It tastes like nothing!

*Ann:* That's right! Pure water has no odor or taste. And it doesn't have any inorganic minerals to clog up your system or be deposited in your body.

*Ted:* Well, Ann, you've got the right idea in my opinion. As long as you're going to drink at all, you're best off drinking distilled water.

*Frank:* What do you mean, "as long as you're going to drink?" You'd die if you didn't!

*Ted:* Not necessarily. If you eat mostly raw fruits and vegetables, which is man's natural diet, you will need little or no more water than is found in the foods you eat. *Frank:* Yeah, right. Anybody wanna go for a burger?

We can't hope to legislate the behavior of everyone around us. Ultimately the choice for what we put into our body is individually ours alone. "What'll it be, Mac?"

[Home](#) > [Lesson 14 - Water Transports Nutrients To All The Body Cells](#) > 8. Questions & Answers

## 8. Questions & Answers

**If fluorides in the water are supposed to help fight cavities, why does an excess of them result in brittling of the teeth (and bones)?**

In truth, adding fluorides to water is an economic measure, not a health measure. Fluorides are industrial waste products for which a market was created for the economic advantage of the people in industry. It's not that it's wrong to seek profit or economic advantage; however, it is when it's at the expense of people's health.

The fact is that fluorides in water do not help fight cavities. The tests that supposedly proved that were no doubt done by researchers who had a vested interest in the results or who were paid off by those with a vested interest. It is sad but true that this kind of thing goes on.

While "excess" fluorides will result in brittle teeth and bones, smaller amounts cause problems of all kinds, too. As stated in the lesson, fluorides are toxic. All toxins are carcinogenic and interfere with normal body functioning. Anyone seeking health should stay completely clear of known toxins, including fluorides.

**You spoke of water containing impurities, and you mentioned inorganic minerals, chemical additives and softening agents. Are there other impurities in water? If so, what are they?**

Anything and everything in water is an impurity. The main reason why waters usually contain so many impurities is because water easily dissolves many substances. That is to say, many substances are water-soluble.

The most salient impurities in water include both living and dead organic matter, including bacteria; corrosion products from pipelines, including lead, zinc, copper and iron; carbon dioxide, which enables water to take calcium, magnesium and lead into solution; iron and manganese, which are taken into solution in the absence of dissolved oxygen; and algae.

Some of the impurities in water make it taste very bad or give it an unappetizing color. Organic matter may decompose and make water smell unappealing. Inorganic minerals in water make it hard, and hard water, because it's already holding so much in solution, is not as good for washing and cleaning as is soft water. For the purposes of this course, keep in mind that impurities in water are toxic in the body and contribute to the need for diseases.

**You spoke of hard water and soft water. What do you mean by those terms?**

Soft water is water that is deficient in or free from inorganic mineral substances, such as calcium and magnesium salts, that prevent lathering of soap. Hard water is water that contains enough calcium, magnesium and other mineral salts to prevent the lathering of soap.

As you can see, water does not have to be devoid of minerals to be labeled "soft." It only has to be "deficient in" minerals, to the extent that soap will lather, to be labeled "soft." Needless to say, distilled water is the softest water there is, since it is devoid of inorganic minerals. However, not all soft water is distilled or good for drinking. Many spring waters are softer than most well waters. Sea water is hard water, as are mineral waters, by definition. In fact, hard water is just another word for mineral water—or vice versa.

As a final note, I might mention that water that is softened by addition of chemicals is more harmful than waters that are naturally soft or are distilled. Naturally soft waters are harmful to whatever extent they contain any impurities. As stated in the lesson, distilled water is the only water fit for drinking.

**What kind of water should be used for bathing?**

The water used for bathing is not so crucial as is the water used for drinking. Soft water is preferred over hard water because its greater solubility means that more dirt, oil, etc., from the body can be taken into solution in the water. Hence, you can get cleaner more easily when you bathe with soft water.

**You presented an entire lesson on water without mentioning the use of water in enemas, colonics, etc.! Please speak on these subjects.**

The only place where water should enter the body is through the mouth. The body does its own cleaning of its internal parts. Putting water in parts of the body where it doesn't belong constitutes interference with normal body processes. It is enervating to take enemas or colonics, and enervation leads to toxemia and disease.

The symptoms of enervation that people experience after an enema or colonic are usually mistaken for symptoms of well-being. This is a common error, but one that needs to be corrected if health is to be obtained. An analogy can be made between enemas and drugs. Amphetamines, also known as "uppers," definitely give a feeling of well-being. Yet, they do not bring health and, in fact, are extremely detrimental to the health. Just because something makes you feel good (at first) does not mean it is good for you. It could be that it's stimulating and enervating you and setting the stage for disease.

[Home](#) > [Lesson 14 - Water Transports Nutrients To All The Body Cells](#) > Article #1: The Fountain Of Life by Herbert M. Shelton

### **Article #1: The Fountain Of Life by Herbert M. Shelton**

Water, from the dew that distills on the rose leaf to the ocean that heaves its vast tide around the world, is one of the many wonders of existence. It makes the beauty of our silvery clouds and golden sunsets; it spans the heavens with the hues of the rainbow; it dances to earth in April showers; it murmurs in brooks and thunders in cataracts; it waters the earth, bids plants to grow and carries our commerce over vast seas. Without it the earth would have forever remained one vast, barren rock—a lifeless desert upon which the winds would sweep up the dust.

Water has given the earth its covering of soil and carpeted this soil with verdure. Deprived of water, plants droop and wither; without water, animals thirst and die. No wonder an early writer has left us the thought that at the dawn of creation the spirit of God moved upon the face of the waters. There is no life without water.

The foregoing eulogy of water is paraphrased from Dr. Thomas Low Nichols. We need only add that, without water, no seed could germinate, no plant could grow. What wonder, then, that water has so often been worshipped as the source of life. The Egyptians worshiped the Nile, the river that made possible their yearly crops, their life and civilization. The Hindus worship the Ganges. Are these people doing other than paying tribute to one of the basic elements of living structures and functions?

Water is a primal need of all forms of life. We have previously emphasized the fact that the cells require a liquid home and that dehydrated protoplasm is as lifeless as dust. It is only in a liquid environment that sperm and ovum can meet and mingle; it is only in a fluid medium that cellular reproduction can take place in the complex body; it is in a liquid medium that the embryo evolves towards maturity. It is only by being dissolved in water that the elements of vegetable matter take on their beautiful forms and colors.

The mystic motto of Thales, "Ariston men hydor" (the best of all things is water) might, perhaps, be explained by the fact that dehydrated cells are as lifeless as dust. In a similar vein, Goethe said of the elements of liquids: "They come from heaven and rise to heaven, returning again to earth." Water is so essential to life that none of its functions can be carried on without it.

Deprive man of water and he is soon reduced to a few pounds of dust. His body is about 70% water, his blood 90%. Water forms the greater part of his brain and nerves. The eyes are composed of little sacs of transparent water. Water not only enters the composition of all his tissues, but those tissues that have least water also possess little vital endowment.

Bone, which is the most passive tissue of the body, has much less water than muscle, which is very active. Water is the grand agent of all man's vital functions. It is essential to the process of assimilation and disassimilation. A lack of water soon manifests itself in failure of function. Not a particle of nutriment can enter one's blood and from there is taken to the cells until it is first dissolved in water. It is water that carries nutriment to the cells; by water, also, the body carries its waste from cells to be excreted. Those who have worshipped oceans and rivers have not been so far wrong in regarding water as a sacred element.

The fountains of Greece were chosen as sites for her temples. Water was the symbol of purification among the Jews; in baptism it became a similar symbol among the Christians. How appropriate was the symbol! It is not only the best medium with which to cleanse the surface of the body, but it is the only medium by which internal waste can be carried to the organs of excretion. It is the only medium capable of circulating in all of the tissues of the body and penetrating their finest vessels without irritation or injury.

Without water, the blood, lymph and tissues could not be kept sweet and clean. It might almost be said that water literally cleanses the tissues.

As water is being constantly lost from the body in its excretions—sweat, breath, urine, feces, mucus—there is need to frequently replenish the supply. Water is the only drink, although we do not take as drink all the water we use. All other fluids we take are either foods (fruit and vegetable juices, milk, soup, etc.) or poisons (beer, wine, whiskey and other alcoholics, tea, coffee and poisoned soft drinks).

There is water in everything we eat, so that under many circumstances of life, it is possible to get all the water the body requires in foods without the necessity of taking other water. While fountains bubble and rivers run, water will not be abandoned by those who love the welfare of their body.

Man's lifelong water requirement is associated with his continuous secretion and excretion. He expels water through the lungs each time he exhales; he loses water through his skin continuously; he loses water through the kidneys just as continuously; he loses water through the bowels and mouth at all times. Because of this continuous loss of water, he must replenish his supply at intervals, the frequency of replenishment depending on the rate of loss. Water evaporation through the skin is hardly noticeable when he is resting; if it is warm or if he is very active, he sweats more; hence there is greater water loss.

The evaporation of water from the skin is a most important arrangement for control of body temperature. Man's normal body temperature is supposed to be 98.6°F., although there is reason to think that this, like all the other "norms" of life that have been accepted, may be slightly high. Heat regulation is of great importance to the body. But sweating serves another important function; namely, that of maintaining normal water balance of the body. Too much or too little water in the fluids of life means trouble. If there is too much water, increased sweating helps to reduce this; if there is too little water, reduced sweating helps to conserve the water supply.

It is said that water is the life-supporter and that more should be taken than thirst demands. But no good reason has yet been offered for the implied principle that thirst is an unreliable guide as to how much water is needed. Dr. Trall stated: "Only a very small quantity of water is necessary as a drink, provided our dietetic and other voluntary habits are physiologically correct. The vast quantity usually taken to the stomach is called for by the feverish and inflammatory state of the system produced by concentrated food, flesh, salt, spices, etc." There is no fixed quantity of water that one must drink during the day. The amount needed is determined by a variety of factors. Age, sex, temperature, activity and the character of food eaten are the chief factors that determine the amount of drink required. It is, therefore, stupid to lay down any hard and fast rule (such as one must drink six glasses of water a day) about the amount of

water needed. When it is hot and we sweat more, we drink more; when it is cold and we sweat less, we drink less. If we are active and thus sweating more, we need more water than when we are inactive and sweating less. Thirst guides us in drinking as hunger guides us (or should) in eating.

That drink which has no fumes is good for us. It leaves us to sing over our daily labors with ruddier cheeks, purer feelings and brighter eyes than alcohol can bestow. When water is neglected for Old Port, and sleep is traded for *stimulants* and *narcotics*, when the beauties of nature and the virtues of walks in the country are exchanged for the "thrills" of intoxicants, not only are the real pleasures of life greatly reduced, but the powers of life are also lessened. Water is the great cleanser and purifier. This has received recognition in religion as in daily life; it is the great thirst quencher and menstruum of vital activities.

Water serves its various functions in the body in proportion to its purity, and not in ratio with which it is laden with minerals and organic substances. Mineral waters and waters that carry quantities of organic impurities are, to the extent that they are thus laden, unfit for use. The old medical notion that water so foul the cows won't drink it is good *medicine*, is but another of the false notions that have been fostered by this profession. The present-day notion that only drugged water (water that has had iodine, lime, chlorine and fluorides added) is fit for human use, is a damaging fallacy.

Not many years ago, mineral springs, sulphur springs and hot springs were special resorts of invalids. When, in some out-of-the-way spot, a farmer found a spring with water so strongly impregnated with "bad smells" and "foul taste" that thirsty cattle would not drink it, he imagined himself possessed of a prospective fortune. Here is a pool, he would say to himself, with water possessed of *curative properties*. A hotel would be erected near the pool or spring, physicians would send patients there to drink the water and bathe in it, and many remarkable *cures* would be reported.

The faith in the *curative* or *medicinal* virtues of mineral waters simply means that the fundamental principle of drugging—that poisons are *medicinal*—has been applied to drink and that impurities have been mistaken for wholesome properties.

Animals, like man, if forced to drink offensive water from springs, learn, as man does, to *relish* it. It is just possible that they learn, also like man, thereafter to find the pure, soft water they once relished to be flat, insipid, unendurable. We know that animal tastes are susceptible to perverse cultivation as much as are man's.

We pollute our water supply as persistently as we do our air supply. Our cities drain their sewage into the rivers and lakes and into the waters along the beaches of the country. Many beaches have had to be abandoned, so great has been the pollution. Some of our lakes smell to high heaven with the odor of sewage. Commercial concerns, manufacturers, etc., drain the refuse of the factories into the streams. Poison sprays poured over the vegetation of the country are washed down to the streams and lakes. With one stroke we poison the soil and the water. Spraying kills plants, birds, bees and many forms of animal life.

It has been found that many of the detergents, germ killers, insecticides, herbicides, various solvents and other synthetic chemicals now so freely employed in our determination to solve all our problems by poisoning the whole world, pass unchanged through (sewage) treatment plants to water courses and unchanged through water treatment plants to consumers.

Some of the detergents seep through the soil into wells, enough sometimes to cause the water to foam when shaken. Even more ominous than these sources of water pollution are the radioactive substances in fallout and from plants engaged in industrial production of fission products. Modern industrialism is rapidly destroying all of our natural resources in the name of "progress," "development," etc., but actually, for the profits it derives from exploitation of the workers and natural resources of the nation.

Rainwater, soft water from an uncontaminated spring (many springs do not provide soft water) or distilled water are the only waters fit to drink. Filtration removes all impurities suspended in water, but it does not remove those held in solution. We are told that distilled water is dead. There is no such thing as

live water. We are told that distilled water, being free of minerals (dirt), leeches the salts from the tissues of the body. Were this true, the only water that is fit to drink would be that which is fully saturated with minerals.

Short of complete saturation, the water would still have a tendency to rob the tissues of their minerals. Ordinary drinking water, containing some mineral matter, would merely rob the tissues of fewer minerals than does distilled water. Water serves, in the blood, to carry minerals to all the cells of the body. Not the crude mineral matters of the soil, but organic salts of foods are the substances it should carry to the cells. There is no evidence that distilled water does not yield up these salts to the cells as readily as does mineral-laden water.

William Lamb, M.D., of England took the position that man is not normally a drinking animal, but that sufficient water for all his purposes is contained in fruits and vegetables and that these should constitute his diet. More than 50% of our food is pure water. Why, then, do we have frequently to take in water other than that contained in our foods? Because we are constantly giving off water in the form of sweat, urine, vapor in our breath and water in our stools, and we give off more than the food supplies.

This is not always true. Many factors determine the amount of water the body loses, and in many instances the food supplies all the water needed. In other instances, it does not. A man working in the fields in the heat will pour out such quantities of water that he will need extra supplies. A stenographer working in an air-conditioned room and taking a diet containing much water may not need any extra water. Our diet, in fact, is often much too dry and may be improved without resort to beer, coffee or tea; but there remain many conditions in which life is glorified with a glass of cool, clear, soft water.

It is advocated in some quarters that fruit and vegetable juices be taken instead of water. This is an irrational program. There seems to be some thought associated with this practice that water is, somehow, an evil. The relations of water to the living, healthy organism and the purposes it serves in the various functions of the body are proof that water is both safe to use and essential to life. As it constitutes the greater portion of the body, there is no reason to fear it. The hydrophobic individual who drinks fruit and vegetable juices instead of water is certainly eating between meals. He is certain to overeat and unbalance his metabolism. Substituting fruit juices for water is not altogether unlike the effort to substitute the oxygen in foods for the oxygen of the air.

It should be understood that milk is not a drink, but a food. We get milk from animals who have prepared it for the nourishment of their young. Fruit and vegetable juices are also foods, not drinks. Liquid foods should be understood as such, and should be thought of as drinks. Soups are also liquid foods. Coffee, tea, cocoa, chocolate beverages, soft-drinks and similar beverages should be understood to be, not drink, but poison.

It is possible to drink too much water and it is possible to take too little. Both extremes are hurtful.

We come to the habit, a cultivated one, of drinking with meals. Our rule should be *never to drink with meals*.

Water, fruit juices, vegetable juices, soups and other fluids taken with a meal inevitably dilute the digestive juices and alter their pH. This retards the processes of digestion. Coffee, tea, cocoa, chocolate drinks and all drinks that contain toxic substances and not only dilute the digestive juices, but also add the inhibiting effects of tannic acid, caffeine, theine, theobromine, etc., to the retarding effects of liquids in general. Such substances with meals cannot be too strongly condemned.

In some quarters, drinking immediately before meals is condemned. If this condemnation is applied to all liquids except water, *Hygienists* can endorse it. But water remains in the stomach such a short time after ingestion that it may be taken five to ten to fifteen minutes before a meal without interfering with the digestive process. The other liquids (which are either foods or poisons) are not so quickly expelled from the stomach. The current practice of drinking vegetable juices and fruit juices shortly before meals is ruinous to starch and protein digestion.

It is generally safe to drink an hour to an hour-and-a-half after a fruit meal. (We formerly said drink could be taken half-an-hour after a fruit meal, but in many cases fruit remains in the stomach longer than this.) Starches require a maximum of two hours to digest in the stomach, so it is usually safe to drink that long after a starch meal. Proteins require about four hours for gastric digestion. It is wisest to wait that long after a protein meal before drinking.

### 1. Introduction

Rest and sleep are two essentials of life that have an importance unrecognized by most people. Sleep and rest are indulged because the need for them overtakes rather than because of an enlightened awareness of their role in well-being.

This lesson endeavors to teach the physiological bases for rest and sleep. Their significance can then be better appreciated.

Sleep is an infant science in that it has not been long studied. The 50 to 100 sleep researchers in this country think of themselves as pioneers, and in a sense they truly are. Also, they are medically oriented, as are most people, unfortunately. Now, about 30 years after sleep research began, sleep researchers have uncovered relatively little knowledge of what sleep is about. However, they do occasionally unearth a gem or two of useful knowledge.

The restorative roles of rest and sleep are everywhere admitted, but the physiological mechanisms are not clearly understood by researchers. Hopefully this lesson can prove not only enlightening but also furnish you guidance you can turn to benefit for yourself and your clients.

## 2. What Is Rest?

Rest is a period of inactivity during which the faculties can restore expended nerve energy. When we create wastes faster than our body can eliminate them and deplete our energies faster than our faculties can restore them, a period of inactivity enables the body to catch up on its homework. Physical and mental inactivity can be called rest.

There are many different kinds of rest. Some are:

1. *Physiological rest*, during which the body and most of its faculties are inactive, as in sleep and in fasting.
2. *Sensory rest*, during which time the nervous system and brain are relaxed or not normally exerted, as in fasting, sleep and meditation. The eyes are closed in sleep and meditation, which curtails a great drain of energy.
3. *Emotional rest*, as in withdrawal from the affairs and excitements of daily life that draw upon our nerve energies.
4. *Mental rest*, as in eschewing those affairs that demand our attention and thoughts.

Essentially, rest is the curtailment of energy expenditure and waste generation. This permits the body to redirect energies to cleansing and restoration.

### 2.1 Relaxation as Rest

To relax means to cease or decrease exertion. The word has broad connotations, and recreation or play might be called relaxation. Generally, relaxation means to let go of that which stresses the body and to undertake a course that does not tense or stress. Relaxation is a variant form of rest.

### 2.2 Only the Body Needs Rest

The cells of the body require rest but not necessarily sleep, but the brain and nervous system sleep. Cells require periodic rest so that they may cope with their eliminative and restorative functions.

### 2.3 Rest is Incidental to Sleep for the Most Part

Many people are apt to confuse the words rest and sleep as being synonymous. Rest, as we have seen; means cessation of activity. Sleep necessarily implies rest due to the immobilization of the body, but the condition of sleep exists only when consciousness has ceased. However, we should note that not all forms of unconsciousness are sleep. Coma, catalepsy and stupor must not be confused with sleep.

## 3. What Is Sleep?

Our foremost sleep scientists have not settled upon an answer to this question. Obviously sleep is loss of consciousness. But what more is there to it? Why should awareness cease? Does not the brain conduct millions of processes continuously even though it has lapsed into unconsciousness?

Sleep scientists have several theories about what sleep is: One is that the neurons become fatigued and simply lower their activities below the level required for consciousness. Another is that the brain inhibits

the reticular activating system.

Another theory is that the brain and nervous system operate on nerve energy, a form of electricity. The body, like an electric car, needs to be recharged at night. Sleep is a partial shutdown for recharging.

### 3.1 Why Should We Sleep At All?

Dr. Nathaniel L. Kleitman of the University of Chicago has concluded that the body generates nerve energy during sleep and that we sleep for this purpose. All other writers and researchers observe and attest to the restorative powers of sleep but do not suggest the physiological basis for these powers.

Among the texts you have is *Better Sleep for a Better Life*. This book details many particulars on the whyfore and conditions of sleep. We shall not repeat them here. We sleep because the brain requires, we may presume, a state of unconsciousness for the regeneration of nervous energy.

### 3.2 The Purpose of Sleep

Experiments with electrosleep indicate that the body generates low-level electricity during sleep. So far, researchers have not discovered where the body stores its electricity.

The primary purpose of sleep seems to be the generation of nerve energy. That seems to be the only reasonable explanation, for most researchers agree that sleep is a restorative. The vitality of the organism is restored under the condition of sleep.

Guyton's *Textbook of Medical Physiology* takes the position that sleep occurs because of neuronal fatigue. He says that, when one of the millions of parallel neurons in the feedback circuits falls out of activity, the lowered level of excitability of other neurons starts a chain of depressed activity that results in sleep. More particularly, wakefulness is attributed to the excitability of the reticular activating system, which is, a network of neurons, and sleep is attributed to lack of excitability.

Perhaps this does chronicle the mechanism of sleep, but other passages in the same physiology text appear to negate this position. Nerves or neurons perform twenty-four hours daily, just as the heart muscles. They need no rest or sleep. Only a certain part of the brain needs sleep, for the brain and nervous system continue to conduct millions of processes under the condition of sleep.

It appears that the faculty of wakefulness must cease in sleep and that neurons are only partially inactivated. Moreover, it is known that the brain is active during sleep except for those areas of the brain involved with consciousness. Some body processes are conducted more vigorously in sleep than in wakefulness.

Guyton is unable to explain what causes fatigue in neurons since, in theory, they are not subject to fatigue. He says: "We still need to explain the cause of fatigue of neurons after 16 hours of wakefulness and their recovery of excitability after 8 hours of sleep." Perhaps the depletion of nerve energy causes fatigue in neurons.

Sleep is primarily for the purpose of generating nerve energy or low-level electricity. Many other beneficial purposes are also served during sleep. The physiological rest obtained during sleep is extraordinarily valuable. During the prolonged rest of sleep, the body restocks its cells and organs with fuel, replaces cells that have lost their vitality and rids itself of extraordinary toxins that may have been uneliminated the previous day. Thus, the value of sleep is manifold.

The benefits of sleep may be chronicled as follows:

1. The regeneration of nerve energy;
2. Refueling the liver and cells with glycogen;
3. Destruction of old cells and replacement with new cells (Multiplication of cells occurs during sleep at a rate of more than twice that during waking hours); and
4. The body expels more debris and wastes during sleep and rest than when active.

Undoubtedly there are other benefits of sleep, but these are the salient ones. For instance, the body uses less nerve energy and generates less waste when asleep.

### 3.3 Sleep As an Essential of Life

We can accept sleep as being absolutely necessary without question. But, as well, getting enough sleep is an essential of life. It is impossible for a healthy person to oversleep but undersleeping is an evil of our times—a transgression most of us commit against ourselves.

When we undersleep, not enough nerve energy is generated to meet needs. We use more nerve energy when we are awake longer and generate less with less sleep, other conditions being equal. When our nerve energy is squandered to meet excessive consciously-directed activities, then nerve energy for unconscious body activities is not available. This may mean poorer digestion, impaired elimination and so on—the body must suffer generally.

With adequate sleep enough nerve energy is generated to meet our normal needs. The question of what constitutes adequate sleep and how to best obtain it is very important. The book, *Better Sleep for a Better Life* treats this subject in depth. In this lesson we'll endeavor to explore other materials to reinforce the wealth of observations in that book.

### 3.4 Some Current Views of Sleep

To be sure, the views offered on sleep in texts and books are few and mostly noncommittal to any stance or position. What scientists really know about sleep amounts to very little, and their views or theories are rather timid.

A view of sleep that is interesting is expressed in *The Complete Book of Sleep* by Diane Hales, a sleep researcher who has haunted many sleep laboratories looking for revelations on the subject. Her observation about sleep is instructive: "We think of sleep as being passive and uniform, but it actually consists of cycles of complex activity. We think our bodies and brains rest during sleep, but in fact our muscles tense, our pulse, temperature and blood pressure rise and fall; we are sexually aroused; our senses evoke a world of sights and sounds. We think that in sleep we shed our fears and feelings, but our personalities set our sleep patterns, and our sleep shapes how we feel and act. We accept sleep as commonplace, yet when we cannot sleep, we yearn for it more fiercely than for the rarest treasure. We are able to go without food or water or companionship more easily than without sleep."

On the all-important question of what sleep is or why we sleep, Ms. Hales is silent, though the book asks these very questions. One speculation ventured is that nature instituted sleep to keep animals quiescent during darkness so as not to injure themselves; so as to survive the perils of darkness. But a most compelling observation is made by Dr. Allen Rechtschaffen of the University of Chicago. He poses the question: "If sleep doesn't serve an absolutely vital function, then it's the biggest mistake the evolutionary process ever made. How could sleep have remained virtually unchanged as a monstrously useless, maladaptive vestige throughout the whole of mammalian evolution while selection has, during the same period of time, been able to achieve all kinds of delicate finely tuned adjustments in the shape of fingers and toes?"

What a good question! To ask the question is to acknowledge that nature does not err and has definite purposes in developing our faculties.

Other observations made by Ms. Hales are worth noting: "But if there is a timeless need for sleep, what is it?"

This question remains one of the most perplexing biological riddles. Aristotle thought that we sleep because of cooling of the vapors of the head. Freud thought sleep was a symbolic journey back to the security of the womb. Pavlov thought of it as a conditioned response. Others have argued that we sleep to repair the ravages of the day, or to purge our brains of extraneous information, or to conserve our

energy. Sleep may be maintenance time for our bodies or a sort of dress rehearsal for our brains.

"Perhaps none of these explanations is correct. Perhaps they all are, for it may well be that sleep—like waking—has many functions. We may be making an enormous and costly mistake by assuming that our nights are any less significant or complex than our days," says Ms. Hales.

I have previously cited Dr. Arthur C. Guyton's text on sleep. Two theories he presents about the mechanism of sleep are worth reviewing. These theories relate to the physiology of going to sleep.

"The first belief is that sleep is a passive process, occurring when the neuronal mechanisms that cause wakefulness become fatigued and therefore succeed to a lower level of activity. The second theory is that active centers in the brain transmit signals into the reticular activating system to inhibit it and thereby produce sleep."

The primary difference between the two theories is that one assumes that the usual slow wave sleep (delta sleep) results from decreased excitability of the reticular activating system due to fatigue, while the other holds that sleep results from active inhibition.

While Dr. Guyton favors the first of these theories, your instructor favors the second. The brain actively seeks sleep when its nerve energy falls below a certain level.

Another theory of sleep holds that we sleep in order to have dreams, so that our "mental mix" may be sorted out. Cited in support of this theory is the gravely ill effects resulting from denial of REM (rapid eye movement) sleep, that stage of sleep during which dreams are conducted. After a few days without REM sleep, test subjects were depressed, less alert, garrulous and unable to concentrate. In short, they suffered many of the same effects as if they had suffered a big deficit in their "sleep account."

Simply stated, the brain sleeps in order to regenerate a fund of nerve energy. Nerve energy is the "money of account" for human vitality.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 4. What Determines The Quality And Quantity Of Sleep We Need?

## **4. What Determines The Quality And Quantity Of Sleep We Need?**

The amount of sleep that a person needs varies according to the individual's body and his or her sleeping conditions. Some people fare nicely on five or six hours of sleep daily, while others require eight or nine hours daily. Why the difference? Sleep needs vary with every individual and every circumstance. People sleep more in winter than in summer! Why should that be so? Mental workers sleep more than physical workers! What causes that? People who work and sleep outdoors get by with one to two hours sleep less than those who work equally arduously indoors and sleep indoors. Why? To answer the above questions, one must understand the intricacies of nerve energy expenditure and the conditions that enable the body to most efficiently regenerate it.

### **4.1 Conditions That Promote Efficient Sleep**

The most efficient sleep is termed sound sleep, slow-wave sleep; delta sleep, stage four sleep or deep sleep. Deep sleep produces about twice the amount of recuperation as does lighter stages of sleep.

Since most Americans are toxic, it is doubtful that sleep researchers have examined the sleep of very many truly healthy people. The data the researchers have charted as normal really reflects the average of unhealthy people.

Truly healthy people sleeping under ideal conditions require less sleep than less healthy individuals. This is due to several factors. Firstly, a healthy person needs less recuperation due to less energy

expenditure. Secondly, a healthy person is capable of a greater proportion of very sound sleep because of less internal body disturbance. Thirdly, a healthy individual can regenerate nerve energy faster due to the increased efficiency of the person's faculties.

The ideal conditions of sleep are determined by both internal and external circumstances. The more comfortable the sleeper, the sounder their sleep will be. Pure air occasions less sleep and quiet surroundings promote deeper sleep. Also, the less light in the sleeping area, the less disturbed will be the sleep.

## **4.2 Conditions That Interfere With Sleep**

Certain internal conditions favor or disfavor sleep. A person with a toxin-free body sleeps more readily and more soundly than a toxin-laden individual. For example, insomnia will often result from drinking coffee. The distress and stimulation from the caffeine may inhibit sleep, especially sound sleep. The body must expend energy in expelling the caffeine. At the same time, it generates less nerve energy because of lack of sound sleep.

Another condition that interferes with sleep is eating at bedtime. The primary reason for sleep is to regenerate nerve energy. However, if a person eats before sleeping, his/her body will direct much of its energies towards the digestion of the food. Since the brain is involved in digestion, less sound sleep will result. Additionally, the body will suffer a deficit of nerve energy because less was regenerated during the digestive process than would have been if the food had not been eaten.

Anything that is in the sleeper's environment or body that disturbs the senses or uses more nerve energy than normal interferes with sleep, thus making it less efficient and effective.

The book *Better Sleep for a Better Life* details specific conditions that interfere with sleep.

## **4.3 Fresh Air and Sleep**

Those who sleep in fresh air invariably report better sleep and a lesser need for sleep than those who sleep inside their homes. Why should this be so? Stated very simply, any improvement in sleeping conditions improves sleep. When a person sleeps in fresh air, the body receives its oxygen needs in a relatively pure state. Air inside homes is likely to have less oxygen and more pollution than fresh air. Impure air furnishes less of our needs and gives the body more problems than does fresh air.

It is very beneficial to sleep by open windows in a quiet environment so that fresh air flows freely during sleep. If the environment is noisy, it is wise to have the house ventilated so that fresh air is continuously funneled to and through the bedroom. Even polluted air from the outside is better than stale air trapped indoors. Sleeping is also improved by working in a fresh air environment during the day.

## **4.4 Exercise and Sleep**

Exercise is a blessing that we should indulge regularly. Optimally, we should exercise daily, but certainly not less than four times weekly. Performed as much as possible within our limitations, exercise confers only benefits and no liabilities. Exercise in the form of jogging, calisthenics, gardening, bicycling, swimming, brisk walking, etc., up to about half an hour daily, takes no time from our waking moments! Sleep needs are reduced by about that amount!

Exercise "fine-tunes" the organism. Elimination is so accelerated by exercise that extraordinary body cleansing occurs. The body not only eliminates extra carbon dioxide generated during vigorous exercise, but it also occasions the removal of accumulated toxins ingested from nonfoods and drugs and toxins created as a result of overeating, eating wrong combinations, eating under stress, etc.

A pure, less toxic body needs less nerve energy. Less expenditure of nerve energy means less nerve energy need be generated, hence less sleep is required by a person who exercises regularly.

## 4.5 Eating Practices and Sleep

Foods that require less digestive and assimilative energy use less nerve energy. Foods that are associated with toxic materials, such as cooked foods, condiments, additives, etc., give the body eliminative problems. Eliminative problems require a great deal of nerve energy to be properly dealt with. For example, a single bout with alcohol can exhaust the body for a day or two. The need for sleep is greatly increased so that the body may recuperate its energy.

Here are some salient principles you should keep in mind relative to diet and sleep requirements:

1. The more wholesome the food, the less nerve energy is required to digest and use it. Wholesome food lessens sleep needs and increases sleep efficiency.
2. The more unfit the foods eaten, the more nerve energy is expended and the more sleep is required. Moreover, sleep will be less efficient when unwholesome foods are consumed.

Fasting individuals require only three to five hours of sleep daily after fasting for a short time. People who eat meat, condiments and cooked foods and who overeat require inordinate amounts of sleep. Despite the extra sleep, they are usually not well rested because they have a perpetual deficit of nerve energy due to their unwholesome practices.

You should not eat for at least two hours prior to bedtime. Though meals do sometimes occasion drowsiness and sluggishness, due to the redirection of blood supply to the digestive organs, we should not expect to sleep well while the body is conducting digestive and assimilative tasks.

Eating beyond the body's need imposes an enervating task upon the body. Processing and disposing of food requires a great deal of energy. Improper combinations or unwholesome foods usually end up in a pathogenic mess that drains the body's resources in eliminative efforts. This drain of energy results in poor sleep and in a correspondingly greater need for sleep. An enervated individual who sleeps 12 hours daily may be less rested than a healthy person who gets only six hours!

## 4.6 Relaxation and Sleep

Relaxation is a great prelude to sleep. In a relaxed state, we drop the cares of the world and let go. Also, muscular tensions are released. When we take it easy and let go of tension, the body redirects its energies to its most needed tasks.

The cares of the world may be difficult to drop. I personally find it easy to let go of them by doing a few words on a crossword puzzle, solving a few chess problems or by pursuing some other consuming interest. Then I lay down, close my eyes and let myself go limp as if I were a bag of sand.

Somnolence comes quickly when the need for sleep exists and the demands upon the brain have been lowered as much as possible. Tensions, worries and stresses increase the need for sleep while simultaneously making it more difficult to fall asleep.

Many excellent relaxation methods can be practiced with benefit. One method that does not help you fall asleep so much as it helps you perform everyday activities in a relaxed and efficient manner is the Alexander Technique. There are instructors in many major cities.

People who are tense and who have trouble falling asleep or staying asleep, besides improving their diet and getting more exercise and fresh air, should search for and find a relaxation method that will help them.

## 4.7 Bedding and Sleep

In America, bedding usually consists of an innerspring mattress over box springs, sheets, a pillow with pillow case and blankets and/or quilts.

For body comfort, the softer the mattress, the better. Of equal benefit is airiness. A soft innerspring

mattress meets these conditions ideally. A thin cotton mattress on top of a foam, air or waterbed mattress works well too. The body is disturbed by pressure points, hot spots, cold areas and areas deprived of air. The body, like the lungs, will suffocate without fresh air. While the skin requires only a fraction of the air required by the lungs, it requires it nevertheless. Plastic materials deny the body air.

Body exudates then collect and irritate the skin, thus causing a lighter stage of sleep and frequent body shifting to overcome the discomfort.

Fabrics that breathe, such as cotton, solve this problem. Sleep should be conducted on cotton surfaces with lots of circulation underneath. Cotton sheets, blankets or materials should be used for cover.

Sleep is more efficiently conducted when the body is comfortable in temperature and when it is physically at ease. If the air temperature is warm, nude sleeping is ideal. Indoors, a fan may prove valuable if the air is very warm. If the temperature is in the sixty- to seventy-degree range, light-weight cotton pajamas or nightgowns will permit the warmer air radiating from your body to rise through the coverings into the cooler air outside the covers. Thus circulation is assured.

Perhaps you know that sleeping on concrete would provide very few contact points between the body and the concrete. The body's weight would rest on these points, thus creating pressure points that interfere with blood circulation and skin respiration. Distress of the areas in contact would soon occur and thus rouse the brain into a lighter stage of sleep in order to conduct a body movement.

On the other hand, a very soft bed permits the underside of the body to make rather even contact with the sleeping surface. Optimal air circulation can occur on the underside if cotton is underneath, and body weight is evenly distributed so as to cause no uncomfortable pressure points.

In nursing homes and hospitals, very hard beds are used. This is in keeping with the current medical philosophy. Bed sores frequently occur, with resulting "infection." Rather than "infection," what really happens is that oxygen-starved cells and tissues that are under constant pressure die and suppurate due to decomposition. No one should be confined to bed all the time. Daily fresh air and sunshine on the body is of inestimable importance. Neither should the body lay on hard or overly firm surfaces.

To sum up, bedding should permit optimal air flow and maintain an even, comfortable body temperature and even distribution of body weight over the underside.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 5. The Value Of Napping

## **5. The Value Of Napping**

For many reasons, our night's sleep may be inadequate. Our daily activities may involve an extraordinary amount of stress that squanders nerve energy. Heavy body toxicity may unduly drain the body of nerve energy. When any of these conditions render us drowsy, sleepy, listless or "down," we need a nap. Many people resort to stimulating drinks (coffee, tea, colas) or foods (nonfoods such as chocolate, toxic foods such as meat, etc.) to "perk" them up. Stimulants of these kinds only exacerbate the problem rather than solving it. They further drain nerve energy even though the drain may not be evident at the time.

A nap of from a few minutes to an hour not only rests the body, but it also permits the brain to substantially renew its fund of nerve energy. In many countries around the world, the siesta is a normal practice. A one- or two-hour nap after midday refreshes people in many parts of the world. This napping practice contributes to their health and well-being.

It is said that a half-hour nap during the day is worth a whole hour of sleep at night. There is truth in

this. Further, it is better to take an hour for a nap and perform efficiently in the afternoon and evening hours rather than forego a needed nap and drag through the whole afternoon. The added efficiency more than offsets the extra time applied when one is not alert or is not feeling good.

The noon nap originated in prehistoric antiquity. Among the ancient Greeks, the first meal of the day was ordinarily of fruits. This meal was followed by a period of sleep—a nap. When rest and sleep are taken during the heat of the day, the meal is better utilized and the body is renewed. Animals in nature also observe "siesta" during the heat of the day.

The healthful custom of taking a nap after noontide has been largely destroyed by the needs of industrial society. This loss has, to a great extent, contributed to our ill health and stimulative habits that make industrial nations so highly stressed and diseased.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 6. Dreams And Their Role In Sleep

## **6. Dreams And Their Role In Sleep**

Why do we dream? What physiological purposes are served by dreams?

Many students of the subject have ventured explanations. Sigmund Freud has, in the last century, described dreams as "the guardians of sleep." This author favors that view.

### **6.1 Dreams As Guardians of Sleep**

The dream stage is called REM sleep. This denotes a period of time during which there are rapid eye movements. These periods always occur after a period of deeper sleep. They last from a few brief moments up to half an hour. Dreams usually occur in 90-minute cycles throughout the night. However, some cycles are devoid of dreams, especially at the beginning of the night if the sleeper is very exhausted. Later, 90-minute cycles usually have the REM stage or a stage of dreaming.

Cited in the book *Better Sleep for a Better Life* are cases of only delta wave sleep on a fluidized air bed. Dreams did not occur and sleeping time was cut in half. This is very instructive in view of the many theories afloat about the purposes of sleep and the necessity of REM sleep or dreaming to insure our well-being.

Dreams are said to be necessary for "sorting out and classifying" the previous day's impressions or data input. They are said to be analogous to the rezeroing of an analog computer in preparation for new problems and input.

Study and reflection upon the whyfore of dreams have led me to believe that they serve a valid physiological role. We note that, under ordinary sleeping conditions, the body has a 90-minute sleeping cycle. However, this cycle is nonexistent when sleep is most efficiently conducted, and extraordinarily tired people may fuse the cycles at the beginning of the night. This would seem to indicate the nonnecessity of dreams where sleep conditions favor the objectives of sleep. Dreams seem to be a tool the body uses when sleep is still needed but is threatened.

For example, when we have a full bladder during the night, we may, prior to waking, have a dream during which, vicariously, we urinate. The dream has supplied ersatz satisfaction to the urge and thus preserved sleep. However, this may only delay the inevitable. But the purpose of prolonging sleep has been served. Dreams of eating, drinking, defecating and discharging other body urges are commonplace. Especially common are dreams of sexual fulfillment.

It is reasonable to conjecture that parts of the brain that are aroused by stimuli are quieted by vicarious fulfillment through dreaming.

## 6.2 Dreams as Tranquilizers of the Mind

In guarding against premature wakefulness, dreams also often tranquilize or becalm the mind. Consider the following, example: Dave had been trying to solve a problem during the day, and he was rather intense and involved with it. His brain had become very involved with the problem, and the impulses to solve it arose again and again, even during his sleep. When these impulses become strong enough to interfere with sleep, his mind "artificially" supplied an answer to allay the impulses and thus preserve sleep.

I have solved problems during sleep too often to recount. However, most of the solutions have proven impractical! It is the rare dream that supplies an answer that is applicable to the problem that besets us. Nevertheless, even a wrong solution is sometimes helpful in giving insights and setting the stage for a solution.

To conduct the processes of sleep for most efficient regeneration of nerve energy, dreams appear to be mechanisms the body uses for calming the mind when problems and other stimuli would otherwise disturb sleep.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 7. Establishing Conditions Most Favorable For Sleep

## 7. Establishing Conditions Most Favorable For Sleep

So far we have been discussing the various conditions favorable to sleep, as well as those that interfere with sleep. One of the foremost prerequisites for sleep is that we be sleepy. As obvious as this is, many people try to sleep when they are not sleepy! We should drink when thirsty, eat when hungry, defecate and urinate upon urge and, likewise, sleep when sleepy.

In a nutshell, we should have our "nest" so prepared that it optimally furnishes the conditions for the soundest sleep. Among other conditions, this means:

1. Sleeping quarters should be noise-free! Noise disturbs sleep. If noises cannot be eliminated, the steady hum or drone of a fan or other machine may mask them.
2. Sleeping quarters should be as dark as possible. Light stimulates the eyes and disturbs sleep. Light of any intensity at all makes sleep less efficient.
3. As discussed in the section about bedding, all the requisites for body comfort should be provided for.
4. Our stomach should be relatively empty. Digestive processes detract from the soundest sleep. We should not have a heavy load of food within when retiring, either juicy or concentrated. Can you imagine what eating several pounds of watermelon before retiring would do to your sleep? Obviously your sleep would be disturbed by several visits to the bathroom during the night.
5. If excited by a movie, a discussion, TV or anything else, do not attempt sleep. Rather, get into some rather passive pursuit such as reading that will bring on the somnolent urge while the emotional condition is allayed.
6. Many individuals cannot sleep alone because they are so accustomed to sleeping with a mate. Sleeping with another represents a certain security and assurance.

On the other hand, sleeping with another has its liabilities. The movements and noises of the

sleeping mate may disturb sleep. If this is the case, an extra bed should be utilized.

The conditions for favorable sleep are more elaborately presented in the booklet, *Better Sleep for a Better Life*.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 8. Sleep Problems In Adults And Their Solutions

## **8. Sleep Problems In Adults And Their Solutions**

Though it seems wise to title an entry as above, it is really superfluous to list the solution to sleep problems when they are, as a rule, no different than other disease problems. Most sleep problems arise from violating the conditions favorable to sleep that you have been studying and from violations of life's laws. Thus, the solution to sleep problems is really the same as it is for other diseases that arise from the same violations.

### **8.1 Insomnia**

Insomnia is an inability to sleep. Obviously, this interferes with the body's ability to recoup the nerve energy it needs for the following day's activities.

If an individual complains about an inability to sleep and that he or she is not well-rested, the person is suffering from insomnia. Many physicians have noted that insomniacs really do sleep but don't realize it. Although this is true, many sleep specialists are now discovering that insomniacs' sleep is very low grade and is not very restful. Moreover, it may be punctuated by periods of wakefulness. Most insomniacs are not wrong about their problem existing. Too many physicians dismiss the patient's problem and prescribe sleeping pills or tranquilizers which ultimately make the problem worse by adding to the body's toxic load.

Rather than immediately searching for methods to induce sleep, you should first look for the causes of the problem. Insomnia results when an individual is assaulted by too much stimuli. Stimuli can result from improper sleeping conditions, but are usually due to body toxicity. This toxicity results from both autogenous sources and from ingested materials. Drugs and drug-like substances are foremost offenders. These include caffeine, condiments, chocolate, soft drinks, cooked foods, wrong foods, over-the-counter and prescription drugs, etc. The solution to insomnia is simple: Discontinue causes! Remove the conditions that interfere with sleep, and implement the conditions that promote it.

Insomnia is usually overcome in a few days during a fast and will not recur if a regime of healthful practices is adopted. A good night's sleep can be had by almost anyone who discontinues body-disturbing practices and institutes healthful practices.

### **8.2 Apnea**

A is a prefix meaning against or without and pnea means breath. Hence, apnea is a condition of being without breath.

During sleep many individuals will miss one or more breaths—they simply stop breathing momentarily. This stoppage of breath usually lasts only a few seconds, but it can last a minute or two in some individuals. The fact that the breath stops at all indicates a less than normal body condition. The longer the period of breathlessness, the more pathological the body's condition. This condition may occur dozens of times during a night in sufferers.

Apnea may occur because the brain is not issuing the proper commands to the lungs and body mechanisms to inhale and exhale. In the case of sufferers from multiple sclerosis, these signals may be misdirected. Or, apnea may be caused by growths or abnormal obstructions. Where these conditions occur, a choking sensation quickly alerts the brain and often awakens the sleeper. Apnea interferes with sleep and may be a significant factor in insomnia. If frequent breathlessness occurs, the body sounds its alarms. The sleeper must be brought to a phase of lighter sleep, even wakefulness, to restart breathing. Fasting and healthful living almost always restore the body to normalcy, thus overcoming apnea.

### **8.3 Snoring**

Snoring is not normal! A multitude of conditions can be responsible for snoring. Enlarged tonsils or adenoids may block the air passage sufficiently to cause the loud "flutter" of snoring. Most snoring occurs because the soft palate, when relaxed, flutters in the diverted current of air. Diverted air may be due to growths, fatty tissue in the throat, nasal deformities or other swelling.

Most fasting people who have previously snored are surprised when the condition disappears. The condition does, however, speedily return if the person returns to its causes. But many have overcome it permanently.

Flabby muscles or fatty growths may cause the condition. Fasting usually causes autolysis of the fatty tissue. A vigorous exercise program that includes head exercises sometimes corrects the condition.

Snoring is almost always present in those who suffer apnea although most snorers do not suffer apnea. The causes of snoring and apnea are sometimes one and the same, i.e., obstructions in the air passages. Solutions to snoring are rare but the surest is a healthful regime of living.

### **8.4 Narcolepsy**

Narcolepsy is a "seizure of numbness." It is an uncontrollable urge to sleep that may come upon the sufferer without warning. Such a sudden urge to sleep may cause an accident or may disrupt activities, though usually the sufferer has enough warning to situate himself/herself harmlessly.

An urge to nap should not be confused with narcolepsy. Even in a healthy person, sleep can be induced if the person suffers a considerable sleep deficit.

Incorrect actions of body control mechanisms are eliminated when the modifying influences of drugs and body toxicity are discontinued and removed. Fasting and a healthful regime will provide the answer to these problems.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 9. Sleep Problems In Infants And Children With Suggested Solutions

## **9. Sleep Problems In Infants And Children With Suggested Solutions**

Sleep problems in children are extensive in our society. These include extended wakefulness, crying, abnormal demands for food, apnea, head-banging, nightmares and soon.

Almost all of these manifestations spring from an abnormal body condition begotten of, today's criminal treatment of children. To feed babies anything other than mother's milk is a tragedy. Freshly expressed fruit juices might be substituted for a feeding of mother's milk here and there, but even that is not advisable before six months of age. All other feeding is a disaster for the infant. Inoculating and drugging infants is criminal in every sense of the word. Feeding them starches, cooked foods, caffeine

and other such fare wrecks their delicate but vital faculties.

Formula-fed babies who are started on cereals within two months of birth, who are given cooked and condimented meats and other unfit foods and are drugged develop many pathologies. These manifest as the "usual childhood diseases" and as sleep problems.

An infant that does not feel right will not act "right." Abnormal behavior comes from abnormal conditions. Usually, a short fast will enable the child's body to cleanse itself. A proper regime of living that includes exercise (yes, even for an infant!), correct foods for the age, fresh air and sunshine, ample sleep, etc., will further improve the child's conditions.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > 10. Nostrums, Medications And Drugs Adminstered For Sleep Problems

## **10. Nostrums, Medications And Drugs Adminstered For Sleep Problems**

Almost everyone has advice for insomniacs, including other insomniacs—but usually their advice just doesn't happen to work in their particular case! One of the latest fads is to take a heavy dose of the amino acid L-tryptophan before retiring. This fad came about as the result of an inquiry as to why drinking a glass of milk seemed to cause sleepiness in those who had sleep difficulties. However, milk is not heavy in this amino acid, hence there must be some other explanation as to why people become sleepy after drinking milk.

Anything that requires extra blood and nerve energy makes us drowsy, especially if taken at or near our regular sleep hour. Tryptophan itself is a fractionated product and as much as half an ounce will cause vomiting and diarrhea. The mechanism whereby sleep is hastened by a heavy dosage of tryptophan is probably from a drug effect, despite medical protestations that there are no side effects. The fact that a small amount of tryptophan will cause vomiting is indication enough that it does indeed cause drug effects.

The list of sleeping pills, tranquilizers, barbituates, aspirin compounds, antihistamines, antipsychotic and antidepressant compounds, chemicals and herbs supposed to induce sleep makes fearful reading. Perhaps we should add alcohol to this list, since it also seems to make people sleepy.

The truth is that drugs do not make us sleepy so much as they induce coma or a comatose state. Drugs bring us nearer to death, and there is little difference between the amount of these drugs needed to put us into a comatose state and the amount needed to produce death! Sleeping pills are all harmful. Natural sleep is the only sleep we should seek and we should pursue this by entering upon an /entirely natural regime of living.

Everything done to cause us to lose consciousness is unnatural. Unnatural responses to needs merely intensify problems instead of solving them. The treating professions prescribe drugs that ultimately make matters worse for the sufferer. Those who advise the use of herbs or special foods make the same mistake. Instead of advising the sufferer to discontinue those practices which cause insomnia, those who would "treat" the symptoms leave causes intact and tinker with modalities that cause drowsiness or coma.

There are over 50 million Americans with sleep problems, almost one in four. People who suffer insomnia usually have a number of other complaints as well. Sleeplessness is but one symptom of body toxicity. Remove the toxicity and all complaints disappear simultaneously. Fasting enables the body to free itself of toxic materials and a healthful regime will not impose toxin buildup.

## 11. Our Biological Clock And Sleep

Humans are diurnal creatures, that is, they conduct their conscious activities during the day. We are instinctively sleepers by night. The pattern of night/day sleeping continues even in subjects who are continuously kept in the dark for weeks at a time. The circadian rhythm is not disturbed by unceasing darkness. Experiments with subjects I kept in rooms without lighting for up to two weeks did not shake the rhythm, though subjects have had their rhythms lengthened and shortened while staying in caves lit with artificial daylight. The change in rhythm they experienced corresponded with the shortened or extended "days."

Our sleep patterns gradually change when we change time zones, or when normal activities are changed by advancing or regressing the clock.

## 12. Improving The IQ Through Sleep

Your intelligence quotient depends upon how efficiently and intensely the brain operates. It is well-known that caffeine will temporarily intensify and excite thinking until the letdown comes. Many stimulants will intensify mental activities. Good health will naturally intensify and enhance mental activities without providing a "letdown." Nothing in the world will sharpen mental acuity as will a few days to a few weeks of fasting. Mental acuity arises from two primary conditions:

1. The less toxins in the blood that flows through the brain, the better the brain is able to function.
2. The more nerve energy there is available, the more of it there is available to the brain for thought processes.

Hence, the more adequate our sleep, the more nerve energy we'll have for the brain and for more intense thought processes. When "you're sharper than a tack" your body is purer and your nerve energy greater than at other, mentally duller times.

Have a rejuvenating sleep!

## 13. Questions & Answers

**Is oversleeping really bad for you? I hear a lot lately that too much sleep can make you sick.**

There is no such thing as oversleep. The body will not sleep beyond need. Consciousness returns when need has been met. We can't control that. However, we can by many devices shorten our sleep and simply refuse to get enough.

Sleep is a restorative agency, not a pathogenic practice, Medical men have said that fresh air is bad for you because it has been proven that city dwellers moving from polluted cities to vacation areas in fresh pure air get sick. Calling oversleeping pathogenic is similar to calling fresh air bad for you.

This attitude comes about because medical opinion regards disease as a war against the body by invading forces such as bacteria or viruses or both. Disease and sickness are not recognized as a body-instituted cleansing and repair process. When the body's vitality is increased by fresh air or by heightened nerve energy derived from sleep extraordinary to normal, the body uses the opportunity to start a healing crisis.

Rather than regarding sleep as an enemy of well-being, you should regard it as one way in which to more quickly help reestablish physiological normalcy. When in the relaxing and reassuring atmosphere of a fasting institution, many fasters start off by sleeping most of the time, sometimes for up to a week. When their bodies are sufficiently cleansed, they cannot sleep as much as is regarded normal. Note that in the case of heavy sleeping they could do so only because the body needed it to regenerate the increased nerve energy to restore normalcy. When normalcy has been reestablished, they find it impossible to get the amount of sleep they regard as normal. Thus we can see that oversleeping is myth, that the body will not, indeed, conduct the sleep process beyond need.

### **What's so great about napping?**

I can do no better than quote from the illustrious longtime Hygienic professional, Dr. V. Virginia Vetrano. Here are her observations on the immense value of napping and of getting additional sleep when it is needed.

Napping is extremely important to every individual from birth to 140 years old. Taking a siesta after lunch improves digestion, absorption and assimilation and promotes better health through better nutrition. Taking naps prevents excessive fatigue and promotes better and more efficient work. Resting and napping actually increase our productivity. Taking a ten-minute rest break every hour helps us to get more done in less time. When one is fatigued, mental acuity and physical powers are greatly diminished. Resting, including napping, sharpens the mind and body. By napping and preventing excessive fatigue, we are less nervous and irritable at night and we can fall asleep more quickly. It has been shown that there are fewer marital problems in those people who rest after lunch than in those who must put in long days without an afternoon nap or rest period.

If you go to bed exhausted, the body must first recuperate before it can begin its anabolic processes, cell renovation, cell renewal, healing and repair. A rested person going to bed will be more fully recuperated in the morning. A person going to bed exhausted will wake up only half refreshed, and must face another day without relaxation, so he is never fully revitalized, repaired, or replenished. As a consequence, toxemia and disease ensue.

Learn to nap and learn to rest. Rest during your coffee break and part of your lunch break, instead of stimulating yourself with too much food and beverage. Rest again until refreshed, upon arriving home from work. Teach yourself to work in a relaxed state, free from all tension. You will notice a definite physical and mental improvement when you secure more rest and prevent fatigue.

**You've said that sleep regenerates nerve energy. My biology book says sleep is for resting fatigued nerves that have been overwhelmed by toxin accumulation. It also says that the fatigue is caused**

**by the need to restore deranged body chemistry, that is, restore potassium/sodium balances. Do you agree with this?**

I became a student of the sleep process in my early days as a Hygienist. I noted that, at first, I was sleeping so much that, even when working, my sleep was sometimes most of the day. Later, after a fast of 12 days I noticed that I was going to bed at a normal hour but waking four to five hours later and unable to sleep further. I tried to find out why and thus steeped myself upon the subject.

I do not regard nerves any more fatiguable than the heart, which is on duty for 24 hours daily. I regard the body as keeping its nervous system in better order than its heart for that is equally vital. Body processes are conducted 24 hours daily and if the nervous system fatigued and "conked out," this would obviously not be possible. The nerve restores its chemical normalcy after transmitting an electrical impulse in fractions of a second. It does not need eight hours in which to restore normalcy.

Toxin accumulation does not itself cause sleep. It does occasion a greater expenditure of nerve energy. A faster who has thoroughly cleansed his or her body will sleep three to five hours daily. But, as we know, a very toxic individual can drag around and deny needed sleep. Toxin accumulation would not cause sleep anyway but coma as in intoxication by alcohol or other drugs.

The body sleeps when its nerve energy reaches a critically low level. An ordinary battery will stop supplying sufficient spark to operate the auto's electrical system long before it is dead. Before normalcy is established, the battery must be recharged. This appears analogous to what occurs in the body!

You will note that I speak in these matters with a note of certainty and finality. After many years of researching the subject and reading all the researches and conclusions, you don't have to be a genius to see where the truth lies—it becomes as obvious as the nose on your face. It yells at you, quite literally. When you're following a wrong premise and give it power regardless of facts, you'll always arrive at a wrong conclusion. I definitely regard your biology book as wrong.

**Why don't we get electrosleep devices if it supplies us with the nerve energy we need?**

Russians, Israelis and even Americans have conducted extensive research on electrosleep. The published researches I've read have failed to give many specifics, though much can be inferred.

There can be little doubt that those subjected to electricity in millivolt ratings can derive from this source a supply of electricity to use as their own as if it were regenerated under the condition of sleep. Those who have obtained electrosleep seem to have been able to pursue normal activities for 22 hours out of 24. Keep in mind that normal activities drain us of nerve energy and that the extra five or six hours of activity daily uses extra nerve energy. That extra nerve energy, as well as that which is normally expended in a sixteen or seventeen hour day, must be supplied by the electrosleep. Electrosleep seemed to do this for the subjects, since when they were taken off electrosleep, they quickly became eight-hours-per-day sleepers again!

I could find nothing in these researches that would indicate what happens to humans when the routines of their normal circadian rhythm are altered by electrosleep. The question of value of electrosleep must be weighed carefully against any liabilities it might have. More

extensive studies into electrosleep must be made and published before its true value can be determined.

### **Does sexual indulgence really make us sleep more?**

Yes, we need more sleep because of sexual activity. There is a great intensity of nerve energy expenditure in the sex act. Under normal circumstances the male will, quite literally, exhaust himself and will often collapse in sleep. The body gets quite a "high" during the sexual climax because it secretes narcotizing endorphins. The overall effect lowers nerve energy to such an extent that the body demands sleep almost immediately to restore the expenditure. Nothing can equal the sex act as a "sleeping potion!" Moreover, the regeneration of sperm in the male requires a great body expenditure of both resources and nerve energy. Those resources are of the finest materials obtainable from the body reserves and cells. The body gives its very best to the reproduction of the species. Nature has placed the survival of the species ahead of individual survival.

### **Isn't sex good for you?**

Occasional sex indulgence is good for both the psyche and body faculties. Its frequent indulgence will, to put it in lay terms, "burn us out." Sexual activity draws upon nerve energies the body requires for its most vital activities. If sexual indulgence persists, the familiar syndromes of enervation, toxemia, irritation, inflammation, ulceration, etc. ensue. Prostate cancer can be a result of excessive sexual indulgence in men. So-called general diseases are due to accumulated body toxins as a result of venery.

Sex can be both good and bad for you. Keep in mind that the conjugal act in animals occurs only when the female is in heat and only for the purpose of procreation. We have a culture that makes sexual activities an end in themselves. This practice may not be harmful if it is not overdone. It is very difficult to pronounce any standards upon these matters.

### **Doesn't sleep do the same thing as rest?**

While the body rests during sleep it does a lot, under the condition of rest only, accomplish what it does under the condition of sleep. Rest enables the body to catch up on its metabolic activities, whereas sleep is primarily for the purpose of nerve regeneration.

### **I've read *Better Sleep for a Better Life*. It was a revelation for me. Why don't scientists take note of it, especially its information about sleep being for regenerating nerve energy? I haven't read any other book that says this.**

I have said previously that Dr. Nathaniel Kleitman has formulated the theory that sleep is for the regeneration of nerve energy. He may have found this idea in Hygiene. Dr. Shelton said fifty years earlier that sleep restores nerve energy. Perhaps Dr. Kleitman's findings were like those of the noted Uri Nicolayev of Russia, who fasted many schizophrenic patients with celebrated results. He was a student of Dr. Shelton's writings and merely applied them in practice. Insofar as Dr. Kleitman has taken note of the Hygienic position, science has recognized the role of sleep.

### **I've heard it said that dreams should be taken seriously because there is always some deep-seated meaning in them. What are your thoughts about this?**

Right off I'll tell you the best thing about dreams is that they don't come about in reality and have no overtones of significance. The only thing you should take serious about dreams is their role in saving the condition of sleep until it is more or less replete. Dreams are the

body's "lightning rod" that satiates vicariously disturbing impulses that arise in the body. Dreams "ground" the stimulating impulses that would normally prematurely return us to wakefulness.

**Is it true that nightmares can be caused as a consequence of atrocious foods or upset stomach ?  
What causes nightmares?**

Nightmares or terrors during sleep can arise from many impulses in the body including those generated by the distresses of a meal that cannot be digested but which gives problems instead. Fitful sleep results from poor body conditions such as in indigestion but also from aches, pains, inflammations and other body pathology. Nightmares may arise from fears that are not allayed during waking hours. Nightmares are nothing more than dreams that the body conducts to preserve sleep.

**Do water beds give you the equivalent of an extra hour of sleep as most salesmen for them claim?**

If air circulation and warmth are properly met, this statement is true. The water bed enables full body weight to be evenly distributed over the entire underside instead of at a few contact points as on floors and hard beds. This extra comfort disturbs the body less than when there are pressure points as in much conventional bedding. The body can more efficiently conduct the sleeping process due to fewer disturbing factors.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > Article #1: How To Put Yourself To Sleep Easily By A.F. Willat

**Article #1: How To Put Yourself To Sleep Easily By A.F. Willat**

If you have difficulty going to sleep when you feel that you need it, and your brain is so active that you cannot stop thinking and it is keeping you awake, you can overcome the trouble by following in detail a certain routine of thinking positively. The reason you have this problem is because something important is on your mind at the time.

Some persons fall asleep easily because they do not take life so seriously and do not worry about other people and their troubles. They are not so "unselfish" and just accept life as it shows up. So, for those persons who are always concerned about others troubles, the following procedure will put you to sleep very easily.

When you are thoroughly convinced that you really need some sleep, all you have to do is to purposely mix up your thoughts so completely that you won't know what you were thinking about. It's that simple, and you need only put your mind on a simple, routine system of thinking which is so easy to follow that it becomes almost automatic to continue it after you have been interrupted by the interjection of unintentional and unrelated thoughts.

Before trying to follow this method, you should put your body in a natural, relaxed position with nothing to disturb your comfort. Lie directly on your back in a straight position and place your arms alongside your body so that the blood can flow freely. Then place your legs in a straight position to get rid of all the possible kinks and bends in all other parts of the body.

Put a pillow under the head, but not under the shoulders. Now, slowly take deep breaths so your lungs fill with air. Then exhale all the way to empty them completely. Inhale again to fill the lungs normally, and then try to inhale a little more after that. Exhale normally, and then try to exhale still more.

Your next step is to imagine walking over to a blackboard with imaginary chalk in your hand and slowly draw a vertical straight line from near the top to the bottom of the board. Do this several times more, as naturally as you can. Now, imagine that you are slowly drawing the figure two (2) extending the full height of the board. Do this a few times in your natural handwriting that you can be proud of. It must be done easily. Next, do the same with the other figures, 3, 4, 5, 6, 7, 8, 9, 10.

Any other routine system of mixing up your thoughts could be as effective, but this method has been used for a long time and is perfectly satisfactory.

If you do it very slowly, you'll probably be asleep before you know it, and when you wake up you won't remember what figure you drew last.

Doing the thinking rapidly will only keep you awake. Using ten seconds or more to draw each figure will stop your thinking, you'll become drowsy, and then lose consciousness entirely.

Even if you should wake up in the middle of the night, you will be able to put yourself back to sleep more easily than before.

You must never doubt your ability to have this routine plan work. Don't think about it. Just do it, and know that if you follow the directions correctly it will put you to sleep every time.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > Rest: A Much-Neglected Health Factor By Hereward Carrington, Ph.D.

## **Rest: A Much-Neglected Health Factor By Hereward Carrington, Ph.D.**

### *Some New Highlights On This Subject*

A wise oriental once said: "He who can perceive inaction in action, and action in inaction, is wise among men."

It is during the hours of rest and sleep—when we seem to be most passive—that something within us is intensely active, recharging us with vital energy for the next day.

When we are active, we are expending energy; when we are seemingly inactive, we are receiving it. For "energy is always noted in its expenditure, never in its accumulation."

Animals instinctively know this. So do babies! As the Irishman once remarked, "They sleep a good deal of their waking day." We spend a third of our lives in sleep, and its remarkable recuperative effects are well-known. Have we not all had this experience? We are tired—fatigued. The head nods for only a few moments, and yet we feel refreshed, invigorated. Those few seconds have changed our whole outlook on life.

But it is not always necessary to sleep in order to obtain these beneficial results. Rest will revitalize us, too; but must be the right kind of rest. Complete relaxation with the eyes closed is a part of this formula—but only a part of it. There is a technique of rest, as there is for anything else. The best results are obtained only from the right kind of rest. How should one go about insuring this?

First of all, a few obvious essentials. The room in which we are attempting to rest should be as quiet as possible, and the light subdued. There should be a feeling of *certainty* that there will be no distraction and disturbances. The muscular system should be relaxed, and this may be accomplished by going over the body in thought, relaxing every part of it in turn as we come to it. (Deep breathing exercises will help in this.) Certain areas should receive particular attention, as they are points of tensions; the solar plexus, the back of the neck, the jaw, the throat, the shoulders. Go over the body several times in this way, relaxing each point in turn as you come to it.

Recent researches have shown that merely closing the eyes rests the brain and mind in a peculiar way. An electric rhythm starts as soon as the eyes are closed, and ceases immediately when they are opened. What the exact purpose and nature of this rhythm are, still remains to a great extent a mystery, but one might well imagine that they serve to clear "negative charges" from the brain. At all events they denote recuperation. The activity of the senses, and particularly the eyes, prevents this from occurring.

Fatigue is of two kinds: muscular fatigue and fatigue of the nerve cells. The former is easily overcome by a short period of rest; every athlete knows this. Exhaustion of the nerve cells, however, is another matter; this is deep-seated, and time is required to recharge the tiny "batteries." It is this lowering of energy in the nerve cells that leads to physical and even mental trouble. Carried to an extreme, it leads to "nervous breakdown."

This life-energy of ours should be carefully conserved. When it is riotously expended it must be replenished. If not, we run into trouble. Overwork, sexual excesses and prolonged strain waste the energies. But more important than all these are the *emotions*. These are the factors which short-circuit the nervous system and exhaust its reserve energies the most quickly. Any amount of thinking will never tire us, *providing* emotions are not associated with these thoughts.

All strong emotions have this effect. It is well-known that fear, worry, anxiety, anger and similar powerful emotions will have this result, but so will intense excitement and foolish enthusiasm! Take a football game. The players become tired, but a brief period of rest refreshes them, and they are ready to "raise hell" that night. But the spectators are exhausted! High tension over too long a period has this effect. And it is the same in our everyday lives. As Dr. Trall once remarked, "A life cannot be both intensive and extensive." A relatively calm and peaceful life will insure longevity; and in the meantime will insure freedom from nervous depletion and breakdown.

All this does not mean that normal enthusiasms should not be indulged in, or that one should become a jellyfish, devoid of energetic thinking and acting. Provided destructive emotions are not present, these would represent merely a wholesome, healthy life. But, just as powerful feelings can drain the cell-energies rapidly, less powerful ones, sustained over long periods, will exhaust them slowly. Fears and worries particularly have this effect. So will frustrations, resentments and inner disharmonies. These will fight against one another and ultimately devitalize their host completely.

There is an old saying that a man can climb mountains all day and be relatively fresh at the end of it, whereas if he has to wash dishes for ten minutes he is exhausted! The reason for this, of course, is that in the first instance his whole being is working in unison, whereas in the latter case he is fighting against himself. His conscious mind forces him to perform the activity while his subconscious mind is resenting and resisting it. The result is that he is like two mules hitched to opposite ends of a rope, pulling against each other. Result: They get nowhere. But hitch them up in tandem, and they will pull you out of the rut. It is this internal emotional conflict which wears down the energy of the nerve cells and in time produces dire results.

No one should be ashamed of lying down for a few minutes some time during the day, closing the eyes and relaxing. This is especially true of elderly people. It rests the heart, equalizes the great blood-lake and restores the energy of the brain and nerve cells. More important still, it will prevent you from becoming fatigued. Towards the end of the day, "tiredness" seems to progress in almost geometrical ratio. That is why it is necessary to go to bed at a reasonable hour, if one has to get up early. If one is tired after sixteen hours, the seventeenth hour will fatigue you far more than one-sixteenth of the waking day, and the eighteenth hour still more, and so on. Those last two or three hours are often the ones which make all the difference between a normal life and one which is headed for ultimate physical and mental trouble.

Two other important factors should be noted in this connection. The first is that a complete change of mental interests will often act as a great reenergizer. Perhaps new areas in the brain are involved; more probably the conscious and subconscious mind are now working in harmony, rather than in opposition.

Whatever the cause, the fact remains that a man may be tired out at the end of a day's work, but as soon as he begins tinkering with his hobby he is no longer exhausted. Travel has much the same effect. A complete change of mental scenery will work wonders in the way of rejuvenation, as we all know.

The second essential for complete internal rest I have rarely seen mentioned anywhere—and yet it is highly important. The vital organs of the body need rest, too, just as our external muscles do. I refer particularly to the digestive organs. It is now generally acknowledged that we all eat far more than we need, in order to maintain the physical and vital wastes of the body. The amount of energy required to convert and digest this quantity of food must be prodigious, and this energy must be drawn from the general fund. A little judicious fasting will work wonders in restoring this vital expenditure. Many people are chronically tired for no other reason: they keep themselves constantly fatigued because of this internal overactivity of the digestive organs—even during the hours of sleep, when a "late supper" is indulged in. Giving these vital organs a rest is highly essential. The benefit to be derived from occasional fasting or semi-fasting are attributable largely to this—the rest given the organs of digestion at such times. The rejuvenating effects of these periods of abstinence and self-discipline have been noted by many who have given them a fair trial. Doubtless you can do the same.

Rest—external and internal—is a fundamental requisite for a healthy, normal life. The human protoplasm needs rest. It must have it. Nothing else will take its place. The human heart beats approximately 100,000 times every day—every twenty-four hours—and yet (if not abused) it can continue to function in this way for eighty or a hundred years. Why? Because, between each beat, your heart rests. It is a momentary rest, it is true, but enough to permit its recuperation. Activity and relaxation should alternate. That is the law of life. Obey this law, and health, harmony and happiness should be yours!

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > Article #3: The Need For Rest By Dr. Herbert M. Shelton

### **Article #3: The Need For Rest By Dr. Herbert M. Shelton**

The motto of the early Hygienists—"health by healthful living"—was comprehensive and included within its scope the whole way of life. It did not refer to a plan of eating or a system of exercise or to any other single facet of life. From the time of Graham forward, it was fully realized that every facet of life was as important as every other if one hoped to maintain good health. It was also understood that all the elemental needs of life had to be met in keeping with the needs and capacities of the sick organism if health was to be restored.

Among the important elements of a valid Hygiene was rest. Hygiene places great emphasis upon the importance of rest. Rest, in which is included sleep, is nature's great restorative process, just as activity and excitement constitutes her great exhaustive process. Activity is necessary to the highest expressions of organic life, but it must be alternated with periods of rest, or else the organism wears itself out.

In life, two simultaneous processes are in continuous operation. First, there are the processes of growth, development and replenishment; second, there are the processes of wear and tear. Collectively, these two processes constitute *metabolism*. To the process of wear and tear, the term catabolism is applied. *Catabolism* is dominant in periods of activity. *Anabolism* is the term applied to the process of replenishment, development and growth and is dominant during periods of rest and sleep. Neither of these processes is ever entirely passive during life, but, in general, it may be said that when one process is at the height of its activity, the other is at its lowest point of activity. *Anabolism* may be said to be the period in which the body renews itself, replenishes itself, refreshes itself and prepares itself for renewed

activity.

It will thus be seen that when we say rest is a cessation of activity, we mean only that it is a cessation of certain forms of activity. The *anabolic* processes are intensely active during periods of rest and sleep. In states of sedations, narcosis, drug-induced *hypnosis*, *anesthesia*, etc., when physical and mental activities are greatly reduced or almost suspended, *anabolic* activities are also greatly reduced or nearly suspended; hence it is that drug-induced inhibition of the activities of life does not result in refreshment and renewal of the body. These states leave the body depressed, languid and unfitted for further activity. Normal rest and sleep, on the other hand, produce alertness, freshness and a feeling of vigor and prepare one for further action. It may thus be seen how important rest and sleep are to the replenishing processes of life.

The infant and young child require much rest and sleep, perhaps primarily because the *anabolic* processes are at their greatest intensity. This is to say that in those periods of life when development and growth are greatest, *anabolism* is most intense; hence, much rest and sleep are required. The invalid also requires much rest and sleep, not primarily because anabolism is more intense in the body of the invalid, but because it is less efficient and requires a longer period of time in which to accomplish the same recuperation and renewal. It is a cardinal principle of Hygienic science that *nothing is remedial except those conditions which economize the expenditure of the forces of the organism*. Those invalids who vainly imagine that they can exercise themselves into vigor usually succeed only in wasting their already depleted stock and work so hard at getting well that they keep themselves enervated. There are times when the invalid needs exercise, but first of all and foremost in the ranks of his current needs, is rest.

We divide rest into four kinds: *physical rest*, which may be obtained by discontinuing physical activity, going to bed and relaxing; *sensory rest*, which is secured by quiet and by refraining from using the eyes; *mental rest*, which is secured by poising the mind, this is to say, by ceasing to worry and to fret and by the cultivation of mental equilibrium; and *physiological rest*, which may be obtained by reducing physiological activities. This last form of rest, may be best obtained by either greatly reducing the amount of food taken or by abstaining from food altogether.

When our primitive ancestors had performed a certain amount of work, they became tired and weak, even sleepy, and were thus forced to rest. By thus regularly and properly meeting the demands of their bodies from rest, they were reinvigorated and made, ready to resume their work. But a time came when man learned to force his body to continue activities after fatigue demanded a halt. He learned to lash his organism with *stimulants*. Without stimulation the brain grows weary and the physical demand for rest becomes so great that we lie down and rest and sleep. But to drive the body and mind with *stimulants* is to exhaust these. Activity, even strenuous activity, does not injure man so long as, by natural living, he possesses the power to work. When fatigue calls for rest, he will rest. Injury results when, by the use of *stimulants*, he forces himself to continue working after nature has demanded a cessation of work. If he lashes himself with *stimulants*, he will overtax himself and not rest when he should. We see a graphic illustration of this in the common coffee-break of today. A few minutes out from activity is provided the worker who, instead of taking advantage of the, opportunity to rest, fills up on stimulants and foodless cooked foods. The result is that the coffee-break, instead of proving a boon, becomes a bane.

To rest a whole day, when greatly fatigued, either of body or mind, is both agreeable and beneficial. A much longer period of rest is required by the invalid who perhaps, is greatly devitalized and much enervated from long indulgence and overactivity, excesses, *stimulation* and emotional excitement. These profoundly enervated individuals may require weeks or even months of rest before organs that have been lashed into impotency will rest into full functioning power.

Physiological rest, which is more commonly known as fasting, is best taken under competent supervision. This is especially true if the period of abstinence is to be a lengthy one. Most people may safely take a few days of fasting without expert supervision, but these frequently spoil the results of their fast by the overeating which they practice immediately thereafter. Indulgent individuals, who are lacking in self-control, should be supervised even during a short fast; otherwise, they are likely to receive but

small benefit from their period of abstinence.

The chronically tired, exhausted individual, seeking to rest, should retire to some quiet, secluded place, preferably in the country, where the air is pure and disturbances are at a minimum, and go to bed and relax. If he is not sick, he need not spend his whole time in bed; but if there is any marked ailment from which he seeks to recover, he should realize that the more nearly he can approach the immobilization of the embryonic period, the more rapid will be his recovery. He should abstain from all *stimulants*, both of a chemical and emotional nature. The noise and excitement of radio and television programs interfere with rest, with poise and with sleep, thus preventing recuperation and retarding recovery.

Our noisy civilization, which is growing more noisy day by day, is as great an evil as are air pollution and water pollution. If we could practically hibernate and effectively insulate ourselves against newspapers, magazines, television and radio and other sources of noise and excitement, we would refresh and replenish ourselves in a much shorter time and with greater efficiency.

[Home](#) > [Lesson 15 - The Roles Of Rest And Sleep In Supplying Body Needs](#) > Article #4: Rest vs. Stimulation by Dr. Herbert M. Shelton

#### **Article #4: Rest vs. Stimulation by Dr. Herbert M. Shelton**

For years I have stood out against the employment of all methods of artificial stimulation (irritation or excitation) of the body of the sick person because such methods tend to exhaust the energies of the patient. One of my critics says of this: "The loss of 'vital power' which seems to be a bogey man of Dr. Shelton is not so bad as he paints it. The body is not a static but a dynamic machine constantly regenerating and losing 'vital power' or energy." We may rant the truth of his statement that the body is a dynamic machine constantly generating and losing energy, without being compelled to grant his contention that it is helpful to waste, by stimulation, the energy of the body as it is generated.

The power of the body to generate energy is limited, the power of the sick body to generate energy is crippled, the sick person, and especially the chronically sick person, suffering from nervous fatigue as the result of a previous state of energy. He is not helped by any measure that further depletes his energy-stores. Stimulation is a forced draught upon the energies of the body. It compels the expenditure of energy, not in doing useful work, but in consisting the stimulant. If it is long continued or often repeated, exhaustion is the result. The depletion of the body's energies is commensurate with the amount of stimulation it is subjected to.

The opposite practice, that of conserving the patient's energies through rest, is a far more rational and an infinitely more successful practice. A workman returns home in the evening very tired from a hard day's toil. We do not prescribe a stimulant for him, but rest and sleep. A sick man comes to us with a tired organism after weeks, months, or even years of overwork, stimulation, dissipation, etc., and we pursue the opposite course. We tell him that he needs more stimulation, that his organs need to be made to work more. We begin a course of treatment that consists of stimulating the skin, the kidneys, the colon, the nervous system, etc. Sometimes, if he is not too badly depleted when he comes to us, we succeed in whipping up a short-lived simulation of health, very often, indeed it is the rule, we see our patient grow progressively worse from the first.

#### **Danger of Stimulation**

The very fact that a period of depression (a reaction), commensurate with the prior period of stimulation, follows every period of stimulation should reveal to us the true wasteful character of stimulation. If we

grant that anything is gained during the period of stimulation, we must see that this is lost in the reaction. The more we seem to gain the more we actually lose.

The stimulation afforded by any stimulant grows progressively less and the subsequent depression progressively greater as the use of the stimulant is continued. Stronger and more frequent doses or a new and different stimulant must be resorted to, and the period of recuperation must be longer.

Another serious objection to the stimulation practice is that it deals with effects only and tampers with the functions of the body and ignores the causes of the troubles present. It seeks to restore health by forcing increased action in the body, rather than by correcting or removing the causes of the disease.

Suppose we assume that we are dealing with a highly toxic patient and it is desirable to eliminate the accumulated toxins from his body. If we set out to do it by stimulating his organs of elimination, but ignore the cause of the toxic state, we would be in the same position as that of the man who attempts to dip a fountain dry without cutting off the water supply. He dips and dips until he is exhausted, only to find that there is as much water in the fountain as when he started. Indeed, if there were no other outlet for the water, the longer he dipped and the more tired he became, the faster would the water accumulate, for, as his fatigue increased, his dipping would fall off and the water would gain on him increasingly. In just the same way we whip up the organs of elimination to greater and greater effort and keep up the process until these organs and, perhaps, the whole organism are exhausted, only to find that the body is as toxic as ever. Indeed, due to the impairment of function that inevitably results from these stimulating measures, the body becomes increasingly more and more toxic.

## **The Importance of Rest**

There is no more effective method of increasing elimination than that of rest. Increased activity increases the production of waste; decreased activity lessens the production of toxins. Increased activity expends energy; rest and sleep conserve energy. The more an organ is stimulated, the less able it becomes to perform its functions. Give it sufficient rest for recuperation, replenishment and repair and its vigor and functional efficiency are increased.

Much energy is consumed in physical activity. If rest is substituted for activity, the energy commonly spent in physical activity is available for use in doing other and, for the moment at least, more important work. Nature does not cut off the appetite, prostrate the patient and cut down mental activities, sexual activities and sensory activities, in typhoid, for instance, for nothing. These are all conservative measures—designed to conserve the energy commonly expended in these forms of activity, in order that it may be available for use in the, at present, more important work of recovery.

## **Rest Is Vitogenic**

Activity consumes the substances of the body, is vitolytic; increased activity increases the consumption of body substance. During rest, the cells, the tissues and the organs are repaired, replenished and renewed. Rest is vitogenic. Resting organs are better able to repair their damaged structures than stimulated organs. Rest and sleep are the great representative restorative processes.

The actual storing up of the energy reserves or the energy sources of the body takes place during rest. Activity expends and rest recuperates the body's supplies. The stimulation (irritation and excitement) of an already depleted body only hastens the exhaustion of the few remaining energy-stores and brings on the final collapse sooner than it would have occurred otherwise. The more the body is stimulated, the sooner it reaches the state of complete collapse. The weaker the body is, the less able it is to withstand the "action" of stimulants—the greater is the necessity of "doing nothing" intelligently.

Only those who have had sufficient experience with both the stimulating (wasting) practice and the resting (conserving practice) to enable them to judge the merits of the two practices are in a position to pass judgment upon them. Anyone who has not completely abandoned the stimulating practice and

employed only the conserving practice on hundreds of patients and over a period of years, and who, in the face of this lack of experimental knowledge of the practice, proclaims the superiority of the stimulating practice and employed only the conserving position as were the armchair philosophers of the pre-Baconian period—he simply does not know, and cannot know, what he is talking about; he is only spinning, spider-like, a fantastic theory out of the web of his fancies.

### 1. Introduction

#### 1.1 Mental Well-Being Is Dependent Upon Good Nutrition

Proper nutrition is not only the foundation of physical health, but it is also the prerequisite for emotional and mental well-being. "A sound mind in a sound body" is how the Greeks of two thousand years ago expressed this relationship. Today we have such terms as psychosomatic, holistic health, dietetics and so forth that also point out the growing awareness that the health of the mind is inseparable from the health of the body.

Nor should this observation be surprising in the least. Illnesses and poor physical health give rise to feelings of anxiety, worry and depression. And, similarly, mental stress and emotional upset can contribute to the many sicknesses commonly thought to be physical in origin. So interdependent are the health of the body and mind that there can be no such thing as a "depressed healthy person" or a "schizophrenic physically sound individual."

It can be said that radiant physical health begets perfect emotional and mental poise and a calm, clear mind produces physical well-being. There is no disputing the fact that a healthy mental and emotional state can be insured through good nutrition.

The fact that mental well-being depends upon nutrition should be obvious if we realize that the quality of our blood determines the quality of our thoughts. Like all other organs, our brain receives its sustenance in the form of oxygen and nutrients carried in the bloodstream. If the blood is almost wholly withdrawn from the brain, unconsciousness occurs. If the brain is drained of blood for a short time, death results.

When the oxygen content of the blood drops due to poor respiration, the oxygen available to the brain also drops, and we become listless and apathetic. Our mental processes become slow and confused.

If vital nutrients are missing from the bloodstream, or if toxins are being circulated through the body, the brain is as surely affected just as the liver, kidneys, bones and muscles are.

In extreme cases of a toxic bloodstream or poor nutrient availability, mental illnesses result. These

illnesses are obvious to even the casual observer. However, in the more subtle cases of "blood poisoning" brought about by faulty nutrition, the mind is also intimately affected.

In fact, the majority of the population has never enjoyed complete mental health because their bloodstreams, which nurture the brain, are in a constant state of pollution. Few people have experienced the crystal clarity of acute mental perception that accompanies a purified bloodstream. Consequently, most people accept their daily fears and frustrations as natural. With optimum nutrition, however, such a compromise in our mental well-being is unnecessary.

## **1.2 Emotions and Their Relationship to Diet and. Health**

Emotions, too, play an intricate role in nutrition—both by affecting our choice of diet and by influencing the use of nutrients within the body. In fact, perhaps the most important reason why optimum nutrition is not universally applied is that eating has so many emotional connotations. To many people, eating and food are connected with the emotional states of pleasure, pain, reward, punishment and so forth.

All of us have pleasant or unpleasant associations with food, and we resist changing these associations. As a consequence, the average person often thinks that proper nutrition means giving up those foods they emotionally favor and eating those they hate. "If it tastes good, it's fattening" is the common joke among dieters.

Not only do these emotions influence our choice of diet, but the diet in turn influences the emotions. Certain foods play havoc with the blood sugar level, sending people into periods of depression or irritability. Other foods make calm children noisy and hyperactive, while certain foods, such as a chocolate candy bar, have been known to trigger schizoid attacks in susceptible individuals.

Clearly, nutrition plays a vital role in our mental and emotional health. By studying this role in detail, we can discover the optimum diet and the proper mental and emotional attitudes that promote total health in the individual.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > 2. How Foods Affect Mental And Emotional Health

## **2. How Foods Affect Mental And Emotional Health**

In an interesting story about a family who followed an optimum diet of chiefly fresh fruits, complemented by some nuts and seeds, the three children in the family had been following a predominantly all-fruit diet for several years. During that period, they were extremely well-behaved. They were kind and gracious to their parents and to each other. They cooperated in their work and play with no signs of irritability.

As an experiment, the mother one day fed the children several slices of whole wheat bread. Within an hour after the meal, the children were fighting among themselves and had several outbursts of anger and emotional fits.

Coincidental? Perhaps, but consider that many people are allergic to wheat products and that wheat eating is usually associated with warlike populations. (See the observation made by J. I. Rodale later in this lesson.)

The point here is that when a person follows a pure, high-quality diet, any substandard foods consumed will quickly make their presence known by their effects on the mental and emotional states.

Not only does wheat eating result in health problems and consequent emotional and mental disturbances,

but also eating foods high in fat tends to dull the mind and cloud the thinking. Fat digestion is so demanding that much blood is diverted away from the brain to the digestive system. As a result, the thinking processes become slower and a mild form of depression occurs.

The above examples represent only mild cases. When extremely poor-quality foods are eaten, their effects on the mind and emotions are much more dramatic—sometimes causing complete mental breakdowns and personality transformations. Unhealthful foods and their effects will be discussed later.

The effects of food on the mind have been studied for many thousands of years by Oriental philosophers. Many of these philosophers have gone so far as to categorize the effects that many commonly-eaten foods have on the mental state.

## **2.1 Classification of Foods**

Although Western science has only recently discovered the relationship between mental states and nutrition, people in the Eastern countries have been aware of the effects of diet on the mind since around 4000 B.C.

The *Bhagavad Gita*, an ancient Hindu text on spiritual conduct, classifies foods into three types:

1. Pure foods ("sattvic"),
2. Stimulating foods ("rajasic"), and
3. Impure or rotten foods ("tamasic").

### **2.1.1 Pure Foods**

Pure foods, which consist primarily of fresh fruits and vegetables, are said to bring calmness and tranquility to the mind. These foods are reputed to increase the clarity of mind and sweetness of disposition. They are especially recommended by those desiring spiritual growth and a meditative mind.

### **2.1.2 Stimulating Foods**

Stimulating foods including spices, meat, eggs, onions, etc., are said to create animal passions and to cause a restless, unsatisfied state of mind. These foods contribute to nervous disorders and emotional outbreaks.

### **2.1.3 Impure Foods**

Impure foods which include putrified, processed and preserved foods, decrease thinking capacity, dull the senses and contribute to chronic mental ailments. They accelerate the aging process and cause early death.

Regardless of our particular beliefs in religious systems, we should appreciate the painstaking observations made over thousands of years by these students of the diet and the mind. They have long known, as is being discovered by scientists, that the quality of our food directly affects the quality of our thoughts.

In his series on *Diet and War*, J. I. Rodale provided a correlation between a country's tendency toward war or peace based on its national dietary. He discovered that the national attitude was more warlike and aggressive in proportion to the amounts of sugar, meat, wheat and rye products consumed by its populace. Throughout history, it has been the meat-eating nomads who have made war on the peaceful agrarian tribes.

### **2.1.4 The Two Ways That Food Affects Our Mind and Emotions**

Basically, foods affect our mental and emotional state in two ways:

1. They either furnish or deplete vital nutrients upon which our mental and emotional health depend, and
2. They either do or do not produce toxic by-products, in the body which poison the brain and contribute to emotional problems.

As for some examples, eating grapes furnishes the blood with readily-assimilated natural sugars and minerals that are conducive to mental activity; consuming white sugar, on the other hand, depletes the body of B-vitamins, and this leads to nervousness and mental depression. Eating fresh raw foods places little or no toxic matter in the body; whereas eating preserved and cooked foods saturates the bloodstream with toxins that poison the body and interfere with brain function.

We can deduce from the above observations that optimum nutrition for physical, mental and emotional health consists of selecting those foods that, first, can supply the body with all of its nutrient needs and that do not interfere with the nutritional balance, and, second, contribute little or no toxic by-products.

Foods that disrupt the nutritional balance of the body and toxify the system are the nutritional culprits of poor mental and emotional health. Most of these culprits are actually "nonfoods" (such as sugar, alcohol, caffeine drinks, etc.) and have no legitimate place in the human diet.

### **2.1.5 Nutritional Robbers**

Every day millions of people ingest various substances that have no food value at all. Worse yet, these "nonfoods" not only do not supply any needed nutrients, but they also rob the body of vital minerals, vitamins, etc. As a result, eating these nonfoods cheats the body of nutrients and has profound harmful effects on the mind and emotions.

Perhaps the most pervasive and insidious nutritional robber is white sugar.

### **2.1.6 Sugar**

Sugars occur naturally in most of our foods. Fruits especially are high in sugars that supply the body and mind with high-quality fuel. Sugars in their natural forms as they occur in fresh, unprocessed foods are a valuable part of the diet.

Refined white sugar, however, is a chemical menace because *it lacks the essential minerals and B-vitamins for its metabolism*. As a result, the body surrenders its own minerals and B-vitamins for use in metabolizing refined sugar.

The sugar-caused depletion of vitamins and minerals from the body upsets the body's nutritional balance and predisposes the individual to mental and emotional illnesses that have their roots in nutrient deficiencies.

White sugar causes emotional outbreaks, especially in children and adolescents. Interestingly enough, it was discovered that the juvenile offender in Chicago on the average consumed over three times more white sugar in his diet than did the nonoffender. Schools that have removed their carbonated drink and candy machines have discovered that vandalism and absenteeism also decrease.

Long-term sugar consumption, as indulged by the majority of the American population, leads to chronic blood-sugar level problems that may manifest as diabetes or hypoglycemia. People with such blood-sugar problems are prone to periods of depression, irritability and nervous attacks. Many times they actually experience "nervous shakes" as their blood-sugar level slides and rises.

An abnormal plunge in blood-sugar levels is insidious—it sends shock waves through every cell in the body and affects the brain and nervous system most of all. An erratic mental state results, and some of the accompanying symptoms are: headaches, fatigue, insomnia, irritability, restlessness, crying spells, nervous breakdowns, excessive worry, inability to concentrate, depression, forgetfulness, suicidal thoughts, illogical fears, allergies and so on.

### 2.1.7 Caffeine, Nicotine and Alcohol

Besides sugar, some other nutritional robbers are the cigarette, the cup of coffee and the martini.

Nicotine, as obtained from smoking tobacco, adds to metabolic dysfunctioning. It impairs the absorption of vitamin C and interferes with the blood circulation. By constricting the blood vessels, nicotine robs the brain of its essential nutrients, particularly blood glucose, its major fuel. In fact, not only does nicotine inhibit vitamin C absorption, but it actually destroys some or all of the vitamin C already in the blood. One of the mental effects of vitamin C depletion is increased irritability. Smokers tend to be quick to irritate and often exhibit emotional outbursts.

The drug, caffeine, found in coffee, tea, cola drinks and chocolate, causes nervous disturbances, including anxiety. One to three cups of coffee contain enough caffeine to cause anxiety and other emotional disturbances. Caffeine also stimulates insulin secretion, thereby disturbing the blood-sugar level in the body.

Alcohol, too, disturbs the blood-sugar level. In fact, low blood sugar occurs in 70-90% of all alcoholics. As a result of studies, it was also discovered that most alcoholics suffer from a niacin (vitamin B3) deficiency that leads to periods of depression and feelings of lack of self-worth. Such emotional states may then lead to more alcohol drinking in an effort to escape these feelings.

All of the above-mentioned nutritional robbers tend to be self-perpetuating; that is, they create the very conditions that often make the user of these items return to them. Caffeine withdrawal symptoms, for example, can be halted by drinking another cup of coffee. The irritability caused by smoking is soothed by another cigarette. The "shakes" caused by a period of sobriety can be removed by another slug of whiskey. The crashing blood-sugar level created by sugar intake can be temporarily raised by a candy bar or other sugary "food." In short, all of these nonfood items are actually *addictive drugs* just as opium and heroin are. If we are truly concerned about the "drug problem" in America, it would be best if we set our own house in order first. This would remove the cause of many of our mental and emotional problems that result from faulty nutrition.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > 3. Emotional Aspects Of Diet And Digestion

## 3. Emotional Aspects Of Diet And Digestion

So far we have discussed how nutrition affects the mind—specifically, how a nutrient deficiency may contribute to a mental or emotional illness. It is equally important to realize that, while diet does affect our mental and emotional well-being, our emotional state in, turn, influences both our choice of diet and how well our food is digested and assimilated.

### 3.1 How Negative Emotions Inhibit Digestion

Depressions, worry, nervousness, anxiety, tension and other negative emotions are all based on the primary emotion of fear. Worry is fear of the unknown; anxiety is fear of upcoming situations; tension is fear of people or demands made by people; nervousness is fear of one's own inability to adequately handle the responsibilities of daily living, and so on.

When primitive man was afraid, he usually tried to run away from the source of the fear. When animals are afraid, their first impulse is to flee. Modern man, however, has fears about the intangibles in life. Most of his fears are due to internal factors, not external, and he cannot run away from them.

Although human fears have moved away from concern about the wild jungle animals to worries over

mortgage payments, etc., the physiological responses to these fears have not changed in millions of years.

Panic is an extreme manifestation of fear, and it is instructive to trace the physiological changes in the organism that accompany this emotion.

As soon as a threat to the organism is manifested as a strong fear, a complex chain of events begins that eventually affects every cell in the body.

First, the hypothalamus gland near the brain transmits a series of strong signals through the spinal column to nerve centers throughout the body. In the throat, large amounts of thyrotropic hormone is released into the system to stimulate the organism. Near the kidneys, a flood of adrenocorticotrophic hormone is produced as the adrenal glands are called into action. These hormones then trigger a series of programmed responses throughout the body.

The blood vessels in the skin and the digestive system undergo a rapid constriction to direct the blood to the muscles in the arms and legs (hence, the term "pale with fright"). This prepares the body for the "flight or fight" response to the fear.

Simultaneously, the spleen is contracting and pouring out a large amount of white corpuscles and platelets into the bloodstream in order to take care of any anticipated injuries. The liver also forces out a stream of blood sugar to feed the extreme demands made by the aroused system.

The saliva in the mouth dries up since there is no desire for food in the presence of fear. The nostrils expand to take in more oxygen and the eyes dilate to take in more visual stimuli. In extreme fear, the abdominal gases move downward and force any stool or urine in the system out, thus lightening the body and preparing it for flight.

The emotion of fear produces the proper physiological reactions in the body so that it may run quickly away or fight if it is cornered. These types of changes in the body are actually very beneficial if there is an imminent danger of physical harm.

These same reactions occur, usually to a lesser degree, for an intangible fear as for a physical threat.

If we worry about bill collectors or rush-hour traffic, our bodies go through similar physiological reactions to when our lives are physically threatened.

Now let's look a little closer at the relationship between fear and digestion.

First, it is obvious that no one whose life is in danger is going to have an appetite.

Dr. Herbert M. Shelton once described an experiment performed on a cat that had just finished eating. The cat's stomach was observed with X rays, and digestion was proceeding normally. A dog was then brought into the room and the cat took notice. Immediately all digestive processes in the cat halted. Its stomach ceased moving and the digestive juices stopped secreting. When the dog was removed, the cat's digestion resumed.

Food cannot be digested or assimilated in the presence of fear. If we eat when we are worried, depressed, tense or fearful, the digestive system cannot handle the food properly. It may be only partially digested and lay fermenting or putrefying in the stomach.

We should never eat when we are emotionally upset or "out of sorts." If we are uncomfortable in body or mind, we should not eat until we feel better and regain our poise.

Additionally, it is not a good idea to try to eat while driving a car, discussing business or personal problems, reading disturbing news, watching television or in any situation that may give rise to intense emotions.

### **3.2 How Positive Emotions Enhance Digestion**

Several years ago, a man was diagnosed by the medical profession as having terminal cancer. He was told that he probably had about six months to live.

He was released from the hospital and he ended his medical treatment as he went back home to live. For the first month or so, he was very depressed and laid in bed all day watching television. He was in constant pain.

Each day in the late afternoon he watched the cartoon programs on television before the evening news. He always laughed at the cartoons and noticed that by the end of the show his pain was not as noticeable. It did return, however, as he watched the evening news.

He decided that there might be a relationship between his laughing and the subsidence of pain. He installed a videotape machine and then bought all the funny movies that he remembered from his youth.

He watched all the slapstick comedies he could find for hours at a time. He bought dozens of joke books and read them. He made it a point to laugh as much as possible during his waking hours.

Gradually, his pain left him. After six months, he was still alive and his cancer had been arrested.

Happy emotions do influence physiological processes in the body, just as do negative emotions. When we are cheerful, carefree and happy, we rarely become sick. One of the results of a happy disposition is improved digestion.

When we feel positive about ourselves and our surroundings, we relish our food more and it is more easily assimilated. Surrounding ourselves with good companionship, pleasant conversation and a wholesome environment makes eating a pleasure, and digestion progresses easily.

When we are relaxed, our stomach and other organs are less tense; they feel less constrained and can perform their tasks more easily. In fact, the physical act of laughing after a meal allows the food to pass more readily through the digestive tract.

We should make every effort to surround ourselves with pleasant emotions and thoughts before and during meals. Prayer, meditation or a period of silence before beginning a meal can help us to "wind down" our activities. By establishing a quiet period before we begin eating, we remove ourselves from the hurried emotions and past thoughts of the day. We take time to renew ourselves spiritually before we renew ourselves physically. Regardless of one's religious beliefs or lack of beliefs, it is simply common sense to observe a period of emotional poise and mental quiet before eating. This may take the form of a prayer, an affirmation about the food we are about to eat, or simply a period of quiet silence where we anticipate the enjoyment of the upcoming meal.

### **3.3 Emotional Factors and the Foods We Choose**

Eating an optimum diet would be simple if we were all rational beings, freed from emotional conditioning. However, in the realm of diet, it is often the emotions and past habits that are king and queen instead of reason and clear perception.

We eat ice cream, spicy foods, candy and other destructive foods primarily because of emotional needs and emotional associations with these foods—not because of any true physiological need or premeditated reason.

People form emotional attachments to foods as a result of childhood experiences, past associations or self-conditioning. Consequently, certain foods are often eaten during particular emotional states, such as depression, etc., or in hopes of inducing a specific emotion, such as contentment or happiness.

For instance, ice cream is often associated with the rewards of childhood. When we were children, ice cream represented a treat or perhaps a sign of parental approval or indulgence. "If you'll be good, I'll buy you an ice cream cone," is a common promise of harried parents.

Thus, at an early age, ice cream is associated with "being good" and with parental approval. Consequently, when we have been good (such as staying on a good diet for a few weeks), we decide to play both parent and child and reward ourselves with a bowl of ice cream. Similarly, if we are feeling depressed or overwhelmed by life's problems, we may eat other childhood "reward" foods to temporarily escape our adult troubles.

Holidays such as Christmas and Thanksgiving are intimately associated with strong emotions and certain festive foods. So strong is this emotional association of food with holiday fun that some health-conscious individuals may eat turkey, pastries and sweets on a holiday in an effort to capture the childhood memories of days long past, as well as for parental approval in the present.

Please note that no value judgement is placed upon the emotional associations and attachments to food. To a certain extent, all of our food likes and dislikes are based upon emotions. Few people eat out of purely rational reasons, nor is it necessary to do so. What is necessary, however, is to be aware of the role emotions play in our food choices. If we are eating certain foods that are not conducive to health because of a disturbed emotional state, we should be aware of our behavior and try to approach our problems in some other manner besides food.

Foods themselves cannot satisfy emotional needs. If we are depressed, eating chocolate chip cookies may stir the memories of a carefree childhood, but they do not remove the cause of that depression. Indeed, the foods we are eating may be creating the emotional problems we are trying to escape from.

For example, in our culture, most children are brought up to associate sweet, sugary foods with approval, love, affection, etc. A child is often given candy as a reward. This type of conditioning becomes an internal pattern which is carried over into adulthood.

When grown-up people feel lonely, bored or in need of reinforcement, they may buy an ice cream cone or put money in the nearest carbonated drink machine. They eat the sugary reward food and feel somewhat better emotionally for a few minutes. This illustrates that a negative emotional state, (boredom, insecurity, loneliness, etc.) may influence the selection of and eating of nonfood items (candy, cookies, snack foods, etc.).

These nonfood items then contribute to a nutritional imbalance which may, in turn, re-create the emotional state that one is trying to escape from. For instance, the refined sugar in sweet foods gives a temporary rise in energy and a false emotional "high." After this energy surge, the sugar has the effect of depleting the body of B-vitamins and other nutrients. This sugar-created depletion then sets the stage for additional emotional distress and depression.

A seemingly inescapable cycle is thereby created: A person is continually eating sugar-filled foods in an effort to escape the depression that the foods themselves are helping to create.

### **3.4 Food Likes and Dislikes**

Many of our food cravings and our dislike of certain foods arise from past emotional associations. There are many teenagers and young adults today who refuse to eat vegetables because, as children, they were scolded by their parents if they did not clean their plates of all the overcooked, lifeless vegetables served them.

Now that they are older, they associate their refusal to eat vegetables with independence from their parents.

A man of this writer's acquaintance will not eat fresh fruit of any sort. As a young child he was forced to eat watermelon by his parents as punishment for not eating his supper.

As another example, the widespread use of dairy products has its roots in emotional childhood associations. Young children were told by their parents (who were told by the dairy industry) that "milk makes you strong." School teachers had posters of the "Basic Four" food groups, with milk prominently

displayed. The drinking of milk is also associated with being bottle-fed as an infant. Milk drinking may then become the bridge between the emotionally stressed life of the adult and the carefree world of the child.

### **3.5 Emotions and the Quantity of Food We Eat**

Not only are our food choices determined in a large part by our emotions, but so is the amount of food we eat and the manner in which we eat. When we are stressed or nervous, we tend to bolt our food down, thereby eating "on the run" and scarcely taking time to chew our food, properly.

### **3.6 Overeating**

Overeating, too, is chiefly an emotionally-caused problem. Food for the overeater becomes both an escape from dissatisfaction with life and a drug to desensitize the emotions. Compulsive eating when no true hunger is present serves as a form of sensory indulgence little different from alcoholism, drug addiction or sexual excess.

The compulsive eater often uses food as an emotional salve. Most commonly, it is used as a substitute for feelings of love and affections. Chocolate candy bars and potato chips may replace meaningful personal relationships in the overeater's life. Food no longer is used as fuel and nutrients for the body, but becomes an easily obtainable form of pleasure that can be indulged in with a minimum amount of social disapproval.

Overeating results primarily from a negative self-image. Compulsive eaters often believe that they are unworthy of being loved. To prove this to themselves, they often become obese and unattractive. They reason, "No one wants me now because I am unattractive. I am fat." By becoming physically unattractive, the obese person is able to avoid facing the real problems behind their lack of love or affection. These problems may be real or imagined psychological unattractiveness or a personality disorder.

Since overeating is often an emotional problem, it can be effectively solved only through a change in the emotional state of the overeater. If compulsive eaters can change their food choices so that they are at least overeating on healthy foods, and not "junk foods," they will at least avoid the additional emotional problems that the "junk foods" create. The chief solution to obesity is the development of a more positive self-image and an understanding that the person is deserving of love and affection.

### **3.7 Undereating and Dieting**

Like the overeater, the compulsive dieter or undereater also usually suffers from emotional or psychological problems. The phenomenon of "anorexia nervosa"—dieting to the point of starvation—has become an increasingly common problem, especially among young women.

Whereas overeating often comes from a desire to "reward" oneself, undereating is often an attempt to "punish" oneself or the people living around the undereater (particularly the parents). By withholding needed food, the undereater punishes himself for either real or imagined personal shortcomings. Undereating becomes a method of punishing the parents in particular, because the refusal of food is a rejection of the most basic child-parent relationship—that of nurturing.

Of course abstaining from adequate food intake to the point of starvation is the extreme result of an emotional disturbance. It should be pointed out that controlled fasting undertaken for reasons of health is not the same as an erratic and prolonged nutrient-deficient and calorie-poor diet.

Although not so extreme as anorexia nervosa, millions of Americans regularly place themselves on diets that are trumpeted in the latest magazines and paperbacks or in mimeographed office newsletters. Often these self-prescribed diets are so poor in vital nutrients and high in empty calories that they cause

serious damage to the kidneys, liver, stomach, etc. As a consequence, the mania for dieting among Americans is creating a nation of mental and emotional misfits.

Let's clarify the difference between *fasting* and *dieting* for weight loss. Many weight-loss diets as published in the popular press permit the dieter to continue eating harmful, low-calorie foods while simultaneously reducing the amount of beneficial foods in the diet. As a result, severe nutritional imbalances occur that may contribute to emotional problems. In comparison, fasting allows the body to reestablish its nutritional balance. So successful is fasting in this regard that it has been used to treat severely emotionally-disturbed patients who had nutrient imbalances throughout their bodies.

In many weight-reducing diets, the person is allowed to have all the coffee, tea or diet drinks desired since these drinks have no calories. Such drinks severely disrupt the already disturbed blood-sugar level and may plunge the dieter into deep depression. Add to this that a dieting person usually increases his smoking habit (if he already has one), and the stage is set for additional nutritional imbalances.

One popular diet instructs the person to give up all carbohydrates (such as fresh fruit and vegetables) and eat only protein (such as cooked meat). This invariably results in protein poisoning, metabolic disturbance, mental confusion, lack of emotional poise, and liver and kidney damage. Incidentally, it is just such a diet that was used by the ancient Chinese to break down the emotional resolve and mental health of their captured prisoners.

Most weight-loss diets make the same nutritional mistakes that lead to emotional problems. First, they ignore the differences between *refined* carbohydrates (which supply incomplete calories and little or no vitamins or minerals) and *unrefined* carbohydrates (which have calories that provide essential nutrients). Second, many of the foods recommended are "reward foods," such as a small slice of pie, a few vanilla wafers, some raspberry jam, etc. These types of foods are included in these diets to entice the person to stay on the diet. Literally, he is allowed to have his cake and eat it too, although not without accompanying difficulties.

What happens on many weight-loss diets is that the dieters grow irritable, depressed and confused. They deprive themselves of needed nutrients by filling up on low-calorie nonfoods that contribute to the nutritional imbalance. The nutrient deprivation and toxic by-products created by these diets often produce drastic personality changes. It is not uncommon to hear the spouses of many dieters remark: "I'd rather have you fat and happy than the way you are now."

Israeli researchers performed a study on ten men and women who were committed to a psychiatric institution as a result of the mental and emotional problems caused by their erratic dieting. They discovered that drastic weight reduction through conventional dieting had its most devastating effect on the nervous system. Six of the ten dieters had never suffered from emotional problems prior to this first attempt at weight loss.

Weight loss and weight control can be accomplished without accompanying negative mental and emotional changes by fasting or by consuming a proper diet. Supervised fasting not only produces a loss in weight, but it also allows a nutritional balance to occur in the body for continued mental and emotional health. The eating of low-calorie, *high-nutrient* foods such as, fresh raw fruits and vegetables allows the weight to normalize without denying the body needed nutrients.

### **3.8 Diet and the Ego**

One last area of dieting and the mind needs to be covered, especially since it is most applicable to those persons who are truly concerned about their diet and are searching for a way to improve their overall nutrition. This area is the relationship between personal pride, or "ego," and the diet we adopt.

Almost everyone is emotionally attached to the diet they follow. I have heard people who dine exclusively at "fast food" restaurants defend their diet with nutritional charts of french fries and chocolate malts. Meat eaters argue that humans are naturally carnivorous. People who follow a

macrobiotic diet believe fervently that grains should be a major part of our diet.

Each group is intensely emotional about the diet they adopt. They believe that they exclusively are correct, and they have a lot of personal pride invested in their chosen diet.

This is especially true of people who have actually taken the time to investigate the effects of diet on health. When they finally discover "their diet," they often become blinded to reason. They embrace their new diet as a mother clutches her newborn, and they will defend it with as much emotion (though scarcely with as much reason).

This is not to imply that there is no optimum diet. Most certainly a best diet does exist, and it is the one that promotes physical, mental, and emotional and spiritual health better than all others. Such a diet, however, can only be recognized and evaluated when we divest ourselves of passionate emotion and self-invested ego.

This is very difficult to do. We are all attached to our personal ideas and theories. We all like to believe that we are right. No one likes to realize that he has been mistaken about a cherished belief, be it political, religious or nutritional.

However, if we are to push beyond emotional and personal identifications with diet and understand the proper role of nutrition in health, then we must be open-minded and be willing to let go of past beliefs when they no longer serve us.

Certainly, personal experience and education can help us in choosing the proper diet. Difficult as it may seem, however, we must approach the idea of optimum nutrition with as few preconceptions and prejudices as possible.

Only when we are mentally and emotionally "clear" will we be able to recognize the correct path to proper diet and, indeed, proper living.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > 4. Methods For Overcoming Negative Emotional Conditioning

#### **4. Methods For Overcoming Negative Emotional Conditioning**

We have seen how many poor diet habits are connected with emotional conditioning from childhood and in our adult lives. To change our eating habits and to adopt a better way of nutrition involves changes on an emotional level as well as changes in our daily activities.

*Awareness* is the most valuable method we can use in overcoming emotional associations with destructive foods such as sweets, fried foods, etc. If we are conscious of why we want a bowl of ice cream, we are in a better position to deal with that desire. By recognizing the impulse as arising from past emotional conditioning and *not from a current real or physiological need*, we are better able to change our habits.

Along with this awareness is a need for education about the foods we desire or avoid. If we understand how eating white sugar forces the body to utilize its own supply of vital nutrients for its metabolism, we are less likely to eat it. If we know the many health benefits of raw foods, we are in a position to learn to enjoy them for that sake. So we must first educate ourselves about proper nutrition and then develop an awareness about the foods we put into our bodies.

Another important method for overcoming emotional conditioning is the development of a positive self-image. Many people indulge in self-destructive eating habits out of a desire to punish themselves for "not being good enough." If people see no worth in themselves, they will have a difficult time in

wanting to improve their health through a change in diet. The desire for good health often indicates a developing positive self-image. Many people suffer from feelings of inadequacy or inferiority. They do not feel they deserve optimum health. What we need to realize is that radiant health and well-being is a birthright of all human beings. Each of us deserves to be totally healthy in mind, body and soul, and we must regain this birthright through proper nutrition and a positive emotional attitude.

## **4.1 Affirmations**

Along these lines, the use of affirmations and meditation can be useful in developing the positive emotional environment we need for making these changes in our diet and in our lives. Affirming the qualities we wish to develop within ourselves is a powerful method for overcoming past emotional conditioning. For example, if we have weak willpower in resisting destructive foods, we can say to ourselves daily:

I am strong in will and restraint.

I eat only those foods good for me.

These statements are called *affirmations*. An affirmation is simply a *positive statement we make about ourselves*. By using these positive statements, you can affect many changes at the emotional and mental level.

You should devise the affirmations that are suitable for you at a particular stage in your life. It is important that you state the emotional qualities you desire in a positive manner. For instance, instead of saying, "I will not worry," it is better to state: "I am calm, serene and centered." It is also beneficial if these statements are phrased in the present tense, *as if they are now occurring*.

These affirmations may be written daily or they may be repeated silently or out loud. Casually they should become a part of your daily life for several weeks to work effectively.

Affirmations are not magical, nor are they simply "self-hypnosis." They are an effective method for surrounding yourself with a positive environment and a healthy mental state in which to grow. They allow you to assume responsibility for your own emotional health, and they serve as a direct means of activating your latent powers. They are a form of a personally devised self-therapy that have only positive, nonharmful results.

Affirmations are the link between our conscious mind and our hidden emotions. As we consciously direct our energies toward a desired quality, we tend to attain that goal. If affirmations are used regularly and in good faith, we can rapidly outgrow those harmful emotional states that hinder our personal growth.

## **4.2 We Alone Are Responsible For Our Mental and Emotional Health**

In 1865 Louis Pasteur made a discovery that is the basis of the "germ theory" of disease. This theory of disease suited modern man's ego quite well. No longer did he have to blame himself for the sicknesses caused by his own transgressions of the natural laws of health, but he could instead blame the germs that invaded his body.

The germ theory effectively shifted man's own personal responsibility for his health onto the shoulders of the medical profession who knew how to kill the offending germs. Consequently, man soon perceived his own personal health as something that was no longer in his hands.

This type of thinking asserts itself in other areas as well. If we feel mad or out of sorts with the world, it is always the fault of our parents, our spouse, our boss or the government. Somebody or something causes our emotional and mental problems. It surely isn't us, we think.

This desire to blame the failure of interpersonal relationships, or even complete emotional and mental breakdown, on "outside" factors such as hidden stress, poor home environment, etc., also allows us to shift the responsibility away from ourselves and to some other person or event. As a result, we seek outside help for these problems in the form of therapists, counselors, psychiatrists, etc.

The fact is, however, that a body that is properly cared for with good nutrition is able to withstand the major causes of emotional and mental illnesses, just as it is able to withstand the major causes of physical diseases.

If we assume responsibility for our own health and supply the body with the highest life-giving nutrition, we can also insure ourselves the peace of mind and stability of emotions that allow us to withstand stress and the other causes of mental and emotional illnesses. A properly nourished person can withstand factors that might provoke mental or emotional outbreaks in less-well-fed people.

In an article on marriage failures, Dr. Cecilia Rosenfeld stated: "One of the prime causes of marital discord—nutritional deficiency—is too often overlooked. In my own practice, I have found that, in a surprising number of broken marriages, spouses suffered from a blood-sugar imbalance. Many of those husbands and wives showed symptoms of irritability, violent temper, abnormal sensitivity and extreme fatigue. Corrective nutritional guidance dispelled these unpleasant symptoms for many spouses—and in the process, often bolstered their crumbling marriages."

Along the same line, Dr. Joseph Nichols, president of the Natural Food Associates, wrote: "The unhappily married are often suffering from dietary deficiencies more than from the kind of social incompatibilities traditional therapists seek to explore."

Blaming our problems on a demanding boss or argumentative spouse then is somewhat akin to ascribing all our physical problems to invisible germs. If we desire good mental and emotional health, we must work for it and assume full responsibility for this facet of our well-being as well. We must create the proper conditions for mental and emotional stability through proper diet and nutrition. This is where an optimum diet helps.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > 5. The Optimum Diet For Mental And Emotional Health

## **5. The Optimum Diet For Mental And Emotional Health**

At this point, it is useful to summarize what we have learned so far about the relationship between nutrition and the mind and emotions in order to determine what constitutes an optimum diet.

First, to insure mental and emotional well-being, the diet must supply all needed nutrients in the form of unprocessed whole foods. Nutritional supplements are useless; they cannot be effectively used by the body and cannot be used to fill in nutrient gaps caused by a poor diet.

Second, all "foods" (nonfoods) that rob the body of nutrients must be eliminated in order to maintain the nutritional balance crucial to mental and emotional stability.

Third, foods that leave heavy toxic by-products in the bloodstream must not be eaten if we wish to avoid poisoning our body and our mind. Even small amounts of these toxins are enough to induce depression in most individuals.

Fourth, foods should be eaten in a harmonious environment with a calm, relaxed disposition.

Finally, foods should be eaten out of true physiological need when hunger is present. They should not be eaten as emotional substitutes, for stimulation or as a means of "escape."

Perhaps the most pressing need is the elimination of all nonfood' items from the diet. These nonfoods include white sugar, white flour, alcohol, salt, condiments, and all heavily-processed foods. These foods alone are the major causes of mental and emotional illnesses, and they perform no positive function in the body whatsoever.

Most, health-minded individuals and health-oriented dietary systems condemn these nonfoods as explicitly harmful. Nonfoods are indefensible from the standpoint of good nutrition and must be immediately eliminated from our diet if we wish to regain our natural mental and emotional stability.

The second priority is the elimination of all foods that leave toxic by-products in the body. Some of the foods which leave toxins in the body are: all foods with chemical additives and preservatives, meats, eggs, dairy products, herbs, artificial and preserved foods, fried foods, cooked foods and certain noxious vegetables such as onions, garlic, etc.

For those people who have not yet adopted a vegan diet (that is, a diet free from meat and all animal products), it is of extreme importance to eliminate all foods containing additives, preservatives, etc., in order to decrease the toxic overload that eating animal products produces. Animal products, and meat in particular, prevent full mental tranquility due to the amount of toxins both naturally contained in them and artificially added to them.

In addition to following a vegan diet, the amount of cooked food should be decreased and eliminated. Eating cooked foods results in a state of mental lassitude and deprives the body of the full nutrient range contained in the foods. For a remarkable state of mental clarity, a raw food diet is highly recommended.

What we discover after examining the above observations is that an optimum diet should consist primarily of the following foods: fresh fruits, vegetables, nuts, seeds and sprouts eaten in an unprocessed state and in an harmonious environment.

These foods provide a full range of all needed nutrients; they leave little or no toxic by-products in the body; they do not result in body loss of any nutrients; nor do they upset the body's natural nutritional balance. They provide the foundation for total physical health and promote an optimum state of mind and excellent emotional health.

These foods alone will not guarantee total well-being—no diet can do that—but they will give us the needed foundation for mental and emotional health.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > 6. Questions & Answers

## **6. Questions & Answers**

**Whenever I'm depressed, I just want to eat and eat. I know it's bad, but what can I do to stop this?**

First, it's important to realize that most depression is caused by a morbid preoccupation with the self. You need to "get out of your self" to effectively combat depression. Food is just a way of trying to distract yourself from your depressive thoughts. Instead of eating, I suggest that you exercise vigorously. It has been discovered that intense activity, such as running and other exercise, is an effective way to deal with depressive tendencies. Also, you can tackle a chore that you have been putting off, or just try to help out another person. These are much more positive ways of dealing with depression than moping and eating.

**I'm a businessman and I have to take clients out to lunch. I try to sell them on my ideas and I usually get a bad case of indigestion. What do you think?**

Unfortunately our society tends to make eating into a business or a required social affair all too often. If you must conduct business while eating, then I would suggest that you make sure you choose foods which are easily digested, such as salads or fruits. In addition, concentrate on the actual chewing of each mouthful of food. If you direct your attention as much as possible to the physical sensation of eating, you will be more relaxed as you eat. Always eat lightly and in small quantities if you must dine in a potentially tense situation.

**I'm a little overweight and I resent you implying that it's because of an emotional problem. My mother and grandmother are also overweight, and it just runs in the family. I've been told it's glandular.**

It's interesting that people think fat may be inherited or that it is "natural." No animals other than humans are obese. No other animals experience glandular disorders that cause weight gain unless they were fed an inadequate and unnatural diet. It is true that obesity runs in the family, but this is because poor dietary habits are transmitted from parent to child—not because of some predisposed glandular condition. True, you may not feel emotionally "sick," although resentment itself is not a healthy emotional reaction, but your weight problem will make it difficult to maintain a high level of emotional well-being. As an experiment, why not fast for a few days and then adopt the optimum diet. I guarantee you that your "inherited glandular problem" will disappear and that you will not suffer from weight problems again.

**Sometimes I find myself crying a lot for no apparent reason. Can a diet cause this?**

A diet that radically affects the blood-sugar level can certainly make a person easily moved to tears and breakdowns. If you will eliminate all sugar, caffeine, nicotine and alcohol from your diet, you will most likely experience a lot more emotional stability. Blood sugar quickly normalizes on a natural diet with none of the above-listed artificial foods.

**Sometimes I follow a good diet for days at a time, and then I just go on a binge and eat all those yummy foods I've been denying myself. I feel bad afterwards, and I want to stop this pattern.**

The most important thing is to first stop thinking of those harmful foods as "yummy" or that you are "denying" yourself of them. Chocolate ice cream, candy bars, pies, pastas, etc., are not treats—they are poisons. You have been conditioned to think of them as reward foods. They harm your body and result in your feeling bad after you eat them. When you try to stay on a good diet, do not be too hard on yourself. We all must unlearn a lot of harmful emotional associations with foods. Most people occasionally feel that they simply must have that "forbidden food." When you get these feelings, stop and look at your emotional state. Are you anxious? Nervous? Worried? If you are experiencing any negative emotional state, stay away from the food you are craving. The craving is a sign that you are trying to use the food as a substitute for facing your emotional problems.

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > Article #1: About Emotions And Health By Marti Fry

### **Article #1: About Emotions And Health By Marti Fry**

Herbert M. Shelton, the father of modern Natural Hygiene, wrote an article entitled "Emotions and Health" for his magazine, *Dr. Shelton's Hygienic Review*, in October of 1978. He describes the

relationship between our mental and emotional states and our physiological processes, especially the process of digestion: "Under emotional stress, any or all of the digestive secretions—saliva, gastric juice, pancreatic juice, intestinal juice, bile—may be checked, and the digestion in process when this inhibition occurs is temporarily, at least, suspended."

Dr. Shelton says the reason digestion is checked during stress is because the manufacture and flow of the secretions needed in the digestive process depends upon nerve energy. Nerve energy "is transmitted to all the organs of the body through an intricate network of nerves. *Emotional stress or shock interferes with both the generation and transmission of nerve energy.*" (Italics are ours.)

He goes on to say: "If the shock or strong emotion comes when eating is in progress, there may be a sudden loss of desire for food and eating will be discontinued. In many cases, great grief, fear, or shock will result in the food in the stomach being vomited. It is not likely that emotions check the actions of enzymes that have already been poured out upon the food in the stomach and intestine, but they inhibit the secretion of added juices that may be needed. Certainly the muscular activities of these organs are inhibited or suspended.

"This impairment of digestion will last during the entire period of shock or strong emotion and until nervous balance is restored. If enervation is profound, reaction may be slow in developing so that the undigested food undergoes fermentation and putrefaction. *Next to overeating and wrong eating, mental influences cause most of the digestive impairments with which people suffer.*" (Italics are ours.)

"These functional impairments eventually result in organic change. Organic changes are endings resulting from repeated toxic crises."

After explaining the relationship between the emotional-mental condition and bodily processes such as digestion, Shelton tells us how we can use this knowledge. "Our Golden Rule is this: If not comfortable in both mind and body from one meal to the next, miss the next meal. If you are worried, apprehensive, grieved, angry, jealous, depressed, irritable, grouchy, petulant, fearful, or otherwise mentally distressed, wait upon the recovery of poise before eating. This is as important as not eating when in pain or when there is fever. It is as important as not eating when fatigued. Good digestion depends upon emotional poise."

Shelton also advises us that we are better off eating light, easy-to-digest foods such as fresh fruits than heavier foods, such as proteins (flesh or even nuts or seeds) or starches, when we anticipate the possibility of upcoming emotional or mental stress. He says that, to avoid discomfort and poisoning from undigested or partially digested food in our system, "there are times and occasions when we should not eat at all. If we anticipate a shock to our nervous system or if one is unavoidable, we will find it much wiser to meet the emergency with an empty rather than with a full stomach."

However, it's not just to avoid temporary discomfort that we should refrain from eating or eat very lightly during or in anticipation of a stressful situation. We should follow this rule for the sake of our long-term health also. Not only is digestion inhibited during stress<sup>1</sup>, but so is excretion (elimination). Continuous or frequent mental or emotional stress, "by inhibiting the functions of life—secretion and excretion—build chronic disease." Shelton recommends that we "free ourselves of our *imaginary troubles* and ingrowing grouches or learn to control our eating." He stresses the following point: "To cease eating, to miss a few meals at exactly the right time—the psychological moment—thus avoiding indigestion and the resulting poisoning, will do more to prevent illness than almost anything else that may be named. It is important, therefore, that we learn to adjust our living habits and particularly our eating habits to our mental states."

Dr. Shelton says that a "big reason why so many epidemics of colds, tonsilitis, diphtheria, measles, scarlet fever, etc., follow so closely upon the heels of the holiday season" is because a large quantity of the least wholesome foods are eaten during a time of great excitement. He says, "Overexcitement and overeating build a septic state of the Prima Via, poisoning the entire body." In the words of Dr. Weger, a medical doctor turned Hygienist, you are "either poised or poisoned." He was, of course, referring to the

retention of wastes during stress. Dr. Shelton says, "But, if there were no other evil effects of overworked emotions than that of checked or inhibited digestion, this alone is quite enough to result in disease. The ductless (endocrine) glands have their functions disturbed by the emotions, so that the whole process of nutrition is impaired."

While a balanced mental state and a calm emotional disposition often reflect a healthy physical condition and wholesome attitudes toward self, others, and life, poise is also necessary in order to maintain a high level of physical health. When great excitement or stresses do exist in our lives, however, let's follow Shelton's "Golden Rule" and miss the next meal. Let's remember that "good digestion depends upon emotional poise."

[Home](#) > [Lesson 16 - Nutrition, Mind And The Emotions](#) > Article #2: [Fruitarianism For Health And Long Life](#) By Dr. O.L.M. Abramowski

### **Article #2: Fruitarianism For Health And Long Life By Dr. O.L.M. Abramowski**

Great as the improvement is in my bodily condition, the change for the better in my mental and intellectual faculties has kept pace with it. My father, when past fifty years, became a hypochondriac and also looked at life from a very gloomy point of view. When I approached the half century, I too, developed this pessimistic inclination, and I had quite accepted my fate—that I was to be an outspoken hypochondriac.

I was dissatisfied with myself and my surroundings and gave up the hope of ever reaching a better condition. Every year onwards seemed to prove to me certainly that life was not worth living!

Especially did I notice this despondent mood on awakening in the morning, when sometimes an actual fear of impending disaster would get hold of me and render my life absolutely miserable.

All this is gone now; hypochondria and despondency are long left behind. Out of the pessimist preparing for death has developed an irrepressible optimist who feels he should live a full century and spread the joyful gospel of health and rejuvenation among suffering humanity with all his youthful vigour and endurance.

Intellectually, the improvement is just as marked—my memory is vastly improved and I can concentrate my thoughts now as I never could before. Out of a decided follower of authority, public Vaccinator, etc., I have developed into a self-thinking critic, an intellectual seeker after truth. I have been able not only to get rid of an incalculable amount of old and erroneous ideas, but to go in for quite a few fields of study and observation with a zest and interest I had not known since my days at the University:

Time never hangs heavily now; all my different occupations, studies and enterprises are treated with the same absorbing interest. Still, I find time for play and exercise with the very fascinating babies in my family and for a social chat with friends in the evening. I have no fear of any disease nor any common everyday accident, as I now know my body creates the disease and is quite able to cope with accidents. I make my plans with the firm conviction that many useful years are yet in store for me and that mine should be a green old age with a quiet, painless death as the closure of my visible existence when the doors open into Life Eternal.

### **Article #3: The Mind-Benders by Kecki R. Sidhwa, N.D., D.O.**

When people show symptoms of mental instability or mental sickness, we invariably swallow the old gobbledygook that modern psychiatry with its drugs, injections, electric shock treatments, prefrontal lobotomy or psychotherapy a la Freud, Jung or Adler will right all the wrongs in a few short sessions. But if the truth be told, and it's time we were told the truth, psychiatry as practiced today is falling apart at the seams.

Both psychiatry and psychotherapy are branches of orthodox medicine. Medicine was once based mainly on magic and still is. Plato, the Greek philosopher, believed that the womb or hysteros had a strong desire to produce children. If it remained sterile for long after puberty, it became temperamental. It started to flow around, and hysteria was attributed to this cause. Hippocrates (the so-called Father of Medicine) prescribed valerian to drive the womb back to its rightful place. In England some physicians still prescribe a mixture of valerian and bromide as a treatment for mentally depressed women. Valerian is a depressant!

Another example of physician—and drug—induced mental and emotional problems was observed in a survey. People who had taken barbiturates for one year or over had chronic psychiatric and physical complaints and made increasing demands for barbiturates. Barbiturates make people more anxious and more depressed in the long run.

Harry Solomon, a professor of Psychiatry at Harvard University, banned all barbiturates, and his patients became much more competent. It has been suggested and suspected that the taking of barbiturates addles the brains of young human embryos and affects the intelligence of the child. Yet, hospitals, doctors and psychiatrists prescribe these drugs in order to "cure" depression, insomnia and anxiety. Treatment by drugs is nearly always assumed to be good, both by the physician and the public, until proved otherwise—this takes some proving and some time—meanwhile the damage has been done.

That mental and nervous disorders spring out of our misbehaviour in life and unnatural living habits, as much as physical disorders, has to be drummed into the minds of the public as much as into the medical profession. Bad nutrition; lack of exercise; polluted air; lack of sunshine; insufficient rest and sleep; enervation; and mental and emotional habits; and the taking of drugs, medicines and social poisons like tea, coffee, chocolate, cocoa and alcohol, all lead to toxemic tissues, resulting in breakdown of brain cells and nervous tissues.

Instead of dealing with these primordial causes of our lack of well-being, the medical profession doles out pills and/or so many sessions on the analyst's couch, both causing further trouble, apart from waste of time and money.

No one knows how much illness and death is attributable to alcohol. The middle-course alcoholic has nearly four times as much sick leave from work as does an average person, and his life expectancy is reduced by ten or twelve years compared with the average. In Britain, about 1% of the population, i.e., nearly 350,000 people, are alcoholics, and a quarter of these show mental and physical deterioration. In America, the percentage is higher, 47%. Psychiatrists, with all their panhandling of substituting one stimulant for another, one drug for another, are unsuccessful at stopping people from drinking. So far, physicians have been more successful at causing addiction than at curing it.

The blame for drug addiction of all kinds can and should be rightly laid at the door of:

1. Physicians and the orthodox medical profession for lulling us into a false sense of security by drug dependence;
2. The manufacturers of drugs, alcohol and other poisons; and
3. The government which tolerates and even encourages sale of these commodities.

Drug companies are not charitable institutions. Our aches and pains, our mental discomforts and our insomnia are their gold. Not surprisingly, their most profitable drugs are those that have the public gently but surely hooked on taking them, as they ensure a regular and enthusiastic clientele. The drug companies, the breweries and the tobacco companies all exploit our addiction to various chemicals. The mind-bending process, already started from early childhood, gets its final coup de grace with the stress, strain, rat race, and political and social injustices of our modern-day society.

### 1. The Philosophy Of Exercise

In order for health to be achieved and maintained, there must exist a proper balance between rest and activity. As certainly as rest follows exertion, so too must activity follow repose. It is on our own two legs that progress, growth, and true health are achieved. If we rest too much and do not balance our rest with the proper amount of physical activity, we can never achieve and maintain our true health potential.

Normal physiological functioning within the human body is dependent upon nutrition, drainage, warmth, and freedom from violence. In order to insure proper functioning for all the cells, body fluids should be in perpetual motion. Exercise is essential in maintaining this grand vital circulation and in giving tone to all vital functions and perfection to all vital changes. It also secures a proper supply of blood to every part of the body, keeps the lymph moving normally and maintains the general health of the entire system. Exercise serves to strengthen and nourish all the various organs and systems of the body. It is, in fact, the most important component of the Hygienic regime for developing vital tonicity for the entire body. When exercise is neglected, all the various muscles, organs and glands and the circulatory and respiratory systems become weakened and sluggish, leading to a decrease in physiological efficiency.

Exercise is much more than simply developing strong muscles. It is body building in the complete sense of the term. Every cell and fiber is involved. The heart, kidneys, liver, skin, hair, eyes, etc., including the brain and nervous system, are stimulated and strengthened in these various functions. The tone and quality of the entire system is improved. The skeletal system, for example, depends upon exercise in order to maintain its size, strength, and physiological functions.

When a part of the skeleton is placed in a cast due to a fracture, muscle tear, etc., in order to prevent further damage and allow time for healing, the bone and surrounding musculature begins to atrophy, reducing the size and strength. However, when the cast is removed and motion is once again possible for the area, the muscle and bones respond by regaining their normal structure and function. The development of respiration; the powers of digestion and assimilation; and the strength of the heart and efficiency of elimination depend largely upon physical exercise. The blood and lymph improve, respiration is deepened, and the lung capacity is increased through exercise.

When a specific part of the body is put into action, the body responds by sending more blood, nutrients,

and nerve energy to that part. This response leads to overall improvement in the nutrition and drainage of the particular part involved. As the metabolism is increased, there is a consequent improvement in the tone and qualities of the tissues involved. Exercise is the most effective and efficient means for bringing about this result throughout the entire system.

The main concept for understanding the philosophy of exercise is: If we do not exercise, muscles begin to lose their tone, becoming weak and flaccid. In time, these muscles can atrophy to the point of wasting away. This same situation is true for the entire body. Not only do the structural parts of the body suffer from lack of exercise, but their function is impaired as well. By an irrevocable law of life—growth, development and strength of mind and body are acquired through exercise. Exercise is as essential to physical vigor, strength and development as air is to life. Exercise is cumulative in its benefits. If practiced correctly and consistently, strength and endurance along with coordination and agility become our reality. Posture is improved, which assures a correct relationship between the bones, muscles, organs and all other tissues of the body. A dimension of grace and poise along with an increase in beauty and symmetry is established and maintained. Most importantly, an overall feeling of joy and happiness from living life to the fullest is experienced. Exercise causes muscles that are tight and tense to be stretched, adhesions to be broken up, and nerve energy to be balanced and improved. It hastens the absorption and expulsion of various growths and deposits. Because of the intimate relationship between mind and body, the benefits derived from exercise on a physical plane also improve the quality of the mind.

The effects of different exercises upon the body are extremely varied. Certain exercises develop great strength, others improve our endurance, agility, flexibility, speed, etc., but no one exercise can do it all. Therefore, it is very important that our exercise program be diverse enough to achieve all the benefits.

If deformity is to be corrected, one can learn specific exercises which will aid in correcting the problem. Some of the various deformities which benefit from corrective exercise are: round or stoop shoulders, spinal curvatures, innominate abnormalities, bow legs, knock knees, club-foot, flat feet, various organ deficiencies, etc. These types of corrective exercises should only be performed under the watchful guidance of a skilled instructor.

Where a person is suffering from some chronic ailment or recuperating from acute symptoms, exercise can play an important and vital role in restoring the individual back to health.

At one point during the history of man, our ancestors were forced to produce great amounts of physical exertion in order to survive. But as civilization has grown and developed, and with technology creating more sedentary jobs, a large proportion of society now reaches maturity without experiencing a great deal of physical exercise. As a result, America has become a nation of fat and flabby weaklings, growing old prematurely and suffering a great deal from the ill effects produced from physical inactivity. Whereas more and more individuals are leading sedentary lives behind a desk, others are forced to overwork their bodies, thus creating injuries. Along with this imbalance, the ever-increasing specialization in work is leading to overuse of some parts of the body and neglect of other parts. As a result of this imbalance within our society, some substitute for the work of securing food, defending property, running from predators, etc., must be created. For it is nature's will that we have exercise. Nature will remove the muscles and render any limb entirely useless that has ceased to exercise. But if we begin to make efforts in restoring the integrity of the inactive body part, nature will once again restore what she originally took away.

Society today is geared towards the development of the intellect. The prevailing feeling today is to ignore physical culturing simply by covering it up with stylish clothing and gaudy cosmetics. However, we need only to open our eyes and compare the soft, flabby, unshapely bodies of the average adult with the fine symmetrical bodies of the well-developed man or woman to realize where true ugliness lies. There is no beauty or joy in beholding a skinny, malnourished physique or a fat barrel-shaped torso that is the rule and not the exception of present day society. We idolize the creative, witty, and intellectual giants of our society, ignoring the fact that they are often weak and sickly individuals. Although we should give credit to these intellectuals for their achievements, many of these people develop their mind

while ignoring their body. No one can give his best intellectual ability to the world if his body is not functioning properly. The thought of our world leaders sitting around a table, smoking, drinking, and eating constantly while deciding the fate of the world is extremely frightening. This human body of ours is responsible for carrying on the works of nutrition—digestion, assimilation, disassimilation and excretion of waste. If any of these functions are impaired, the brain, which is the organ of the mind, is also impaired.

The importance of keeping the body at a high degree of physical perfection while obeying all the laws, rules and requirements of nature is of greatest necessity. Our full potential can only be achieved when a powerful intellect is backed up by a powerful physical body — a body where the organ and tissues are strong and vigorous enough to sustain the mind, even during its most strenuous activity.

As has already been mentioned, there is a normal and inseparable relationship between the mind and the body. When there is an imbalance between these two, then the potential of both suffers. Nature has joined them together in a bond that is intimate and very delicate. The mind is dependent upon the body not only for its nourishment from the blood, but for the sensory stimulation it provides through the eyes, ears, nose, skin, and tongue. Nature has inseparably harnessed body and mind together so that they pull together in perfect concord. So long as they are allowed to do this, only good can come.

The importance of exercise can never be overemphasized. As practitioners of Natural Hygiene, you must always make your clients aware that complete health will never be maintained without regular exercise. Many schools of so-called natural healing spend a great deal of time on diet, vitamins, herbs, and techniques of body manipulation, but few ever deal with the value of exercise. Perhaps it is because the concepts and truths are too simple and not esoteric or sophisticated enough for these intellectually-oriented approaches. The philosophy of Natural Hygiene embraces the simple truths of life, and recognizes that life is motion and that we soon lose that which we don't use. As this lesson progresses, we will discuss in more detail many of the benefits derived from exercise. The fact that exercise decreases nervous tension, increases the clarity of the mind, leads to more efficient use of organs and systems, produces more power, endurance and flexibility, etc., makes it a very important component of the Hygienic system.

Exercise, as an integral part of Hygiene, must be considered in wholistic terms. Whatever forms of physical culturing we are involved in, it must influence the entire body in a balanced manner. The weight lifter who engages only in that activity but not in any other form of physical activities will have highly-developed muscles but a poorly developed cardiovascular system.

In order to insure a balanced program of physical conditioning, three types of exercise must be utilized. These are contraction, stretching, and aerobic exercises. Each type is unique and provides benefits not offered by the other two. In proper combination, these three types of exercise will provide the essentials for developing a strong, healthy body.

[Home](#) > [Lesson 17 - Exercise And Its Beneficial Role In Nutrition And Digestion](#) > 2. Effects Of Exercise On The Bodily Systems

## **2. Effects Of Exercise On The Bodily Systems**

### **2.1 Musculoskeletal System**

Like most animals, man is endowed with the ability to move in relationship to whatever situation arises, as well as the ability to move different body parts in relation to each other. As a result, we are capable of

maintaining various postures and counterbalancing the effects of gravity. We are also capable of transferring mechanical energy to the outer world by doing work as well as by absorbing various mechanical effects. These skills are the result of the ability of the skeletal muscles to transform chemical energy into mechanical energy during their contractions.

The human body is composed of many different individual muscles, each with its own particular job to do. From a functional point of view, however, the mass of skeletal muscles in the organism may be looked upon as one large organ of movement, which constitutes about 40% of our total body weight. The reason for this consideration is that most activities, especially those connected with more vigorous activities such as athletics, are the result of the integrated activity of nearly all the muscles in the body. Thus, as Hygienic practitioners, you should develop exercise programs that will utilize all the various muscles. A program that includes stretching, contracting and aerobic exercise will fulfill this requirement.

Though the skeletal muscles function like one large organ, the instantaneous distribution of activity is continuously changing as the individual muscles are called into action or released into passivity, depending upon how our central nervous system responds to the particular activity.

Individual muscles, in most cases, act as a functional unit with other similar muscle groups. These groups are usually categorized as *flexors*, *extensors*, *supinators*, etc. In most situations, it is possible to determine one or a few prime movers. These prime movers are then assisted by *synergists* and are controlled or stopped by antagonists that are placed on the other side of the instantaneous axis of movement. So even though it is anatomically possible to define individual muscles, a functional or physiological subdivision of the individual musculature is not possible.

The skeletal muscle is made up of a series of different sense organs: mechanoreceptors, thermoreceptors, pain receptors, etc. Of these, only the mechanoreceptors have been thoroughly studied. The two major mechanoreceptors are the muscle spindles, situated in the center of the muscle, and the Golgi tendon organs located within the tendons.

All skeletal muscles in the body are made up of numerous muscle fibers. In most muscles these fibers extend the entire length of the muscle. Each muscle fiber is innervated by a mixed nerve (motor and sensory) located in the middle of the fiber. Each muscle fiber contains several hundred to several thousand myofibrils. Each myofibril in turn is made up of myosin and actin filaments, which are specific protein molecules responsible for contraction. The myofibrils are suspended inside the muscle fiber in a matrix called sarcoplasm.

The muscle spindles are suspended in a network of connective tissue that is parallel with the muscle fibers. During exercise, the skeletal muscles are continuously undergoing lengthening and contraction. When a muscle fiber is lengthened, sensory impulses are generated and the muscle spindle becomes excited. On the other hand, when a muscle fiber is contracted, the effects of the muscle spindle become inhibited. This response of the muscle is known as the dynamic stretch reflex.

The dynamic stretch reflex is caused by the potent signals originated from key receptors located in the muscle spindle and transmitted by the primary nerve endings of these same spindles. When a muscle is suddenly stretched, a signal is transmitted through these primary endings to the spinal cord and will continue as long as the degree of stretch increases. The end result is a reflex contraction of the same muscle from which the muscle spindle signals originated. Thus a sudden stretch of a muscle causes reflex contractions of the same muscle returning the length of the muscle back toward its original length.

The muscle spindle is also responsible for the "negative stretch reflex." When a muscle is shortened (contracted), exactly the opposite effect of the dynamic stretch reflex occurs. Upon contraction, the muscle spindle becomes inhibited, thereby discouraging the further shortening of the muscle. Thus the negative stretch reflex opposes the shortening of the muscle in the same manner that the positive stretch reflex opposes lengthening of the muscle. Therefore, it is the muscle spindle reflex that maintains the relative length of a muscle.

The Golgi tendon is entirely an inhibitory reflex and functions exactly opposite from the dynamic stretch reflex. Located within the muscle tendons (that portion of muscle which attaches to the bone), the Golgi tendon is stimulated by relative muscle tension. This is different from the muscle spindle, which is responsible for detecting relative muscle length. The Golgi tendon detects tension transmitted into the spinal cord causing reflex effects on the specific muscle involved. When muscle tension becomes extreme, as in extreme physical exertion, the inhibitory effect from the Golgi tendon organ can be so great that it causes reaction and is a protective mechanism which prevents tearing of the muscle from its bony attachment.

The following points should not only help in summarising what has just been discussed, but should also provide a conceptual picture of the role of skeletal muscles in exercise.

1. Skeletal muscles allow the organism to adapt to whatever situation arises in the environment.
2. The muscular system helps to maintain proper physical posture as well as counterbalancing the negative effects of gravity.
3. The muscular system is composed of many different individual muscles. Depending upon what their duties are. They are either flexors, extensors, supinators, pronators, etc. These muscles function in groups. Depending upon what activity is taking place, one or two muscles are the prime movers. Other muscles support the prime movers as synergists and yet other muscles provide antagonism that balances the prime movers. During most physical activities, the skeletal muscles of the entire body continually function as an integrated unit.
4. The skeletal muscles are intimately connected and are directly dependent upon the smooth functioning of the entire nervous system. In order to maintain the nervous system, attention must be given to all the areas of Hygienic living. Poor nutrition, lack of rest, etc. lead to an imbalance in proper regulation of nerve force, leading to a decrease in vital energy and less effective mechanical activity.
5. The sense organs of the musculoskeletal system provide the means by which the tone of the muscle is maintained. These organs provide the means to insure the maintenance of muscular stability by providing the necessary information for either contraction or relaxation of the specific muscle.

It is important to look at the muscular system in a wholistic manner. Though it is possible to develop individual muscle groups with specific exercises, this can only cause an imbalance with various other muscle groups that are not simultaneously developed. Therefore, it is important to provide a balanced and consistent exercise which will provide the necessary strength, flexibility and endurance to the entire muscular system. The end result will be a muscular system that is highly developed and functioning in harmony with all the other systems of the body.

The functions of the skeletal system are complex and varied. Besides providing a structural frame that muscles, nerves, organs and all other various tissue can surround and attach to, the skeletal system provides storage for many nutrients and produces blood cells. Bone tissue continually undergoes a process of bone destruction and repair. Large osteoclastic cells are continuously engaged in destruction of bone cells and osteoblasts continuously repair the damage.

According to Wolff's law, bone develops its greatest strength along the lines of greatest stress and strain. An increase in physical activity stimulates osteoblastic (building) activity, while a decrease favors an increase in osteoclastic (destructive) activity. In this manner the osteoclastic cells are encouraged to remove the useless bony structures and osteoblasts are stimulated to replace them with stronger bone in the region where greater strength is required. The more activity an individual engages in, the stronger and more durable the skeletal system becomes.

In our society, as an individual becomes older, his or her level of physical activity dramatically decreases. As a result, the bony structure begins to demineralize, leading to a weakening of the entire structure. As the individual becomes weak and feeble, the bones may begin to spontaneously fracture. Had the individual maintained his or her exercise program, he or she would not have become dependent

upon others to provide the movements no longer available to him.

## **2.2 The Respiratory System**

### **2.2.1 Basic Mechanisms of lung expansion or contraction**

The lungs can be expanded and contracted by (1) downward and upward movement of the diaphragm to lengthen or shorten the chest cavity and by (2) elevation and depression of the ribs to increase and decrease the diameter of the chest. Inspiration takes place when the diaphragm contracts, pulling the lower boundary of the lung cavity downward, increasing its longitudinal length. Expiration takes place automatically when the diaphragm relaxes, allowing the elastic recoil of the lungs to draw it back upward. During normal inspiration, respiration takes place simply by contraction of the diaphragm. However, the mechanical means by which respiration takes place during exercise is a little more involved.

As we've already mentioned, normal inspiration takes place principally when the diaphragm contracts, thereby pulling and lengthening the lungs. This creates a lower pressure in the lungs that is automatically filled by the higher atmospheric pressure outside the body. Usually, expiration is an entirely passive process; that is, when the diaphragm relaxes, the elastic structures of the lungs, chest cage, and abdomen force the diaphragm upward.

During exercise, a greater demand is placed upon the mechanical structures of respiration. More muscles come into activity in order to increase the amount of oxygen now needed by the rest of the body. During inspiration, not only does the diaphragm contract, but muscles from the chest, neck and spine also contract and aid in the process. Expiration is no longer passive; it is aided by contractions from the abdominal muscles as well as from the lower rib muscles. From a mechanical point of view, if these various muscles are not strong and capable of functioning efficiently and effectively, the tissues of the body will not be supplied with sufficient amounts of oxygen during exercise.

### **2.2.2 Diffusing capacity of respiratory membrane**

During respiration, oxygen is taken into the lungs from the atmosphere. In the lungs oxygen is exchanged with CO<sub>2</sub> (waste product from cell metabolism) from the bloodstream. The oxygen is carried to all the tissues in the body in order to nourish and provide the necessary component for developing energy necessary for cell functioning. The overall ability of the lungs to exchange gases from the blood is expressed in terms of its diffusing capacity. In the average individual, the diffusing capacity for oxygen under resting conditions averages about 21 milliliters/minute. However, during strenuous exercise, the diffusing capacity for oxygen increases to about 65 ml/minute, or three times the diffusing capacity under resting conditions. In order for this to happen, three bodily functions must take place:

1. More blood vessels must become available, thus creating more surface area for the gaseous exchange between the lungs and the blood.
2. Dilation or expansion of all blood vessels.
3. Stretching of the lung surface responsible for gaseous exchange, thus making the walls thinner for gas exchanges and increasing the surface area.

The more an individual exercises, utilizing increased respiration, the more efficient the diffusing capacity will become. During rest or slight activity, only a small portion of the lung is used, resulting in a significant portion becoming dormant. The same holds true for the circulatory system where a significant number of blood vessels are not utilized. This disuse will lead to a decrease in the ability of the system to provide the necessary oxygen for the tissues even during the slightest degree of activity.

During strenuous exercise, the average individual may require as much as 20 times the normal amount of oxygen. Due to the increase in cardiac output, however, the time that blood remains in the area of gas

exchange is greatly reduced. As a result, the oxygenation of blood could suffer for two major reasons: the blood remains in contact with the lungs for shorter periods of time, and far greater quantities of oxygen are needed to oxygenate the blood. However, the blood is almost always fully oxygenated when it leaves the lungs even during the heaviest of exercise, due to two major factors:

1. As we've already mentioned, the diffusing capacity for oxygen increases about three fold during exercise.
2. The blood stays in the lungs about three times as long as necessary for oxygenation. Therefore, even with the shortened time of exposure during exercise, the blood can still become fully oxygenated.

As you can see, with exercise, the lungs and their structural synergists become stronger, more resilient and much more efficient. More tissues in the body are oxygenated while simultaneously more blood vessels and lung tissue are utilized. The lungs are interdependent upon all the other systems of the body. Only when all these systems are functioning smoothly and efficiently can we achieve the high levels of health and enjoyment that life has to offer.

## 2.3 Cardiovascular System

Perhaps the single most important factor that we must consider in relation to the cardiovascular system is "cardiac output." Cardiac output is the quantity of blood pumped from the heart into the aorta each minute. Venous return is the quantity of blood flowing from the veins back to the heart each minute. Although blood can temporarily increase or decrease in central circulation, the total cardiac output must be equal to venous return. The average cardiac output for normal young males is about 5.6 liters/minute. When including all adults and females, the cardiac output is an average of approximately 10% less than that of the normal male. Since cardiac output changes with body size, the output is commonly stated in terms of the cardiac index. The cardiac index is determined by cardiac output per square meter of body surface area. The average cardiac index for adults is about 3.0 liters per minute per square meter.

When a person rises from a reclining to a standing position with the muscles becoming taut, as if preparing for exercise, the cardiac output rises 1-2 liters per minute. Cardiac output usually remains almost proportional to the metabolic body rate; the greater the degree of activity or the muscles and organs, the greater will be the cardiac output. Therefore, the work output during exercise increases in linear proportion to the cardiac output. In bouts of very intense exercise, the cardiac output can rise as high as 30-35 liter per minute in a well-trained athlete.

This is 5-6 times the normal value.

During heavy exercise, tissues can require as much as 20 times the normal amount of oxygen and other nutrients that are transported via blood. Thus, transporting enough oxygen from the lungs to these tissues may demand a minimal increase in cardiac output of five to six times its normal value! Since this is far greater than the normal, instigated cardiac output of the heart, several factors which will insure this massive increase of cardiac output during this heavy exercise are called into play. They are as follows:

1. Before exercise begins, the autonomic nervous system is stimulated by the thought of exercise. This stimulation increases the permissive level of the heart pumping from 10-20 liters per minute, depending upon exertion caused by the exercise. Simultaneously, extra quantities of blood are pushed from the periphery toward the heart by constricting veins and increasing systemic filling pressure. These factors may increase cardiac output as much as 50% before exercise even begins!
2. At the onset of exercise, the blood vessels of the muscles become dilated, due to the signals transmitted from the motor cortex to the sympathetic nervous system. This instantaneously increases the cardiac output. The by-product of this sympathetic activity increases heart activity, mean systemic pressure, and arterial pressure.
3. The direct effect of increased metabolism in the muscles causes an increased use of oxygen and

other nutrients as well as the release of vasodilating substances. Thus, local vasodilation and local blood flow increase tremendously.

In summary, an intricate setting of background conditions of the cardiovascular system insures the required blood flow to the muscles during heavy exercise. These conditions include increased activity of the heart muscle. The local vasodilation in the muscles occurs as a direct consequence of muscular activity and finally sets the level to which the cardiac output rises. Thus, it is mainly the muscles themselves that determine the amount of increase in cardiac output, up to the limit of the heart's ability to respond.

The heart, like any other muscle, can be strengthened or weakened, depending upon the amount of activity or exercise it undergoes. According to Starling's Law, the heart is an automatic pump that is capable of pumping far more than the normal value of 5 liters per minute of blood which returns from peripheral circulation. Thus, the primary factor that determines how much blood will be pumped by the heart is the amount of blood that flows into the heart from systemic circulation, which is greatly enhanced by physical exercise. After a certain point, averaging about 15 liters per minute, cardiac stimulation (such as the stimulation of exercise) is necessary for this increase in the permissive level to which the heart can pump. Exercise greatly increases the effectiveness by which the heart provides blood and thereby oxygen and other vital nutrients to all areas and tissues of the body.

In juxtaposition with this increase in cardiac efficiency, these vital blood pathways are cleaned out and overall circulation is enhanced. Like any muscle, when there is an increase in activity and usage, there is an increase in size or musculature enlargement. Heavy athletic training causes the heart to enlarge, sometimes as much as 50%. Coincident with this enlargement is an increase in the permissive pumping level of the heart that may be as great as 20 liters per minute (as opposed to the maximal normal level of 13-15 liters per minute). So, when exercise is integrated into each day of our lives, there is an overall long-term increase of effectiveness of the entire cardiovascular system.

In summary, exercise greatly increases the demand of blood flow to the muscles and tissues. To insure this required increase of blood flow, there must be an increase in arterial pressure and an overall, increase in the activity of the heart muscle. As a direct consequence of muscular activity, there is local vasodilation of the muscle tissue involved that sets the final level of the rise in cardiac output. This rise is vital in the insurance of muscular efficiency. The heart acts like any other muscle in that it can be strengthened and enlarged with heavy exercise or weakened by neglect. As Hygienic practitioners, it is important to realize the relevance of exercise in providing blood, oxygen and other vital nutrients, to all areas of the body and enhancing overall cardiovascular efficiency in circulation. Only with maximal cardiovascular efficiency can we maintain our strength, endurance and clarity of mind.

## **2.4 Other Systems**

Generally speaking, during heavy exercise there is a constriction of blood flow to certain organ systems that are not as immediately involved in the physiology of exercise as are the musculoskeletal, cardiovascular and respiratory systems. The organs of the gastrointestinal tract and the kidneys in particular are affected by the detour of blood flow and energy during exercise.

### **2.4.1 Kidneys**

Severe exercise appears to have at least two principal effects upon the kidneys: diminished urine flow, and diminished renal (kidney) blood flow. When the blood volume becomes too great, the cardiac output and arterial pressure increase. This has a profound effect on the kidneys, causing loss of fluid from the body and blood volume to return to normal. Conversely, if blood volume falls below normal with a decrease in cardiac output and arterial pressure, the kidneys retain fluid and the progressive accumulation of fluid intake rebuilds up to the normal blood volume. During severe exercise, the rise in body temperature causes increased sweat and respiratory loss of water, which intensify kidney changes.

The sweat excreted during heavy exercise contains 300-600 mg. of urea per liter (a concentrated waste product that is diluted by the kidneys to prevent poisoning of the system), thus to a considerable extent compensating for the decrease of excretion of urea through the kidneys during exercise.

During heavy exercise, there is a great reduction in renal blood flow, and a slight alteration in the filtration rate of the kidneys. The reduction of renal blood flow is progressive for at least 30 minutes after the start of exercise and is directly related to the severity of the exercise. (Chapman, 1948 a.b.).

This drop in renal blood flow can be explained by the diversion of blood to the working muscles and the brain. Recovery of renal plasma flow is considerably slower than is the recovery of pulse rate or blood pressure (Chapman et al. 1948). The resting kidney has a large inbuilt safety margin so that the renal blood flow can be drastically altered without significantly altering the functioning of kidney filtering.

## **2.4.2 Gastrointestinal Tract**

It appears that strenuous exercise inhibits both secretory and motor functions of the stomach. Studies done by Campbell, 1928 came to an early conclusion that exercise of moderate intensity (such as running 1-2 miles slowly) inhibited both secretion of gastric juice and the rate of gastric emptying of its contents. Lighter exercise (such as walking) did not change the rate of gastric excretion and actually appeared to enhance the rate of emptying into the stomach. The amount of exercise required to inhibit gastric function varied with the physical fitness of the individual. To generalize their findings, "exercise which produced no discomfort helped digestion, and exercise which produced discomfort delayed it." These observations were extended later in the century, concluding that all types of exercise after a meal prolonged the final emptying time of the stomach more than the same activity preceding the meal. When fluoroscopically examined immediately after exertion, the stomach appeared either totally inactive or had only feeble peristaltic movements. Recovery, however, was prompt and emptying was greatly accelerated during the second hour after exercise.

In summary, there is evidence that heavy exercise has certain effects on kidney functioning. The sweat excreted during heavy exercise contains a high concentration of urea, thus compensating for the decrease of urea excretion via the kidneys during exercise. When there is an increase of sweat and respiratory loss of water, there is an intense change in the kidneys. Also, during extreme exercise, there is a drop in renal blood flow due to the diversion of blood to the brain and working muscles.

It also appears that strenuous exercise inhibits both secretory and motor functions of the stomach, although the amount of exercise required to inhibit gastric function is dependent upon the physical fitness of the individual. Though exercise tends to temporarily inactivate stomach function during exertion, there is a prompt recovery and acceleration of function in the post exercise hour.

[Home](#) > [Lesson 17 - Exercise And Its Beneficial Role In Nutrition And Digestion](#) > 3. The Three Major Categories Of Exercise

## **3. The Three Major Categories Of Exercise**

### **3.1 Contraction Exercises**

Unlike the aerobic and stretching exercises, when we talk about contraction exercises we are considering primarily the development of muscular strength and endurance. Muscular strength refers to the amount of force that one can generate in an isolated movement of a single muscle or group of muscles. The greater the muscular strength of an individual, the greater the amount of force he or she will be able to

generate. Muscular endurance refers to the amount of time an individual can perform a particular contraction of force, i.e., how many sit ups, push ups, curls, etc. Muscular endurance involves a specific muscle or group of muscles, unlike cardiorespiratory endurance, which involves the total body.

Muscular strength and endurance can be developed by any one or combinations of three different modes of physical contraction exercises. These forms are termed isometric, isotonic and isokinetic contractions.

Isometric training involves muscle contractions against a resistance, greater than the force that can be applied where no movement of body parts takes place. Pushing against a sturdy wall or a parked car results in contractions of the muscles involved, but will not lead to any perceptible movement of the body or the objects involved. Numerous exercises can be devised simply by applying force by different parts of the body upon common objects around the house as a source of resistance.

Isotonic training involves the actual movement or lifting of a steady resistance through the range of motion of the various joints involved. A classic example of isotonic exercise is the lifting of weights.

Isokinetic training involves a constant speed of movement against a variable resistance. The strength of a muscle varies at different angles as a result of change in the angle of pull and perspective leverages.

Thus when we lift a constant resistance, the muscle is not exercised to the same extent at the middle of its motion as it was at the beginning. In other words, if we are curling a 50-pound weight, the closer we come to completing that curl, the stronger the muscle becomes. During isokinetic training, the resistance changes to match the strength of the muscle at each point in the range of motion.

Research has shown that each of the three forms of strength-training procedures produce substantial increases in strength, power and muscular endurance. In comparing the different forms as to which offers the most complete program, very little has been written on isokinetics. This is due to the fact that it is a relatively new science and is not totally understood., So, most of the comparison is between the isometric and isotonic procedures, and is as follows:

1. Both isometric and isotonic produce substantial gains in muscular strength, with many studies indicating that isotonic exercises provide the greater gain.
2. Both muscular endurance and recovery from muscular fatigue is faster in muscles that have been trained isotonicly.
3. Isometric procedures develop strength only in limited portions of the total range of motion, whereas isotonic procedures produce a more uniform development in muscle strength.
4. Isometric procedures involve no joint movements and can be safely and effectively used during the period of recovery from injury in order to prevent substantial loss of muscle size and function.

As mentioned earlier, research on isokinetic training is limited. However, a major advantage to this form of training over the other two forms is in the area of rehabilitation. Isokinetic exercise allows the muscle to exercise through a full range of motion with varying degrees of resistance. The resistance will depend on the strength of the the muscle at different angles in the range of motion. Although more research needs to be undertaken, isokinetic procedures appear to be just as effective as either isotonic or isometric—perhaps even moreso.

As Hygienic practitioners you should keep in mind that while contraction exercises are extremely beneficial in muscle strength and endurance, these procedures do very little for the development of the rest of the systems in the body. In fact, without balancing the contraction exercises with aerobics and stretching, these procedures could even be harmful. Keep in mind strong muscles and a weak heart do not make for a good combination. Develop exercise programs that utilize contraction training one day, aerobics and stretching the next. In this way you will be utilizing different areas daily while allowing other areas a chance to recover.

## 3.2 Stretching

Along with the other two categories of exercise, stretching is of crucial importance. Regardless of how superb and strong a physique may appear, without proper extension and stretching of the muscle groups, there will be an imbalance of posture. Additionally, there may be a muscle-bound disequilibrium which could deter the overall well-being and mental poise of the individual.

Stretching should be done in a slow, static manner. The body itself provides necessary weights and counterweights through a variety of balanced static postures. Stretching postures must maintain proper vertebral extension. If done correctly, stretching brings steadiness, health and lightness to the limbs. A thorough stretching program exercises every muscle, nerve and gland in the body. It secures a fine physique which is strong and elastic without being muscle-bound. In turn, stretching postures reduce mental and physical fatigue and soothe the nerves. Only when the body is fit and flexible can it serve as a vehicle of mental poise. Physical abuse and bodily disuse result in atrophy and dysfunction of the delicate mind-body interactions that lend us the ability to live and function in a constant state of total well-being.

## 3.3 Flexibility

Flexibility can be defined as the range of possible movement without a joint or a sequence of joints. A study (Kras, H.1972) done on several hundred adults who had complaints of chronic lower back problems revealed that approximately 80% had severe muscle weakness and joint inflexibility diagnosed as the cause, while only 20% had a specific anatomical disease or lesion as the cause. Thus, there is an obvious tendency in our society to neglect the body through lack of physical exertion including stretching and flexibility exercise.

Following is a summary of some recent research done on flexibility and exercise. (H.H. Clarke, 1975-76). There is little agreement among researchers with regard to the definition and limitations of "normal" flexibility. Flexibility is highly specific and varies for each joint or joint group. Thus, the flexibility of certain joints cannot be used to generalize the flexibility of other areas of the body. Although specific data is not available, there is a relationship between flexibility measures and differences in sex and age. Although flexibility can be increased with persistent exercise, the magnitude of increase is a very individual matter and is dependent upon the specific types and forms of activity. The connective tissues primarily responsible for resistance to movement include muscle, ligaments, joint capsules, and tendons. (These terms are sufficiently defined in the definition section.)

Research, logic and experience indicate that stretching exercises are effective in improving flexibility. Although many athletes and physicians still view such tragedies as muscle pulls, tears and strains as inevitable within a heavy exercise program, there is a growing awareness that these injuries are not accidental and can be predicted and thus prevented. Many of the top professional football teams (i.e., Steelers, Broncos, Redskins, etc.) now employ "flex" coaches to direct the players in stretching exercises. This is a prevention against injury.

An important factor to remember while incorporating a stretching routine into your daily exercise program is not to stretch or strain beyond a "pleasant tension." There will be some discomfort initially, due to the trauma of the stretch to the unconditioned muscles, but the pain will most likely be in the form of a nagging ache or dull pull. "Pleasant tension" refers to a slight, dull discomfort of the muscle as a whole, with no accompanying sharp or burning sensations. When there is a sharp localized sensation in the ligament, back off; this is more than "pleasant tension." In other words, stretch just beyond what is comfortable. It is important not to hold tension while stretching; this defeats the purpose. Stretching, like all other forms of exercise, is a release. While holding a stretching posture, if you feel tension in a specific area, concentrate on relaxing that area, and releasing that tension. One should not hold the breath while stretching; instead, breathe normally. Oftentimes an exhalation is conducive to the release of tension. One other important point about tension: Don't hold tension in your face. There is a tendency

while releasing tension from the legs, back, arms, abdominal region, etc., to transfer the tension and sensation of discomfort to the face. Thus, often times one may find oneself with a furled brow, squinted eyes and clinched teeth. Let this tension go, along with the rest of it.

Stretching should be slow, consistent, sustained and static. Stretching should not be ballistic. Dr. Herbert deVries, Ph.D, lists some advantages of static stretching exercises:

There is less danger in going beyond the safe limits of stretching when doing static exercise because the exerciser moves into the position slowly and stops before harm is done. With ballistic exercises, the exerciser may realize too late that he or she has passed the limit. Also, the energy costs for slow, static stretching is lower than for rapid ballistic stretching, so the exercises aren't as tiring to the athlete.

Furthermore, static stretching tends to relieve muscle soreness, while ballistic exercises may cause severe muscle soreness. Thus, it is recommended, when integrating stretching into your exercise program to increase your overall flexibility, be consistent and static in your movements. Listen to your body as you flow into the postures, never letting the tension accumulate, but rather relax into the stretch. Your body will let you know what your individual "pleasant tension limit" is, and don't take the stretch any further. You will not achieve the extreme position of the stretching posture overnight. It takes persistence, patience and cautions.

As Hygienists, we want to improve our level of vitality, strength, and endurance and then maintain it. If a person is overly tense or unable to sleep, their vitality and endurance will decrease. Conversely, when tension and stress cease, vitality increases. Stretching enhances the quality of life by giving us flexibility and endurance while enhancing our mental poise. We were born with a potentially wide range of motion; however, many people are caught in the laziness of today's society and do not use but rather abuse their potentials of strength, endurance, aerobics and range of motion. The high quality of life that is available to all of us thereby is reduced to laziness. Through exercise and the other requirements of Hygienic living we gain our health. Health is not a commodity which can be purchased with money. Instead it is an asset to be gained by hard work and proper living practices.

### **3.4 Aerobic Exercise**

A wild cat, such as a tiger, lion, cougar or panther, stretches, runs, leaps, etc. every day. It is trim and vital and has an incredible endurance level. Place this animal in a zoo and, though its stretching continues, its physique "goes to pot" and the cat becomes lazy. Why? Its aerobic exercise has ceased.

An individual's capacity for sustaining heavy, prolonged muscular work is dependent upon the supply of necessary oxygen to the working muscles. The word 'aerobic' literally means "with oxygen." Therefore, "aerobic work" is defined as work performed when sufficient oxygen can be supplied by the body to reduce the necessary performance of the task. According to Cooper, 1970, the most beneficial aerobic exercises include jogging, running, swimming, cycling, brisk walking, handball and basketball. The aerobic demand for these various forms of exercise is highly dependent upon the amount and rate of the work performed.

Aerobic exercise is a mandatory component in the overall Hygienic program of exercise. Some of these aerobic activities are far less demanding than jogging or swimming or some of the other exercises mentioned above. Low-intensity aerobic exercises, such as walking, must be of longer duration, but they are highly effective and are certainly regarded as aerobic activity. Choosing an aerobic type of exercise is dependent upon individual considerations such as age and level of physical fitness. Nearly anyone, regardless of physical condition, can effectively contribute to his/her own method of aerobic fitness.

Aerobic training activates many wonderful changes in the body. Your lungs will process more air with less effort, your heart will grow stronger and pump more blood with each beat, the number and size of the blood vessels carrying blood and nutrients to the body tissues will be increased, tone of the blood

vessels and muscles will be improved and total blood volume will be increased.

The earliest to develop and most natural forms of exercise are walking and running. Primitive human beings survived by being able to walk or run great distances. We still have the bodily structure that was designed to cover 25 or more miles a day, but today our body rebels as soon as we attempt a 30-minute walk, let alone a 15-minute jog. We marvel at the stamina of the Tarahumara Indians of Mexico, who race at high altitudes in kickball games and relays that often last up to two days and cover one to two hundred miles. Perhaps our fascination with their stamina is a subconscious recognition of our natural potentials. According to Dr. Thaddeus Kostrubala, M.D., for 3 million years the genus of homo sapiens had to run to survive. He also says that our femur thigh bone is designed specifically for running.

In order to zero-in on specific characteristics of aerobic activity, some advantages of a well-planned jogging or running program are briefly mentioned below. Running should be done for 30-45 minutes four or five times weekly. Keep in mind that the length of the work out must be gradually worked into and thus will vary with the individual. The advantages of integrating a running program to your life are rich and many.

A running program is a simple, effective way to stimulate the circulation and exercise the heart. It provides a gentle, steady and prolonged demand on the heart, more so than does a series of short, choppy, ballistic exercises. Running exercises many parts of the body simultaneously. It can be adapted to the age and physical fitness of the individual and can be performed at nearly any time or place. Another advantage of running is that it requires no special facility or equipment, therefore the costs are minimal. Running is a good therapy to reduce anxiety and depression.

A runner's feet hit the ground 1600 to 1700 times during each mile. This can be rough treatment if done improperly. There are many criticisms of running as an exercise due to the high rate of injury. A recent *Runner's World* poll reveals that 22% of runners suffer from knee injuries, 20% from achilles tendon injuries, 10% from shin splints and 9% from forefoot strain and fracture. It is a current consensus among experts who practice sports medicine and run or jog themselves that most of the injuries are due to overwork, faulty shoes, weakness, lack of flexibility and improper running techniques. According to Dr. George A Sheehan, M.D., running causes a loss of flexibility in the back of the legs. Because of this lack of flexibility, exercises that stretch the muscles in the entire legs and back are a necessary component in the exercise program. It is possible to increase your chances of avoiding injury by not running on a hard cement surface, selecting high-quality running shoes, performing stretching exercises to counteract the lack of flexibility caused by the contractile reactions of running and by improving the overall muscle strength of the major muscle groups involved.

Regardless of what form of aerobic exercise that you chose to adhere to, take the necessary cautions to prevent injury, be persistent with it, and the benefits of aerobic fitness will enhance your total well-being.

Aerobics is not a total physical fitness program. It must be integrated into a consistent exercise program which also includes stretching and contractile, strength building exercise. Though these three categories of exercise often overlap, all three (aerobics, stretching, contractions) are necessary for maximum health and joyful living.

## 4. Exercise And Nutrition

Some of the first accounts of athletics and nutrition go back to the early Olympic Games in Greece. It was indicated (Harris, H.S., 1966) that there was a considerable insistence by Greek doctors on the importance of the diet that led to a keen interest in the diet of their athletes. Very little meat was originally consumed in Greece. The diet consisted of whole grains such as barley or wheat, eaten in cereal or bread form, and a variety of vegetables, such as onions, carrots, cucumbers, marrows, beans and various green leafy vegetables. Fruit was abundant, especially grapes and figs, apples, pears and nuts. The pomegranate was a prize. Although the Greeks did consume large amounts of goat milk products, adequate nutritional requirements were contained within the former food groups.

During the 1900's there developed the popular belief that any form of sustained muscular exercise required an abundance of meat foods. It was postulated that during exercise the substance of the muscle was consumed, and therefore hard work would remove a considerable portion of the muscle material that could only be replaced by eating animal protein. However, a study was done in Zurich (Eggleton, 1948). Two scientists climbed one of the Bernese Oberland peaks, one living on a nitrogenous-free diet (free of meats), while the other ate a diet containing nitrogenous foods. They found that when they were resting quietly, the amount of nitrogen excreted was not increased by their physical effort, either during or following the climb. This served as the basis for the modern outlook on the relationship of muscular performance to nutrients, which is that the muscle oxidizes the sugar and fat for the production of its energy, and does not use up its own substance. Thus, it is only when the muscles are chronically inactivated or during starvation that the muscle tissue is actually used up.

Energy requirements are obviously dependent upon the amount and quality of the expended energy during various tasks. This is also modified by other factors. For instance, energy requirements vary widely with age. A newborn baby requires less total energy than either a full-grown man or woman.

Individuals vary to a certain extent in their caloric requirement, and in certain diseased states this variance is even greater. In colder climates, there is a greater loss of heat to the surrounding air, and thus more caloric intake is required to balance this offset. In a warmer climate, less heat is radiated by the body and therefore less calories are needed.

As previously stated, there is a difference between the caloric requirements for carrying out various types of physical exertion. Some items of interest from the original data published by Mary Schwartz Rose in the United States are noted below. In a healthy human being, sleeping generally requires 65 cal./hr.; standing relaxed requires 105 cal./hr.; light exercise, 170 cal./hr.; walking slowly, 200 cal./hr.; walking moderately fast, 300 cal./hr.; severe exercise, 450 cal./hr.; running slowly, 570 cal./hr.; an very severe exercise, 600-650 cal./hr.

Studies done just following W. W. II (Eggleton, 1948) indicated that a robust man doing heavy industrial work can metabolize 4000 calories of food during a working day. This raised the question of whether one variety of food is better than another in making up the calories consumed. Eggleton says that a good deal of evidence from the work on muscles and muscle extracts indicates that carbohydrates are the main fuel for exercise although some studies show that a proportion of the muscle fibers do utilize some fat for energy.

It is estimated that pure carbohydrate provides 1800 cal./lb. and so does pure protein; but pure fat provides 4200 cal./lb. The belief of these heavy laborers is that every time meat is consumed, a certain amount of fat is also consumed, and thus the total amount of food required to provide the same amount of calories is less when eating meats, than when eating just carbohydrates and proteins.

It is clear to see that our society is obsessed with caloric intake, with total disregard to the quality and composition of the foods which are consumed. There is much controversy about the composition of diet

for athletes. Much of the controversy concerns the amounts of protein, fat and carbohydrates consumed and their relationship to exercise and athletic performance. When discussing the quality of diet with regard to these three nutrient groups, we must examine two salient questions: (1) Whether an excess of one of these three nutrients is more important than any of the others, when pertaining to exercise, and (2) Whether the consumption of one or the other of them on the day of exercise or the athletic event is likely to be of much significance.

As far as the latter question is concerned, the only substance which is likely to have a significant effect when taken before an event is sugar. By sugar we mean the simple sugar from fruits are most readily used, and then the more complex sugars which are broken down from starches (carbohydrates).

A study was done on the relationship of breakfast to athletic performance (Holdi & Synn, 1946) concerning the carbohydrate intake of swimmers with relation to a 100-yard swim. The results showed that the composition of the meal, as far as carbohydrates were concerned, did not effect either the blood sugar level at the end of the swim or the performance. They concluded that the energy reserves of the body were more important than the composition of the pre-swim meal. The implications are that a long-term maintenance of a quality diet has a much greater effect on performance than does the administration of a quality meal just prior to exercise.

Another study (Karpovich, 1941) showed that the amount of carbohydrate metabolized in exercise is dependent upon the amount of carbohydrate in the diet, and the lower the carbohydrate in the diet, the higher the amount of fat metabolized. Karpovich also claims that when energy is derived from fats, the work performed is actually 10% less economical than when the energy is derived from carbohydrates. There is also little doubt that protein or fat, since they need such a long digestion period, produce little benefit when administered just before an athletic event.

In regard to the former salient question of whether an excess of the three nutrient groups (carbohydrates, fats, proteins) is more important than any of the others when dealing with activity, we find that all three substances are equally important and are readily available in appropriate amounts in the Hygienic diet.

Though recent trends in nutritional advice tend to overemphasize protein, all protein in our bodies does not come from outside protein sources. There is a constant interchange of carbohydrates, fats and proteins within our bodies. Food is used not only for the formation of the body, but also for the energy expended in daily exercise and activity. Though carbohydrates and proteins are somewhat interchangeable, carbohydrates are more readily required in volume during physical, metabolic exercise than proteins.

For the utmost efficiency in exercising and for physical exertion, we need a good deal of both simple and complex carbohydrates in our daily diet. Through the gradual decomposition of monosaccharides (simple sugars) and polysaccharides (complex sugars or carbohydrates), our metabolism and activity level is sustained. Therefore, it seems that the ideal diet for an active person or an athlete is based on fresh fruits, vegetables (including leafy green vegetables and roots to maintain the necessary amount of protein and calcium), nuts and seeds.

As mentioned earlier, we find that in many societies there is too much emphasis on caloric intake, with little regard to quality and composition of diet. We must consider that some foods convert into calories at a higher rate than others. For instance, simple sugars contained in fruits convert to calories more readily and thus caloric discharge ceases much sooner, than do more complex sugars contained in many vegetables and legumes, which are more slowly converted and burned into calories. Meat and dairy products are even more slowly broken down and converted, and cause a lot of wear and tear on the digestive organs. In this respect, a diet centered around fresh fruits, vegetables and a small amount of nuts and seeds is far superior to a diet centered around meat and dairy products.

## 5. Questions & Answers

**Why is it necessary for me to integrate all 3 of the major categories of exercise into my exercise program?**

Certain exercises, such as weight lifting only done on the upper body, or running, develop a few individual muscle groups. This causes an imbalance with the other muscle groups that are not simultaneously developed. For example, weight lifters often become muscle-bound because of their excessive contraction exercises (building strength and endurance) that leave no room for flexion and extension of those tightened muscles. One of my patients actually had broken blood vessels (bruises) on the surface of the skin from being so muscle-bound that it infringed on the circulation. We have found that integrating the proper combination of contraction, stretching and aerobic exercise into daily life and being consistent with it will provide the necessary strength, flexibility and endurance in the muscular system, maintaining an optimal level of functioning so that it may harmonize with the other systems of the body.

**Why are people so obsessed with caloric intake, rather than the quality of the food they eat?**

In today's society there are many fads and fad diets that insinuate that the only relevant factor in weight loss is caloric consumption. With this assumption, many people feed their dieting bodies a set number of calories, but calories consisting of highly refined foods and often non-nutritional substances. Their bodies are forced to feed off of this refined food, but the energy derived from a low nutrition diet is less efficient. It seems logical that the quality of food is directly related to the quality of activity. Note that these effects are long term (over a long period of time) and that one wholesome pre-exercise meal is likely to have little immediate effect on the quality of exercise. It seems, however, that people are realizing more and more the superficiality of caloric consumption exclusively and the great importance of the quality and composition of food consumed.

### Article #1: Staying In Shape For Life By Richard K. Schmidt

I once knew a man who exercised every day. His routines were sometimes as long as three hours, yet he never missed a day. I asked him one time what he was training for, why he stayed in such good shape. He merely replied: "I'm staying in shape for life." I then asked him how he was able to do it, how he managed to face such a gruelling workout day after day without a miss. He said simply: "I enjoy doing it. I look forward to my workout everyday."

This sounded logical, but I still went away with the impression that he had some unusual powers of self-discipline and self-motivation. Not many people in the world could do what he did. He just didn't seem to have the same motivation problem that most of us have.

Motivation is indeed a serious problem for all but a select few. But how do we overcome this motivation problem? How do we become more consistent with our daily exercise programs? Is there an ideal

exercise program that will help us do this? This paper is designed to help answer these questions.

For the past four years, I conducted a study on Exercise. I wanted to find out why it is so hard for people to motivate themselves to exercise. I talked to many people—some who were jocks and some who weren't. All, I found, agreed on the same thing: Exercise is important but hard to do. Rarely did I find anyone who was satisfied with his degree of consistency. I heard many excuses and alibis. They ranged from overcrowded schedules and personal problems to physical ailments, mental stress and plain laziness. However, in reality, all these were nothing more than the motivation problem in disguise.

Being a former professional athlete myself, I know how it feels to be in good physical shape. I want to stay in good shape all the time. But now that the ole coach isn't around to drive me, it's hard to psych myself up for the workouts. If I don't have anyone to work out with, it becomes twice as hard. The daily routine becomes as appealing as facing the Sahara Desert. Many others feel the same way.

Based on the information I gathered, I concluded that the motivation problem is linked directly to the exercise program itself. The more the person enjoys the exercise, the sport or the workout, the easier it is for him to get involved and challenge is the main attraction. The desire for exercise because we need it is, at best, secondary.

Obviously, the root of the motivation problem is in the head. Exercise Reform is a head trip—mind over matter. We are basically lazy creatures, prone to do only what is convenient and enjoyable. We just naturally need fun reasons to do things. The key, then, to Exercise Reform, is to find some way to make the workout as convenient and enjoyable as possible. An exercise program has to be designed to accomplish this. It has to be tailored to the average person with a busy schedule, to the person who doesn't play sports, who is faced with the task of working out on his own, often without the support of a workout partner, felt, if I could devise such an ideal program for myself, to overcome my own motivation problem, perhaps it would work for others as well.

It took the better part of a year to design such a program. I tried many different time schedules, different exercises and routines. Finally, I arrived at a comfortable program and spent the next three years experiencing it and studying the results. I am now convinced that it's the ideal program I was looking for. It has solved my own personal motivation problem—I consider it a complete success. The results of the past year, especially, leaves no doubt that almost anyone can achieve the same success.

Anyone can win out in his motivation struggle with his own personalized exercise program. However, in designing such a program, the person must focus on three main areas: He must: 1) choose a suitable time of day to work out; 2) choose the proper exercises for his program; and 3) focus on building the program into his bodily system. These are the three keys to consistency in the Exercise Reform.

## **Choosing The Proper Time For Exercise**

As we consider the first of these keys, we are trying to choose the best time of day to work out. In doing so, we must focus on the most important thing: We must choose a time of day when we cannot be disturbed or interrupted by anyone or anything. This must be our time, a sacred, inviolable time that we devote entirely to ourselves.

However, finding a suitable time slot in a busy schedule is not easy. It seems we must give up something. Giving up an hour's sleep in the morning is the most logical thing to give up. For the lark, the day person like myself, giving up an hour's sleep in the a.m. is not hard. Most day people enjoy getting up early. But for the owl, the night person, it may pose a serious problem. But once over this obstacle, the owl, like the lark, will find many advantages and rewards connected with the early a.m. workout. Early a.m. is the most ideal time of day to work out for the following four reasons:

First, we must get up in the morning anyway, usually for reasons other than our own. But getting up an hour early is getting up because we want to, for our own reason—to work out and maintain our good health. This also eliminates the chance of oversleeping, causing us to be late for work and other

commitments.

Second, getting up an hour early clears the workout away before the regular daily activities begin. This eliminates unforeseen complications such as changes in schedule, minor illnesses, extra tiring days, etc. from causing cancellation of late scheduled workouts.

Third, in the early a.m. the stomach is empty and exercise does not complicate digestion as it would from exercise later in the day.

Fourth, in the summer, morning workouts are coolest, more comfortable and less taxing to the body than workouts during the heat of the day. (During the winter, indoor exercising with the use of the indoor runner's treadmill prevents cancellations of the routine due to extra cold mornings.)

I personally find the early a.m. workout the most peaceful and enjoyable experience of the day. I get up at 4:20 a.m. and jog for an hour from 4:30 to 5:30 a.m. This really puts me on top of the day, clears my head, keeps me mellowed out and in balance all day. I find I'm much more alert and aware of life; I'm able to experience it to the fullest and enjoy it more. My appetite is better, and at the end of the day I rest better. But if I feel sleepy during the day, I take a short nap, especially if I went to bed late the night before. This eliminates another common excuse for postponements and cancellations.

Once you overcome the obstacle of getting up an hour early, you too will find the early a.m. is not only the most enjoyable time of the day to work out, but the most ideal, all things considered. It's the only time of day when no one can disturb or interrupt you: They are still in bed. And once you have established this "sacred" time of day, you have taken the first big step toward consistency in your Exercise Reform.

## **The Exercise Routine**

Once our time of day is settled, we must then focus on the next of the keys—the routine itself—what kind of exercises we'll be doing. We are looking for a few good exercises for our ideal routine. Our most important consideration here is to select exercises we find enjoyable to do. They must, however, be exercises that will provide us with a good upper and lower body workout. The routine must be both simple and effective, and it must not be too time consuming. If we hate our exercises, we will soon dread and hate our routine as well. A troublesome conflict will then arise, and, instead of looking forward to our workout, we begin finding more and more excuses for postponement and cancellations. This is an unnecessary conflict and burden on our lives. It is the most common cause for failure in Exercise Reform because it undermines our motivation. It robs us of the joy of exercising and all the little rewards our daily exercise programs brings to our lives.

We know we must exercise our bodies for good health. It is up to us, then, to devise an exercise routine that keeps us exercising consistently—not for the need of it, but for the enjoyment of it. That's why I have adopted a routine I find thoroughly enjoyable.

My principle exercise is the jog. It is the most complete and enjoyable exercise we can do. It requires only a few supplementary exercises to give us the balanced, ideal routine we are looking for. In addition to my daily jogging routine, I add four sets of fifty pushups for my major upper body supplementary exercise. I do a set of these every quarter hour during the jog. After the hour jog is over, I add the supplementary exercise routine consisting of four torso-limbering exercises: Toe-toucher, Windmill, Sidebender and Trunktwister. I do only one set of each of these exercises and only twenty repetitions per set. This takes about five minutes and my routine is done. The important thing here is that the workout is over at the time I'd normally be getting out of bed. After a shower and perhaps a fruit breakfast to complete the a.m. preliminaries, I look forward to the day with great expectations, unbelievable energy and a positive attitude that makes life a real joy to live.

An hour's jogging, of course, is a goal to work up to. It should be done gradually, depending on age and physical condition. This goes for choosing the exercises and number of repetitions as well. The main

thing is to choose supplementary exercises that work the upper body to supplement the jog if it is being used as the principle lower body exercise in the program. These exercises must be simple, effective, not too time consuming and, most of all, they must be enjoyable to do. The routine then becomes enjoyable, something we look forward to each day. In this way we take the second big step in solving the motivation problem in our Exercise Reform.

## **Making The Exercise Program a Way Of Life**

Once we have decided when we're going to exercise and what exercises we're going to do, getting the program built into our system is relatively simple. All that is required is that we become loyal to our newfound routine for a few months. The principle of "building it in" is to make the exercise program a way of life, an integral part of our life activities. We want the workout to become a necessary bodily function like eating, sleeping, defecating and urinating. These bodily functions are so much a part of our life activities that we do them each day and scarcely notice. That's the way it must be with our exercise routine. We must do this routine each day if we expect it to become a vital bodily function.

Some people advocate alternating exercises or even the routine itself every other day. I disagree. The key to consistency is building the routine into the system. This can only be achieved by doing the routine, like all other bodily functions, *every day*.

Trying to become consistent with our Exercise Reform should be looked upon as a project, an exercise in goal-setting and self-discipline. That is the way I approached it. The first year while I was still designing my program, I allowed myself one miss per week. At first it was hard to maintain this level of performance. Gradually, however, my body became accustomed to the exercise and my mind to the routine. The workouts became easier and easier to do because the workout had become built into my system. The second year I allowed myself only one miss per month. This was easy. The routine by then had become effortless, very enjoyable and rewarding. The third year I missed only three days. I was so much into the routine by then that I wouldn't have missed a workout for anything. It just never occurred to me to miss. Last year, the fourth and final year of the study, was a complete success—not a single miss—complete mastery over the motivation problem. I was indeed staying in shape for life and was enjoying every minute of it.

Such excellent progress can also be yours once you've completed the third big step in your Exercise Reform—once your workout has become like a bodily function, completely built into our system.

The three steps you have just taken in your mind can be taken just as easily in reality. You too can achieve success in your desire to become involved in your own Exercise Reform. It doesn't matter that your daily schedule is crowded. It doesn't matter if you're not an athlete or in good physical shape.

Even if you must work out alone—you can succeed. In designing your own exercise program, all you need do is focus on these three steps: (1) Choose a time of day when you cannot be interrupted by anyone or anything, and think seriously about the early a.m. hours for your workout. (2) Choose exercises for your routine that are simple, effective and not too time consuming. But most of all choose exercises you like and will enjoy doing every day. (3) You must do your routine faithfully every day until it becomes built into your system like a vital bodily function.

Following these steps should produce the desired results—the ideal exercise program you have been looking for, the program that helps you overcome the motivation problem and keeps you exercising consistently, not for the need of it, but for the sheer enjoyment of exercise. In this way you too will have no trouble "staying in shape for life."

## **Exercise: A Hygienic Perspective By Ralph C. Cinque, D.C.**

That daily exercise is essential to develop and maintain good health is one Hygienic principle upon which there seems to be universal agreement. Even the medical profession encourages regular exercise as a means of prolonging youthfulness and promoting cardiovascular well-being. The overall merits of regular exercise are fully recognized, and we have no need here to further expound upon them.

However, there exists a great deal of confusion regarding the relationship between exercise and health. Many people equate health with physical conditioning. The classical American model of male health is represented by a robust well-muscled physique, with erect posture, great strength and power. Without necessarily deriding this ideal, I must insist that it is not synonymous with health. There is not always a direct proportion between the level of physical conditioning and the level of overall health. Physical conditioning is only one aspect of health. The best athlete is not necessarily the most healthy. The one who runs ten miles is not necessarily in better health than the one who runs only five, or one, or for that matter, none at all.

I once overheard a well-developed body builder relate to his companion that he was subject to occasional episodes of gout. Every few weeks one or the other leg and foot would swell up and produce agonizing pain. He would be crippled for days at a time and would have to resort to large doses of aspirin and other pain-killers in order to obtain relief. This incident made a tremendous impact on me because this particular body builder had an absolutely splendid physique. His muscular development, his posture, his body weight, his carriage, his symmetry, and his proportions were virtually ideal. He had the physique of a Greek god. By all popular notions, he was a picture of health. Yet, it should be obvious to the readers of this article that his health was far from perfect. Gout does not develop without causes, and being well-muscled does not lessen its implications or severity. How ironic that in the process of building an admirable outward condition, he built a morbid internal condition. It is likely that his interest in body building prompted him to follow a high-protein diet and to use protein supplements, liver extracts, etc., and that these practices were mostly responsible for the development of gout.

Although it is true that those who engage in regular physical activity achieve greater longevity than those who are largely sedentary, it has not been shown that superb athletes achieve greater longevity than those of moderate ability. With the exception of cardiovascular diseases, the incidence of degenerative diseases among athletes (such as cancer and arthritis) is approximately the same as for non-athletes. Lou Gehrig died of amyotrophic lateral sclerosis. Babe Ruth died of cancer. There have been many outstanding athletes who have died tragically of crippling diseases.

Acute diseases are equally as common among athletes. Many an athletic contest has been postponed due to colds and flus. Tennis star Jimmy Connors was recuperating from a month-long bout of mononucleosis right before one of the Wimbledon tournaments, and some have suggested that this was a factor in his loss to Borg.

Despite strong evidence to the contrary, the popular notion today is that exercise will insure us against disease. We are told that as long as you run everyday, you can eat all the fatty meats you want and not develop arteriosclerosis, for the running will keep down blood cholesterol and prevent arterial plaquing. We are told that playing tennis regularly will enable the body to "burn up" the caffeine and other toxic alkaloids of coffee and cola drinks, so drink all you want. Regular exercise will keep down blood pressure, so why cut out salt? Exercise diligently, perhaps excessively, and ignore every other aspect of Hygiene. That is the advice we receive from many of the "experts."

As Hygienists, we must stress the fact that exercise does not insure against disease and it does not remedy disease. All it can possibly do is supply the body's need for activity. If the individual who exercises but ignores proper diet fares better than the one who neither exercises or eats correctly, we can

account for this by recognizing that the latter ignored two life essentials while the former ignored only one. Exercise does not undo the effects of dietary abuses, but a lack of exercise may compound the effects of dietary abuses.

The body has physiological needs that can only be met through vigorous physical activity. The development of muscular strength and endurance, a powerful heart, great respiratory capacity, vibrant circulation, thorough lymphatic drainage and superb neuromuscular coordination all require the influence of regular exercise. However, from the standpoint of overall health, there is a limit to the amount of good that the body can derive from regular exercise. The body's actual physiological needs for exercise are not as great as some people believe. We do not have to become marathon runners in order to avoid cardiovascular disease. One can achieve high-level health without ever developing outstanding athletic capabilities. Of course we have no objection to vigorous physical training, and we recognize that it is the only way to enhance performance. Possessing great strength, speed and endurance is practical and desirable even if it doesn't guarantee great health or longevity.

Vigorous exercise entails a tremendous energy expenditure. This expenditure is compensated for in the physiological benefits that we derive from exercise. The amount of energy that we can safely expend in physical activity depends upon the level of our overall health and vitality. The invalid, who is in great need of rest, can only engage in brief and mild periods of exercise without enervation. The seasoned athlete, on the other hand, may be able to perform amazing feats of strength and endurance without dissipation. It is difficult to designate arbitrarily what constitutes excess in the realm of physical activity because individual factors are the most important considerations. What is excessive for one person may be unproductive for someone else.

The initial effect of exercise is to deplete the body of nerve force and tissue substance. The secondary and lasting effect, however, is to strengthen and build the body. This occurs while resting as the body prepares for future episodes of activity. Exercise must be vigorous in order to be effective. Slow walking, sauntering along on a bicycle, casually twirling the extremities—these activities are of little value. Subjecting the body to stress (within reasonable limits) is what exercise is all about. Exercise must be invigorating, strenuous, challenging and taxing in order to occasion dynamic physiological changes. Only by placing great demands upon our bodies can we acquire great strength and stamina.

A short period of vigorous activity is more beneficial than a long period of mild activity. A short but hard run will build greater power than a long slow jog. It is also less depleting. Lifting a heavy weight a few times will build greater strength than lifting a light weight many times. A good exercise regime will provide for both endurance, the ability to sustain an activity over a long period and strength, the ability to overcome resistance in a single instance, as well as speed and agility. A well known jogging expert advised a woman recently to run slower in order to increase her jogging distance to ten miles. My advice would have been just the opposite, that is, to run a shorter distance harder, thereby deriving greater physiological benefits and less profound exhaustion.

Determining the best manner in which to train depends upon what one's objectives are. The person who is exercising for general health and fitness will have different goals than the one who is trying to achieve excellence in some particular sport. Obviously, one can only become a great long-distance runner if one habitually runs long distances. One can only become a great cyclist if one cycles regularly. Great swimmers become so only by putting in many hours in the pool. Developing outstanding capability requires participation far in excess of the body's physiological needs for activity. However, expenditures of this kind can be made without depleting the body as long as the individual gradually subjects his or her body to greater stress, and makes a point to secure enough rest and sleep to fully compensate for the added exertion. For example, one should not attempt to run long distances (30 to 40 miles per week) while going to school full time and working (as I once tried to do). It is possible to become progressively more enervated even as one's level of conditioning improves. However, for the individual with a less hectic schedule, who is able to rest 9 to 10 hours every day, such a running program may be entirely constructive.

Unfortunately, many runners do overexert themselves. The effects of excess vary from mild to severe strains and sprains. Pronounced physiological depression marked by weight loss, loss of libido, insomnia, amenorrhea 'in the female, and digestive disturbances have resulted from an overly strenuous training schedule. These problems are usually resolved easily by securing more rest and curtailing one's activity. In some instances, too rapid progression is found to be the crux of the problem.

Which activities are best from a Hygienic standpoint? As always, we refer the argument back to Nature. Those activities that conform with physiological principles relating to joint motion and body mechanics are most desirable. Formal exercise is really just a substitute for natural activities that we would perform in a state of Nature. All natural activities require total body participation. When we run, jump, climb, swim, etc., our bodies are acting as a unit, even though certain muscle groups may be playing a predominant role. Such activities not only strengthen and condition us, they enhance body energy, coordination, balance and freedom. By entailing a fluidity of motion, these activities enable us to avoid excessive strain and tension. In contrast, activities that entail rigid postures, isolated muscular efforts, and limited ranges of motion, may have the opposite effect, that is, to increase tension and to stress the joints and muscles.

Perhaps running is the most natural human activity. Like deer, human beings are running animals. We are capable of running great distances smoothly, effortlessly and efficiently. Certainly we are not aquatic animals and bicycles never grew on trees. Team sports are popular because of cultural influences, not biological inclinations. Running is considered to be the most superb exercise for strengthening the heart, lungs and circulation. It is not necessary to run great distances in order to derive these physiological benefits. Running 2 to 3 miles every other day is fully adequate to achieve optimal cardiovascular conditioning. Those who wish to run greater distances can do so, but no one should feel compelled to run longer than this for health reasons. Running sprints, running up hills, running up stairs and other variations are likely to be of greater value than just jogging. Running alone is not adequate for good conditioning. Such activities as vigorous calisthenics, weight training and gymnastics round out an exercise program that includes running. This is particularly important in regard to developing the upper torso and extremities, which are largely undeveloped by running.

When is the best time to exercise? Again, we must apply Hygienic reasoning. Eat when you are hungry. Drink when you are thirsty. Rest when you are tired. So it would follow that you should exercise when you feel vigorous. It is a mistake to use exercise as a stimulant, to perk ourselves up through exercise when our bodies are actually calling for rest and sleep. A feeling of relative vibrancy should precede and occasion our workouts and not vice versa. If we feel languid, we should rest until our energies have been recuperated to the point that we feel like becoming active. If you happen to feel all washed out on any given day, it would be unHygienic to force yourself to exercise in spite of it. Just as we can rouse up an appetite by eating, even in the absence of hunger, so too can we rouse up a feeling of invigoration by exercise, but the latter is just as artificial as in the former. Get in tune with your body and seek always to supply your body's needs as they fluctuate in the course of daily life. There is really no best time to exercise, just as there is no best time to eat. Some mornings I feel inclined to start running right out of bed, and I do so. Other mornings I feel no such inclination, so I postpone or cancel my usual run. Learn to live with a flexible schedule in regard to exercise, and for that matter, all aspects of Hygiene.

Can a person attain great athletic ability eating fruits, nuts and vegetables? The answer is a qualified yes. I was introduced to Hygiene by two brothers, both in their 30's, who had been Hygienists for many years and who were excellent runners of marathon caliber. Eating Hygienically lends itself to great athletic achievement, particularly in endurance activities. A high alkalizing diet, composed largely of fresh fruits and vegetables, enhances one's oxidative powers and one's ability to sustain muscular effort. On the other hand, such a diet promotes rather slender body build. I have never met a raw fooder with a "Charles Atlas" physique and doubt that I ever will. For one thing, the diet is too low in protein. Secondly, raw vegetable foods do not stimulate anabolism the way cooked foods do. Yet, lean muscularity may be closer to the biological norm for physical development than the immense size that we generally associate with classical body building. It is unlikely that human beings in a state of Nature,

living on the spontaneous products of the trees in a gentle climate, would tend to massive physiques. Peoples throughout the world who are known for achieving great longevity tend, as a rule, to be rather slender. Keep in mind that I do not object to weight training or bodybuilding, but only to the excessive bulkiness that many weight lifters develop.

Many Hygienists are too thin and underdeveloped. In most cases, barring pathological causes, this is the result of an overly restrictive diet, both in regard to quantity and variety of food and to inadequate physical training. In all fairness, however, we must recognize that the paucity of outstanding athletes among Hygienists is due mostly to the paucity of Hygienists. Yet, Hygiene has not been without its talents. Among our practitioners, for example, Dr. Sidhwa is a first-rate long-distance runner. Dr. Burton is a prominent cyclist in Australia who competes regularly in grueling races. Dr. Benesh is a veteran physical culturist who, at the age of 67, engages in weight training, running and vigorous calisthenics. The last time I visited him, he said apologetically that he was running only six miles a day, but added quite candidly, "I try to take it at a fast clip." Dr. Shelton, himself, was an outstanding weight lifter and had a rugged build that matched his personality.

What role does exercise play in the recovery of health? I believe that it plays a greater role than some Hygienists think. Unfortunately, many Hygienists are preoccupied with food and fasting. To them, life is one great cleansing. They live from one fast to the next one. Or they consume themselves in concerns over food in between. Purification becomes their greatest goal in life, elimination the ultimate purpose in living. They fail to see fasting for what it is—a temporary expedient that enables us to secure a foundation from which to build ourselves. The only contests they wish to enter are fasting marathons. They never give their bodies a chance to enter a building phase. They deny themselves, by their imbalance, the opportunity to grow, to develop a physique, to acquire great strength, speed and endurance. Instead of practicing Hygiene so as to live, they live so as to practice Hygiene—a most unHygienic endeavor. It is no wonder that such individuals remain weak, puny and pedestrian in their lives.

Among feeble children, particularly, I have found exercise to be of greatest importance in building vigor and promoting growth and development. Those with weak digestion can derive much benefit from engaging in vigorous physical workouts. The role of exercise in promoting recovery in tuberculosis, and other respiratory problems, is well known. Exercise strengthens not only our muscles, but our entire organism, including our minds. It is possible that exercise has a more profound effect upon the organism than any other single Hygienic factor.

### 1. Prologue

#### 1.1 Human Anatomy, Physiology and Psychology Evidence Our Dietary Nature

The next two lessons are complementary in that both endeavor to establish, beyond refutation or doubt, all the particulars of human dietetic character. Once you're aware of correct dietary fare you'll be able to render one of the greatest services possible in America today! You'll be able to teach your clients how to eat for health rather than for disease, suffering and early death, that is now so commonplace in America.

In no area of our living regimes do we transgress our biological mandate as grievously as in the matter of diet. If our correct diet is fruitarian fare, then America consumes less than 10% of its correct dietary. Since the bulk of America's fruit is consumed by less than 25% of our populace, it should come as no surprise that there is such a great preponderance of disease amongst us.

In sallying forth into the world to bring the message of healthful living to others, you must be armed to the hilt with the knowledge to substantiate the truths you've learned. Moreover, you must understand the principles so well that you can readily adduce the truth for anyone who approaches you from some esoteric aspect of diet.

People are very little impressed by facts, unfortunately. Nevertheless, you should be cognizant of the facts! You should also learn emotional approaches which have a profound and abiding effect upon the client. Remember that the nature of your emotional approaches should be gentle, not hostile. Remain alert to the emotional state of your client. Help the client to remain comfortable by addressing him/her as a spectator to third party practice rather than as a guilty participant.

In the latter part of this lesson, some emotional approaches are suggested. Should you wish to impress your client with the correctness of the dietary you will guide him or her to, you might embody the

emotional approach in a narrative around your own experiences with others. Most Americans have addictions to pathogenic fare, i.e., cooked and fried dishes, condiments, fermented foods, etc. Americans are "hooked" on so many abominable dietary practices that we can marvel only that they survive as well as they do.

Today's "nutritionists" are subservient to the "basic four" food concepts. While this concept may look good on paper, it is a disaster in practice, because most of America's health problems stem largely from its observance. According to these nutritionists, we do not have any fixed dietary as have most animals in nature. Rather, humans are considered to be some sort of omnivorous creature above all the laws of nature. Many assert we have definite carnivorous leanings. Quite a few nutrition experts have termed our incisor teeth "fangs," in defense of the erroneous position that humans are meat eaters.

To term our incisor teeth fangs or even to liken them to Tangs is an outrage even to the most superficial observer.

Humans are well-equipped in all their anatomical features to gather fruits, but most unsuited to capture animals and rend them. Fangs and pointed teeth that penetrate and kill, rip and tear are a feature of all carnivores except birds.

Let's put this matter of human carnivorism on a personal level. Can you picture yourself quietly stalking a rabbit and pouncing upon it? If it should slip away, can you picture yourself exploding with a blinding burst of speed that may be 30 to 50 miles per hour for the short distance needed to overtake your prey? Can you picture yourself catching the rabbit in your mouth, and then sinking your fangs deeply into its vitals, crushing and killing it? Can you picture yourself ripping the animal to shreds and swallowing it in bloody bits and chunks without thorough mastication? Can you savor the animal's blood, guts, bones and organs? If you cannot carry out this practice with gusto and delight, you are not of a meat-eating disposition.

You must admit that we are not anatomically equipped as carnivores. You must also admit that the idea of attacking, killing and rending animals on the spot does not appeal to humans psychologically—we are not natural killers. What most of us do not realize is that we are not only psychologically but also physiologically unsuited to utilizing meat as a food.

When a natural carnivore swallows hunks of carrion unchewed, the flesh is digested in the stomach of the carnivore with ease and facility. Should we swallow large hunks of flesh without chewing, we'd digest very little of it before putrefaction set in. This putrefactive material would cause us many problems until it could be expelled from the intestinal tract. Why does a carnivore so readily digest something we can handle almost not at all?

Flesh is a proteinaceous food that is digested in an acid medium. Humans, relative to carnivores, secrete a very weak hydrochloric acid and little of the protein-splitting enzyme, pepsin. Carnivorous animals have a concentration of these flesh-digesting media 1100% greater than humans! Should a lion swallow your hand whole he would quite readily digest it. Should a human do the same thing, I leave to your imagination what would happen. Digestion is among the things that wouldn't happen!

There are hundreds of anatomical features that we humans have which place us among frugivorous animals. We are anatomically fruit eaters. Not everyone will admit our lack of claws and fangs and possession of gentle sensitive hands suits us for fruit gathering rather than animal catching. They fail to see that our likeness to fruit-eating creatures places us in the fruit-eating camp. Most people fancy that we're in no animal camp at all—we're humans, gods of a special sort not heir to the principle that apply to animals. They consider us to be not animals at all—just humans!

Aspects of being that disturb most people are best not aroused or discussed. In tutoring people in the ways of health, you must often assume an experienced stance wherein you give guidance. You must exhibit a certainty about the beneficial result that will accrue from the healthful measures you teach. Thus you can adroitly steer clients to our correct dietary and related health practices by tactfully and confidently suggesting a regime that will enable them to become healthy in short order. When it comes

to diet you'll develop your own operating methods for effectively teaching it to others and inspiring them to adopt it.

Let's return to our consideration of humans as meat-eaters. Natural meat eaters have built-in equipment with which to apprehend, capture, kill and rend their quarry. Claws and fangs are very much a part of a carnivore's equipment. Let's consider the human mouth. We couldn't catch an animal in our mouth or dispatch it that way if we tried. Two witnessed dogs catch other animals many times by charging them and snapping their powerful jaws on them at a vital spot. I've seen these dogs sink their fangs deep into the throat of animals much larger than themselves and inflict fatal wounds. A human could not grab an animal in its mouth as does a dog, coyote, wolf or cat. Even biting a live animal with our teeth and mouth opened to the fullest would not permit for the insertion of any animal other than very small ones. And, if the animal was alive, we might have more damage inflicted upon us than we could inflict except with the brute strength of our hands and arms. On the contrary, the human mouth is excellent for biting into fruits or the insertion of fruits and chewing. Obviously we are adapted for eating small items. Lesson Seven has demonstrated that our diet naturally consists of fruits.

The anatomical features that distinguish humans from carnivores such as cats, dogs, eagles, jackals and other carnivorous animals are many. There are few features wherein we are alike. Humans are also very dissimilar to omnivorous animals such as hogs, bears, and the like. Almost everything about these animals is different from humans.

We are also very dissimilar anatomically to grass-eaters. We all know we are not grass-eaters. We reject the idea of eating grass and weeds, the natural dietary of cattle and other herbivora. It's completely contrary to our nature to do so. Eating animal carcasses in their freshly killed or putrefied state is equally contrary to our nature. Psychologically, such actions do not appeal to us. Practically, such a way of life is impossible. We are unique as humans. Nevertheless, we are remarkably like apes in our anatomical features and our physiological processes. Apes are primarily fruit-eaters. Could it not be that we are similarly developed because of similar dietary adaptations? Do not dietary adaptations, more than anything else, determine the features and characteristics of all creatures? Are humans really an exception?

Keep in mind that our mental disposition matches our anatomical and physiological disposition. What we admire naturally (as contrary to acquired perversions) is in accord with our dietary. Our aesthetic standards attribute beauty to fruit trees, and fruit but not to dying and bleeding animals. We savor fruit and are repulsed by blood. We do not savor grass or insects.

Probing this subject narrows our natural dietary down to fruits. In ascertaining our natural dietary you must envision us in a state of nature. Cookstoves were not furnished as part of our natural equipment!

Neither were the many tools and devices we now use. We were once like the apes today—tree-dwellers who lived upon the fruit of the trees, namely fruits and nuts. We functioned totally with our natural equipment for acquiring and eating foods.

Most of the anatomical features that differentiate us from carnivores, omnivores and herbivores have little meaning to people who have been steeped in meat-eating, as most Americans have been. But it takes on meaning when we can relate it to our attitude to meat-eating on the natural level. Most people cannot stomach the idea of eating animals in the way that natural carrion-eaters do. The idea of raw blood, offal, bones and flesh is repulsive, especially if the eater must apprehend, capture and rend the flesh.

Simple facts about our physiology may impress people who suffer the results of meat-eating. For instance, osteoporosis, which nearly 100% of Americans suffer in some form, may be due in large part to meat-eating. The body must draw base minerals from bones and teeth with which to neutralize the acid end-products of meat-eating.

One of the most telling facts is rather simple. About 5% of the flesh volume of all animals consists of waste materials that are normally eliminated by the kidneys—uric acid, a precursor to urine. Uric acid is

a poison to humans, not only because it is a toxic waste product but because it is non-metabolizable.

All carnivorous animals secrete the enzyme uricase. Uricase breaks down uric acid so that it can be eliminated quite readily. Unfortunately, humans absorb uric acid when meat is eaten. The uric acid stimulates the body like caffeine or other drugs until the body neutralizes it by drawing upon alkaline reserves. In the absence of such reserves, the body draws upon bones and teeth.

What happens to the calcium urate crystals that are formed as a result of this neutralization? For the most part, the body excretes them. Inasmuch as they're in the circulating media of blood and lymph, the body does not eliminate them with dispatch, especially in view of the enormity of the eliminative tasks of most people. Hence the body "buries" the crystals "under the rug," that is, it shunts them aside to areas in which they do the least physiological harm. The body has a tendency to concentrate neutralized uric acid as calcium urates in the joints, lower back and the feet. These deposits lead to arthritis, bursitis, lower back pains, gout, rheumatism, etc. Once an arthritic sufferer recognizes this bodily process as the cause of his suffering, he is usually quite willing to give up meat-eating. Fasting will, in most cases, enable the body to slowly autolyze these deposits and return to normal. A proper diet will not cause such a condition in the first place nor after correction has been realized.

All transgressions of our natural diet have pathological results whether evident or not. The body functions perfectly within the context of its natural dietary and other healthful practices.

Be forewarned that many people are difficult to persuade. They will not believe you against all the dead weight of habituation and wrong practices. But our natural dietary is not a matter of belief. It is a matter of knowledge—of being armed with the truth about our dietary character. This lesson and the next will yield many nuggets with which you can arm yourself.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > 2. Necessity Of Different Approaches To Nutritional Science

## **2. Necessity Of Different Approaches To Nutritional Science**

These classes in nutritional science will approach the subject from many interesting aspects. The aim is to make you an expert in matters of nutrition. This involves a great depth of understanding as well as knowledge. This lesson will endeavor to supply both understanding and knowledge.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > 3. Understanding The Role Of Foods In Nutrition

## **3. Understanding The Role Of Foods In Nutrition**

In understanding the role foods play in the nutritive processes we must establish criteria for the efficiency with which we can handle different types of foods and the needs they meet. To simplify your understanding of the value different foods have, we have signed numerical ratings to the various food properties, mastering an understanding of the properties of foods that make them proper raw materials for our bodies we so easily gain the knowledge we need for nutritional expertise.

I could tell you that by weight of intake, we should eat 97% luscious ripe fruits (including tomatoes,

peppers, cumpers and avocados), 1% nuts (which are also fruits) and 2% vegetables (leaves, stems and stalks). Then I could say that is all that you need to know about our dietary. In truth that statement does effectively summarize our dietary. However, you'll still be learning about the intricacies and subtleties of diet and human nutrition long after having completed this course and having studied such conventional and unconventional literature on the subject. Nutrition is still a formative and exploratory science.

With this lesson we're going to approach the subject in such a way that we can utilize a rating chart and determine whether a food is good or poor in the diet, and readily determine why it is a good or poor food.

Naturally these things are based very much on subjective experience. They are also based on studies and familiarity with the experience of others as well as on the infant science of nutrition.

You will not have to look very closely to see that those foods which our other lessons have pointed out as those of biological adaptation receive the very highest ratings, being, quite literally, perfect foods. The criteria which foods must meet to be beneficial in human dietary include the food's edibility, aesthetic and physiological conditions, and nutritive factors.

[Home](#) > [Lesson 18 - Ascertainig The Human Dietetic Character, Part I](#) > 4. Edibility Of Foods

## **4. Edibility Of Foods**

### **4.1 Negative Considerations**

Foods that contain antivital or harmful factors will be rated according to our body's ability to deal with these factors. These factors merit minus ratings on the charts. Obviously, we eat for nutriment and not for poisons. The degree of toxicity is thus rated.

### **4.2 Aesthetic Considerations**

Any food must be relished by the unperverted palate in its natural, raw or living state just as Nature delivers it to us. In Nature we were developed on and thus adapted to a totally living food diet. It is imperative that we observe our adaptations. While we will consider some foods in a cooked state as notated on the listings, the rating reflects the lower nutritive values of cooked foods accordingly.

Delectability of food is also a good guide to its value in human nutrition. We must be able to eat our fill of any single food—to make a meal of the item in and of itself for its own sake—if it is to be considered a proper food in our dietary. Palatability or deliciousness is a very valid guide to a food's fitness. Foods should be a gustatory delight. We call this quality "taste appeal."

### **4.3 Physiological Considerations**

In considering the physiological aspects of food digestion, we must consider two factors: the ease and efficiency of digestion. Ease of digestion refers to the ease with which the body handles a given food without pathogenic factors setting in. Efficiency of digestion means how well the body system obtains its needs from a given food relative to the energy it must expend to obtain its needs. For example, the body easily processes vegetables but does not efficiently make use of their nutritive content.

## 4.4 Nutritional Factors

The nutrient complement of the food is rated according to how well it furnishes our needs, not according only to its amount of nutrients. The nutrient complement we have considered includes all nutrients except fuel values. The nutrients considered, which are proteins, vitamins, mineral salts and essential fatty acids, are given four categories.

For the purposes of rating, each category is given equal value. I am the first to admit this is an arbitrary system. This system is not reflective of the respective values of the nutrients in any absolute sense.

1. Protein Adequacy. Protein sufficiency is not determined only by what the food contains. Rather it is determined by the ability of the body to digest and make use of the food's protein complement relative to our needs.
2. Vitamin adequacy of a given food is determined by our body's ability to assimilate its needs from that food.
3. Mineral salts are another vital component of foods. We have rated foods for this component based upon each food's content of usable mineral salts. Minerals in a native or inorganic form, rather than being a nutrient, are antivital or toxic to the body. Most stems, stalks and leaves hold some amount of unprocessed mineralized water. These waters are usually heavy in inorganic calcium, phosphates, potassium, magnesium, and other minerals. Without plant elaboration we cannot use these minerals. Instead, they contribute heavily to atherosclerosis and ossification.
4. Essential fatty acids are necessary in the nutrient complement of our diet but need not be in every food. Nevertheless we rate each food for its content of these acids. The three most important essential fatty acids are linoleic, linolenic and arachidonic.
5. Fuel value is perhaps the single most important consideration of a wholesome food. This is because about 95% of our food intake is utilized for "stoking our furnaces" with the fuel required for the body's energy. Thus, in this criterion, we are concerned with the net gain of energy from a given food in the quantities we can and would eat of it in a mono meal.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > 5. Other Food Qualities

## 5. Other Food Qualities

There are other factors that we could consider in determining suitability of foods in human alimentation. One significant factor is the role of foods in maintaining body pH. Some foods are alkaline-forming (acid-binding) and others are acid-forming in metabolism. Acid-forming foods place a heavy burden on the body. Humans require a diet preponderately of foods that are alkaline-forming in their metabolic reaction.

Let's review the criteria for rating the value of foods. This time we'll append the rating values for foods based on their usefulness in the human dietary.

*Water content* of foods, while important, does not enter into rating value. We are not natural water drinkers. Water has a neutral value. Nevertheless, most proper foods possess water sufficient to meet our needs. Nuts, seeds and dried fruits are exceptions to this rule. All meals eaten should consist of such foods as will render them water sufficient. Our water needs are ideally supplied by our diet.

## 6. Summary Of Criteria Relative To Goodness

We have not given any weight to these considerations because the value of a food in the human nutritive processes is not determined by this factor. Because other factors considered herein are congruous to their goodness (alkalinity) or badness (acidity) we have let these other considerations stand.

There are many valuable nutrients in acid-forming foods, particularly in nuts. Conversely, there are many alkaline-forming foods that are of little use in the human diet. Therefore this criterion is ignored in our deliberations and ratings.

Let's review the criteria for rating the value of foods. This time we'll append the rating values for foods based on their usefulness in the human dietary.

ENTRY NUMBER	CONSIDERATION	RATING VALUE
1.	TOXICITY	Minus (-)0 to 100
2.	EDIBILITY IN THE RAW STATE	Plus 0 to 10
3.	TASTE APPEAL (Deliciousness)	Plus 0 to 10
4.	EASE OF DIGESTION	Plus 0 to 10
5.	EFFICIENCY OF DIGESTION	Plus 0 to 10
6.	PROTEIN ADEQUACY	Plus 0 to 5
7.	VITAMIN ADEQUACY	Plus 0 to 5
8.	MINERAL SALTS ADEQUACY	Plus 0 to 5
9.	ESSENTIAL FATTY ACIDS	Plus 0 to 5
10.	FUEL VALUE	Plus 0 to 40

## 7. Ratings Of Generally Available Foods

NAME OF FOOD	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	TOTAL RATING

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > 8. Questions & Answers

## 8. Questions & Answers

**You have given a very low rating to vegetables and even suggest that we limit our intake to about 2 to 5 %. You've said before we eat vegetables as insurance or protective foods. If they're such good protective foods why not make them half of our food intake? If they really protect us, I think they're good for a bigger share of our dietary intake.**

Vegetables rate much lower since, in examining the charts, it is obvious that they lack many qualities of prime foods. Many vegetables have some toxic factors. They are not savored as are exquisite fruits. They are not digested with the ease and efficiency of fruits. They furnish us no energy at all in most cases. Some actually use more of our energy to process than we can get from them! I calculate that 90% of our eating should be involved in obtaining fuel values. The other 10% should be in association and would be proteins, fat, and minerals with vitamins and other food factors included. Foods such as vegetables fail to furnish caloric values. Nutrient insurance is all they can possibly furnish. Even in this consideration, we really don't need them.

**You equate protein with vitamins, minerals and fatty acids. Isn't protein more important than that?**

Proteins are the building stones of all living beings. They compose some part of every living cell, fruits included. Yet protein is not more important than other food factors that we ingest, neither relatively nor absolutely, infants thrive on mothers milk which is about 1.2% protein. As long as we get that amount of protein with all essential amino acids amply represented, we're getting as much as we need.

I don't think we need as much protein as a growing baby. If we get 1% protein from a diet that averages seven pounds of food a day we'll be getting 32 grams of protein, though this represents about 50% less than the U.S. RDA, it is still more than a healthy body can make use of. It is wise to point out that the body is capable of meeting about 70% of its protein needs by recycling its own protein wastes. There are thriving pockets of people in the Caribbean who are superb specimens of healthy humans that have an intake of only 15 to 20 grams of protein daily.

### **What should we do if a client comes to us who is overly thin and on a protein-deficient diet?**

In the field of practice, you'll have many clients that are deficient in many ways, proteins included. One person can have a well rounded diet on a single food and get all he or she needs of every food factor. Another person might subsist on a diet which supplies four or five times our protein needs but, if the diet is cooked or fed to a metabolic cripple, the protein may be largely unavailable. You will not be dealing with deficiencies, per se. In most cases where there are some body reserves you'll advise the client to fast as long as indicated and then realiment the client on a diet of proper foods prepared and served in a manner we have taught you to observe. Your clients' bodies are their sole remedial means. If the conditions for healing and regeneration are established, you must leave them entirely alone. Anything other than this practice will constitute interference. Protein deficiencies are not nearly as likely as other deficiencies and none of these are as likely as toxemia. Toxemia will be the condition of nearly every client you'll get.

### **How do you determine which nutritive factors a client is deficient in? If most Americans are sick in some way and malnourished, how would I tell what is wrong or what the deficiency is?**

In view of my previous response I think the question should be declared already answered. But I bid you, as professional health practitioners, not to get into diagnosing. You don't have to know, in most cases, the particulars of a client's deficiencies. These deficiencies may actually be the result of chronic toxemia that has lowered the person's capacity for assimilation and utilization of foods. If the client is thin, start him out on a diet of easily digested fruits, especially melons, oranges, grapes and other succulent fruit fare. A mono diet of a single fruit would be in order, or at the very least, mono meals. A simple diet of proper foods will give the body some surcease and enable it to purify itself of its toxic burden and to repair damage and rebuild tissues. Don't expect instant results or miracles, because it's often a slow process. The client should take little food while in the eliminative state. When hunger increases, the diet should have its caloric values increased by greater intake or by more concentrated foods such as bananas, figs, dates, or raisins.

Should a client have reserves of fat, and most of your clients will be either normal or overweight, induce them to undertake a fast so the body can eject its toxic load with more facility. Then, after an appropriate period of fasting, start feeding them on a small amount of a single fruit and increase that as indicated.

You'll learn more about these methods in our lessons on fasting as a part of nutrition. Further, you'll learn that your response to all deficiencies, illnesses, and morbid blood and tissues will be much the same. You'll vary your guidance and establish healthful conditions

for your client in accord with his physiological circumstances. The variations will be very few. Just a few patterns will emerge that you can master thoroughly.

**You've got a great idea about rating foods as you have. But you give some very low ratings to some good things, especially to lettuce and celery, which you praise so much. Below what rating would you refuse to eat a given food?**

Keep in mind that this chart is primarily intended to appraise the value of a food in the human diet on its merits when eaten alone. There are some fine complementary foods such as lettuce and celery that may be added to other foods to achieve certain nutritional objectives. For instance, when lettuce and celery are added to an apple meal, the combination supplies needed additional protein and mineral salts. These two vegetables do not interfere significantly in the digestion of many fruits. Ideally, we should eat primarily foods of the highest rating with some secondarily-rated food. A few nuts should be eaten on occasion. The avocado is a fruit of nut-like consistency that is extraordinarily wholesome. I would say that I would refuse to eat anything rated below 30 and I would not eat higher-rated cooked items. Further, I would be cautious about eating some highly rated foods that had toxic materials in them. This especially applies to cooked foods where an inorganic mineral complement has been created, and where food derangements have taken place that will give the body digestive problems additional to those encountered in the finest foods.

**I'd like to know more about the unprocessed mineralized water in vegetables. Why is this so harmful?**

Our bodies cannot use inorganic minerals. The body treats inorganic minerals as poisons and utilizes its energies in trying to expel them. Whether the raw minerals come from hard water, from fresh leaves, stems and stalks or from the by-products of cooking decomposition, the body cannot use them. Instead, they create an eliminative problem. If uneliminated these minerals are likely to combine with fatty substances and harden, thus ossifying the brain and clogging arteries and veins. It is said that herbivores are short-lived because of the abundance of inorganic minerals in their food.

**What do you have against spinach to rate it so low? I'd rather eat raw spinach than a cooked potato, which you rate much higher.**

Spinach contains oxalic acid and unprocessed raw minerals, like all other leaves. Fruits, on the other hand, have pure water — they are finished products. Oxalic acid cannot be metabolized with any degree of facility by the body. To neutralize it, the body draws upon calcium supplies, even calcium from the bones if necessary. Oxalic acid gives a peculiar taste that is readily recognized. I know of no normal palate that can abide it. The calcium of spinach is more than offset by its oxalic acid content. Spinach is not a food you can live on. You'd have a calorie deficit with every meal of it. If a few leaves of it were added to a salad or to some starch, fat or protein meal, there is little to object to.

**Dr. William Howard Hay said all diseases are the result of acid-alkaline imbalance. Why don't you tell us which foods are acid-forming and which are acid-binding? Think how important that is if a client is suffering acidosis.**

If a client suffered true acidosis he would be dead. Over-acidity is readily corrected by fasting or by a simple diet of mono fruit meals. Causes of acid-alkaline imbalance are eating foods that are predominantly acid-forming, notably cereal foods, meats, dairy and poultry products, seafood and even nuts.

Within a day or two of going on a proper diet, the acidotic condition is corrected. Celery

happens to be a heavily alkaline food that helps a lot. So, too, are figs which are rich in alkaline salts. The worst thing that can happen is to use drugs or antacids. This does not solve the problem. While relief may ensue, the cause, an acid-forming diet, yet remains. Fruits and vegetables quickly establish an alkaline balance.

**I've heard so much about how important salt is in the diet. You give it all zeros and give it a minus 100. Does this apply to sea salt or vegetable salts too?**

You can readily determine just how important salt is in the diet when you see physicians in this country putting hundreds of thousands on salt-free diets. If salt were essential, no one could do without it. Salt is not digestible or usable. It stays in our bodies until we can in some way eliminate it. The body takes on extra water to hold it in suspension so it offers less harm to cells. It deserves all zeros for, in addition to rating all zeros, it has harmful effects that create disease, notably congestion, high blood pressure, edema and other conditions that earn it a big minus rating.

Sea salt is equally as poisonous as the refined variety. It is extracted from sea water and, in addition to salt, it contains other minerals that are in an inorganic and unusable state. As you perhaps know, sailors prefer death through dehydration rather than death from drinking sea water.

Vegetable salts are dehydrated vegetables that are ground up and are often mixed with additional salt. These are also unwholesome in the diet.

**You gave honey a good rating in every department except nutrient content and toxicity. Why did you do this?**

The bee laces its honey with several acids, some for which only the bee has enzymes for reconversion. Such acids are poisonous to bacteria and humans alike. That's one of the bee's ways of preserving its food supply. Those acids earn the toxicity rating even though, of its six acids, about half are metabolizable. If you tried to make a meal of honey only, you'd find it tasty and fully calorie sufficient. But you'd probably get a bellyache unlike any you've ever had in your life. You would probably get other problems too. Honey is very poor in nutrients right down the line. It has practically no protein, vitamins, minerals or essential fatty acids. Only the pollen that is incidentally in the honey has any appreciable amount of nutrients. Honey is, literally, sugar water the bee has obtained from flowers as its reward for performing a service. The sugars in honey are primarily levulose and fructose. The bee dehydrates and thus concentrates them. Honey is developed by bees for bees. Nature did not make us dependent upon the industriousness of bees for our sustenance.

**I love turnip greens in my salad. You have given them a zero rating in the diet, which means they're worthless. How do you come to that? There are some northern peoples, especially in Northern Europe, who practically live on turnip greens and turnips.**

Turnip greens will not long sustain life. They are one of the richest green leaves in nutrients, yet they furnish no calories. Further, they contain unprocessed mineral water and mustard oil that makes them toxic in the diet. Turnips have relatively little mustard oil and are rather wholesome in the diet. They contain a complex sugar instead of starch as their fuel component. A meal can be made of turnips and relative good health will result compared to a conventional diet. Yet by no means are they an excellent food. There are many other foods that are better.

**You gave oranges a nearly perfect rating. As far as I know, oranges are a high water content, low**

**calorie food. How many oranges would you have to eat a day to live on them?**

That is a most appropriate question since we have rated this as a food you could fare well on in and of itself. To illustrate this point, a Florida man lived on oranges and only on oranges without ill effect for six years. In fact he was described as being robust in health all the while. The weight of the oranges you should consume to sustain yourself would have to be about 10 pounds of peeled oranges daily. That is about 20 oranges. That would give you 2,250 calories, 45 grams of protein, 1800 milligrams of calcium, 2,250 milligrams of vitamin C, 9 grams of fats, 18 milligrams of iron—in short, a surfeit of all our needed nutrients. As a great lover of oranges I can't consider such a diet as being unpleasant. I've consumed a mono diet of oranges myself for periods of up to two weeks and find them a most excellent food. I was coming off a fast at the time and gained almost ten pounds of weight on them.

**How can you rate fruits so high when it is aid we can't get enough protein, calcium or iron out of them?**

I think I just indicated the falsity of your statement by citing oranges as being more than replete with the nutrient needs of life. Oranges furnish about twice our real protein needs, ten times our iron needs, about 100 times our real Vitamin C needs, and about 9 times our calcium needs. Keep in mind that the Recommended Daily Allowance is usually from 100% to 500% higher than our real needs in a healthy condition. Almost any fruit you can name, when eaten in an amount sufficient to supply your caloric needs, also supplies you amply with other nutrient needs.

**That is surprising, but my question is along the same lines. Why do you give the same fuel value rating to dates and watermelons? According to my food composition handbook, a 100 gram serving of dates has 274 calories and a 100 gram portion of watermelon contains only 26 calories. How can a 90% difference end up with the same fuel value rating? Also, this same book shows turnip greens as having 28 calories per 100 gram serving, more than watermelon, yet you give turnip greens a zero fuel value rating. Can you explain these discrepancies?**

There are reasons that our ratings are more or less correct despite these apparent discrepancies.

Keep in mind that water is a neutral factor in foods. If you took all the water out of watermelon, 100 grams of its residue would contain about 340 calories. This corresponds to the caloric content of 100 grams of dates without water content. Watermelon has about 13 parts water for each part of solid. Five pounds of watermelon contains about 600 calories, which is about the same as eight ounces of dates. Both would be considered ample servings.

In the summer you need more water and less calories. Watermelon fills the bill well in that regard. In the winter, you need more calories and less water. Dates are a valuable addition to the diet at that time.

Turnip greens occasion the use of more body energy in processing and expelling than can be appropriated from them. Most of their calories are in cellulose. True, they yield 28 calories of heat when burned in a firebox. Humans can't get all of that energy out of turnip greens. Watermelon, on the other hand, is composed of simple sugars which we can make 100% use of. There is a greater than 900% energy gain over the energy expended in digestion and appropriation of watermelon.

I hope this response clears up the seeming discrepancies in our ratings chart.

## **How would you rate brewers yeast as a food?**

I'd rate it below zero. It loses out on every count, even though it has lots of protein and nutrients. Unless disguised, brewer's yeast is repulsive stuff. Even if disguised, it is indigestible. When we eat brewer's yeast, bacteria decompose it resulting in the formation of gases and poisonous by-products of protein decomposition. Your urine will turn yellow within an hour of taking it, showing that it has been excreted rather than digested and used. Because it is not digested, it can furnish no nutrients. It gives, instead, drug effects which many mistake for nutrient effects. Keep your clients off this junk the brewers industry has foisted off on health seekers as a food.

**Dr. Airola says that garlic is a real miracle food with great healing properties. Many other health authorities say the same thing. You classify it as very toxic from the beginning. In fact you give it ten rating points as a food and 80 demerit points as a poison! Who am I to believe, you or Dr. Airola? He's a well known authority on nutrition and, until my introduction here, I'd never heard of you. I've always heard garlic is a wonderful medicinal food, not a poison. It is usually recommended as one of the first foods to add to the diets of sick people. Can you justify your stand?**

I imagine Copernicus had an extremely hard time about his concept that the world was round in an age when all the authorities said it was flat and when everyone believed it was flat. But we know valuable truths arise first in the minds of a few and gradually spread to the masses.

Garlic is treasured for its drug effects, not its nutritional effects. It contains two potent poisons, mustard oil and allicin. These poisons earn garlic its minus rating.

As a food, I doubt that anyone can manage to eat a single bulb of garlic by itself. Consider garlic as a food in itself. If you tried to eat enough to obtain the fuel values you needed, presuming of course an amount of garlic was eaten to represent our caloric needs, you'd probably not survive the ordeal! When anyone praises the medicinal value of something, they're talking about drug effects, not nutritional effects. It is absurd to speak of anything as having healing properties. Healing is totally, exclusively and only a faculty of the organism and belongs to absolutely nothing outside of the organism. Dr. Airola is praising a drug as a food and in matters of healing, does not seem to understand physiology.

I would advise you to believe no one. Investigate matters for yourself. To believe is to be credulous. To know is to be virtuous. Learn the "nitty-gritty" of everything. Don't rely on so-called authorities. Remember, every wrong system of the past and present had and has its authorities. Don't trade on authority. Trade only on the truth you can ascertain.

I don't ask you to believe me. I ask you to examine everything I say and question it just as you are now doing. Put everything to the test. You'll betray the trust of your clients if you guide them wrongly. Learn the truth so that you may truly help them.

**Isn't it possible, in view of our knowledge of nutrients and tasty natural foods that combine well, that we can create meals far more wholesome and delicious than just any single food item? For instance, an avocado with greens and tomatoes really tastes great and gives us a complete range of our needs.**

Yes, we can construct meals. The rating charts are based on the outlook that, in nature, we were adapted to certain fare and that we ate primarily or only of that fare during its season as is the case with present day animals. But the fact that we can construct well-rounded meals

does not mean they are more wholesome than a single food with a high rating. The meal you suggest is an excellent one. However I would advise not to eat an oil/protein salad meal such as you suggested more often than once every other day. The body is very provident and conserving. It's a lot wiser than our wildest imaginations can lead us to contemplate. For instance, if you're having steamed potatoes, then the addition of such auxiliary fare as cucumbers, bell peppers, broccoli, lettuce, and celery is judicious. If you're having nuts or avocados the addition of the same salad fare plus tomatoes is also justified. Our bodies usually handle vegetable fare rather easily. Yet our bodies are inefficient at getting much food value from vegetables other than a goodly part of their rich nutrient load.

**Isn't it unhealthy to eat only one food at a meal? The law of the minimum says we must get all our nutritional needs in each meal for that meal to do us good. Why not balance out every meal as recognized nutritionists recommend?**

I assure you that our "recognized" nutritionists are about as far off in this matter as in the foods they're placing their stamp of approval on in America today. I presume you've heard of Dr. Frederic Stare who chairs the department of nutrition at Harvard. He claims we should eat for enjoyment. He says such a practice is the healthiest thing to do, and has renamed junk foods joy foods. I hope you aren't giving credence to these "recognized" nutritionists who're busily engaged in selling our health down the river—for a price of course.

The balanced meal concept is based on ignorance and assumptions. The law of the minimum has nothing to do with what we eat at a given meal. I repeat that the body is immensely wise, provident and conservative. Did you know that about 95% of our iron needs can be met from recycled iron? That about 70% of our protein needs can be met from recycled proteins? That the body, contrary to what nutritionists tell you, maintains amino acid pools? That, contrary to what we're told, it stores vitamin C in the adrenals? That the body carries about a five year supply of Vitamin B-12 and receives its supply from bacterial activity in the lower intestine just as is the case with other animals? The law of the minimum applies to the least available needed nutrient at time of synthesis.

When you recognize these factors you begin to realize that the balanced meal concept is incorrect and unnecessary. It gets us into eating protein/carbohydrate/oil and other incompatible combinations at the same meal. Instead of getting a "balanced" meal we get an indigestible mess. In fact, about half of America's meals end up with some degree of indigestion, from mild to severe. That's why the makers of antacids are so many and so rich that they can advertise widely on TV, radio and in other media. If we don't digest our meals, it should be obvious we're not going to get the nutrients we need from them either. Obviously the balanced meal concept is a fallacy.

On the other hand, the foods of our adaptation are the building blocks of balanced meals. These foods give us nutrients in proportion to our ability to handle them. Our development in nature has been built around the foods that best serve us. It might be said we adjusted so as to thrive on them. While the proteins, fats and starches as may exist in fruits are, in a sense, incompatible, they are so organized and our adaptations are so tailored that we handle them with ease and efficiency. Thereby we receive their full goodness while getting our primary need, calorie-rich carbohydrates.

If we get less than our needs of a nutrient at one meal, the body's reserves and providence will carry us on stored past surpluses. Until another meal is indulged that again furnishes us a surfeit of that nutrient, our reserves will be less, that's all. We'd best eat of foods of our adaptation as do the animals in nature and worry not. That is the message you have to get

across to your clients as well.

Our nutrient needs are much smaller than the world at large wants to admit. This "the more the better" philosophy has sabotaged our collective health. When we get all we need of anything, that is enough. Enough is all we need. Surpluses of proper foods eaten in the regular course will cause problems. If we overeat on wrong foods and foods incompatible with each other we compound the problem immeasurably. Because this is so often the case, it's no wonder that America is such a sick nation! More than 80% of our ill health is attributable to dietary indiscretions. If we corrected our dietary errors alone the health of this country would improve by more than 80%. That's because our dietary fare represents the ever-whelming burden that breaks the camel's back of health, so to speak.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > Article #1: Are We Vegetarians Or Fruitarian?

### **Article #1: Are We Vegetarians Or Fruitarian?**

At this point in our study of the character of our natural dietary, I feel it is important to address this question: are we vegetarians or fruitarian? The true answer to this question is extremely important. Nothing could possibly contribute more to your success as a health practitioner than the mastery of the knowledge of our dietary character.

There are about twenty million people in this country who call themselves "vegetarians." Most vegetarians fuel their bodies with what is called vegetarian fare. That is, they fancy themselves as a class of herbivores or plant eaters. We Life Scientists contend that we are not ruminants or herbivores.

Why are we delving into such a narrow-ranged inquiry? There are many amongst us, even those who call themselves Hygienists or Life Scientists, who feel that vegetable fare is proper for humans. If I felt that were true, I would not be pursuing this inquiry. Of course, that does not mean, ipso facto, that I'm right. I will nevertheless endeavor to demonstrate that vegetarian fare lacks the most fundamental requirement for human food and that it fails to meet many necessary criteria to be the basis of the human dietary.

In our life practice and those we endeavor to instill in others, we must strive for dietetic perfection. The best diet, as a component of a well-rounded health regime, will yield the greatest measure of health. From that abundant health springs the greatest joys in life. That which is good is also beautiful. That which is wholesome makes us wonderful for ourselves, for others and for society. An ideal diet is the basis for the best possible level of health. Thus this inquiry is conducted for the purpose of ascertaining what constitutes an ideal diet.

Our natural foods must necessarily appeal to ALL our relevant senses. It follows that our natural foods must delight our eyes, be of a fragrance that tantalizes our olfactory senses, and be of such titillating quality to the taste buds as to be ambrosia. Eating should always be a gustatory delight. Our development in nature was such that discomforts and unpleasantness were never a condition of life. Only when we deviate from our natural adaptations do we suffer. Hence it is a truism that our natural foods are enchanting to the eye, captivating to smell, ecstatically delicious to eat and harmonious in the body. This truism invites comparisons based on sensual involvement in the selection and consumption of foods.

When we were entirely the children of Nature, we did not have utensils or cookstoves as a part of our

endowment. We had to eat our foods as we found and gathered them in nature. So the ascertainment of the value of foods is necessarily based on the condition in which foods come to us from nature, in their living or raw state, at the peak of perfection. The comparisons I am about to set forth must be valid for you only if they relate to your preferences.

Which would you prefer? The aromatic sweet flesh of a properly ripened pineapple or a head of broccoli? Would you rather have a delectable sun-ripened peach or a few raw collard greens? Would you prefer a stalk of celery or a bunch of purple concord grapes? Which entices you the most, a colorful juicy orange or spinach greens? Does a head of cabbage attract you as much as a properly ripened, brilliantly yellow and brown speckled banana? Which lures your eye most for beauty, a large red delicious apple or a freshly dug carrot? Does a basket of brussels sprouts turn your head as much as a basket of strawberries? Is the heavenly delicacy of a Cornice pear matched by anything you've ever eaten from the lettuce family?

If you've ever eaten a cherimoya, mango, mangosteen, soursop, sapodilla, fig, date, watermelon, cantaloup, honeydew or other mouthwatering delights, you know well their joys. Can you compare the eating of any single vegetable in its raw state to eating any of these heady delights? Can you not see that, in order for a food to be a natural item of human dietary, we must be capable of relishing that food eaten by itself in the raw state?

Not only must the food be a gourmet experience in its living state but our fill of it must furnish us with most if not all our nutrient needs. This is a most vital consideration.

Can you name a single vegetable that you'd ravish, as a full meal of itself in its raw state? Almost any vegetable that you can name fails in the first prerequisite of a food: it must furnish us amply of our fuel requirements. Almost every vegetable you name does not furnish us with any significant amount of caloric values. All green leaves, regardless of their calorie rating, yield us no net increase in calories. The energy of digestion and assimilation often exceed the calories obtained therefrom. Most of the calories of vegetables are bound in indigestible cellulose. Ruminants with four stomachs, true herbivores, can digest cellulose and thereby obtain fuel and nutrient values. We humans become as thin as a rail if we try to sustain ourselves on vegetable fare.

The potato, a tuber, is regarded as a vegetable. If eaten raw, it cannot be relished. Moreover, its starches cannot be utilized for two reasons. First, most of its food values are inaccessible to us because they are encapsulated in cellulose membranes. Secondly, those values which are freed quickly exhaust our supply of the starch-splitting enzyme, ptyalin (salivary amylase).

Cereal grains, which are popularly regarded as vegetables even though they are not, have the same drawbacks in digestion as does the potato. Grains occur in an edible state but a day or two in their cycles. Otherwise they're inedible except upon heavy soaking or sprouting. Even when soaked or sprouted, every grain is deficient in one or several aspects of its nutrient complement. Most also offer digestive problems. The gluten of wheat, for instance, is indigestible. We simply don't possess the enzymes to break it down. Wheat protein is bound as gluten. Further, most grains contain phytic acid, which we cannot handle. They bind calcium and thus rob us of that mineral salt.

An examination of every vegetable reveals it, when it stands on its own, as unsuited for human sustenance in some significant aspect or other. Fruit, on the other hand, supplies us amply with all our needs including proteins, mineral salts, vitamins, fuel and other vital food components, known and unknown.

We can relish fruits in their raw ripe state without any special preparation beyond pitting and/or peeling. I know of very few vegetables that would even begin to furnish our needs amply that we can make a meal of, even if we did relish them. Turnips, rutabagas, kohlrabi, fresh sweet corn, sprouted legumes and fresh sweet peas (where starch has not set) would be some of the near exceptions.

Without cookery and condiments most vegetables are unappealing. We must jazz up their lack of taste appeal with stimulating herbs or unwholesome flavorings, fats, seasonings, etc. We must deceive our

senses in order to consume vegetables. Condiments and cooking are very destructive to our health.

Most vegetarians eat fruits, even a preponderance of fruits, yet call themselves vegetarians. Many vegetarians consume fish, milk and dairy products and eggs and still fancy themselves vegetarians. Of course these products are not even vegetables. Vegetables are plants. But the seeds of plants, the legumes, the grains, certain fruits such as cucumbers, squash, pumpkins, tomatoes, eggplants and peppers are regarded as vegetables though technically they are not.

Not all fruits meet the proper criteria as food for humans. Nuts and avocados are suitable as food but we could not sustain ourselves on them whereas we can sustain ourselves indefinitely on grapes, bananas, oranges, figs, dates and many other fruits. We'd never make it on fruits such as cucumbers, tomatoes, eggplants, peppers and squash any more so than we can make it on cabbage or celery.

A good indication of what our natural foods are can be determined by the natural preferences of a child that has been fed nothing but its mother's milk. Does it like cereals or bananas? Apples or cabbage? What will a child go for if let to choose its own food? In my experience such a child always has chosen fruits. When served vegetables, my child found them a chore to eat, though he ate them to some extent.

We have considered vegetables and fruits based on aesthetic appeal and fuel requirements. There are other touchstones for consideration which we shall now explore. Humans are classed as frugivora or frugivores or fruit eaters because of their anatomy, their primate character, their digestive faculties, their psychological disposition and their background in nature. Research has shown that we had an arboreal past—that we were once tree dwellers. At that time we depended upon the products of tree, and later upon the fruits of stalk and vine, for our sustenance.

For example, Dr. Alan Walker, an anthropologist of Johns Hopkins University in Maryland, has done research that shows that humans were once exclusively fruit eaters. By careful examination of fossil teeth and fossilized remains of humans with the aid of electron microscopes and other sophisticated tools, Dr. Walker and other researchers are absolutely certain that our ancestors, up to a point in relatively recent history, were total fruitarians. These findings were reported in depth in the May 15, 1979 issue of the New York Times.

These findings complement other findings and verify the consistent scientific classification of humans as frugivora.

Creatures that live in accord with their biological heritage do not develop disease. They live out their normal life spans and die natural deaths. Humans have by and large strayed from their natural dietary and for that reason suffer disease and early death. Humans who undertake to live on their natural dietary and observe other modalities of healthful living also live unto a ripe old age and die a natural death. Although it is a rarity, people who touch base with life's requisites have lived well past 100. In Hunza such a lifespan is a rule rather than the exception, even though their dietary is far from ideal.

Green leaves and stalks contain a greater concentration of vitamins, minerals and other nutrients than fruits. But they also contain, in most cases, compounds we cannot handle well. Lettuce contains minute amounts of a poison called lactucarium, which is a soporific. It is contained in a milk-like substance, just as in the poppy. Large amounts of lactucarium can be gathered and converted to substances resembling opium and heroin.

Celery has bitter properties in the leaves which make them repulsive to the normal palate. Anything that disagrees with our taste buds has, ipso facto, been rejected at that point. That is not to say, on the other side of the ledger, that a pleasant taste is the sole criteria by which to select foods, even with foods as they occur in nature, our taste is the surest guide we have if our taste buds are unperverted.

I deeply believe that we can add certain vegetables to our diet in small quantities with some benefit, most notably lettuce and celery. Their wealth of vitamins and mineral salts as well as their high quality protein amply supplement and insure adequacy of a fruitarian diet. Our bodies handle small amounts of such vegetable fare rather efficiently and without protest. In conjunction with a vegetable meal certain

fruits can also be added, especially bell peppers, tomatoes and avocados. Secondarily we can add nuts on occasion or seeds such as pumpkin, sesame and sunflower. These seeds have the same dietetic character as nuts even though humans probably never ate them in nature.

It is well to always keep in mind that we are not naturally herbivores, graminivores, carnivores, insectivores or omnivores. Neither are we oil, protein or starch eaters except incidentally. Our protein needs are met amply from fruits but the occasional addition of nuts, seeds and greens insures dietary protein adequacy. However, we do not handle concentrated foods containing oil, proteins and starches with any great degree of efficiency. They are best eaten infrequently, perhaps two or three times weekly as Proteins require about 70% as much energy to digest and assimilate as they furnish whereas sweet fruits are so efficiently handled that the body is able to utilize over 90% of their caloric energy after deducting energies expended in ingestion and assimilation. Moreover, proteins are not used for energy as long as carbohydrates and fats are available.

*That to which we are physiologically adapted is also most effectively and efficiently utilized.* Vegetables, I repeat, yield us no calories as a rule though we do obtain from them a plethora of nutrients. Even so, fresh ripe raw fruits furnish us amply of our needs including proteins, vitamins and mineral salts. Even our very small need for essential fatty acids is well met by fruits. When we meet our requirements, that's enough. Enough is all we need. Oversubscription can be like overloading a truck or a mule—it is very taxing and damaging.

Though vegetables are not natural to our dietary I must reiterate this observation: Not all vegetables are bad in our diet for they are consonant with our needs. On the same order, not all fruits are good for us. Many fruits are poisonous. Some, though not poisonous, are not handled well, such as oily fruits like Brazil nuts and pecans, high protein and fat content nuts and seeds such as almonds and sunflower, and starchy fruits such as pumpkins and chestnuts.

No natural food in the world rivals fruits for exquisiteness and wholesomeness. Inasmuch as tables of composition of foods show fruits replete with our needs, and inasmuch as we can more efficiently make use of the nutrients of fruits than any vegetable, legume or grain, we can safely confine ourselves to completely fruitarian fare with great benefit.

While the condition and quality of fruits available in our marketplaces are lamentable, the same goes for everything else sold as foods! So we are still better off with fruits. Some fine quality fruits can be obtained and we should concentrate upon those. Dried fruits have considerable goodness too. We should complement our fruit meals with some dried fruits, especially if we're in need of high caloric intake.

I believe the points made herein support overwhelmingly that we are fruitarians. Thus I rest my case.

<b>THE CARNIVORA</b>	<b>THE OMNIVORA</b>	<b>THE HERBIVORA</b>	<b>THE ANTHROPOID APES</b>	<b>MAN</b>

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > Article #2: Research Yields Bombshell Of A Surprise!

## Article #2: Research Yields Bombshell Of A Surprise!

The prestigious New York Times newspaper, in its May 5th issue, surprised your editor more by printing an article than the surprise they express by the findings revealed.

The gist of this article is some research done by an Anthropologist, Dr. Alan Walker of Johns Hopkins University in Maryland.

Dr. Walker has come to the startling conclusion that early humans were fruit eaters—not just fruit eaters but exclusively and only fruit eaters—eaters of nothing but fruit. This comes as quite a bombshell from a noted publication that has a vested interest in a heavy meat-eating society.

By careful examination of fossil teeth and fossilized remains of humans with the aid of electron microscopes and other sophisticated tools, Dr. Walker and other researchers are absolutely certain that our ancestors, up to a point in relatively recent history, were fruitarians.

Hygienists are not necessarily fruitarians but all will tell you that humans are, by physiology and anatomy, Frugivores. A cursory study of biology will reveal this, even if written by meat-eating professors, which most of our Biologists are.

The scope of the article is rather far flung. They trace humans through history as expanding to herbiage and nuts and, finally, to meat as a full-fledged omnivore.

But the essence of the article is that, though we undertook omnivorous eating practices, our anatomy and physiology have not changed—we remain biologically a species of fruit eaters.

Our dietetic character is established by our disposition toward fruits. Our natural diet has great eye and taste appeal. It passes from the stomach in digestible form in from 10 minutes to 30 minutes after ingestion.

Contrast this with concentrated fat and protein foods which take three to five hours to pass out of the stomach.

We do not have the four stomachs that herbivores usually have. This rules out most herbiage.

We have only one starch-splitting enzyme versus a multitude of them in omnivores and starch-eating animals. Our ptyalin is very limited. This rules us out as starch-eaters which includes grains or cereals. We are not graminivores.

Neither are we carnivores. It is repugnant to our thoughts to kill and eat an animal while it is yet warm and bloody, to eat its brains, heart, offal and blood as true carnivores do. True carnivores do not chew meat—they have in their digestive tracts a hydrochloric acid so concentrated, about 1100% more so than ours, that it will digest the flesh from our hands if they swallowed them. But our acids are so weak we

digest meat poorly even if we chew it thoroughly. Even then we cannot handle uric acid except at great expense to our vitality and well-being. Cholesterol plays havoc with our circulatory system. So don't think we're natural meat-eaters. We're suffering very dearly for our dietary indiscretions—America has more sick people than any country in the world.

Can you imagine the dismay with which our meat and dairy industry not to mention our extensive junk food industry will view such damaging propaganda? Can you not see how many advertisers will have second thoughts about placing advertising in the New York Times?

Well, it doesn't quite work like that. The junk food advertising in the New York Times amounts to about nil. It is a newspaper that "prints all the news that's fit to print." It serves a cultured, aware audience.

But one of the surprising things that came out of this article is its attribution of the harmfulness of our shift from our natural diet of fruits to other items of food that range from eggs and insects to milk and meats.

I have checked with many Life Scientists in other areas of the country. Not one has seen nary a mention of these universally significant findings. I've examined our local papers. You'd never know about it. After all, our local papers serve the industries that a general knowledge and observance of these findings would destroy outright.

Most Hygienists/Life Scientists do not make sweet fruits their primary item of diet. Few do. Your editor's diet has been only 70% to 80% fruitarian, perhaps more if you consider nuts, tomatoes, bell peppers, cucumbers, avocados, eggplants, and other such items as fruits, which they are. Then your editor's diet might be considered about 95% fruitarian with the balance being the green leaves and stalks of lettuce, celery, kale, collards, Chinese cabbage, sprouts, broccoli and cauliflowers.

Actually we all naturally have a "sweet tooth" and it is with reference to fruit-eating that we are frugivores.

When I was a youngster I was accused of wanting to eat only desserts and leaving the good substantial food to waste. Now I'm sort of intrigued by all-dessert meals in fact I eat so many of them now I sometimes go days with nothing but. Now that the melon season is upon us plus all the other goodies, I'm afraid my vegetable and nonsweet fruit eating are going to take a back seat. In the mulberry season your editor ate only mulberries for two or three days running on several occasions.

The salutary truths contained in these findings will be hedged by most who learn of it. It will be said that fruits do not supply us with sufficient proteins or nutrients or no longer do. Much will be said but this does not negate the truth. It will all be in defense of wrong learning and wrong notions. Even many Hygienists/Life Scientists will pooh-pooh an all-fruit diet.

If you don't go along with an all fruit diet, then why not add some greens, sprouts, nuts and seeds? But you should make your diet of mostly fruit. You'll attain to a high state of health, mental well-being and functional vigor. If you eat a salad every second and third day with a protein, that's often enough to assure more than adequate nutriment.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > Article #3: Are We Meat Eaters?

### **Article #3: Are We Meat Eaters?**

Almost any argument can be effectively destroyed on the emotional level. When you invoke a picture of realism in the presentation of argument it will either build or destroy your argument. The truth should

win out regardless of what side of an argument you're on.

Hygienists have often been taunted with "I don't want any of your rabbit food." An emotional rejoinder that leaves them agast is "I'd prefer it to your buzzard food."

Some folks will tell you humans are meat-eaters and that they personally are meat-eaters. Of course they're not true carnivores. You can create revulsion in them for meat-eating by simply telling them: "When you can take a live rabbit and crush its head in your mouth, start chewing it up and eat it, hair, skin, bones, brain, gristle, guts and all, then you can tell me you're a meat-eater. Until you can do that with relish, get off your phony argument." That will really floor them.

Another sure argument that will floor your detractors or intellectual protagonists is to ask some pertinent but innocent question. You might ask your meat-eating argumentative friend if he or she secretes uricase. Of course few will know what you're talking about. "Uricase? What's that?" they may ask. You counter, "You don't know what uricase is and you're telling me you're a meat-eater? Uricase is an enzyme that is secreted in the intestinal tract of all carnivorous animals! Humans do not secrete this enzyme. Thus, when humans eat meat they cannot break down toxic uric acid. When uric acid is absorbed it creates havoc in the body. To neutralize uric acid the body must draw upon its reserves of valuable alkaline minerals, especially calcium." Because grain and meat-eating humans have a predominantly acid-forming diet, the body must oftentimes get the necessary base minerals from its bones to neutralize the acids. The resulting calcium urates cause kidney stones, accretions in the joints that result in arthritis and, in all events, osteoporosis of both bones and teeth.

You can thoughtfully adduce many arguments when you are "homed in" on the criteria for our natural diet. For instance, you might ask your detractor to picture a three year old child in a playpen. Into the pen we place a rabbit and an apple. Will the child be hostile to the rabbit, kill and eat it and play with the apple? Or will the child eat the apple, and befriend and play with the rabbit?

It is said there is no winning an argument. "Convinced against his will a man remains of the same opinion still." But, if there are spectators who observe out of interest, the arguments are telling. When eating meat in the future it will be difficult for him or her to eat it without conjuring up the picture of blood, offal, bones, hair, etc.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > Article #4: Are We Milk Drinkers?

### **Article #4: Are We Milk Drinkers?**

America's dairy industry has no intention of letting Americans become weaned. We are to remain sucklings all our life.

One of the most telling arguments against milk drinking is to elucidate the realities of milk-drinking. Consider the following statements. Milk would be much fresher and more wholesome if taken directly from the teat of the cow as it is done in nature by calves. The fact that a person suckles vicariously does not make it suckling any the less. It's no different than paying someone to kill your animals for you. When you pay the butcher you pay everyone—and you're a killer by proxy just as much as someone is who buys a contract for someone else's death.

Should anyone argue seriously that milk is the one perfect food you can agree with them that this is true—for a calf. Then you might inquire if their bodies secrete rennin and lactase. These enzymes respectively break down the casein of milk, the calcium/protein component and lactose, the milk sugar. Humans normally cease to secrete these enzymes at about age three, and thereafter can no longer handle

milk. It's no accident that our number one "allergy" is milk. The body properly objects to substances it cannot use for food.

Yes, milk may be the one most perfect food but that does us no good if we can't digest and use it. Further, when our bacterial flora decompose it, fermenting part and putrefying part, the by-products of decomposition will cause many problems we didn't bargain for.

[Home](#) > [Lesson 18 - Ascertaining The Human Dietetic Character, Part I](#) > Article #5: Are We Grain Eaters?

### **Article #5: Are We Grain Eaters?**

Grains are grass seeds. The grains of today are rather tall, but they're huge compared to the seeds from which they're developed. Grains have been cultivated and eaten humans for only about 8,000 years.

In nature we did not eat grains or grass seeds. We did not develop any gathering or digestive equipment for grains. Natural grain eaters must be able to efficiently gather, grind and digest grains. Humans fail on all counts. Our teeth handle grains poorly. In fact, humans refuse to chew tasteless and hard grains. Even so, humans, not being starch eaters, cannot digest more than a handful of grains, if that much. True starch eaters secrete a plethora of starch-splitting enzymes in copious amounts. Humans secrete one starch-splitting enzyme, salivary amylase (ptyalin) which is quickly exhausted. After a mouthful or two of starch, the eater palls and stops.

Nope, we're not grain eaters. The way we do eat grains by mechanical gathering, refining, cooking, etc. makes them palatable but more pathogenic.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > 1. Humans Developed To Their Hight State Entirely On Fruits

### 1. Humans Developed To Their Hight State Entirely On Fruits

Humans declare themselves to be the highest form of animal life. Paleontology teaches that hominid forms of life appeared on Earth some sixty million years ago. Distinct human forms have been identified from fossil finds dating back about four million years. Pre-hominid beings were insect eaters but, as some types of pre-hominids took to the trees, they gradually became fruit eaters.

Fruit eaters, proving quite harmonious to the needs of fruit-bearing trees, stimulated the growth of better and more nutritious fruits. Evolving trees developed the bearing of fruits as a viable way of existence.

The interplay between fruit-eating animals and fruit-bearing trees begot an ever greater profusion and variety of fruits. Myriads of different fruits were developed to attract fruit eaters. In this symbiotic relationship, trees grew fruits as foods for animals in exchange for a service—the service of seed distribution, thus insuring survival of kind.

On the other hand fruits proved such wonderful fare for fruit eaters that they became the raw materials for superior growth and endowment. Our ancestors of sixty million years ago weighed just a few pounds. They thrived so well on the fruit diet that they became too heavy for tree life. These precocious developers were called primates. The brains of certain branches of primate life, notably those branches which became humans, developed rapidly and became quite large relative to other forms of life.

Let us examine how this symbiosis between humans and fruit trees created the superb creatures which we regard ourselves as being.

#### 1.1 The Evidence of Paleontology

Paleontology is that branch of science which deals with fossil remains. Inasmuch as our objective is to establish that fruits are our natural fare and that we thrive best on an all-fruit diet, we'll refer to fossil evidence that particularly affirms our adaptation to fruit.

Dr. Alan Walker of Johns Hopkins University in Maryland examined the fossil remains of humans. After making detailed examinations, especially of the teeth, he concluded that humans were exclusively and only fruit eaters. Walker's examinations were detailed in the May 15, 1979 issue of *The New York Times*. His findings came like a bombshell into our culture, where fruits are relatively sparse in the diet.

## **1.2 The Evidence of Anthropology**

Anthropology is the study of humans. The study of anthropology involves the origin and development of humans in cultural, social, physical and racial aspects.

Anthropologists have established that human culture, social organization and body adaptations arose from a background in nature as a fruit-feeding animal. Humans, like their primate and simian cousins in nature, are clannish in social organization. Most of their acculturation involves the beauty of their natural foods, fruits, and the trees which produce them. Physically, humans developed on fruits just as our simian and other primate relatives in nature. In consequence anthropologists and biologists have classified humans as frugivores or fruit eaters.

## **1.3 The Evidence of Archaeology**

Archaeology concerns itself with the artifacts of past peoples and civilizations. Archaeology also confirms our fruit growing and consuming past. Archaeological finds show that we've been heavy eaters of fruit from remotest antiquity. On the other hand, we've eaten grains only for the past six to ten thousand years. Our meat-eating past as civilized peoples has been limited to recent times and has usually been confined to those peoples living in the far North. Most of the world's peoples still consume little or no meat. Grains have become a practically universal diet, though there are pockets of tuber, legume and fruit eaters.

Throughout Europe the mounds and great stones attest to fruit cultivation. Much pottery from ancient times has upon it inscriptions and drawings of fruit. Fruit-gathering and storing vessels are found over much of civilized earth. The records left by our ancestors attest to the great role fruits played in our dietary.

## **1.4 The Evidence of History**

Much of our recorded history was destroyed during the destruction of the great libraries of Alexandria and Carthage. What remains tells us of great gardens and orchards. Herodotus, the Greek historian, records that Greeks were heavy eaters of olives, figs, dates, grapes, apples, oranges and other fare. This noted historian wrote: "The oldest inhabitants of Greece, the Pelasgians, who came before the Dorian, Ionian and Elian migrations, inhabited Arcadia and Thessaly, possessing the islands of Lesbos and Lakemanas, which were full of orange groves. The people with their diet of dates and oranges lived on an average of more than 200 years."

Another Greek, the poet Hesiod, said, "The Pelasgians and the people who came after them in Greece, ate fruits of the virgin forest and blackberries from the fields." Plutarch, the Greek biographer, observed: "The ancient Greeks, before the time of Lycurgus, ate nothing but fruits."

Pythagoras, one of the wisest of the ancient sages, is credited with being the father of mathematics, modern astronomy, philosophy and other sciences, and was perhaps the greatest, of all Greeks. His fare was almost entirely fruits. He left his mark on the world as no other man before him did. He was the author of the philosophy of the Essenians from whence originated many of the principles of Christianity as we know it.

Much of our history indicates that our ancestors were fruitarian. But, history books today omit or falsify our past and our fruit-eating nature. Biology and physiology books are also so altered. Even such a simple word as frugivore has been omitted from most current dictionaries and encyclopedias.

## **1.5 The Evidence of Legends and Traditions**

Much of organized religion had its origins in sun and tree worshiping societies. Apollo is a god of the apple tree. His name means apple. Avalon means the fabled island of apples. The Garden of Eden was an

orchard. Its walls corresponded with the ancient "para desa" or walled orchards. These walls kept the orchards intact from animals and retained the day's heat to protect against the night's chill.

The most fabled land of fruits was Java. After this land was named, Japan, Hawaii and many other countries paid homage to Java as their homeland. Israel was once the land of Yahveh (YHVH), which may be pronounced the same as Java. Such names as valhalla (originally avalhalla) merely means "apple hole" or a place for apple storage. Many places throughout Europe as well as many of the pagan deities have names that correspond with Java and the names of fruits.

Henry Bailey Stevens has created an excellent book, *The Recovery of Culture*, which gives evidence of our fruitarian past as found in lingering legends and beliefs. Sir James G. Fraser's *The Golden Bough* is the most thoroughgoing publication ever on the origins of deities, beliefs and rituals. A reading of *The Golden Bough* will quickly reveal that most systems of reverence were built around climate, the sun, trees and the fruits they produced.

## **1.6 The Evidence of Anatomy**

What we are is attested to by our anatomical makeup. Our physical character has been determined by our arboreal past.

Fruitarians of the mammalian primate order have revolving joints in their shoulder, wrist and elbow joints. These allow for free movement in all directions. They have hands and fingers with apposable first digits (thumb) for grasping and gathering the product of trees. Fruit gatherers and tree dwellers have stereoscopic binocular vision. This makes possible vision that is precise in its ascertainment of positions of limbs and objects. Frugivores developed larger brains than their animal counterparts. All have only two mammary glands and usually have only one offspring per pregnancy. The teeth of humans are identical in almost every respect to our anthropoid relatives in number, kind and usage. We do not here intend to prove the biological relationship of our simian relatives. We only wish to prove that our teeth are practically identical to acknowledged frugivora.

Anatomically, humans are in most particulars unlike herbivores, carnivores and omnivores. Every organ and system differs radically because each is suited to the animal's respective modes of food acquisition, eating and digestion.

## **1.7 The Evidence of Physiology**

The structures of humans attest them to be in every respect fruitarians. This fact is irrevocably confirmed by the functions of the human body. Every alimentary function is geared to a fruitarian dietary.

In keeping with other frugivora, human saliva is alkaline. An alkaline environment of the mouth and, consequently, the stomach, is chemically necessary to handle starches which are sometimes incidental to fruits. Further, it initiates the neutralization of the acids of many fruits.

In contrast, the saliva of meat-eating animals is of an extremely acid character. Proteins such as those found in meats require an acid medium for their digestion. The high acidity of the saliva of carnivora greatly assists in dissolving and digesting flesh with almost no mastication.

The natural food of humans is readily absorbed without any digestion other than the proteins, fats and starches incidentally it. The simple sugars of fruit undergo no change in the stomach or duodenum, being absorbed directly as fructose and glucose as it exists in fruits.

The fare that is recommended by conventional nutritionists is classified into the "basic four food groups." The foods listed under the "basic four" present nearly impossible digestive tasks to the body, especially when combined into a single meal as advocated. Over 50% of the meals eaten in America result in indigestion. The cause for this indigestion is the eating of wrong foods wrongly combined.

Even if eaten alone, legumes result in digestive problems. We are not physiologically equipped to handle

the heavy concentration and combinations of fat, starch and protein found in legumes.

Indigestion and gas result from the eating of legumes, especially if they're eaten with foods other than green leaves, stalks and stems.

Even if eaten alone, meats will digest poorly and invariably undergo putrefaction to some extent before absorption. Even if eaten alone, grains and starchy foods stress the human digestive faculties.

Inordinate amounts of mechanical, chemical and nerve energy are required for the digestion of grains, whether eaten raw or cooked.

Physiologically, meats furnish us practically nothing except amino acids. Almost no energy is derived from flesh when man eats it. The amino acids of proteins will be broken down for energy only in the absence of carbohydrates and fats, which are our primary sources of energy. Hence, ingestion of protein foods beyond our small need of 20 to 30 grams daily is without justification and in practice is generative of pathological by-products.

Foods other than those of our biological adaptation usually have some indigestible components that make them toxic in the human body. For instance, milk is pathogenic to humans. We do not have the enzymes rennin and lactase to break down casein and lactose respectively. Wheat is pathogenic because we do not have enzymes to break down phytic acid and gluten. Other grains are similarly pathogenic. Vegetables often have toxic substances, notably oxalic acid, mustard oil, allicin, aloin, glycosides, toxic alkaloids, etc.

When we consider human physiology, we must do so within the context of nature rather than in the environment of modern acculturation. Thus, we must consider foods that we would have eaten raw in the natural state in our pristine environment as being consonant with our physiological faculties. All the evidence points to fruits as being the food of our adaptation. The evidence points to nothing else—no insects, no grass, no grain, no leaves, stems or stalks, no animals, no tubers or roots and not even any nuts! The most conclusive evidence submitted has stated that we were exclusively and only fruit eaters.

Humans secrete a paucity of enzymes as compared with meat-eaters, omnivora, starch-eaters, etc. We secrete a very weak solution of hydrochloric acid necessary for meat eaters. We secrete very little of only one starch-splitting enzyme, amylase (ptyalin). And our ability to digest fats is also very poor. We have the ability to efficiently handle only one type of food—foods comprised of monosaccharides or simple sugars. Only fruits meet this requirement.

Fruits are said to be "cleansing" foods. The fruits do, not, of themselves, cleanse the body. The ascription is earned because the body handles fruits so efficiently it can redirect much of the energy that had been expended on wrong foods to the tasks of extraordinary elimination. Further, raw fruits or their juices do not leave any toxic substances in the body.

Fruits are our ideal food and the only foods capable of meeting our physiological capabilities in every respect.

## **1.8 The Evidence of Psychology**

Of all the areas that have been explored as to our dietetic character, this aspect of our being has received scant attention. Fortunately, our psychological disposition has not changed with respect to our dietary nature, just as our physiology and anatomy are the same today as they were millions of years ago.

Imagine yourself in a state of nature today without tools, without any ability to make a fire—with only the resources of your natural equipment in a very food-rich environment. Let us say that, in your immediate area, there are open spaces and trees. Let us presume that a substantial number of these trees bear fruits and nuts. Let us presume that in the open spaces grow grass, tubers and weeds. Let us further presume that the environment has a prolific fauna of birds, rabbits, squirrels, hogs, deer and other creatures.

Picture yourself in this environment. Can you imagine for a moment that you would delight in the capture of a deer with your bare hands under the speed you could develop by running or by surprising the deer and pouncing upon it, then sinking your "fangs" into it and dispatching it by a fatal bite to its jugular vein, heart or other organ? Would you relish a bloody face and body while you feasted upon flesh, offal, bones, blood and organs? Would this delight your palate, or does the very idea repulse you?

Can you imagine gathering the miniscule seeds of grass for hours on end for sufficient calories to meet your bodily needs? And then more hours of laborious chewing a few hard grains at a time to ensalivate and comminute them preparatory to digestion?

Can you imagine digging tubers and eating them as tuber eaters do? Unwashed—with soil and tuber too. With your snout, you'd unearth the tubers and quickly dispatch them, digesting them readily with copious quantities of the four to six starch-splitting enzymes that true starch eaters have. Do you relish this, or does the very idea repulse you?

Do you think you'd relish weed eating? Do you think you could get your requirements from these precursors to today's vegetables?

Or would you warm to the idea of taking ripened bananas directly from the stalk? Of plucking ripe figs and mouthing them in the tree's shade? Of breaking open luscious melons and eating their sweet succulent nectar?

Just think what appeals to you most and what is most repulsive to you. You can readily determine, from your own feelings, our psychological disposition toward improper and proper foods when you consider them and your relationship to them in a totally natural context.

If you see a squirrel, is it your natural disposition to snatch and eat it, or to be kind to it? Do you have the heart to try and kill the charming little creature? Does anyone who has yet within him/herself a streak of humanity have the nerve to do that?

The world has become very much perverted. People actually do relish the sight of packages of beefsteak, chicken legs and breasts and other prepared and embalmed carrion.

Despite these perversions, it is the rare person that does not look with favor upon watermelons, cantaloupes, pineapples, strawberries and other fruits. Despite their eating perversions, most peoples' palates are easily won back to fruits by taking them through a fast and then realimenting them on fruit fare. Fruits are not only our best foods, they are our only biologically-mandated foods.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > 2. Fruits Still Best Meet Our Needs Despite Their Present Lower Quality

## **2. Fruits Still Best Meet Our Needs Despite Their Present Lower Quality**

We often hear the cry today that we cannot subsist on fruitarian or fruitarian/vegetarian fare today because of the lowered quality of this type of foodstuff due to artificial fertilizers and pesticides, among other things. This argument is quickly disposed of in two ways. First, whatever may be said against this kind of fare on this account usually goes double for the fare the eater is partaking of in its stead. Secondly, one may cite the actual components of fruits and demonstrate in a most convincing way that fruits contain all our needs in the quantities determined to be essential in the human dietary.

## 2.1 Tables of Composition of Fruits Compared to our Recommended Daily Allowances

In support of this lesson's message we are happy to introduce you to the composition of some of our most common fruits. So that this comparison will have meaning for you, we have chosen 1 1/2 lbs. dry weight as the given amount of each food. This amount of food yields, in the case of fruits, about 2,400 calories, more than enough to sustain a very active healthy person even though less than the RDA. Fruit yields far more calories than conventional foods.

The average American eats about seven pounds of food a day. More than 40% of this caloric intake is in the form of fats. The average American has a caloric intake of 3,380 calories per day. We have listed the RDA for various food components as well as our actual needs as determined by realistic norms for fruit-eaters and in light of RDA's of other countries.

It must be distinctly understood that the RDA's listed are for a 150-pound man and that the needs of women and children will vary from this. Heavier men will usually require more than the RDA's listed.

This table of food composition has numbers assigned at the headings. Following is the legend for those numbers.

1. NAME OF FOOD. In its fresh ripe raw condition.
2. WEIGHT IN POUNDS of 1 1/2 pounds (680 grams) of the food, dry weight with natural water content.
3. GROSS CALORIE CONTENT. We obtain about 90% of the energy potential from fruits, whereas from proteins we obtain about 30% of their energy potential. We must actually expend more energy in processing foods such as celery and lettuce than is obtained from the food. Calories are meaningful in the human dietary only from the standpoint of utilization rather than what energy the food will produce in a firebox.
4. PROTEIN CONTENT. Note that the RDA is nearly three times higher than our actual need. All listings are in GRAMS.
5. VITAMIN A. Values are in International Units or I.U.
6. VITAMIN B-1, Thiamine in milligrams.
7. VITAMIN B-2, Riboflavin in milligrams.
8. NIACIN in milligrams.
9. VITAMIN C in milligrams.
10. CALCIUM. Listings are in milligrams.
11. MAGNESIUM. Entries are in milligrams.
12. PHOSPHORUS. Entries are in milligrams.
13. POTASSIUM. Figures indicate milligrams.
14. IRON. Figures indicate milligrams.

<b>1 Food</b>	<b>2 Wt. Lbs.</b>	<b>3 Cal.</b>	<b>4 Pro</b>	<b>5 Vit.A</b>	<b>6 B-1</b>	<b>7 B-2</b>	<b>8 Nia.</b>	<b>9 Vit C</b>	<b>10 Calcium</b>	<b>11 Mag.</b>	<b>12 Pho</b>	<b>13 Pot</b>	<b>14 Iron</b>

Dates, Dried	2	2450	20	450	.8	.9	20	0	530	520	560	5800	27
Figs, Dried	2	2450	38	720	.9	.9	6.3	0	1130	640	690	5760	27
Grapes	8	2440	36	3650	1.8	1.1	11	146	440	220	730	6228	15
Mango	8	2442	26	177600	1.8	1.8	40	1295	370	670	480	6990	15
Orange	11	2450	50	10000	5.0	2.0	20	2500	2050	550	1000	10000	20
Papaya	13 1/2	2340	36	105000	2.4	2.4	18	3360	1200	720	960	14000	18
Peaches	14	2360	38	93000	1.2	3.0	62	434	560	620	1180	12400	31
Pear	9	2440	29	800	.8	1.6	.4	160	328	287	440	5200	12
Persimmon	6	2430	22	79000	.9	.6	.3	410	460	260	780	5700	15
Pineapple	10	2390	18	3200	4.0	1.4	9	785	800	600	370	6700	23
Watermelon	20	2390	46	54280	2.7	2.7	18	640	640	730	920	9200	46

For comparison purposes let's now consider some foods you'd never under any circumstances eat 1 1/2 pounds of (dry weight) but which might be added to the diet on some occasions with advantage insofar as it gives you excellent nutrient insurance.

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>	<b>11</b>	<b>12</b>	<b>13</b>	<b>14</b>
<b>Food</b>	<b>Wt.</b>	<b>Cal.</b>	<b>Pro</b>	<b>Vit.A</b>	<b>B-1</b>	<b>B-2</b>	<b>Nia.</b>	<b>VitC</b>	<b>Calcium</b>	<b>Mag.</b>	<b>Pho</b>	<b>Pot</b>	

	<b>Lbs.</b>												<b>Iron</b>
Kale	12	2050*	225	485000	8	13	105	10100	9800	2000	5040	21000	112
Iceberg Lettuce	33	1960*	135	49800	9	9	45	905	3020	1660	3320	26425	75
Looseleaf Lettuce	25	2050*	148	216000	7	7	35	2050	7700	1700	2850	30096	158
Celery	25	1940*	103	27400	3.5	3.5	35	1025	4250	2510	3190	38870	34
Broccoli	14	1980*	223	155000	6	15	56	7000	6400	1480	4820	23680	68
Almonds	1 1/2	4200	130	None	1.7	6.3	25	None	1640	1900	3530	5400	33
Pecans	1 1/2	4800	64	900	6	1	.6	14	510	1000	2030	4220	17
Sunflower Seeds	1 1/2	3950	168	350	14	1.6	38	None	840	270	5250	6400	50

\* These items would yield few if any calories. In fact, you'd probably expend more calories in processing most of these foods than you'd obtain from them.

I feel these listings serve as sufficient examples to indicate that fruits, with certain exceptions, meet our needs. Apples may be seen to be the most deficient of the fruits. Yet there were whole cultures of ancient times that subsisted on a diet that was about half apples!

If we eat a *varied* diet of fruits, the excesses of one, in view of the body's ability to husband excesses, compensates the deficiencies of the other. So we might paraphrase an old saying: "Eat and be merry. Eat and don't worry. Eat correctly without sorrow and you'll enjoy many a tomorrow."

## 2.2 A Brief Note on the Present Theory of Caloric Needs

An examination of the peoples the world over who live active lives and thrive on from 1,200 to 2,000 calories per day affords us grave suspicions as to our supposed calorie requirements. Raw food fruitarians rarely eat more than 2,000 calories per day even if they labor hard and long!

1. Fruit fare yields more calories than conventional American fare. While conventional fare will yield 3,380 calories in the firebox, it does not yield this amount of energy to the human digestive/assimilative system.
2. Cooked foods have some of their caloric values destroyed.
3. Cooked food eaters require more energy for digesting, processing and removing the toxic debris of cooked foods.
4. Cooked foods are usually eaten with condiments which are toxic. More internal energy is required to deal with toxic materials.

5. The average American is toxemic. More energy is required for body maintenance purposes than in non-toxemic persons.
6. Healthy fruitarians, conversely, require less calories for internal maintenance and, because of extraordinary health, make more efficient use of the calories they obtain.
7. Fruit fare yields more than 90% of its calorie potential. Conventional fare yields only about 65% to of its calorie potential. Taking this into account, plus the extra energies involved in maintaining a perpetually pathological condition, it can be seen why fruitarians thrive on about half the calories considered needed.

These considerations, of course, resolve nothing. There are serious discrepancies between what conventional nutritional science says we need and the actual needs of raw-food fruitarians.

### **2.3 Observations on the Significance of These Charts**

These charts have been prepared and presented to establish that fruits, as our natural foods, supply our real needs amply. They often supply many times over what we are said to need by conventional standards such as the Recommended Daily Allowances.

We do not support the idea that "more is better." To have a margin of safety is an excellent practice, but gluttonizing on nutrients overloads and burdens the body unduly. This burdening occasions pathological problems. The body is wise beyond our comprehension and provident beyond our knowledge. It flourishes on fruit fare and will never suffer any of the grave consequences said to result therefrom. Supplying the body with enough, is all that we need concern ourselves with.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > 3. Some Charges Made Against Fruits And Fruit Eaters

### **3. Some Charges Made Against Fruits And Fruit Eaters**

Most Hygienists/Life Scientists may be called timid fruitarian idealists. They are all too willing to admit, even proclaim, that we are naturally frugivores and that our ancestors lived either on nearly all or completely fruitarian diets. "A fruit meal is the ideal," they espouse. Yet most of these same people are unwilling to try subsisting on fruits! Some Hygienists think we must supplement the fruit diet with some cheese, others think we must have some vegetables. Still others think fruits are great but should be supplemented with nuts (which are also fruits botanically).

The "consensus" diet that we have advocated consists of fruits, vegetables, nuts and seeds.

Nevertheless many Hygienists eat seeds, nuts, sprouts, green leaves, stalks, stems, tubers and grains almost to the exclusion of fruits! These peoples fruit intake largely consists of avocados, tomatoes, peppers, cucumbers and squash.

When asked why they do not eat more fruit despite giving lip service to fruit as the ideal, most Hygienists will tell you that although fruit may be alright for short periods of time as a "cleansing" or "elimination" diet, it is not to be taken except as a luxury. These are the charges made against fruits:

- a. Fruits are protein poor;
- b. Fruits have too many free acids;
- c. Those who subsist on fruits become neurotics;
- d. Fruits are too poor in iron and anemia results if only fruits are eaten;
- e. Those who eat only fruits will suffer nutritional imbalances and deficiencies;
- f. Fruit eaters cannot maintain weight and are too thin;

- g. Fruit eaters become over-alkaline and often suffer alkalosis; and
- h. Fruits are deficient in calcium as well as protein and results in stunted growth in youngsters.

Taken together, these statements sound like quite an indictment. Yet, almost the same charges were made by the medical profession against both fruits and vegetables 150 years ago. Fruit eating was then said to result in fevers, biliousness and other maladies. Fruit was treated as a dessert or as a decorative accessory.

Of course this indictment has never been heard by tribes and peoples who subsist almost totally on bananas, custardy coconuts (before its fats and fibers form), dates, figs and similar fruits. Orangutans of the East Indies live exclusively on fruit and are the most intelligent and human-like of our primate relatives.

How can one defend the concept of fruit as our natural food? Is this stance hypocritical? Is there substance to the aforementioned charges? Is fruit really our natural food after all? Is it possible that it no longer supplies our needs? Has the human constitution changed? Here we have many questions arise that need answering.

### **3.1 "Fruits Are Protein-Poor"**

The charge is made that fruits are protein poor. It is true that if you compare a banana in the dry state with its 5% protein content to a soy bean in the dry state with 35% protein, the banana is, indeed, protein poor. But the protein content of any food has relevance only to our need of it as an item of diet. So we must understand our need for protein relative to our diet.

A growing human baby gets a mono diet of its mother's milk for many months before it touches any other food. Mother's milk for her rapidly developing infant contains only 1.1% protein. Surely no one can argue that a grown person can require more protein than a growing child relative to its weight or as a percentage of its diet. If anything, the grownup who has attained full development requires less protein than a nursing tot. A grown person might get adequate protein on as little as half a percent of his or her dietary content.

The RDA for protein is said to be 70 grams daily for an average man of 150 pounds. This figure is well over twice the actual human need. In fact, it is about three times the actual need as established by tests by Dr. Chittenden of Yale and Dr. Hinhede in Denmark and many others. Further, there are groups of physically-robust people in the Caribbean who thrive on an average intake of about 15 grams of protein daily. (They eat cassava or manioc.) Keeping in mind that the body can obtain up to 70% of its protein needs by recycling its proteinaceous wastes, it becomes somewhat evident that protein needs in humans have been overblown. The meat, dairy, poultry and fish industries have made their mark, even on those who reject animal products as items of food.

Can we continue to say that fruits are protein poor? In view that, if protein is one per cent of our diet, our protein needs are amply met, then fruits are protein adequate! When we've eaten some 2,250 calories worth of almost any fruit except apples, we've also ingested some 25 to 40 grams of protein. Inasmuch as most fruits do contain all the essential amino acids, I would adjudge that fruits meet human needs for protein amply.

History bears out beyond refutation that humans have been fruit eaters during their entire sojourn on earth excepting a period beginning during the ice ages. Even then, a preponderance of our ancestors still ate fruits. Most migrated south to warmer climes and continued to eat fruits. Grain eating is not more than 10,000 years old. Meat eating, though much older than that, was mostly confined to northerly peoples. Almost all mythology is built around trees and climatic factors that affected trees. Only relatively recent mythologies connect humans to grain culture and animal husbandry.

### **3.2 "Fruits Have Too Many Free Acids"**

The charge that fruits have too many free acids is false and rather pointless. Fruits have no free acid. All are organic. Vinegar, cheese and fermented milk are substances with free acids, namely acetic and lactic acids.

Humans are primarily sweet fruit eaters. Yet even grapefruits, plums, sour cherries, sour grapes, lemons, limes and other acidic fare have no free acids.

The human body metabolizes most acids in fruits very well. Benzoic acid, tannic acid, oxalic acid and prussic acid, none of which are free acids and all of which are rare in fruits, are among those acids that give humans metabolic problems. Humans handle citric, tartaric and malic acids very well. These are the primary fruit acids: Perhaps the occasions when fruit acids give problems occur when acid fruits such as lemons, strawberries, pineapples or grapefruit are eaten along with sweet fruit such as bananas, dates, figs, raisins, persimmons or non-fruit fare.

### **3.3 Those Who Subsist on Fruits Become Neurotics**

The third charge that those who subsist on fruits become neurotics is simply ridiculous. If fruit is, as we contend, a perfectly wholesome food furnishing all the needs of human life, then it will occasion nothing but great health. While we are the first to affirm that nervous malfunctions or neurosis have physiological bases, we also point out that these problems stem from toxemia in almost every such case. They often, but not always, precede neurosis. Most neuroses are complicated by anxieties, insecurities, worries and other emotional disruptions begotten by an inhumane social system. I daresay we have uncounted millions of neurotics and few are fruit eaters. Unfortunately, our psychologists do not recognize the physical basis of neurosis and give credence almost completely to emotional, social, economic and mental factors. Physical derangements often lay the groundwork for mental derangements. Hence the charge that fruits cause neurotics is a charge which I don't think has ever been substantiated.

There are fruit-eating societies of humans in this world and descriptions of them bespeak the most peaceable, congenial and harmonious dispositions of any peoples on earth.

### **3.4 Fruits Are Too Poor in Iron and Cause Anemia**

The charge that fruits are too poor in iron and cause anemia is likewise without foundation. The body can recycle up to about 95% of its iron supply and needs very little from the outside. It is said that our RDA of iron is some 10 milligrams daily. This, like other RDA's, is some two to three times too high. Nevertheless, oranges sufficient to meet our caloric needs supply about twenty milligrams of iron daily. In fact, if you compared all the fruits and their iron content, you'd find every one meeting the RDA for iron with surfeits. A food that might be said to be deficient in iron by these RDA's is, of all things, a mother's milk!

Should fruits be charged as being Vitamin B-12 poor, then the same can be said of all foods, even the foods that animals eat. Only meats and certain kinds of algae have what is termed sufficient Vitamin B-12. But if animal fare such as grasses, leaves, grains, herbs and fruits do not furnish animals with vitamin B-12, how do their organs come to be so rich in it? Why are the organs of fruit-eating primates rich in it? How is it that fruitarian societies are not anemic from lack of Vitamin B-12? The truth is that humans, like all other animals, obtain ample supplies of Vitamin B-12 from bacterial production in their intestines. Even garlic eaters usually do not destroy enough of their symbiotic bacterial flora to deny themselves of an adequate supply of Vitamin B-12.

So I adjudge the charge that fruit eaters are anemic to be without any substantive evidence whatsoever.

### **3.5 Those Who Eat Only Fruits Suffer Nutritional Imbalance and Deficiencies**

The charge that fruit eaters will suffer nutritional imbalances and deficiencies likewise finds no basis in fact. Fruits, eaten judiciously according to their seasons, furnish us with every nutrient factor, known and unknown, in plenteousness. Those ancient Greeks whom we admire so much for their statuesque bodies, were fruit eaters. Most ate heavily of apples, dates, oranges, olives, figs and grapes. The Greek and Roman gods are ascriptions born of reverence for fruit trees and food-bearing plants.

### **3.6 Fruit Eaters Cannot Maintain Weight and Are Too Thin**

The charge that fruit eaters are too thin is not borne out by even the simplest investigation. Personally, I've gone down into the 120-pound range and came back to the 150-pound range with excellent muscular development, on a diet almost entirely of fruits. My wife has to watch her intake of heavy-calorie fruit foods, especially nuts, lest she become too heavy. As previously pointed out, the Greeks thrived on fruitarian diets. Pythagoras, one of the giants of Grecian literature, philosophy and mathematics, was a fruitarian and had a whole school of followers who, likewise, were fruitarians. Actually, the teachings of Pythagoras very much parallel the teachings of Gautama Buddha, whose teachings Pythagoras was conversant with. Buddha was, in essence, a tree worshipper as were fruitarian societies. Bacchus is portrayed as heavily overweight and this is attributed to fig gluttony.

### **3.7 Fruit Eaters Become Over-Alkaline and Suffer Alkalosis**

The charge that fruit eaters are over alkaline and often suffer alkalosis is, likewise, baseless. We humans can harmlessly excrete excess alkaline substances but, if we get excess acid-forming substances as from meats, animal products, cereal foods, etc., we really have problems. The body must rob its bones, teeth and other alkaline structures for the alkalis, mostly calcium, necessary to neutralize the acids generated from acid-forming foods. The maker of this "alkalosis" charge simply ignored physiology. It ill becomes vegetarians or fruitarians to make such a charge.

### **3.8 Fruits Are Deficient in Calcium as Well as Protein and Results in Stunted Growth in Youngsters**

Fruits are said to be deficient in calcium. To investigate this I made charts of a number of fruits and their composition. Our fuel needs can be met amply by fruits. Calcium and a plethora of other nutrients are a component of every gram of fruit food. When we have eaten sufficient fruit to supply our caloric needs, say about 2,250 calories, how much of our RDA for calcium have we met? The RDA is set at 800 milligrams per day for a 150-pound man. This, like other RDA's, is some two to four times too high. Nevertheless, let's look at some fruit foods and their calcium content when 2,250 calories worth have been consumed.

Oranges, a widely-consumed fruit, have about 2,050 milligrams of calcium, 2 1/2 times the RDA. Apples have 315 mg. Apricots have 782 mg. Cantaloupes have 1,078 mg. Figs have 1,130 mg. Bananas have 224 mg. and banana-eating societies have excellent bone formation by all standards. Grapes have 440 mg., dates have 530 mg., mangos 370 mg., pineapples 785 mg., watermelon 640 mg. and so on down the line. Obviously fruits supply us amply with our calcium needs. The saying that fruit eaters suffer stunted growth does not withstand serious inquiry. As previously noted, statuesque Greeks were fruit eaters.

### **3.9 Build Your Confidence in the Fruitarian Dietary**

Fruit eaters are not usually fat, brawny hulks as are grain, milk and meat eaters. The question arises: are these standards forming a criterion of health or pathology?

Let me cite an example. Murray Rose, an Australian who set swimming record after swimming record, was primarily a fruit eater though he partook of some seaweeds and vegetable fare.

Now if we confirmed fruitarians were to start making charges against those who want to eat "exciting" foods such as, cooked dishes, often laden with condiments, vegetables, cereals and even dairy products such as yogurts, and cheeses, many could be well-substantiated. Wrong foods create toxemia.

The illnesses that beset almost all Americans amply attest to this fact. Even those who pride themselves on a vegetarian diet or a "health" diet or even a Hygienic diet often find themselves suffering toxic conditions. Toxemia arises out of practices that cause toxins to be ingested, generated and/or retained. Fruit eating is universally said to be cleansing and promoting the function of elimination, and it is recognized for its non-toxic nature.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > 4. Questions & Answers

#### 4. Questions & Answers

**As far as I'm concerned, you've nailed down the cause for fruitarianism. But isn't it impossible to nourish yourself well with the general low quality of fruit today? With all the artificial fertilizers, insecticides, and depleted soils, how can we hope to be well-nourished on fruits?**

Even with these definite detractions, eating low-quality fruits is still the best we can do if we cannot procure organically grown fruits. Whatever can be said against fruits on this score goes double for everything else other than fruits. This problem does not only exist with fruits!

Should you have fears in this matter, you can invoke insurance in the form of super nutrient-concentrated foods such as green leafy vegetables and nuts.

Keep in mind that there has been little deterioration in fruit quality since the tables of composition were made that are reproduced herein.

**You mentioned that some doctors found we needed about an ounce of protein a day, less than 30 grams. Who are these doctors and how did they prove it?**

One such doctor was Dr. M. Hinhede of Denmark, who was entrusted to the nutritional welfare of that country for the duration of World War I. Having conducted many experiments on a mono-potato diet, among others, he maintained subjects in fine health for protracted periods while doing hard physical labor. (Some oil on the potatoes and green leaves were also eaten.) The protein intake of his subjects was 30 to 40 grams daily. When he took over as the "food czar" of Denmark, he decreed that animals cease to be reared as food and that the land be devoted to vegetarian fare. He effectively put Denmark on a low-protein diet. As a result, the health of Danes greatly improved, the death rate plummeted and there was never a food shortage. He wrote a book, *Protein and Nutrition*, which presents his studies. Professor Russell H. Chittenden of Yale University was one of the pioneers of nutritional research. He conducted many varied experiments. These experiments involved diets, restricted diets and limited protein intake. In his *Nutrition of Man* we learn of his experiments with his fellow professors and students on food intake. We learn how he reduced food intake severely yet his subjects still continued to grow and thrive.

Chittenden reduced the protein intake of Yale athletes to a mere 25 grams of protein daily,

yet they continued to gain weight, became more muscular and performed better than before. Among the many experiments he conducted were competition between his vegetarian athletes and meat-eating athletes. The vegetarians, on the average, outperformed the meat eaters by a large margin.

**Is there any harm in adding a meal of sunflower seeds and a salad of vegetables to a general fruitarian program?**

Having been on fruitarian fare for a long time and then having a meal of sunflower seeds and tomatoes, with some vegetables such as broccoli and celery, I can attest to its tastiness. All tables of composition say I'm getting more than enough of everything I need. They don't tell about the extra sleep required after even a moderate meal of such fare, nor the drowsiness the following morning, nor the mental dullness nor the physical disinclination to activity.

I would say this indicates in part a body that is accommodated to fruitarian fare—in fact, one that has a marked preference for fruitarian fare! It can handle such food, but it greatly burdens the system. Unaccustomed expenditure of energies and nerve force produce what is, in effect, a hangover.

I would say that for one accustomed to fruitarian fare there is some harm in indulging in such a meal. Yet the books show that there is great nutritional gain to be had by eating such a meal. Personally, I find I'm better off without it. The definitive answer remains to be rendered in this matter.

**I just love potatoes about any way they're prepared. Are potatoes so terribly bad if eaten with vegetables?**

I've just cited what Dr. M. Hinhede of Denmark did for millions of people on a diet heavy in potatoes. He kept one man in good health for 12 years on a mono diet of potatoes.

Potatoes are not our natural foods. The cell coverings of their starches prevent our access to the potato's food value if they're eaten raw. Cooking breaks the cells and releases the starch which, by the heat, has been partially dextrinized. But the heat required to break down cellulose does far more damage than that.

Potatoes are not a wholesome food. However, they are far less harmful than the conventional American diet. Fruits are far superior on every count. When you consider that the body must digest and convert the starchy/dextrinized potato to glucose for body use, does it not seem far better to eat fruits whose sugars are already in the form of glucose (fructose or levelose)? NO digestion is needed for fruits—just eat and appropriate.

**What about eating the seeds of fruits? Pumpkin seeds and nuts are actually the seeds of fruits, not the fruit itself. Is it good to eat the seeds of apricots, apples, peaches, grapes, melons and so on?**

During our millions of years sojourning in nature, there is evidence that our dietary consisted of some nuts that were primarily oily and proteinaceous and had little or no starch. I want to emphasize that nuts were usually secondary and constituted a very small part of our diet. As fruit eaters, we obtained our water needs from our fare and thus developed no water-drinking equipment as a part of our anatomy. Had we been nut and seed eaters, this would not have been the case. Thus it may be said that we are incidentally nut and seed eaters.

I advise you to limit your and your clients' intake of nuts to small portions on rather infrequent occasions, certainly not more than three or four times weekly. This is meant to

apply to an oily fruit, the avocado, as well, because it has the same consistency as some nuts. Apple, peach and apricot seeds are outright poisonous. Melon seeds are not relished, though the melons themselves are great. Pumpkin seeds are of about the same consistency of nuts, as are sunflower and sesame seeds. Grape seeds should not be eaten. In the use of fruits, keep in mind that the fruit adequately supplies our needs. Our symbiotic role in nature—our implied compact with trees—is to eat the fruit as our reward for distributing the seeds.

**I feel you've proved your point about fruit being our natural food. But where do you find anyone today who lives on just fruits? Hasn't everyone gotten off base?**

Yes, it's true that fruitarians are so rare that they seem nonexistent. I would consider myself fruitarian, though I eat perhaps 2 to 3% vegetable fare such as lettuce, celery, broccoli, sprouts and bok choy.

There are other fruitarians in this country, especially in California, Florida and Hawaii. There are tribes and societies of fruit eaters in the Amazon of Brazil and in the Southwest Pacific. There are some fruit eating societies and groups in Europe and Africa, some in Asia and some in Australia. But, relatively, fruitarians are very rare.

Indeed, almost everyone is off base. Likewise, almost everyone suffers some physical problem.

**How do you suppose fruits developed in the first place?**

There is symbiosis or mutual cooperation and harmony in nature. It is not a jungle where only the fittest survive its vicissitudes, as is widely thought. There are few vicissitudes in nature.

Trees bearing fruit developed alongside creatures that demanded fruits. Trees responded to this beneficial patronage by developing even more profuse amounts of luscious fruits. Those creatures demanding a variety of fruits fared better and better as they grew and improved, thus demanding even more fruits.

We observe in nature how symbiosis works by noting that bees are specifically provided nectar by flowers. The bees, in gathering this nectar for food, contaminate themselves with pollen from the anthers of the flowers. When they visit other flowers they perform the service of spreading the pollen to the stigma of the flower pistil. This facilitates pollination, a valuable service. As you know, without bees, flowers of trees will not be pollinated to any great extent. Likewise, without fruit-eating animals there would be no fruit trees. The development of fruits and fruit eaters was mutual and parallel.

**You've spoken about fruits without their water content. If you don't consider water, what amount of proteins, mineral salts, fatty acids and vitamins should our foods contain to meet our needs?**

Let's look at a fine food, bananas. Let us consider 1 1/2 pounds, or 680 grams, of dry weight bananas. The protein content of this amount of bananas is 31 grams, or about 4.5% of total dry weight. Its mineral matter comprises 22 grams, or about 3.3%. Its fats amount to about 5.2 grams or about .8%. Its carbohydrates amount to about 610 grams which is, as you can see, about 90% of the total weight. The rest is unusable cellulose, which is neutral in character in the human body. That is, it is neither harmful or helpful.

Inasmuch as bananas are excellently qualified to meet our needs, you can see that our primary need is for fuel values. Other nutrients, though being equally essential, comprise a

small percentage of the whole.

### **Are dried fruits as good as fresh fruits? Should we eat them at all?**

Dried fruits are never as good as fresh ripe fruits. Yes, we should eat dried fruits when the fresh fruits available to us do not meet our caloric needs. Dried fruits have lost a substantial part of their vitamins and some of their minerals due to oxidation. Dried fruits are good primarily for their fuel values. They are usually ultra-sweet and thus serve as wonderful desserts when eaten with other fruits.

### **If we get all the Vitamin B-12 we need from bacteria in our digestive canal, then why do vegetarians have less B-12 than do meat eaters?**

There could be many reasons for the variance in amount of B-12. The body takes up from the ileum the amount it requires for use and storage. While both meat-eaters and vegetarians have about a five-year reserve supply of vitamin B-12, the levels of B-12 in the blood stream of meat-eaters is much higher than that in fruit-eaters and vegetarians, Meat eaters represent a pathological norm. They may have more B-12 in the system because of increased need due to their condition, or it may be that their bloodstream is contaminated by the meats they eat as well as being profusely supplied by intestinal bacterial activity. The higher amount of B-12 may be due to both increased need and increased supply.

We must regard nutrients in regard to our need for them. Getting enough is all that is necessary.

### **Why are vegetarians warned so much about Vitamin B-12 deficiency? Why do so many use cheese, eggs and other dairy products to get Vitamin B-12?**

Many vegetarians fall victim to the propaganda of commerce. Such unsuitable items of diet ruin health—not enhance it.

### **How does the body rob its bones and teeth of calcium ? Isn't that a ridiculous statement to make?**

When the body is in an emergency situation that requires base mineral salts for food metabolism, it does autolyze its teeth and bones for the needed base organic salts. Some such emergency situations include ingesting white sugar, or acid neutralization as in uric acid from meat, or when its supply is exhausted due to an acidotic diet sparse in alkaline minerals. This is how osteoporosis and osteomalacia occur.

### **If Hygienists and Life Scientists give only lip service to fruit as the ideal, what do they really eat?**

They do eat a lot of fruit, but it usually comprises considerably less than half of their intake. Much of their intake is in nuts, salads, steamed potatoes, rice, cheese, steamed squash, steamed sweet potatoes, steamed broccoli and steamed corn. While most eat around 50 to 80% raw, I would regard the 20 to 50% eaten in cooked form far less than ideal.

### **When I eat fruits, especially bananas, I get gas. Why is this so?**

When you get gas, that means you're not properly absorbing the sugars of the bananas. Bacteria are fermenting it. I usually eat bananas alone and do not have this problem. I sometimes eat bananas with other fruits and with celery and lettuce. I still do not have this problem. If your body is not absorbing the sugars available from bananas, there must be some physiological faculty involved that is not functioning properly. I suggest that you fast for a period of time and then try bananas again a day or two after breaking the fast.

Fruits do not cause gas. Failure to absorb their carbohydrates makes them available to our bacterial flora which create gas. Overeating, of course, can cause quite a bit of gas. Eating wrong combinations can cause lots of gas. That food material that is not absorbed will be dealt with by intestinal flora which ferment and/or putrefy it in accord with the character of the food.

**I've tried a few fruit meals for a few days running. They don't stay with me very long and I get hungry again very quickly. Is that normal?**

It is normal to absorb meals of fruits quickly. But it is abnormal to be hungry again immediately after such a meal has been appropriated, for the body usually shuts down the appetat upon having absorbed its needs of sugars and nutrients.

There exist several possibilities as to why you feel hungry so quickly. Possibly you're mistaking appetancy for hunger. Possibly you have gastric irritation. Possibly your body has not yet accommodated to fruit meals and still has irritations that drive you to yet seek the old satisfactions and stimulations. But it is unlikely that the fruit meals are not supplying your needs or that you are feeling true hunger as a result of your bodily needs.

Demonstrated irrefutably in this lesson is the nutritional adequacy of fruits in supplying human needs.

In the previous lesson we demonstrated that fruits are the only foods that meet, all relevant criteria for a human food. This lesson has shown that specific nutrients for which RDA's have been established are contained amply within the various fruits available to us on our markets.

Further, this lesson has dealt with charges made against fruits as foods and refutes them on a charge-by-charge basis. The lesson shows that the charges are groundless and are of a nature as might be inspired by the meat, grain and dairy industries who have a commercial interest in promoting their products.

[Home](#) > [Lesson 19 - Ascertainning The Human Dietetic Character, Part II](#) > Article #1: Fruit Eating By Dr. Herbert M. Shelton

### **Article #1: Fruit Eating By Dr. Herbert M. Shelton**

Fruit is food. Indeed, fruits are among the few substances produced in organic nature that seem to be designed specially to serve as food. The old medical prejudice against fruit, so strong during the last century that cities passed ordinances against bringing fruits into the cities during the summer months, was hammered down by Hygienists, and Americans learned to relish fruits. Unfortunately, in certain Hygienic circles this old anti-fruit prejudice has been revived. Some of our Hygienists have developed a groundless fear of a number of wholesome fruits.

Fruits supply the body with an abundance of minerals, sugars, vitamins and, in the case of some of them, considerable high-grade protein. The sugar in fruit is ideally associated with minerals and vitamins and need not be rejected as one does (or should) refined sugars. Fruit sugar is superior as human nutriment to honey, which is so ludicrously lauded in many quarters. Indeed, honey, when compared with the sugars

of fruits, ranks about on the level with white sugar.

Most fruits are abundant in minerals, also containing important trace minerals, so that they form important and vital ingredients in the diet of the growing child. Most of them are deficient in calcium, but this is easily compensated from other wholesome sources. Fruits are commonly rich in vitamin C but contain less of other vitamins. They are, however, on the whole, excellent sources of vitamins.

They are commonly low in protein, rarely containing over two to two and a half percent and many of them containing much less than this. The date, banana, avocado and a few other fruits contain small amounts of excellent proteins. Supplemented with nuts and green leaves, their proteins become valuable additions to the diet. A fruit and nut diet is improved by the addition of green leafy vegetables. A large green salad each day makes such a diet almost ideal.

Most fruits contain more or less acid—such as malic, citric, tartaric, etc., being present. The prejudice that has grown up around fruits is a revival of the medical prejudice against acid fruits. They were declared to cause "acid diseases," and were regarded as especially objectionable in rheumatism.

Fortunately, the body is able to oxidize the organic acids of fruits, at least of those fruits that we commonly use as food. These leave an alkaline ash upon being oxidized. There is often some difficulty with the acid of prunes, but there is no ground for the prejudice that has been revived against oranges, tangerines, lemons, grapefruit, tangelos, tomatoes and similar citric-acid bearing fruits.

The acids of berries are also easily oxidized and these, also, leave an alkaline ash. The acid radical of organic acids is expelled as carbon dioxide through the lungs; the alkaline salts left help to alkalinize the blood. Teeth have been kept uninterruptedly immersed in lemon juice for as long as six months and the acid had no effect on their enamel. There would seem to be no foundation for the idea that eating oranges or drinking orange juice injures the teeth.

It should be generally known that when acids are taken into the mouth there is a copious outpouring of an alkaline saliva, which bathes the membranes of the mouth and the tongue. This secretion of saliva is kept up long after the acid has been swallowed. Any acid left on the teeth or in the mouth is quickly neutralized by the alkaline saliva. We are too prone to overlook the body's own provisions for its safety.

In the late spring and summer, when such fruits as peaches, plums, apricots, nectarines, cherries, the various berries, canteloupes, watermelons, grapes, figs, etc., are plentiful, it is well to make a large part of the diet fruits. In the fall, when pears, apples, persimmons and the citrus fruits come into season, these should constitute a large part of the diet. Certain of these fruits, like the tomato, grapes, oranges, and grapefruits are plentiful throughout most of the year and may be eaten all the time. The avocado is abundant through most of the year, but is best eaten during the cooler periods of the year. Such sundried fruits as figs, dates, raisins, peaches, apricots, pears, etc., may be freely eaten during the winter months.

The melons make an excellent breakfast during the season of the year when they are ripening. They are best eaten alone. A large piece of watermelon makes an adequate breakfast, even for the physical worker. Canteloupe, banana melon, casaba, cranshaw and the Persian melon, in season, make a delightful and satisfying breakfast. If more food is desired for breakfast, it should be taken half an hour after eating the melon.

Nearly all of what we see of so-called allergy to fruits is indigestion resulting from wrongly combining the food eaten. Fruits with starches, fruits with sugar, fruits with proteins, and similar combinations are prone to decompose, producing gas, discomfort, skin eruptions. Melons with other foods may cause marked distress—eaten alone, they digest with the greatest of ease. In very young children there may sometimes be a short period during the development of a child, when its digestive system cannot handle a certain fruit, for example, an apple. It is well to leave some fruits out of a child's diet until its development has progressed to a point where it can easily digest the fruit that gives trouble.

Great improvement in the ability to digest and handle foods follows a fast. It is no uncommon thing to find that an individual who has trouble with a particular article of food, can take it with the greatest of

ease after a fast. If we can learn that what is called allergy is not a permanent possession, but that when its causes are removed, it ceases, we can understand that it is possible for us to become able to enjoy any wholesome food. It amazes those who are "allergic" to strawberries, for example, to see no trouble develop if they are placed on a strawberry diet.

When fruit is eaten with a meal of bread, flesh, potatoes, butter and the rest of the usual meal, the fruit usually being taken at the end of the meal, but often at the beginning, the indigestion and discomfort that result from such combining of foods will almost certainly be blamed on the fruit, which may be the only wholesome article of diet in the meal. The discomforts following such a meal may range all the way from a little gas formation that scarcely attracts the attention of the eater, to a painful indigestion accompanied with nausea, vomiting and diarrhea. The fruit, kept away from the other foods, and eaten as a fruit meal will digest easily and result in no discomfort.

Fruits that are peeled and sliced and permitted to stand for long periods of time before eating are hardly wholesome foods. They change color, lose flavor, undergo oxidation with resulting loss of food value and tend to decompose readily. Fruits added to breads, cakes, pies and various other kinds of pastires can also occasion considerable indigestion and distress. In this latter case, not only is the food spoiled in preparation and cooking, but the combination is indigestible. Fresh fruits, with cleaning as the only preparation, are most easily digested. The addition of sugar, syrups, honey and other sweeteners to fruits can also result in indigestion and discomforts.

Fruits have fallen into disrepute with many people for the reason that they find that they suffer with discomfort after eating them. It was Dr. Dewey who said that fruits demoralize digestion. He was especially opposed to eating apples. This trouble with fruits grows out of the practice of wrongly combining them. Strawberries and melons are commonly singled out as fruits that "I am allergic to," and these foods are wholesome and toothsome. If taken alone as in the case of melons, or properly combined as in the case of strawberries, they almost never cause any trouble. Skin rashes and intestinal disturbances that often follow the eatings of fruit or that follow a particular fruit may, almost always, be traced to wrong combining. In the few cases where this is not so, a correction of the way of life, so that normal digestive power is reestablished, soon enables the individual to eat fruit. I do not think that there is anyone who cannot eat freely of fruits if due care is taken in combining them.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > Fruit: Best Food Of All by William L. Esser

## **Fruit: Best Food Of All by William L. Esser**

Of all the foods that we can eat, fruits are the best in every respect. They are objects which enchant the eye, delight the smell and thrill the normal taste beyond the sensation incited by any other food. In itself, fruit is perfect. It requires no preparation of any kind other than cleansing, coring or peeling. Cooking, seasonings, additions and substractions make it less, not more palatable.

Beyond its appeal to the senses, it possesses most of the essential proteins, minerals and vitamins necessary for maintaining health at its highest level. Obtained in large enough variety, fruits (with the addition of nuts which are also fruits) would be ample for the maintenance of ideal health.

Many facts indicate that humans were originally frugivorous or fruit-eating animals, not omnivorous as we are presently. That humans have strayed from their natural diet for the past few thousand years does not mean that organs have changed so as to be suited to the prevailing diet. The changes that have occurred are the weakening, softening and degeneration of a creature of true grandeur. If any change has occurred, it is that we have become diseased creatures. We have lost our physiological excellence. For this reason, it is more important that we adhere more closely to our natural diet. The ruinous habits of

eating must be dispensed with entirely. Only pathology has resulted from our unnatural dietary.

Fruits constitute our ideal diet and should comprise most of its bulk. Vegetables, nuts and seeds can be added with great benefit when the rules for food combining are observed. It is never the fault of the fruit. Fruit should be ripe at eating time. Overly-ripe fruits should be shunned. Fruit is most luscious and at the peak of perfection when it is plucked from tree, stalk or vine in a just-ripened condition. No store-bought fruit can approach freshly-picked fruit for quality or flavor.

Whenever possible, fresh fruit should be bought from the grower, rather than at the market which obtains much of its stock from storage houses. Those living in colder climates have little choice during winter time, however. Much care must be exercised in selecting the best available.

Ability to judge various fruits in the market to determine their fitness is an accomplishment which can only come with experience. Most fruits, regardless of whether they belong to the acid, sub-acid or sweet classification, possess an elating sweetness and flavor when they are ripe. Experience will teach you to judge a good apple among a whole bushel of inferior ones at a single glance. Care must be taken to avoid fruits which have been damaged by frost, blight, rot or any other similar influence. Fruits today are sprayed excessively against insects and before they are eaten, they should be carefully washed and brushed, in order to eliminate the poison from them.

Some unripe fruits contain starch and various other carbohydrate substances which are distasteful and unwholesome. On the other hand, decay sets in on over-ripe fruits, and the sugars are changed to carbon dioxide, alcohol, acetic acid and other harmful by-products. Over-ripe fruits deteriorate rapidly in their nutritive values. These changes, plus the loss of water, account for the sponginess and insipidness of fruit which has been stored for long periods of time.

Fruit is potentially alkaline. Alkalinity occurs after it has passed through the processes of digestion. If the fruit is of poor quality, improperly combined or the digestion is weak, it often remains in an acid and its absorption creates many unpleasant symptoms such as nervousness, sleeplessness, frequent urinating from bladder irritation, intestinal gases, mucus in the stools, throat irritation, etc. Most of the time, however, the symptoms which follow the eating of fruit are not the fault of the fruit, but of impaired digestive faculties. There are those who will eruct and experience flatulence and distress in the bowels regardless of what they eat. People so affected are ill and should put a stop to eating until their digestive system has recovered its powers. Fruits should not be haphazardly mixed with other foods, or even other fruits! Even the best digestion cannot successfully cope with indiscriminate and chemically-incompatible mixtures. A good policy is not to eat more than one or two kinds of fruit at a single meal.

Fruits can be divided into three classifications: sweet, sub-acid and acid. Sweet fruits can be combined tolerably well with sub-acid fruits but should not be as a matter of practice. But the combining of sweet fruit with acid fruit can prove quite distressful. For example mixing bananas and grapefruit or dates and oranges is worse than not eating anything. The best plan in combining fruits is to mix only fruits of the same classification. For example bananas, dates, figs and raisins are sweet fruits. Apples, pears, most grapes, mangos and papayas are among the sub-acid fruits. Berries, cherries, peaches, pineapples, etc., are among the acid fruits.

Melons of all kinds should be treated as a fruit category in themselves and should be eaten alone. Nuts may be eaten after the end of a fruit meal, preferably after a fruit meal of acid fruits. Lettuce and celery may be beneficially added to fruit meals in small quantities.

As with any food, chewing plays a vital part in the thorough digestion of fruits. Every particle should be systematically liquified, thereby insuring absorption and assimilation. This is doubly important when you realize that most fruits undergo no digestion in the stomach. The swallowing of carelessly-chewed food is a major reason why food lies in the stomach and ferments. The digestive juices are unable to break down large pieces of food and bacterial decay sets in. Drinking a glass of orange juice or any other fruit juice in one or two gulps does more harm than good. It should be sipped slowly and tasted, if eaten at all, not swallowed as though one were trying to quench a fire. Fruits should never be eaten cold.

Room temperature is ideal.

Fruits should not be considered merely as a dessert or a between-meal refreshment, nor in the same light as the "apple a day keeps the doctor away" philosophy. They are due much higher regard. To take them as a "laxative" or to cleanse the bloodstream, or to take fruits in any way which savors of medicine instead of food is wrong.

Fruits are the finest kind of food. They should be treated as such. Sick people should not be eating. A sick body requires rest and fasting, not food, regardless of the nature of the illness. The major part of one's diet should consist of fruit. It is the most delicious, wholesome and perfect food that can be had.

[Home](#) > [Lesson 19 - Ascertaining The Human Dietetic Character, Part II](#) > Article #3: Proteins In The Fruitarian Diet By Dr. Herbert M. Shelton

### **Article #3: Proteins In The Fruitarian Diet By Dr. Herbert M. Shelton**

Can man get adequate protein from a fruit diet? This is to ask: If a man were to attempt to live as a strict frugivore, could he be adequately nourished? We put this question in relation to the protein of this diet because there is no question about the ability of a fruitarian diet to supply adequacies of fats, carbohydrates, minerals and vitamins.

In an article entitled "Why I don't eat Meat" by Owen S. Parrett, M.D., which has had wide distribution, the author says, "W.C. Rose of the University of Illinois, an authority in the field of protein, says that "less than twenty-five grams a day is all one needs."

"If a man were to eat no meat, eggs or milk he would still get on the average 83 grams of protein a day. A woman would get 61 grams of protein a day. This fact was discovered in a research project made by Dr. Mervyn Hardinge of the College of Medical Evangelists under Dr. Frederick J. Stare of Harvard, well-known authority on nutrition.

"Dr. U. D. Register, leading biochemist, and Dr. Hardinge, both active in the field of human nutrition, said to me that fruit alone, if amply supplied in sufficient variety, would provide people with enough protein to meet the actual body demand."

Many efforts have been made to live upon a diet of fruits only, usually with only marked degree of success. It has usually been found that such diets are improved by the addition of green leafy vegetables. It is probable that this need has resulted from an insufficient variety of fruits. Certainly when we consider the wide range of food substances included under the term fruit, there would seem to be no necessity for inadequacies in the diet of the fruitarian. Nuts, which are fruits, are nearly all rich in protein of high biological value, capable of supplying adequacies of all the amino acids essential to growth and reproduction.

The biologist defines a fruit as "a ripened ovary with or without associated parts." To make this a bit more complete, a fruit is the matured ovary of the flower, its contents and all intimately connected parts. Fruits are often more complicated than this description indicates. In addition to the development of the ovary wall, the calyx may also become fleshy and envelope the ovary as in the apple and pear; or the end of the stem (receptacle) may enlarge and form a part of the fruit, as in the strawberry and blackberry. Tough shells or rinds may form for protection, as in nuts and lemons; or a delicious flesh may envelop a hard inner stone, as in the peach and plum. Some fruits, as the potato and peanut, are matured underground.

All of these developments serve to perform a few simple functions:

1. They protect the ovules and seed while they are maturing
2. They prevent loss of water.
3. They provide for seed dispersal.

An animal eats the fruit and discards the seed at a distance from the parent plant. Edible fruits may thus be said to be the coin with which the plant compensates the animal for services rendered—that of dispersing the seed. A seed is a matured ovule enclosed in the fruit. Many fruits are merely mechanical devices to secure seed dispersal and are not edible. We need not consider these in our discussion of fruits.

A brief glance at the evolution of a fruit may help us in forming a clear picture of a fruit. The ovary grows as the seed develops, giving rise to a fruit. A fruit, in this sense, is not necessarily a fleshy edible product, but the seed-carrying organ of the plant. It is customary to include nuts in the category of fruits, although, it is the seed rather than the seed-carrying organ that we eat.

A fruit may consist of a single ovary with but one seed, as in grains, nuts, cherries, plums and peaches, or it may evolve from a single ovary which has several seeds, as the bean, pea, apple and orange. Then there are flowers which possess several ovaries which combine to form compound fruits like the strawberry or raspberry.

With the foregoing explanation in mind, it should not be difficult for each of my readers to answer himself the question: Is the tomato a fruit or a vegetable? Fruits are all produced by plants and, in this sense, they are all vegetables. But they are special parts of plants and are classed as fruits because of this. The tomato, as the matured ovary of the tomato flower containing seed, is quite obviously as much a fruit as the apple or orange. The cucumber squash, pumpkin and similar foods are fruits.

Confining ourselves, in this discussion to edible fruits, and ignoring those fruits that serve only as seed dispersers and have no food values, fruits are either dry or fleshy, simple or compound, depending on the character and development of the ovary which formed them.

1. Examples of fleshy fruits are the apple, pear, cherry, peach, apricot, plum, nectarine, mango, banana, tomato, and gooseberry.
2. Examples of dry fruits are legumes (beans and peas), acorn, hickory nut, pecan, walnut and almond.

Thus it will be seen that the term fruitarian may be used in a wider sense than is commonly thought. Indeed, in a biological sense, it may be made to include eating practices that probably should be foreign to man. This is to say that there may be more than one fruitarian category in nature. We are justified in classing the grain-eating birds as fruitarian, but it is doubtful that grains should form a part of the normal diet of man.

There are fruits that are poisonous, some of them poisonous before ripening, others poisonous after ripening. These latter should be excluded from man's diet. An excellent example of a fruit of this kind, one that is commonly eaten, is the cranberry. Sumac berries we refrain from eating, because, although tasty, they are toxic. Some plant substances are poisonous to some animals and not to others. An example is belladonna, which, highly poisonous to man, is non-toxic to the rabbit after it is six weeks old. After this age the rabbit secretes an enzyme that enables it to digest the two toxins in the plant. Man produces no such enzyme.

In the same manner a fruit that may be poisonous to man may prove to be an excellent food for other animals. Nothing seems to eat the sumac berries. It may be possible that they are toxic to all forms of life. They are regarded as good herbal medicines, precisely because they are toxic. My readers should keep always in mind the rule of medicine: *If the plant is non-toxic, it is food; if it is toxic, it is "medicine."*

## Lesson 20 - The Physiology Of Digestion

- [1. Introduction](#)
- [2. The Journey Of Food](#)
- [3. The Physiological Determinants Of The Optimum Diet](#)
- [4. Questions & Answers](#)

### 1. Introduction

It has often been said: "You are what you eat." More appropriately, this should probably be: "You are what you digest and assimilate."

Man eats everything. He considers himself an omnivore of the first order. Roots, nuts, tubers, seeds, eggs, blood, milk, fish, fowl, and fruit have all appeared on man's plate. One culture eats worms and gnats with relish. Another culture considers decaying animals a delicacy. Man has practiced cannibalism both in the past and in the present.

And so man brags: "I can eat anything. I have an iron stomach."

It is true that man's physiology allows him to eat almost anything that does not immediately kill him. Sometimes even great quantities may be consumed, as witnessed by the champion crayfish eater of Louisiana who ate 63 pounds of crayfish tails at one sitting. It is a mistake to assume, however, that the body can digest and assimilate everything that passes between our teeth, or that foods doing no immediate harm will not eventually cause problems.

Consequently, most of what man eats is for naught, because much of the food eaten by the average human being is totally unsuitable for his digestive physiology. If we want to understand what foods are appropriate for man to eat, we must first understand the physiology of digestion and assimilation. We need to know how our body acts upon the food we eat. When we understand the principles of nutritional physiology, we can then determine the natural diet for man.

#### 1.1 What is Nutrition?

Dr. Herbert M. Shelton gives us this definition of nutrition: "It is the sum of all processes by which raw materials (foodstuffs) are transformed into living structure and prepared for use by the body."

No one understands these processes completely. The transformation of an apple, for example, into the cells that make up the brain, blood and bone is an event that defies scientific duplication. The changing of food into the person that is you could be considered a miracle—yet it is a miracle that happens repeatedly throughout every day.

We can follow food through the body as it undergoes processing by the digestive organs. We can give names to the various enzyme interactions and to the catalysts that accompany food absorption. We cannot, however, tell you how the life force present in a fruit becomes part of the life force that propels your body or awakens your consciousness. These are the limitations of the science of nutritional physiology, and we must keep our discussion within the scope of these boundaries.

From a purely physiological point of view, nutrition can be described by the mechanical and chemical actions of the body upon the food ingested. Notice that the body is active and food is passive; the body acts upon food—food does not act upon the body.

As Dr. Herbert M. Shelton states: "Food is inert substance and, therefore, has no power to make living organisms. It cannot act, but is acted upon. The living organism uses what it can of the food consumed and rejects the rest. A particular food may be good, but to feed more of it than can be utilized...is worse than useless."

The idea that foods have in themselves no power to act upon the body distinguishes Life Science and Natural Hygiene from other traditional schools of nutrition. Many nutritionists still believe in "food therapy"—that is, that certain foods can perform specific actions upon the body to effect a cure or treatment. Life Science decrees that there are no "cures," whether they be in the form of medicines, herbs, foods or juices; instead, the body is a self-healing mechanism. Hopefully, by studying the physiology of nutrition, you will be able to see the fallacy of regarding foods as active healing agents.

Nutrition is the physiological processes the body conducts as it transforms food into material for its own growth and maintenance. This lesson discusses these processes in the order that they occur in the body as food is appropriated, digested, assimilated and finally eliminated from the body.

[Home](#) > [Lesson 20 - The Physiology Of Digestion](#) > 2. The Journey Of Food

## **2. The Journey Of Food**

Food enters the body through the mouth and exits through the anus. In between, it undergoes digestion (from the mouth to the stomach), absorption (from the stomach to the small intestines), and elimination (from the large intestine, or colon, to the anus). In most cases, these three stages of food processing take place in a total of about twenty-four hours in a relatively healthy individual. This journey takes place in what is on the average over fifteen feet of a single connected tube from the mouth to the anus.

This fifteen feet of elasticized tubing (which includes the esophagus, stomach and intestines) is said to be continuous with the outside environment. That is, there is one entrance from the outside world to the food tube (the mouth) and one exit (the anus) with no other outlet inside the body proper.

Food in this tube (usually called the gastrointestinal tract) is technically considered to be outside the body. As food passes through this tube, it may be partially absorbed by the body. At any time, the food itself may be rushed back out through the mouth (vomiting) or quickly expelled through the anus (diarrhea).

This is the reason that man can seemingly eat anything. His digestive-absorptive-eliminative tract, or tube, actually holds the ingested food outside of the body proper. If a healthy person should eat harmful foods, they may be carried through the body to the nearest exit without actually being absorbed or entering into the body from this tube.

However, many individuals, through years of improper eating, have degraded the natural power of the body to expel unsuitable foods. Consequently, the body gradually starts to absorb noxious substances from foods which a healthy organism would reject outright.

Consider this example: If a young infant is given a swallow of strong coffee, he or she will probably vomit it back up or experience immediate diarrhea. This is because the gastrointestinal tract of a young child is still sensitive and strong enough to actively inhibit such substances from entering the body.

People who have been vegetarians for several months will often experience this reaction if they, should

attempt to eat meat again. A healthy body will try to protect itself from harmful non-food items.

The gastrointestinal tube is the pathway all food must follow in its process of digestion and assimilation. What occurs along this path is discussed in the next sections of this lesson.

## **2.1 The Appropriation of Food**

Appropriation is the making of something into one's own. Appropriating foods, then, is the act of taking food into the body. The first step toward digestion and assimilation of food is the physical selection of food. This selection is guided primarily by visual and olfactory cues.

Our first contact with food is visual. Young children originally try to discover what is good to eat and what is not by sticking everything within their field of vision into their mouths. If it tastes good, it is food and is swallowed. If not, it is spit out. While effective, this is not the best way to choose food. A variety of items such as rocks, dirt, loose coins, and so forth are often swallowed by children in their exploring quest for suitable food.

Gradually, the child learns to recognize food items by sight. An orange is orange and is for eating, and a baseball is white and is for knocking over breakable items. Very quickly, children learn to recognize food by visual cues alone, and adults soon take this aspect of food appropriation for granted.

Visual appearance of food is an important part of the digestive process. People start to salivate at colorful pictures of food dishes. If the food is pretty and served in a visually pleasing manner the amount of digestive juices secreted is greater than if the food appears distasteful or if it is served in unpleasant surroundings.

The visual appeal of an apple hanging on a tree in an orchard is evident; that same apple stuck in the mouth of a roasted pig, however, does not raise the same expectations in the eater.

Food that is simply unfamiliar is often automatically rejected. Some people refuse to eat yellow tomatoes because they "look funny." Thereby they may miss a wonderful taste sensation.

All of this may seem obvious, but it is often overlooked in the physiology of nutrition. The body begins to respond immediately when food is placed within the visual field. If the food itself or the surroundings within which it is presented are unappealing, then actual digestion and assimilation of the food will be impaired. If, on the other hand, food is artfully presented in a visually pleasing manner, digestion is enhanced.

This does not mean that a lot of artifice should be used in preparing food. On the contrary, if food is naturally attractive, such as fruits or vegetables, then a minimum of 'stage dressing' is required. Notice that advertisements for steaks and hamburgers prominently feature salad with vegetables, their attractive colors of red, green and yellow to contrast with the distastefully brown or black meat. Digestion, or lack of it, begins with the eyes.

## **2.2 Olfactory Cues**

The nose is the next organ involved in the physiology of digestion. The fragrance of food stimulates the olfactory nerves, which in turn starts the salivation process. This does not mean, however, that food must be overwhelmingly 'fragrant,' as is the usual case with cooked foods and spices and onions.

Smelling food is actually a subtle experience that may require re-educating the sense of smell if it is jaded by over-seasoned cooked food. An apple gives a subtle bouquet of odors to whet the appetite. The smell of ripening bananas or a bowl of strawberries is more enjoyably overwhelming to the healthy individual than is the stench of onions and garlic piled upon burnt meat.

The eyes and the nose, then, are the first organs used in the process of digesting and assimilating food. It is important, therefore, that time be taken to appreciate and select food according to its appearance and smell.

## 2.3 Alimentation: From the Mouth to the Stomach

After food is chosen according to sight and smell, it is brought towards the mouth and saliva starts to secrete. The mouth is the first step in the digestion of food proper.

The digestion of food can be viewed as two concurrent processes: 1) *Mechanical*, or the actual movement of food as it is broken down into smaller particles; and 2) *Chemical*, or the splitting of food into its simple nutritive components. In the mouth, mechanical digestion is performed by the actions of the teeth and tongue, while the saliva furnishes the first step of chemical digestion.

## 2.4 The Mouth

The teeth perform the first mechanical operation of digestion. Food is first bitten by the *incisor* teeth at the front of the mouth. Then the *canine* teeth (next to the front teeth) shred the food into smaller parts as it is passed back to the *bicuspid*s, which continue tearing it into smaller portions. Finally, the *molar* teeth (in the back of the mouth) finish the grinding and crushing of the food.

Chewing by the teeth increases the surface area of the food so that it may be more easily penetrated by the digestive enzymes. Chewing the food is a very important part of digestion. Not only does it break the food down into more easily digestible...particles, but it also stimulates nervous impulses that cause the secretion of gastric juices, and thus prepare the digestive system for the food to be swallowed.

The teeth are very powerful. The front teeth, which tear and shred food, can exert a force of up to 80 pounds. while the grinding molars can apply 100 to 250 pounds of force against food particles!

At the same time that the teeth are doing their work, the tongue is performing the other aspect of mechanical digestion in the mouth by moving the food back and forth, from side to side and mixing it with the saliva.

The salivary glands help perform chemical digestion in the mouth. There are three pairs of salivary glands in the mouth. They continuously secrete saliva to keep the mouth from drying out. During the day, these glands produce from 1 to 1 1/2 quarts of saliva.

The saliva prepares the food for swallowing by lubricating it with *mucin*, which gives saliva its slippery characteristic. Imagine how hard it would be to swallow food "dry" without this natural lubrication.

The first digestive enzyme is also contained in the saliva. It is called *ptyalin* or *amylase*. This enzyme starts the digestion of starches in foods, Ptyalin helps convert starch to a sugar called *maltose*.

Since this enzyme is the major factor in starch digestion, all starchy foods should be chewed thoroughly and mixed well with saliva. Human beings, however, are not well adapted to eating starches, so the amount of starches in the diet should be restricted.

Saliva also has a solvent action upon food. It is only after the food is somewhat dissolved that it can be tasted.

In addition to ptyalin, saliva has an enzyme called lysozyme that digests bacterial cell walls, thus killing certain microorganisms. Saliva also has a cleansing action as its constant flow helps to dissolve and remove food particles from the teeth.

After mechanical and chemical digestion has progressed to a certain point in the mouth, the tongue gathers the food together into a small ball and then elevates the mass of food back into the pharynx of the throat. This is the first stage of swallowing and the beginning of the food's journey down to the stomach.

## 2.5 From Mouth to Stomach

After food rolls off the tongue, it is no longer under voluntary control. It is now moved through the

system under the control of the involuntary nervous system. Short of self-induced vomiting, it is now up to the wisdom of the body to move the food as it sees fit.

After leaving the tongue, it will take about 8 seconds for the swallowed food to reach the stomach. Most of this time is spent traveling down a tube called the *esophagus*.

The food passes down this tube in a peristaltic (wave-like) motion. These *peristaltic* waves are strong enough so that even if suspended upside down, a person can swallow about a half-ounce of food and it will work its way against gravity into the stomach. This is why astronauts can eat in "free fall" or zero-gravity. This is also why they must eat in small sips or swallows, being careful not to take in over a half ounce of food per swallow.

Pure liquids can move down the esophagus in only one second, eight times faster than the peristaltic waves move the solid food.

## 2.6 The Stomach

The food passes from the esophagus into the stomach through an opening called the cardiac orifice. As soon as food enters the stomach, a hormone called *gastrin* is released into the bloodstream.

This hormone is carried to the gastric glands in the stomach which causes them to secrete digestive juices. These gastric juices help in the chemical digestion of the food, while the rhythmic contractions of the stomach contribute to the mechanical process of digestion.

The gastric juices in the stomach are secreted at the rate of two to three quarts per day. These juices contain primarily hydrochloric acid (HCl) and digestive enzymes.

The hydrochloric acid makes the stomach a very acid environment with a pH factor between 1.5 and 3.0 (as compared to pure lemon juice, with a pH factor of 2). This acid environment caused by the HCl secretions serves two functions: 1) it acts as a denaturant in digestion of proteins; and 2) it kills small parasites that are often found in all foods.

Three primary enzymes are also present in the gastric juices. The first is *pepsin*, which aids in the hydrolysis of proteins. The pepsin enzyme begins breaking down complex proteins into their simpler forms. It does not actually split the proteins into amino acids (the end-product of protein digestion), but it prepares them for that process which occurs in the intestines. The pepsin enzyme works best in a fairly acid environment. An acid environment is also conducive to protein digestion.

The second enzyme is called *lipase*. This aids in the hydrolysis of fats. Lipase starts the digestion of fats by aiding their breakdown into glycerol and fatty acids. The lipase enzyme works best in a more neutral pH environment than does the pepsin enzyme.

The third enzyme, found only in the gastric juices of infants, is called *rennin*. Its primary function is the hydrolysis of milk proteins. Adults do not have the rennin enzyme in sufficient quantity to digest milk products. Consequently, the only time milk should be used in the diet is during infancy and young childhood. Even at these times, the only suitable milk is that from the lactating mother. Milk from cows, goats, etc. is not of the same composition as is mother's milk and should not be consumed by humans of any age.

These three enzymes, along with the gastric juices, are mixed into the food by the mechanical actions of the stomach. The stomach contracts in waves at the rate of three per minute. The stomach has a capacity for holding up to two quarts of food in volume. When a person is fasting, the actual volume of his or her stomach may be less than two ounces.

The gastric juices mixed in by the contracting and relaxing stomach are initially stimulated by the thought, sight, smell and taste of the food. This occurs before any food has actually entered the stomach. These juices are sometimes called the "appetite juices", and they may be suppressed if the food appears unappetizing, smells bad, or is eaten in an unpleasant environment.

Digestive secretions in the stomach are increased by attractive and well-liked foods as well as by a state of contentment and happiness. The secretions are decreased by large meals, large amounts of fat, poor chewing, poor appearance of food and negative emotions.

In the presence of intense pain, fear, or depression, gastric juices may be almost completely suppressed for up to twenty-four hours. This fact alone is reason enough not to eat when upset or feeling out of sorts.

The stomach empties at the slow rate of about 3/100 ounce for each peristaltic wave. At three waves per minute, it can take up to five hours for two pounds of food to leave the stomach.

The emptying time of the stomach also varies with the type of food present. Water and liquids leave the stomach most rapidly. Carbohydrates empty more quickly than proteins; proteins, in turn, leave the stomach more quickly than fats.

Within five minutes after fat enters the stomach, a hormone called *enterogastrone* enters the bloodstream and travels to the stomach, "this hormone inhibits the motion of the stomach and causes it to empty at a much slower rate.

Not all foods undergo the same digestive processes in the stomach, and not all foods leave the stomach at the same rate. Proteins digest in an acid environment, while fats need a neutral environment. Carbohydrates leave the stomach at a faster rate than proteins, and so on.

Even among the carbohydrates (fresh fruits and vegetables), digestion time may vary a great deal. Below is a chart listing the time that various foods remain in the stomach:

Food	Minutes Held In Stomach
Parsley	75
Lemon	90
Grapes	105
Tomato	120
Carrot	135
Almond	150
Apple	165
Banana	180
Peanut	195
Eggplant	210
Persimmon	225

Since different foods require different sets of environments in the stomach to digest properly, it is reasonable to assume that if these foods are put into the stomach at the same time, difficulties could occur. That is exactly what happens.

Consider the all-American cheeseburger. A bite of it might contain a starch (bread) a protein (meat), a fat (cheese), and an acid (tomato), what happens when a single bite of this hits the stomach?

The starchy bread was probably not chewed very thoroughly in the mouth and the starch-digesting enzyme had little chance to do its work. So, the bread reaches the stomach in an unprepared state. The meat will require a very acid environment to digest. This makes it difficult for the starch to digest, since acids are inimical to starch digestion. The fat in the cheese requires a more neutral environment than the meat protein to digest, and its fat content causes the stomach to slow its digestion. At the same time, the acids in the tomatoes interfere with the starch digestion of the bread.

In this single bite, there are over seven different types of food requiring four different sets of enzymes and digestive conditions, and all digest at different rates!

At best, such a conglomeration of food in the stomach will slow digestion down to the point of fermentation. This will lead to autointoxication. At worst, the food simply becomes half-digested and is pushed sluggishly through the system, releasing its poisons and gases throughout the body.

The same people who would never mix water, kerosene, or oil with their gasoline for their car will sit down to a meal and give their stomachs a mixture of mashed potatoes, steak, butter, and beer.

Fortunately, the stomach does not break down as fast as an abused automobile. But the stomach's resilient quality causes people to think they are getting away with their dietary indiscretions.

If different foods are to be put into the stomach at the same meal, they should at least be of the same type that requires the same set of digestive conditions. Ideally, of course, only one food should be eaten at a meal to insure optimum digestion.

Since food combining is such an important area, it is covered in a separate lesson in this course.

## 2.7 The Small Intestine

The small intestine consists of about 9 feet of inch tubing coiled in the abdomen. This tubing leads from the stomach to the large intestine. It is in the small intestine that most of the digestion and absorption of food occurs.

Food passes into the small intestine from the stomach by entering the *duodenum*. The duodenum is the smallest segment of the intestine, being only 8 inches long. Food travels through the small intestine by weak contracting waves of motion that propel the food toward the large intestine.

The other two segments of the small intestine are the *jejunum*, which is 3 feet long and connects the duodenum to the *ileum*, the final 3 feet of the small intestine.

The small intestine interior has many folds. Along the surfaces of these folds are tiny finger-like projections called *villi*.

The villi of the intestine move back and forth, like thousands of tiny tentacles, passing through the food as it is moved along the intestinal tract. The villi play an important role in the absorption of food from the small intestine.

Through the center of each villi is one or more fine white vessels called *lacteals*. The lacteals are part of the lymphatic system. Their principal function is probably the absorption of fat.

As food passes through the small intestine, it is taken up, or absorbed, by structures in the wall of the

intestines, especially the villi, and is then secreted into the lacteals. Some of the digested food is absorbed by the numerous blood vessels that line the villi. This digested food directly enters the bloodstream.

As digestion progresses in the small intestine, portions of food are moving in large quantities into the capillaries of the intestinal villi. Blood from the intestines containing these products of digestion is collected in the *portal vein*, which is connected to the liver.

The liver removes the excess glucose from the blood (glucose being one of the end-products of digestion) and stores it as glycogen, to be used later in normalizing the blood-sugar level and for supplying energy. It also attempts to detoxify harmful elements in the food (such as pesticides), and regulates the level of nutrients available to the body.

The liver is one of the master organs in the body. It receives all the end-products of digestion. The bulk that remains behind after the vital elements are extracted by the villi in the intestine and sent to the liver is then pushed down toward the large intestine. Normally, most of the contents of the intestines have been absorbed by the time the food reaches the middle of the jejunum segment of the intestine, or about 3 feet along the 9 feet of tubing that makes up the small intestine.

The tone and motility of the small intestine is increased by foods served at room temperature, fibrous foods, and high-carbohydrate, low-fat foods. Movement is slowed by cold, dry, and high-fat foods.

## **2.8 The Large Intestine or Colon**

The small intestine joins the colon in the region of the right groin. At this juncture is the *ileo-cecal* valve whose purpose is to control the speed of passage of substances from the small intestine and to prevent any wastes from returning to it from the large intestine. The ileo-cecal valve opens into the colon into a pouch known as the *cecum*, the first receptacle for waste residue.

At the tip of the cecum is the appendix. Due to the appendix's position near the waste receptacle, toxins from a diet high in meat, heavy starches, etc. can contribute to its inflammation which may result in a condition known as appendicitis.

If a person suffering from appendicitis simply abstains from all food (fasting), then the body can conduct its housecleaning and clear up the inflammation without removal of the appendix.

From the cecum, the large intestine ascends on the right side to the middle of the abdomen, then crosses to the left side and descends again. These three sections are called the *ascending*, *transverse* and *descending* colons.

One of the chief functions of the colon is the reabsorption of much of the water used in the digestive process. If all the water in which the digestive enzymes were secreted was lost in the feces, man would have to drink liquids continually.

If too much water is expelled with the feces, then a condition known as diarrhea exists. Diarrhea happens because of an irritation in the stomach and small intestine due to unsuitable food or inflammation. In this case, the colon expels all of its waste residue upon entry without holding it for water reabsorption.

On the other hand, if the waste material moves too slowly through the colon, then excessive water is reabsorbed and the feces become hardened. This is called constipation.

Waste material may move too slowly through the colon for a number of reasons. Perhaps the most usual reason is that peristaltic nerves are paralyzed by toxicity from decaying foodstuffs.

Another reason for the slow movement of waste through the colon is that the passageway has become very small due to poor tone or to hardened feces clogging the intestinal walls.

After several years on a conventional low-fiber diet, the average adult continually carries around about

ten to twenty pounds of fecal material on the colon walls. In many instances, the distended abdomens in overweight individuals are not due so much to fat as they are to accumulation of feces over a period of years. Autopsies on such individuals have sometimes revealed over fifty pounds of fecal material in the body!

When the body is abused by the modern diet, the colon often suffers the most. Fortunately, a diet high in natural fiber (that is, raw fruits and vegetables) can greatly aid the body in restoring the health of the intestines.

The last portion of the large intestine is the *rectum*. This segment serves as a storage chamber for the feces until defecation. The feces are eliminated from the rectum through an opening called the anus.

And so the journey of food through the body is completed. Many healthy individuals process the food from the mouth to the anus in about sixteen to twenty-four hours. Most adults eating a conventional diet, however, generally take from forty-eight to seventy-two hours for their food to complete its journey. Much of this added delay is due to incompatible food combinations and lack of colon vitality.

Now that we've followed the bodily journey of food from its beginning to end through the gastrointestinal tract and learned about some of the physiological processes that accompany this journey, we will proceed to determine an optimum diet, one that promotes digestive efficiency and general well-being.

[Home](#) > [Lesson 20 - The Physiology Of Digestion](#) > 3. The Physiological Determinants of the Optimum Diet

### **3. The Physiological Determinants of the Optimum Diet**

A wealth of information exists about the physiology of food digestion and absorption. Unfortunately, the science of nutrition has often depended upon "rat experiments" and artificially induced deficiencies, rather than upon the true needs of humans, to determine dietary requirements.

A more reasonable approach to determining the true dietary nature of humans is to study human anatomy and physiology. By studying human physiological nature, certain characteristics of the proper diet can be deduced that are in accordance with the inherent nature and anatomical makeup of humankind. This approach does not depend upon contrived experiments, nor is it already biased by what the majority of people believe a traditional diet should be. Instead, human physical capabilities and predispositions are the chief factors in determining true dietary needs.

#### **3.1 Food Appropriation**

The diet of most animals is largely determined by their food-gathering equipment. The long neck of the giraffe enables him to feed upon the foliage of trees. The teeth and claws of the lion are its means of killing and rending animals for its meals. The eagle's eyesight and power of flight make this creature a formidable predator of ground rodents.

So, it is salient to ask, how are you physiologically equipped to obtain your food? You have no sharp claws for tearing, no pointed teeth for slashing, nor are your eyes or sense of smell very well developed for hunting. You cannot run fast enough to chase down your prey nor can you naturally swoop through the sky or dive deep into the ocean.

You do have a marvelous set of fingers with an opposable thumb and limbs for reaching and climbing. Actually your food-gathering capabilities are very similar to the chimpanzee's!

Only man can plant and harvest. He can peel oranges and bananas and pick berries and grapes. He can climb the trees for fruits or gather the vegetables from the ground. Of all the creatures on the earth, man is most ideal for being a gardener and caretaker of the plants and trees.

Man's hands set him apart from the other animals in his food-gathering capabilities. Man appropriates his food by picking fruits from trees or by planting vegetables. It is the hands of man that are used to obtain his food, and the most natural things for such a being to eat are those foods that can be gathered and harvested—the fruits, vegetables and nuts of the earth.

### **3.2 The Mastication of Food**

Man's teeth are not curved or sharpened like those of the wolf or tiger, nor are they wide and flat like those of the grass-and-grain-eating animals. Instead, they are shaped most similar to the fruit-eating monkey's.

The saliva in man's mouth has a different acidity entirely than that of the meat-eating animals; it is much less acidic. Nor is man's saliva as efficacious in digesting starches as is the saliva of grain-and-tuber-eating animals.

Man's mouth is actually best suited for eating succulent vegetables and fruits.

### **3.3 The Stomach**

If a dog swallows a bone and it proceeds to its stomach, it will be completely dissolved by the dog's strong gastric juices. Carnivores may safely gulp hunks of meat whole because of the high acidity of the juices in their stomachs.

Humans have choked to death on similar chunks of meat. It is interesting to note that almost all of the fatal chokings on food have involved pieces of meat (vegetarians, beware: peanut butter is a close second on fatal food chokings).

Unlike the grass-and-grain-eaters (such as cattle), man's stomach cannot process large amounts of cellulose. He cannot regurgitate and re-chew his food as does the cow, for example.

Nor can man's stomach digest a mixture of all different types of food. Each food requires its own special set of digestive conditions in the stomach. Notice too that little or no starch digestion occurs in the stomach, and that fat digestion is a lengthy process that is only successful for small amounts of unheated fats.

Obviously, anything in the world can be put into the stomach, and probably has. However, the physiology of the stomach is such that only foods in compatible combinations can be effectively digested.

### **3.4 The Intestines**

The length of man's intestines is much longer than that of the carnivore's. This is because meat tends to putrefy rather quickly in the intestines and must be expelled quickly. Man's lengthy intestinal tract cannot handle low-fiber foods such as meat quickly. Consequently, such foods decrease the motility of the intestines and fermentation results, along with eventual constipation.

Cancer of the lower intestines occurs only among populations of meat-eaters. It is virtually unheard of when a diet high in natural fiber (raw fruits and vegetables) is adopted.

Constipation also disappears on a high-fiber diet. Fruit-and-vegetable-eating animals maintain excellent tonality of the intestines and usually experience a natural bowel movement after each feeding.

### 3.5 The Optimum Diet

Let's review the physiology of digestion so that we may determine the optimum human diet. First, it is obvious that man is built to be a gardener and harvester of fruits, vegetables and nuts. He does not possess the physical apparatus that the carnivorous animals have. Second, the teeth, saliva and digestive enzymes of man point to a diet consisting mainly of fruits and non-starchy, vegetables.

Third, the length of the small intestine is too long to handle putrefying meat and is too short for grasses and grains. Humans should eat a high fiber, high-moisture diet to insure health of the small and large intestines.

From these observations, it is evident that the optimum articles of diet for man are fresh fruits and succulent vegetables. Strictly speaking, based upon man's digestive physiology, the following raw foodstuffs make up the optimum diet, listed in order of preference:

1. Fresh fruits;
2. Succulent fruit-like vegetables;
3. Leafy greens and sprouts;
4. Non-starchy vegetables; and
5. Nuts and seeds.

The following foods, while not optimum, can be handled by man's digestive physiology in small amounts when properly combined:

1. Starchy vegetables;
2. Grains and
3. Legumes.

The next foods, while sometimes eaten on a vegetarian, diet, are not well adopted to man's physiology and place an undue strain on the organism:

1. Free oils; and
2. Dairy products.

These foods are definitely disruptive of man's health and are not compatible with his physiology:

1. Meat;
2. Eggs;
3. Refined starches and sugars;
4. Salt, herbs, spices, etc.;
5. All processed, preserved and artificial foods; and
6. Cooked foods.

The person desiring optimum health should eat exclusively from the first list of foods. These foods are most compatible with human physiology. Within this category, foods should be eaten in moderate amounts and in proper combinations.

The ultimate diet that is most conducive to human physiology and that promotes the highest level of health is the mono-fruit diet; that is, the eating of a single variety of fruit for each meal.

[Home](#) > [Lesson 20 - The Physiology Of Digestion](#) > 4. Questions & Answers

### 4. Questions & Answers

**I have just started the diet of fresh fruits and vegetables recommended in this lesson, but I'm**

### **experiencing diarrhea. What's wrong?**

Nothing, actually. It is perfectly natural to have alternating periods of diarrhea and constipation when you are first changing your diet. Your entire intestinal tract is being swept clean by a high-natural fiber diet and its tone is improving to the point where it can do some much-needed "housecleaning." The diarrhea you are experiencing is probably occurring due to the elimination of very old fecal deposits along the colon walls. Some people, however, have periods of diarrhea because their intestines are very sluggish due to years of abuse. They are not ready for a natural diet high in fiber and roughage. If you feel that this is similar to your case, try eating foods such as bananas, avocados, melons, etc. that are low in roughage. Eventually, your intestines will be toned-up enough so that you experience a normal bowel movement after each meal.

### **I don't really understand this business about putting only one food at a time in my stomach. Seems pretty boring!**

Of course, meals should be enjoyable and satisfying. While the mono-diet is the ideal diet, it may be difficult for the person used to the average mixed diet of meat, potatoes and gravy to suddenly eat only grapes or bananas for lunch. If this is the case, continue eating your usual foods, but make sure that they are combined for better digestion. In other words, instead of having mashed potatoes and bread (two heavy starches), try a baked potato and salad for ease of digestion. Gradually, as the diet improves, you will be attracted toward simpler eating without feeling like you are making a "sacrifice."

### **It makes sense that our anatomy is most like that of the fruit-eating animals. But, it seems like man can adapt to anything. Whatever he wants to eat, he can get away with.**

If you are satisfied with the low-level of health "enjoyed" by modern man, then it is difficult to make a complete diet change. Consider this, however: very few individuals have experienced the highest state of well-being that accompanies radiant health. People transgress natural dietary laws almost from birth. Consequently, if you think good health is merely the absence, of painful symptoms, you are missing the point entirely. Optimum health produces such marked improvements in physical, mental and emotional health that it becomes a joy to live according to the laws of nature. True, you can eat anything you want—that is man's free choice. However, you can only achieve perfect health by living in accordance with the innate dictates of your own physiology.

## Lesson 21 - Symptoms During Dietary Transition

- [1. Introduction](#)
- [2. Some Unpleasant Symptoms And Their Causes](#)
- [3. The Recovery Of Health](#)
- [4. Questions & Answers](#)
- [Article #1: What To Expect When You Improve Your Diet By Stanley S. Bass, D.C.](#)
- [Article #2: The Three Phases Of Metabolism](#)

### 1. Introduction

#### 1.1 "In Sickness and in Health ... "

It was three o'clock in the morning. My wife was not beside me in bed.

From the bathroom came a series of gags, groans and wrenching noises. Finally the lavatory was turned on and water was splashed about.

My wife slipped back into bed. "Blah," she moaned, "I didn't know getting healthy made you so sick."

That was several years ago when my wife had changed over from the typical American diet of high-fat and fried foods to a diet centered around fresh fruits and vegetables.

The fatty foods in her old diet had caused her gallbladder to become clogged with noxious bile. Now that she had improved her diet, her body had a chance to clean out the old deposits of bile and pre-gallstone materials.

The old bile salts had been released into her digestive system in an attempt to eliminate them once and forever. The inconvenient time of three A.M. was when her body chose to clean the toxins out by vomiting.

Afterwards, however, she felt very good. Since this time, she has no longer suffered from gallbladder attacks and her digestion of wholesome fats has greatly improved.

At the time of her induced sickness, however, she was confused. Why would she suddenly become violently ill when all she had done was to improve her diet and take better care of herself? This is one of the mysteries of health improvement that needs to be explained fully so that you know what to expect when the body finally gets an opportunity to heal itself.

#### 1.2 The Obstacle To Good Health

Most people do not mind making sacrifices if they feel they will be rewarded eventually for those sacrifices.

People seeking health decide to sacrifice their old comfortable diet patterns and habits from a desire to be rewarded by good health.

Imagine their surprise when they discover that after improving their diet, they sometimes feel much worse (for a temporary period). They feel betrayed and disappointed. "Why do I feel so terrible when I'm trying to do all the right things?" is a common complaint.

Why should the recovery of health and the improvement of the diet cause unpleasant symptoms? Why shouldn't we be rewarded with immediate good health and radiant well-being as soon as we change our "evil ways?"

Unfortunately, good health is not immediate—but then again, neither did poor health occur immediately.

Think about this. Didn't you feel healthy and free from pain as a young child? Have you noticed how small children have an endless supply of energy and are oblivious to physical discomforts, such as cold, that would make an adult suffer? Now look at some of our older citizens. Some of them are so crippled with arthritis they can hardly move. Every day is the discovery of some new pain or some developing crisis in the body.

Poor health and illness is progressive; it does not occur overnight. Good health and well-being is also progressive; It may take weeks, months, or years.

To understand this a little more, let's look at how the body does its work in cycles.

### **1.3 The Cycles of the Body**

Like all aspects of nature, the body has its own individual cycles. There are biological rhythms within the body that dictate periods of tissue repair, tissue growth, waste elimination, and so forth.

We cannot rush the body through its cycles, nor can we expect it to progress in a linear fashion as if racing to a specific goal. Healing occurs in cycles. Some days the body has a high-energy level and it rebuilds damaged tissues. On such days we may feel great. On other days, the body must do its housecleaning and remove accumulated toxins. When this happens, we may experience low levels of energy or even depression.

Most people lead a lifestyle and follow a diet that inhibit the body in its cyclical work. For instance, when the body is trying to clean house via a cold, people become impatient. They try to suppress the cleansing cycles with drugs or food and the body must sometimes abandon its efforts.

The body behaves in a sort of up and down motion as it conducts its healing processes. One day it may cleanse heavily and we feel rotten. The next day, the toxins have been removed and we feel great. We feel so great, in fact, that the body decides to dig a little deeper and remove some of the older toxins, and then we feel worse. This is a continuing cycle in the process of healing, but do not despair: Once a certain level of health has been reached, we do not notice the cycles as much and they cause progressively less discomfort.

Why does the body go through these cycles? How does it know what to do next to promote our healthful recovery? And, still, why do we have to feel bad as we get well?

### **1.4 The Body As A Healing System**

Your body wants to survive forever; it wants to be free from all pain and illness; it actively desires complete healing to take place within it at all times. Your body is your friend and partner in your effort to regain health.

The body has the innate capacity, knowledge and wisdom to heal itself at any time—if it is allowed to do so.

The body possesses its own healing ability and the wisdom to direct this ability. The only thing we must do is to let the body conduct its work with as little interference as possible. We can furnish it with the highest-quality food when it needs it or withhold food when it does not desire it. We can exercise and

rest the body, and give it fresh air and sunshine.

Other than that, all we can do is wait intelligently and not become alarmed by the symptoms of its healing or try to suppress those symptoms.

The body will not try to kill itself, nor will it allow healing to progress in such a manner as to cause us serious discomfort. But the body is wise enough to want to accelerate the healing process as rapidly as possible. This may involve major cleansing efforts when literally pounds of old stored toxins are dumped into the system to be eliminated.

If you have faith and trust in your body's ability to heal itself, the unpleasant symptoms which may accompany this healing become more bearable and are not a source of fear or misgiving.

Ultimately, we must let our body perform its health-restoring work at its own pace. We must believe that the body alone is capable of performing all the needed healing functions.

The human body has perfected itself over millions of years and through thousands of generations.

It is the perfect healing system. The cellular intelligence that drives the body is infinite in its capacity. We need not have any fears about its wisdom or ability to restore itself to the highest-possible level of health and well-being.

## **1.5 Body Awareness**

A two hundred and seventy-five pound woman was admitted to the hospital after she complained about "indigestion" pains.

Two hours later, she gave birth to a child. She had no idea that she had been pregnant.

An elderly man complained of a continual dull headache for weeks. He went to a doctor who asked him about his habits, activities, and so on.

Upon repeated questioning, it was determined that the man had not experienced a bowel movement in weeks. He was not even aware that he was constipated and that this might be the source of the headache.

We might find such stories amazing, but to a certain extent they are true for everyone. Most people today have such a low level of body awareness that they do not realize they are suffering from poor health until a severe blow lays them low.

Unless illnesses and disease propagate to a dramatic climax, many people are unaware that anything is even wrong with the body. Modern man has become desensitized and removed from his own body.

A lack of body awareness accompanies a sickened condition. In fact, it is this absence of consciousness that permits the body to degenerate. If a person is attuned to his body's needs, he becomes aware when something is going wrong and he can fast, change his diet, etc.

Increasing good health also increases our awareness of the body. As the major pains and aches disappear, we become more sensitive to all the body's needs. The minor irritations that were not noticed previously may now enter our awareness.

For example, suppose you had a slight headache or an ingrown toenail. At the same time, you were suffering from a violently bleeding ulcer that caused you to vomit every two or three hours.

Do you think you'll notice that headache or sore toe? No, you'll be too busy worrying about the ulcer to pay any attention to the other minor pains.

After the ulcer is gone, however, you might suddenly realize, "My head hurts, and, boy, does my toe feel bad!"

This is exactly what happens when the body goes through its healing process. As you gain health, you become more aware of the minor pains that may have plagued you for years.

In fact, these little aches may have been around so long that you've grown used to them. After the diet is changed and the body improves, these aches may enter your awareness again.

It's not that your increasing health has given you any new pains, but that the new body awareness that accompanies an improvement, in condition allows you to notice these old problems.

The new sensitivity is a blessing. Now your body can tell you what it needs, what to avoid, and what habits to discontinue. If you have stopped eating meat, for instance, your body will become more sensitive to the harmful effects of such food. If you were to eat that same food again, you might become sick. This is the body's way of saying, "That stuff's no good for me, and I'm strong enough now to let you know."

Body awareness is one of the first gifts of health. This new feeling should not be mistaken for morbid sensitivity. It is your guardian angel that will guide you past the pitfalls of poor foods, unhealthy practices, and other life destroying habits.

[Home](#) > [Lesson 21 - Symptoms During Dietary Transition](#) > 2. Some Unpleasant Symptoms And Their Causes

## **2. Some Unpleasant Symptoms And Their Causes**

Suppose you have made the decision to change your diet and improve your health. You understand how the body heals itself and you are more aware of its needs. Yet, you may not have complete faith in your body.

A splitting headache, chills, nausea, a dripping nose, increased body odor, reappearance of old aches and pains, rashes, boils, drastic weight loss—all the symptoms that can shake the faith of the most sincere health seeker.

Without proper understanding or support, you could panic at these symptoms and believe your new diet or way of life is the cause of them. You might revert to your old unhealthy practices because you became afraid.

Thousands of people have experienced the same sort of problems as they improved their health. Books about fasting and dietary changes should be read so that you may feel reassured. Case histories, such as the one below, may help you understand these changes.

### **2.1 A Case History**

Larry was a college junior and had become a vegetarian after graduating from high school. He had tried to improve his diet, but college life put him under stress and so he started drinking coffee in the evening to stay awake and study. After staying up late, he felt tense so he started smoking marijuana for relaxation and to get to sleep.

He also had little time to prepare lunch, so he got in the habit of eating a quart of fruit flavored yogurt for lunch every day.

When the summer came, Larry decided to kick his coffee and marijuana habits. The hot weather was also making him feel uncomfortable eating dairy products, so he gave up his daily yogurt. He had been suffering from sore throats and nasal congestion, and he changed over to a diet of raw fruits and vegetables to allow his body to cleanse itself.

The first day of his new diet Larry felt pretty good. He had distilled water for breakfast instead of the

usual two cups of coffee and ate fresh fruits for lunch. He had a salad for supper and went to bed early to get plenty of rest. The next morning he woke up feeling miserable. He had a sharp headache that raced up his neck behind his ears. He could hardly breathe. His sinuses were clogged shut. He felt worse than he had in weeks.

The headache stayed all day and into the next day. Now he noticed he had developed a hacking cough that convulsed him. He started spitting up hardened balls of mucus from his lungs.

The third day his nose was continually draining. As fast as he could blow it, his nose would clog back up. All the time, his headache had never left him, even when he tried to sleep.

By the fourth day, the headache had subsided a little.

His cough had worsened, however, and now pieces of hardened gray material were being expelled from his lungs.

"I can't stand it!" he thought, "Why am I feeling so miserable as soon as I gave up my bad habits?"

Why indeed? First, Larry's headache is a symptom of caffeine withdrawal. Coffee, tea, cola drinks, and other caffeine-containing substances are addictive poisons. When a person drops his caffeine habit, changes occur in the vascular and nervous systems. These changes occur as the body tries to renormalize itself and eliminate the poisons. Headaches often accompany caffeine withdrawal, and some people who give up their coffee habit may experience edginess and irritability for a few days.

Larry's clogged nose and sinuses were related to the consumption of dairy products. Mucus buildup occurs when milk is consumed. After such foods are eliminated, sinus drainage may occur for two weeks or more. The elimination of old mucus is a healthy sign for such deposits may become the breeding places for many diseases.

The coughing and spitting of hardened phlegm resulted from the cleansing of the lungs of the tar deposits which had been caused by smoking. Smokers lungs are often crusted black with tar and chemical deposits. When smoking is stopped, the lungs try to cleanse themselves and the old deposits are expelled by coughing. This is why a cough should never be suppressed. Coughing is one method that the body has of expelling toxic wastes from the system.

After about two weeks, Larry started to feel better than ever. He had plenty of energy without his coffee. His nose, throat, and lungs felt so much cleaner that he had no desire to smoke or eat dairy products. He had suffered for awhile, but now he was reaping the rewards of improved health.

## **2.2 Some of the Toxins in Your Body**

Everybody is a walking time bomb. Each person carries within him the seeds for disease and illness. These seeds are the environmental and dietary toxins that may be stored within the body and which may spring full force into a debilitating disease.

What are some of these toxins, and where do they come from? How can we get rid of them? What symptoms can we expect when they start to leave the body?

## **2.3 Drug Toxins**

Surprisingly enough, one of the largest sources of body toxins is the drugs people take to fight disease (or so they think). Medicinal drugs are very strong—they have to be to overcome the body's natural defense system.

When such drugs are taken, they must either be eliminated from the body or stored within it for later elimination.

As a person's health improves and all such medicines and drugs are discontinued, the old toxins may enter the bloodstream for elimination. The circulation of these old drug toxins in the system may

produce bewildering symptoms that could alarm the health seeker.

For example, an elderly man had been taking a form of digitalis (a heart stimulant) for several years. He discontinued the drug as he improved his health through exercise.

After a few days off the drug, he experienced erratic heart beats, a racing pulse and chest pains. He was frightened and wondered if he should take his old drug again.

He was reassured that these symptoms were due to his body trying to renormalize itself and eliminate the old toxins from the heart drug. Sure enough, after a few days his heartbeat became steady and regular as the drug toxins were finally eliminated.

Every drug used, whether legal or illegal, leaves its mark upon the body. As the body regains health, the drug deposits are put into circulation for elimination. Since a combination of past drug deposits may enter the Bloodstream at once disconcerting symptoms may arise. Drug detoxification can be a lengthy process, but it will be aided by fasting and a diet high in fresh fruits.

Be forewarned: Old drugs that were taken even many years ago may reappear in the bloodstream as they leave fatty tissues and the organs. Drug toxin elimination may express itself in a series of rashes as they leave the body through the skin.

## **2.4 Caffeine and Nicotine**

Heavy smokers or coffee drinkers may experience similar symptoms when they withdraw from their drug. Nervous irritability and emotional outbreaks are common symptoms of these drug addicts when they are detoxifying.

Nicotine and caffeine damage the nervous system and upset the vascular system, so symptoms such as headaches, edginess, and extreme lassitude may be expected. Such symptoms from these drugs usually lessen after three to ten days.

## **2.5 Salt and Other Condiments**

Once salt use is stopped and the health improves, old salt deposits in the body exit through the skin and kidneys. Sometimes the elimination is so intense that a person may have a continual salty taste in the mouth for days. The skin may become crusted with salt or it may smell of the particular condiment that is being eliminated (such as onions, peppers, or vinegar).

In Mexico, corpses have been found in the desert that were untouched by buzzards and hyenas. The reason? The people had eaten such large quantities of hot peppers all their lives that their skins were actually too spicy for the scavengers to eat. Condiments can never be used by the body, and so they must either be stored or eliminated when the health is improved.

Salt elimination may also cause a temporary rise in blood pressure. People who go on salt-free diets may actually experience a slight increase in their blood pressure as the heavy elimination of salt begins. Later the blood pressure renormalizes itself and eventually becomes below the norm on a salt-free diet.

## **2.6 White Sugar Withdrawal**

Eliminating sugar from the diet may make a person feel slightly nervous and hyperactive until the energy levels adjust to a sugar-free diet.

Mood changes, however, are usually more noticeable than any physical symptoms when sugar is eliminated. Reformed sugar addicts may feel periods of unaccountable depression as their blood sugar level tries to right itself. Getting off the sugar roller coaster, with its rapid rises and falls in blood sugar levels, is easier when a diet high in raw foods is followed. Such a diet renormalizes blood sugar levels and promotes tranquility of emotions.

## **2.7 Heavy Metal Elimination**

Almost every person is poisoned by deposits of heavy metals in the body. Lead, aluminum, copper and arsenic collect in organs throughout the body. Because of their heavy weight, they are difficult to eliminate, and may cause discomfort as they leave the body.

Lead enters the body through auto exhaust, paints and canned foods. Aluminum may come from preparing or storing food in aluminum containers. Arsenic is present on sprayed foods, and so on.

Since these metals are heavy, they tend to remain in the body until a cleansing diet or fast is followed. As these metals come out, headaches and a general achiness all through the body may occur. The gums may hurt and the kidneys may throb as these metals leave the organs and bones.

Occasionally, you can actually taste the metal that is being eliminated. Lead, especially often leaves a metallic taste on the tongue when it is leaving the body.

Heavy-metal poisoning can make you feel uncomfortable all over, and it is very common due to all the environmental toxins. As you eliminate these metals, bear the uncomfortable body aches and realize that they are leaving your body forever.

## **2.8 Meat-Eating and the Acid Body Condition**

Meat-eating creates an acid condition in the body. When meat is eliminated, the body tries to reestablish its naturally-healthy, alkaline condition. As the acid condition of the body changes to one of alkalinity, symptoms may arise that may confuse the new vegetarian.

A sour, disagreeable odor may emit from the body as the acids leave or are neutralized. Hair may fall out and the breath may turn foul. Urine may be very dark and a sharp, bitter taste may be in the mouth.

Weakness of the arms and legs may occur. Many people confuse this weakness for protein deficiency. Instead, the weakness has resulted from a consumption of too much acid-forming protein in the past. The body's energies are directed toward neutralizing these old toxins and so you may feel weak for a temporary period. Once the toxins are taken care of and an alkaline condition is reestablished, then strength returns to the limbs.

The discomfort of an over-acid body caused by meat-eating can be quickly overcome by a high-alkaline diet, such as fresh fruits and vegetables.

## **2.9 Specific Symptoms**

Most people who change their diet and improve their health may experience one or more of the symptoms described below. Depending upon your past health, these symptoms may be mild or intense, short-term or long-term, temporary or recurrent.

As you improve your health, however, and stay on an optimum diet, all symptoms will gradually disappear.

*Under no circumstances should these symptoms be halted by drugs.*

Relief from some of these symptoms may come through fasting and rest primarily.

Moderate exercise is also beneficial, if your strength allows. Sleep and freedom from stress is vital.

Sunshine and fresh air will also aid in detoxification.

## **2.10 Headaches**

A headache is the body's chief warning signal of body toxicity. The toxic load in the body has increased so fast that poisons are circulating in the bloodstream and cause irritation to the brain and nerves.

Aspirin should never be taken for a headache. For some relief, lay down and rest with a cool, damp cloth across the eyes and forehead. Fasting may also help. Have someone massage the neck and temple. Avoid all stress at this time.

## **2.11 Upset Stomach and Diarrhea**

When food is not being digested properly or is passing right through your body, then it is time to stop all food intake. This is your body's way of telling you it doesn't require any nourishment at this time, but instead is busy cleaning.

Careful food combinations and avoiding heavy foods are advised.

Diarrhea should not be halted by medicines. Rest and abstinence from food are your best resorts.

## **2.12 Constipation**

A new diet may occasion temporary constipation. Brisk walking of at least one mile a day will help end this problem.

Eating foods naturally high in water and fiber will eventually remedy this condition. If little food is eaten, drink distilled water whenever thirsty.

On a diet of fruits and vegetables, constipation disappears, never to return.

## **2.13 Weight Loss**

Weight loss is entirely normal when the diet is improved. Some individuals become alarmed when their weight falls rapidly. In most cases, this is not a cause for alarm.

From five to fifteen pounds of water weight alone may be lost when salt is completely eliminated from the diet. In some individuals, five to twenty pounds of old fecal matter may be eliminated from the colon. All of this is useless weight, and you should say, "Good riddance!"

The body will also try to eliminate all diseased tissue in an effort to rebuild a healthy body. It will try to strip itself down to the bare foundations and then begin to add on only healthy tissue.

Weight loss may occur for six months to a year. Exercises for muscle growth, such as weight lifting and swimming, will help rebuild the body with lean, muscular tissue. Be sure that your diet includes sufficient amounts of sweet fruits that are high in calories to balance out the low-calorie salads.

Usually, you can expect to weigh about twenty pounds less after you renormalize your body from the typical high-meat and fat diet of most Americans.

## **2.14 In General**

Almost all the symptoms experienced during a dietary change are due to the body's efforts to detoxify itself as rapidly as possible!

You can help in this process by fasting and getting plenty of rest. Be sure you get all the sleep you want and try to avoid stressful situations. During detoxification, you need as much peace and privacy as possible.

Never halt any symptom with medication. It will only reappear later in greater intensity.

Above all else, cultivate a positive attitude about what you are doing. Do not feel like you are punishing yourself or that you are making any great sacrifices. You are recovering your health, and that is the greatest reward that can be expected.

Realize that your sincere efforts will give you health beyond your expectations. Do not dwell upon your

temporary discomforts. Instead, indulge in positive activity, such as exercise, gardening or helping others.

All symptoms will pass in time. The pain today will be a memory tomorrow. The discomforts you endure now mean an absence of suffering, later. You are healing yourself with your courage and wisdom. You have much to be thankful for.

[Home](#) > [Lesson 21 - Symptoms During Dietary Transition](#) > 3. The Recovery Of Health

### **3. The Recovery Of Health**

Now that you have an understanding of the symptoms that may occur when the diet is changed and health improves, you can evaluate the various ways in which the diet may be modified.

The intensity of the symptoms experienced is often related to the method used for the dietary transition, such as fasting, gradual diet improvement, quick diet changeover, and so forth.

#### **3.1 Fasting - The Quick and Easy Way**

A prolonged supervised fast is the quickest way to make the transition to health. Dietary changes can be made more easily after a period of fasting. Fasting, however, can be accompanied by intense symptoms, and the reactions experienced while fasting may alarm the first-time faster. For this reason, a lengthy fast should be undertaken in the presence of an experienced practitioner. Unsupervised fasts from three to five days, however, may be safely undertaken by people who are educated in the mechanics of starting and breaking a fast.

Below is a case history of a person who used fasting to make the dietary transition:

#### **3.2 Fasting - A Case History**

"I had tried to improve my diet off and on for several years. One day I would eat fresh fruits and salads. The next day it would be ice cream and potato chips.

Or maybe I would last a week on a good diet. Then I'd go out and eat Italian food for a reward. Then I'd eat healthy for a day or two, and the next day I would fix a huge cheese casserole.

I was always seesawing. Finally, I said 'Okay, this is it. No food at all for a few days.'

I went on a seven day fast and drank only distilled water. After the fast, I felt so clean and wonderful that I didn't want to mess up my body with junky foods.

I tremendously enjoyed fruits and unseasoned salads after my fast. I wasn't craving all that cooked food. I made myself a promise that if I ate cooked foods one day, I would fast the next day. This helps me to break the momentum that would otherwise wreck my healthy diet.

Fasting is the easiest way to get back to a healthy diet and stay on it. It's much easier for me to change from a 'no food diet' (fasting) to a 'raw food diet' than it is to start over again from my old cooked food, junk diet."

#### **3.3 Rapid Dietary Change**

Some people desire to make as rapid a change as possible in their diet. This is admirable. After all, if your house is on fire, you don't want to linger, but to get out as fast as you can. So it is with an unhealthy

diet—you don't want to drag your feet when your health is in question.

You do want to succeed, however. Unfortunately, rapid changes in the diet often fail. Changing the diet overnight is extremely difficult, although a few individuals have done just that.

Caution is advised if you want to make major and sudden changes in your diet. Your mind might be ready, but your body may rebel. After all, you wouldn't expect a lion to suddenly start eating hay for breakfast. True, eventually a carnivorous animal can thrive on vegetarian fare, but it is usually introduced gradually. Man, however, is naturally fruitarian/vegetarian, so he will have an easier time in changing his diet, but still be aware that some people do not take to rapid changes in their diets, habits, living arrangements, or anything else for that matter.

If you want to go from a meat and potatoes diet to a raw fruit diet in a few days, fine; but be aware that your body may react so strongly that you could become discouraged and feel very sick. If such a rapid change is intended, it is best to fast before attempting it.

Remember that your present state of health is the result of years of bad living habits and poor diet choices. It may be unreasonable to expect your body to change completely overnight.

Here is a case history of one person who did make an almost overnight change in his diet:

### **3.4 A Rapid Change in Diet - A Case History**

"I've always been an all-or-nothing person. I'd do something 100 percent or I wouldn't do it at all.

I had been on a conventional diet, eating lots of fast foods, and getting most of my meals out of cans and packages. I didn't pay much attention to what I ate, just so it filled me up.

"Then one summer my brother died from cancer of the colon. It shook me up. I started reading and found out that cancer of the lower intestine usually occurs when a low-fiber diet is eaten, like meat, dairy products, fast foods—in other words, my kind of diet.

That was all it took. One day I had been eating hamburgers, and the next day I was eating only oranges. Pow! I was an overnight fruitarian.

I nearly died. I had diarrhea continually for five days. Everything I ate came right out. I guess I should have fasted, but I didn't know anything about that. I just kept eating fruits.

I weighed 185 pounds. After a few months, I was down to 110 pounds. I was a walking skeleton. People stared at me.

I found myself continually weak. Climbing up a single flight of stairs took several attempts.

There were days when I felt like I was going crazy. All my family and friends looked like strangers. My own face even looked unfamiliar to me.

I had so many toxins circulating in my system that I could not think straight. This lasted about six months? Finally things started to change.

I started gaining weight and getting my strength back. In fact, I had more energy than I ever had in my life. I would wake up before sunrise and run several miles. I became continually happy and was always smiling.

Today I honestly don't know how I went through those six months. I wouldn't recommend that anyone be so radical as I was. I believed I came close to killing myself.

Don't be too tough on yourself; you took this long to get sick, so take your time to get healthy."

### **3.5 Gradual Dietary Change**

This method may take the longest time, but it produces the least intense symptoms. The disadvantage of

changing the diet slowly is that people may backslide too easily, or their health may be so poor that they can't afford to wait a long time. Since the symptoms of healing are spread out over a long period of time, it may be years before the person feels truly healthy. Still, this is an easy way to change the diet for those who do not want to experience the strong reactions sudden changes entail.

Symptoms will occur even with a gradual transition. Depending upon how you lived in the past, these symptoms may reoccur for several years or until an optimum diet is strictly followed for a length of time.

Gradual changes in the diet are fine, provided that continued/forward movement toward a goal is maintained. If you take two years, for example, to eliminate all meat from your diet, you might be more susceptible to eating it again after you thought you had given it up. As long as you are definitely improving your diet every week and are not fooling I yourself, then your progress is probably satisfactory.

The best thing about changing the diet over a period of months is that you have the time to educate yourself about the symptoms you may be experiencing. You are also more likely to stick with your improvements if they are implemented over a period of time and are made a part of your lifestyle. Some people change their diet one week, but are back to eating the old foods the next week. Slow, sustained progress is better than fast, erratic changes.

Here is a case history of a person who slowly changed her diet:

### **3.6 Gradual Diet Change - A Case History**

I was fifty-three years old when my husband and I decided to change our diets. We had recently retired to our country home, and we decided it was time to take better care of ourselves.

We became vegetarians almost by accident. We were working hard outside in the summer with our garden, and we would get so hot that we didn't want to eat meat.

Besides we had so many garden vegetables that it was easy to make a meal on them.

The first summer we ate meat maybe twice a week. About the only effect we noticed was a strong desire for afternoon naps.

During the fall and winter, we stayed on our twice-weekly meat diet, and started to eliminate all sugar from our diet. I really noticed an improvement when we stopped using sugar. I also cut back on our salt to help my husband's blood pressure.

When the spring and summer came, we started eating more fresh foods and these took the place of our bread, milk and eggs. Since we never ate out, being away from the city, we avoided most rich foods.

Finally by the following fall, we had just about stopped eating any meat unless guests came by. We eating a salad at about every meal, and I stuck to only cooked food per meal.

We just kept feeling better and better. The bursitis in my shoulder disappeared and my husband lost his pot belly after all these years.

When the next spring and summer came around, we became total vegetarians and started having complete days with only raw foods. Every now and then, we would steam or bake a few vegetables.

Our diet is still not perfect I but all the improvements we've experienced encourages us to continue as far as possible. We're lucky, I guess. We have plenty of homegrown produce and get to stay outside a lot. But I think anybody can start to make improvements in their diet and health—no matter how small."

### 3.7 What The Future Holds

Body purification is a lifelong process. Your body will always strive to a higher state of health. It will always be eliminating toxins as soon as they become present.

Consequently, you can always expect some cleansing symptoms to occur even after you have achieved a high state of well-being. The symptoms, however, will be of a much shorter duration and of a much lower intensity.

For instance, that cold you used to get each year for a week may only last two days or one day. You may only notice a temporary cleansing lasting only a few hours or overnight instead of the ten-day periods of sickness that used to plague you.

Gradually, all the old symptoms will disappear. Your body will/be in such a high state of health that you will experience little discomfort during its cleansing cycles.

You will have passed through the suffering and pain of toxic elimination. You will have reached the birthright of every human being—perfect health.

[Home](#) > [Lesson 21 - Symptoms During Dietary Transition](#) > 4. Questions & Answers

### 4. Questions & Answers

**I've tried to change my diet several times. Each time I would be fine through the day, but by supper time I would feel depressed. What's happening?**

A mild form of depression is very likely to accompany a change in diet. There are two reasons for this. First, by the end of the day during which you ate wholesome foods, the body has had a chance to eliminate a large amount of toxins. These toxins are circulating in the bloodstream before they leave the body, and tend to depress the mind. A little vigorous exercise an hour or so before the evening meal and productive, relaxed pursuits after supper can effectively combat these temporary periods of depression.

The second reason for such mild depression is that you are making a major change in your life, and consequently you are losing a part of your old identity. We often identify with foods we eat and feel that they define who we are (for example, "I'm a meat and potatoes man," or "My family was raised on fresh bread"). As certain foods vanish from our diet, we sense a temporary loss which is overcome by reading inspirational health literature and educating ourselves about the harmfulness of our old foods.

**I fasted once for four days and got the worst headache of my life. I could hardly stand up. I got scared and broke my fast. Is that okay?**

Make no mistake—a radical change in the diet or a period of fasting may sometimes give rise to symptoms that can scare you silly. This is especially true if you have had little experience in this area or have no friends or relatives you can talk to. It certainly helps to have a knowledgeable person you can confide in and be reassured by.

Whether or not it was "okay" to break your fast is really up to your body. Perhaps your body was telling you to slow down and to break your fast and continue with a slower cleansing method. More than likely, however, had you continued for another day or two, your headache might have vanished forever.

Educate yourself and try again. You can do it!

### **I ate a bunch of mangoes last summer and I got a rash all over my thighs. Is this an allergy symptom?**

It's not an allergy symptom—it's a symptom of an overly toxic body. Mangoes did not cause the rash, but instead allowed the body to get rid of old toxins.

Skin rashes, boils, eruptions, etc., are extremely common as the diet is changed and toxins come out. Do not confuse these skin problems with allergies. People are not allergic to wholesome foods—they are "allergic" to the toxins and poisons in their bodies.

[Home](#) > [Lesson 21 - Symptoms During Dietary Transition](#) > Article #1: What To Expect When You Improve Your Diet By Stanley S. Bass, D.C.

### **Article #1: What To Expect When You Improve Your Diet By Stanley S. Bass, D.C.**

If I were asked, "which is the area of greatest misunderstanding and confusion in the field of nutrition?", I would immediately be forced to reply, "It is the failure to properly understand and interpret the symptoms and changes which follow the beginning of a better nutritional program."

What is meant by a better nutritional program? It is the introduction of foods of higher quality in place of lower-quality ones. For example—if a person replaces a protein-rich food such as pork with beef, the beef may be considered the superior of the two due to its easier digestibility, lower and less-saturated fat content, etc.—chicken is superior to beef, and fish is superior to chicken because of its more rapid digestion and lower-saturated fat content. Lima beans, lentils or chick peas which are eaten at the same meal with vegetables are superior in all the nutrients mentioned. Then we ascend to the nuts and seeds which are eaten in the natural state (raw and unsalted). To summarize—the closer the food comes to its raw, unfired form, the higher the quality is. In this condition, all the enzymes are found intact. The amino acids are in their finest form. The minerals, vitamins, trace elements, carbohydrates and life force are present. This life force, in turn, is capable of reproducing tissue which is full of life and longer lasting in structure.

This same classification of quality which we analyzed in relation to protein-rich foods applies to the carbohydrates (the starches and sugar-rich foods), the fats, the mineral-rich foods (vegetables), etc.

The quality of a nutritional program is dramatically improved by *omitting* evil and toxic substances such as coffee, tea, chocolate, tobacco, salt, pepper, etc.

What is the relation of quality of foods to recovery from illness? It is this in a nutshell—the *higher* the quality of food that we eat, the *quicker* we recover from disease—provided we are able to properly digest and assimilate the quality level. To this must be added the knowledge of: (a) proper food-combining, (b) proper order of eating the different kinds of food at a meal (e.g. the most easily digested food should be eaten first, the more complex one second and the most-concentrated item last), (c) the correct quantity of food to be consumed (of each type) in the meal, and (d) the correct time for eating (when hungry, and not by the clock).

### **When Diet Improves, the Body Casts Out Accumulated Toxins and Unfit Tissues**

Now what happens when a person follows these rules and makes a decided improvement in the quality

of the food consumed? Remarkable things begin to happen to the body (as well as the mind). The amazing intelligence present in every cell of the body, the wisdom of the body in its operation immediately becomes manifest. The rule may be stated thusly: When the quality of the food coming into the body is of higher quality than the tissues which the body is made of, the body begins to make room for the superior materials which it uses to make new and healthier tissue. This is the plan of Nature—of evolution. The body is very selective and always aims for improvement—for better health. The body *always* tries to produce health and *always* will, unless our interference is too great. Only then do we fail to recover and degenerate further into disease. The remedial nature of many conditions such as colds, fevers, cuts, swellings, and injuries, furnish endless examples of how the body tends toward health—*always*—unless we do something to stop the process.

## **"Withdrawal" Symptoms Follow Use of Improved Diet**

What are the symptoms or signs which become evident when we first begin to omit the lower-grade foods and instead introduce superior foods—those which are more alive, more natural than we are accustomed to? When the use of a toxic stimulant such as coffee, tea, chocolate or cocoa is suddenly stopped, headaches are common and a letdown occurs. This is due to the discard by the body of the toxins called caffeine and theobromine which are removed from the tissues and transported through the bloodstream to the eliminating organs. When the blood coagulates through the brain during its many bodily rounds before the noxious agents reach their final destination for elimination, these irritants register in our consciousness as pain—in other words, headache. The letdown is due to the slower action of the heart—the resting phase which follows the stimulation or more rapid heart action forced upon the body by certain poisons called stimulants. The more rapid heart beat (or pulse) produces a feeling of exhilaration and the slower action produces a depressed state of mind. Usually, within three days, the symptoms vanish and we feel stronger due to the recuperation which follows. To a lesser extent, the same process occurs when we abandon lower-quality foods and replace them with better foods. Lower-quality foods have undergone more reparation. Spices, salt and other ingredients have been added and they tend to be more stimulating than less-prepared and more-natural foods. Animal foods such as meat, fowl and fish are more stimulating than cheese, nuts and vegetable proteins. Consequently, the withdrawal of stimulation which follows the abandonment of animal food produces a slower heart action—a resting base—which registers in the mind as relaxation or a decrease in energy. This initial letdown lasts about ten days or slightly longer and is followed by an increase of strength, a feeling of diminishing stress and greater well-being.

## **Don't Judge Results Prematurely**

Now, let us return to the symptoms which occur in the process of regeneration.

The person who starts a better diet, stays on it for three days to a week and then quits will say, "Oh! I feel better on the old diet—the new one made me feel weak." He ailed because he didn't give his body a chance to adjust and complete its first phase of action—recuperation. If he had waited a while longer, he would have begun to feel better than before he started.

During the initial phase (lasting about ten days on the average to several weeks in some), the vital energies which are usually in the periphery or external part of the body such as the muscles and skin begin to move to the vital internal organs and start reconstruction. This shunting of much of the power to the internal region produces a "feeling of less energy in the muscles which the mind interprets as some weakness. Actually, the power is increased, but most of it is being used for rebuilding the more important organs and less of it is available for muscular work. Any weakness which is felt here is not true weakness, but merely a re-deploying of forces to the more important internal parts. Here it is important for the person to stop wasting energy, and to rest and sleep more. This is a *crucial phase* and if the person resorts to stimulants of any kind, he will abort and defeat the regenerative efforts of the body. It is important that he have patience and faith here and just wait it out, and after a while he will get

increasing strength which will exceed by far what he felt before he began the new program. Success in recovery or improvement of health hinges upon the correct understanding of this point—*realizing* that the body is using its main energies in more important internal work and *not* wasting it in external work involving muscle movements. Be wise—take it easy here and relax. Just coast in your work and social obligations until you're out of the woods.

As one continues on the improved dietary and gradually raises the food quality, interesting symptoms begin to appear. The body begins a process called "retracing." The cellular intelligence reasons something like this—"Oh! look at all these fine materials coming in. How wonderful—now we have a chance to get rid of this old garbage and build a beautiful new house. Let's get this excess bile out of the liver and gallbladder and send it to the intestines for elimination. Let's get this sludge moving out of the arteries, veins and capillaries. These smelly, gassy brain-stupefying bowel masses have been here too long—out with them. These arthritic deposits in the joints need cleaning up. Let's get these irritating food preservatives, aspirins, sleeping pills and drugs out of the way, along with these other masses of fat which have made life so burdensome for us so long. Let's get going and keep going till the job is done—till we have a beautiful house and from then on we'll keep it a beautiful, ideal model house."

[Home](#) > [Lesson 21 - Symptoms During Dietary Transition](#) > Article #2: The Three Phases Of Metabolism

## **Article #2: The Three Phases Of Metabolism**

### **First Phase: Drastic Weight Loss**

During the first phase (called *catabolism*), the accent is on elimination, or breaking down of tissue. The body begins to clean house—to remove the garbage deposited in all the tissues—everywhere. During this period the body "removes the ashes from the furnace preparatory to getting a better fire." Here the accentuation is on removal of the gross and immediate body obstructions. Wastes are discarded more rapidly than new tissue is made from the new food. This becomes evident as weight loss. This persists for a while and is then followed by the second phase—called stabilization.

Here the weight remains more or less stable. During this phase the amount of waste material being discarded daily is equal to the amount of tissue which is being formed and replaced by the newer more vital food. This occurs after the excess of obstructing material in the tissues has been removed. This stage persists for a while and is then followed by a third phase—a building-up period (called *anabolism*) wherein weight starts to go up, even though the diet is lower in calories than it was before. At this point, much or most of the interfering wastes have already been discarded—the tissues which have been formed since the diet was raised in quality are more durable and do not break down easily.

Also, new tissues are now being formed faster. This is due to the improved assimilation and increase of enzyme efficiency which resulted from the recuperation of the digestive mechanism—made possible by the ceasing of wrong food combining. The body's need for the usual amounts of food decreases and we are able to maintain our weight and increased energies with less food. Many are able to function very efficiently on two meals a day and eventually even on one meal a day. As the body progressively increases in efficiency and decreases in tissue breakdown under exercise, so do we gradually need less and less food to maintain life. The higher the percentage of raw food one lives on, the slower the rate of tissue degeneration which one evolves into. A sick body requires a gradual, carefully-worked-out entry into this stage—where one is able to live on a 100% unfired (raw) diet.

Returning to the symptoms which occur on a superior nutritional program—people who have had

tendencies in the past to recurring skin rashes or eruptions will frequently tend to eliminate poisons and harmful drugs through the skin with new rashes or eruptions. If they go to a physician now who is not familiar with this aspect of nutrition, he will diagnose it as an allergy. They ask, "How come I'm eating better now than I did before and instead I'm getting worse?" They don't understand that the body is "retracing." The skin is getting more alive and active. It's throwing out more poisons more rapidly, now that the body has more power, which is saved by the discontinuation of those hard-to-digest meals. These toxins being discarded are saving you from more serious disease, which will result in-if you keep them in your body too much longer-possible hepatitis, kidney disorder, blood disease, heart disease, arthritis, nerve degenerations or even cancer-depending upon your structural weaknesses. Be happy you're paying your bills now on an easy-payment plan.

With some, colds which haven't appeared for a long time may occur, or even fevers. *This is nature's way of housecleaning.* Understand that these actions are constructive, even though unpleasant at the moment. *Don't*—but *don't* try to stop these symptoms by the use of certain drugs, or even massive doses of vitamins, which will act as drugs in huge concentration. These symptoms are evidence of a remedial process. Don't try to "cure" the remedial process! These are *not* deficiency conditions or allergic manifestations—*not* if you're eating properly in quality, quantity, combination and sequence. Here is where experienced advice is of great value. Unfortunately there are few books present today which give full guidance to the average reader. Try to find guidance through a doctor or teacher who has the requisite experience in this most confusing of all subjects-nutrition in relation to health and disease.

### **Body Purification Can Be a Long Drawn-Out Process**

You may be eating perfectly in quantity, quality and observing all the correct rules, and still symptoms will occur. Those who have lived better lives in the past—who have eaten better foods and who have abused their bodies less with overeating, will have reactions ranging from almost none at all, or very mild, to symptoms which may be uncomfortable or acute. Those who have lived worse lives and poisoned themselves more will experience more severe symptoms if their liver, kidneys or other important eliminating organs have been damaged. When they have been renovated to the point of fair working order, they will no longer produce symptoms.

Headaches may occur at the beginning. Fever, colds, the skin may break out, a short interval of bowel sluggishness, occasional diarrhea, feelings of tiredness or weakness, disinclination to exercise, nervousness, irritability, negativity or feeling mentally depressed, frequent urination, also may occur. However, the great majority of people find their reactions tolerable and are encouraged to bear with them because of the many improvements which have already occurred and are becoming more evident with each day. This acts as an inspirational force to them.

The symptoms will vary according to the materials being discarded, the condition of the organs involved in the elimination and the amount of energy you have available. The more you rest and sleep when symptoms are present, the milder they are and the more quickly they are terminated. Be happy you are having symptoms. *Realize deeply* that your body is becoming younger and healthier every day because you are throwing off more and more wastes which would eventually have brought pain, disease and much suffering. Those who have the worst symptom-reactions and follow through to their successful termination, are thus avoiding some of the worst diseases which would have eventually developed had they continued their careless eating habits.

### **Blissful State of Health Comes Eventually**

Don't expect to go on an ascending scale of quality improvement in the diet and think you will feel better and better each day until you reach perfection. The body is cyclical in nature and health returns in a series of gradually diminishing cycles. For example—you start a better diet and for a while you feel much better. After some time, a symptom occurs, you may feel nauseous for a day and have a diarrhea with a foul-smelling stool. After a day you feel even better than before and all goes fine for a while.

Then you suddenly develop a cold, feel chills and lose your appetite. After about two or three days (assuming you don't take drugs or do anything else about it) you suddenly recover and feel better than you did for years. Let us say this well-being continues for two months, when you suddenly develop an itch or rash. You still don't take anything special for it. This rash flares up, gets worse and continues for ten days and suddenly subsides. Immediately after this you find your hepatitis is gone and your energy has increased more than ever before. The rash became an outlet for the poisons in the liver which produced hepatitis. This is how recovery occurs, like the Dow-Jones Average at the beginning of a bull-market recovery. You feel better, a reaction occurs and you don't feel as well for a short while. You recover and go even higher. And so it goes, each reaction milder than the last as the body becomes purer, each becoming shorter in duration, feeling better than ever before and lasting longer, until you reach a level plateau of vibrant health. Here you become relatively disease-free and are filled with ever-increasing joy, life and the happiness which comes from sheer well-being. The mind opens up and expands to ever-higher horizons and your soul will shout for joy. You begin to love the world, the universe and everything in it. This is the natural state of the mind—blissful, joyful and at peace with the universe—and it can only be attained by alignment with biological laws. The first laws we must learn to obey are the laws of Nature. We must learn to eat simple, pure and natural J foods properly prepared and combined, and our bodies in return will cast off the evil we have taken in during our lives.

Nowhere is the principle of forgiveness of sins more manifest than here—in our own bodies—when we forsake our evil and destructive ways of eating (the defiling of the temple of the soul). God (or Nature, if you please) gives us a whole new chance for a new glorious life. All repentance must begin here in the body, through purer diet and natural foods. Then, just have faith, sit back and watch what happens. Before your own eyes, you will see signs daily that will cause you to wonder at this vast intelligence in operation that staggers the comprehension. The mysteries of the body, the operations of Nature, the vital forces working in Nature and the Cosmos are far beyond what our minds are prepared to understand at present.

Every great physician or scientist who ever lived marvelled in awe and humility at the wonders of Nature. Yes, we are, "Fearfully and Wonderfully Made." Let us give ourselves a chance to experience what it means to be really healthy and fully *alive*—to feel the joy of living by aligning ourselves to (God's) Nature's laws as intended for man, through the eating of natural (normal) foods. This indeed is the prime prerequisite in man's physical, mental and spiritual unfoldment.

### 1. The Basis Of The Food Combining System

#### **1. The Basis Of The Food Combining System**

The food combining system, as a whole, is simple and easy to understand. It logically evolved from the study of gastric physiology and the actions of enzymes and digestive juices. Hygienic food selection and the principles of food combining are based on the nutritional needs of humans and the limitations of our digestive systems. It is not what we eat, but what we digest and assimilate, that determines the nourishment our bodies receive. Food combining is based on the discovery that certain combinations of food may be digested with greater ease and efficiency than others.

Correct food combinations result in an immediate improvement in health by lightening the load of the digestive organs. Better nutrition is assured, and there is better digestion, less fermentation and putrefaction, more comfort, less distress and less gas. So-called food allergies often disappear as a result of proper food combining. (See article in the Case History section of this lesson. This article was written by Richard Hill, a young man who had to learn the hard way.)

Fermentation causes irritation and poisoning. Proper food combining removes fermentation as a cause of indigestion (though there are many other conditions that can cause digestive problems, such as overeating; eating hurriedly or when tired, worried, angry, fearful, grieved, etc.; or when you are in pain or have a fever or inflammation).

The successful results obtained through the utilization of the food combining rules can be explained and substantiated by the facts of physiological chemistry, particularly the chemistry of digestion.

No food program, nor any food combining program, will cure disease. Healing can be effected only by removal of the causes of disease. Incorrect food combinations can be an important cause.

## 2. What Is Food?

### 2. What Is Food?

Food is any substance which is eventually convertible into such end-products as tissues, body fluids, etc., and can be utilized by the organism in the performance of its functions. To be correctly classified as a food, a substance must:

1. Be capable of liberating energy when oxidized;
2. Be capable of being utilized for growth, maintenance and repair;
3. Be capable of being stored within the body and
4. Produce no nutritionally significant toxic effects

For example, some plants contain large amounts of oxalic acid (see definition) and should not be used as food. Many plants which contain smaller (nutritionally insignificant) amounts of oxalic acid are excellent foods. On the other hand, tobacco, which is a plant, contains proteins, carbohydrates, minerals, vitamins and water, which are the constituents of food. But tobacco also contains considerable quantities of poisons. Dr. Shelton says that one of these is one of the most virulent poisons known to science. Therefore, tobacco cannot be a food.

Nutrients in foods are chemical substances of known composition and structure, classified as carbohydrates (such as sugar, starch and glycogen); lipids (fats); proteins (amino acids linked together); salts (minerals); and vitamins, needed in small quantities (or, traces) by the body. In addition, foods contain indigestible materials—cellulose (fiber).

Water, oxygen and vitamins, together with proteins, carbohydrates, fats and minerals, form the constituents of the body—the blood, tissue, bones, organs, muscles and so forth. Foods must be taken into the digestive tract and prepared for use by the organism before their constituents may be used by the body.

### 2.1 The Best Food Is Raw Food

In our discussion of food combining, cooked foods and flesh foods will be mentioned. Uncooked foods from the plant kingdom constitute the ideal Hygienic diet, for those not yet ready to use exclusively raw plant foods, information on food combining of other foods is included.

People with impaired digestion may have been advised to avoid raw food. If serious pathological conditions exist, or if there are organic limitations caused by surgery, it would probably be advisable for such people to seek the help of a Hygienic doctor. Most such people can be helped by Natural Hygiene, but some of them may need careful supervision in changing from conventional eating and living patterns.

People whose digestive impairments limit the use of uncooked food should utilize raw foods to whatever extent they can while they aim for restoration of as much normal function as possible. The rational approach to such restoration of normal function is not drugs or surgery, but rest and fasting, followed by a gradual implementation of improved eating and living practices, adapted to the limitations of that individual.

The goal should be the gradual achievement of a diet predominating in uncooked foods, because the nutrients available in raw foods are several hundred percent greater than those remaining after food has been cooked or otherwise processed. *More details about the damage done by cutting, cooking, seasoning and flavoring food will be given in future lessons.*

Raw foods improve the total inner environment. Sluggish bowels begin to move, eventually cleaning out waste that may have been lodged in the folds of the intestine for months. The layer of mucus that forms

in the intestines when cooked food predominates is removed, greatly increasing efficiency in the absorption of nutrients. Food wastes don't stay in the bowel long enough to putrefy. The transit time of raw food in a healthy body is 20 to 24 hours, while cooked food may take three days or longer.

Many scientific researchers and medical doctors now, recognize the value of raw food, both in health maintenance and for improvement or remission in chronic illnesses.

John M. Douglass, M.D., internal medicine specialist at the Southern California Permanente Medical Group in Los Angeles says, "It's a sad commentary that we think we can compensate with a pill for all the heat-labile nutrients and enzymes that are lost in cooking." He says also that experience shows that the raw food diet works for many diabetics, although it's not always easy for them to follow and must be planned carefully.

Dr. Paul Kouchakoff, medical researcher of the Institute of Clinical Chemistry, Lausanne, Switzerland, revealed circa 1930 that after eating cooked food, the human body develops leucocytosis, the abnormal proliferation of white blood cells. Leucocytes are created and rushed to the intestine. When he fed patients on an 80 percent raw diet, no leucocytosis developed.

More details about Dr. Kouchakoff's experiments, and other reports about the phenomenally superior value of raw food, will be given in future lessons. The above preliminary information is included in this lesson so the student may, at the outset, be motivated to apply his newly-acquired knowledge of food combining principles to the best food available, which, undeniably, is food that is utilized in its unchanged raw state.

*The 80 percent raw food diet:* For those who are not yet ready, or willing, to change to an all-raw diet, a good start would be the achievement of an 80 percent raw diet. For most people, this is not difficult to achieve. It can be appetizing, interesting, varied, satisfying and economical. The information in the two lessons on food combining will contain all the details you need about utilizing both raw food and (if you use it) cooked food, so that you may work out your goal of eventually achieving an all-raw diet, even if you must take a roundabout route by first implementing the 80 percent raw diet.

The best and quickest way to achieve an 80 percent raw diet is to never eat cooked food more than once a day, and as part of only one meal. One should try for more and more days on raw food only. Even the people who are coping with digestive problems may eventually achieve these goals as they learn to apply the principles of Natural Hygiene to their own needs.

## 2.2 Food Classification

Foods vary widely in character and nutritional constituents. In order to intelligently implement the principles of food combining, reference points are necessary. A food classification chart will be included with Lesson No. 23, listing and classifying specific foods. In this current Lesson No. 22, we will classify the broad categories in which foods can be placed. This classification of food categories will provide clarification and greater understanding of our discussion of the principles of digestive physiology and chemistry that decree correct food combining.

*Proteins:* All foods contain some protein, and the amounts of protein in different foods vary widely. We classify as protein foods those that contain a comparatively high percentage of protein—these are the concentrated protein foods. Such foods include:

1. Nuts and edible seeds
2. Soybeans
3. Animal proteins
4. Cheese
5. Eggs
6. All flesh foods (except fat)

The less concentrated proteins include avocados, olives, coconuts and milk. Combination foods (starchy

proteins, to be combined as starch) include legumes, grains, peanuts and chestnuts: Green vegetable proteins (to be combined as starch) include peas in the pod, lima and other beans in the pod, and mature green beans in the pod. Sprouts contain significant amounts of protein, especially in the early stages. (More about sprouts later in this lesson and in Lesson No. 23)

Bananas (1.1 percent) contain almost as much protein as avocados (1.3-2.2 percent) and olives (1.4 percent). Dried fruits (2-5 percent) may contain twice as much protein as avocados. Broccoli (3.6 percent), brussels sprouts (4.9 percent), collards (4.8 percent), sweet corn (3.5 percent), kale (6 percent) and a number of other vegetables contain more protein than avocados. Romaine lettuce (1.3 percent) contains valuable protein. None of these foods are classified in the protein category, but should, nevertheless, be regarded as excellent sources of protein.

*Starches:* The carbohydrates are the starches and sugars. The combination foods (starchy proteins) referred to under the protein category are classified as starches for purposes of food combining. These include dried and fresh legumes, grains, peanuts and chestnuts. The starchy vegetables are potatoes, mature corn, parsnips and salsify, as well as Jerusalem artichokes; the mildly starchy vegetables are carrots, globe artichokes, beets, winter squash and several others (complete list in the classification charts in Lesson No. 23).

*Nonstarchy and green vegetables:* Lettuce, celery, cabbage, broccoli, summer squash, turnips, green beans, kale and a long list to be found in the classification charts.

*Fats:* The recommended fats are nuts, seed and avocados. No other fats are recommended. (See charts)

*Fruits:* Divided into three categories—sweet fruits, subacid fruits and acid fruits. Bananas, persimmons, sweet grapes and fresh figs, as well as all dried fruit, are in the sweet fruit category. Sweet apples, sweet peaches, pears, sweet cherries, some grapes and several other fruits are subacid fruit. Citrus, pineapples, strawberries and all tart fruits are in the acid fruit category. (See classification charts for complete listings.)

*Tomatoes:* Acid fruit without the sugar content of other acid fruits. Used with vegetable salad or any green nonstarchy vegetables, but not at a starch meal. May be used with nuts or seeds, as well as with avocados.

*Melons:* Watermelon, canteloupe, honeydew and many others. (See charts)

*Syrups and sugars:* All kinds of sugar, syrup and honey—not recommended.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) >  
3. The Chemistry And Physiology Of Digestion

### **3. The Chemistry And Physiology Of Digestion**

For food to be utilized by the body, it must first undergo a series of processes which we call digestion. After we perform the only really voluntary actions involved in the process of nutrition—putting the food into our mouths, chewing and swallowing—the balance of the digestive process is the function of the autonomic or involuntary nervous system.

The changes which foods undergo are largely effected by enzyme and digestive juices. The conditions under which "such action" can occur are sharply defined, and this is the logical foundation of the food combining system. Physiologists have ascertained the details of the chemistry of digestion through long and painstaking labors. It has remained for the Natural Hygienists to make practical application of this great fund of vital knowledge. Knowledge of the physiology and chemistry of digestion can lead us all

to a food program that will insure better digestion and better nutrition.

### 3.1 Enzymes

Enzymes are proteinaceous organic catalysts in all living organisms, both plant and animal. Our digestive juices contain enzymes that accelerate chemical reaction by catalytic action, without themselves being used up in the process.

Digestive enzymes can be used over and over again but eventually are replaced by the body. There are many different kinds of enzymes, and digestive enzymes are not the same as the enzymes in raw, unprocessed food. Digestive enzymes break down the complex substances we ingest into simple components that can be utilized by the body.

There are five types of digestive enzymes in the human body.

1. *Hydrolases* facilitate hydrolysis, the breakdown of substances in water within the body.
2. *Adding enzymes* build proteins by adding amino acids, one by one.
3. *Transferring enzymes* transfer organic substances from one compound to another so the body may use them in various ways.
4. *Isomerases, or rearranging enzymes*, rearrange molecules in organic substances; they also rearrange amino acid enzymes.
5. *Oxidases, or oxidizing enzymes*, are released in the presence of oxygen and rapidly bring about a change in the color of food. They act on foods in the mouth while one is masticating or whenever the food is exposed to oxygen. These enzymes are also present in apples and other fruits. They are released when the fruit is cut and react so as to rapidly bring about, a change of color to brown.

It is not necessary to memorize the names of these enzymes, but the information about the, action of the different types of digestive enzymes will help you to understand the underlying rationale of food combining.

Each digestive enzyme is specific in its action. It acts only upon one class of food substance. Each stage in the digestion of food requires the action of a different enzyme, and the various enzymes can perform their work efficiently only if the preceding work has been properly performed.

Body chemistry is, to a large extent, determined by the the food we eat. When certain foods are eaten regularly, the digestive enzymes and secretions are of a character to handle those foods. When the diet is altered, more and more of the digestive juices secreted will be of a character to digest the foods in the new diet, and less and less of the digestive juices will be of the character to digest the foods in the old diet.

The type of digestive juice fitted for the digestion of one type of food is of no value in digesting another type of food. Therefore, it is essential that food be taken in combinations that do not interfere with enzymatic action.

### 3.2 The Process of Digestion

Digestive speed and efficiency vary with individuals and circumstances. However, certain general statements can be made. Fruits pass through the stomach quickly; low-protein and low-starch vegetables also pass through the stomach rapidly, with little change; vegetables containing much starch must be retained in the stomach longer, for more thorough digestion; and proteins require a still longer time »for gastric digestion. Fruits may remain in the stomach for thirty to sixty minutes, low-protein and low-starch vegetables a little longer, concentrated starches about two hours and concentrated proteins approximately four hours. Some foods may take five or six hours or more to leave the stomach. Some examples are combination starch/protein foods like legumes (including beans), grains, cooked cabbage and flesh foods.

Most digestion occurs in the stomach and small intestine. Digestion, especially starch digestion, actually begins in the mouth, with mastication and insalivation of the food. This sends the proper signals for the release of the digestive juices suited to the character of the food eaten. Digestive juices are present in the saliva and in the gastric secretions of about five million microscopic glands in the walls of the stomach.

The digestive glands supply different enzymes and juices of varied strength and character and with specific timing, depending on the different foods ingested. The digestive juices may be more or less liquid, of varying degrees of acidity or alkalinity and with complex and elaborately contrived variations.

After food is masticated, insalivated and swallowed, gastric digestion is initiated. Involuntary movements of the stomach slowly mix the food with gastric juices secreted by the glands in the walls of the stomach. Pepsin, a protein-splitting enzyme, and hydrochloric acid are secreted, as well as lipase, a fat-splitting enzyme, mucus and diluting juice, along with other factors needed in the digestive process. An alkaline secretion protects the walls of the stomach from the acids. Mucus is a natural lubricant that is secreted by the cells of the mucous membranes lining all of the hollow organs of the body. It keeps the body tissues moist and prevents them from drying and cracking.

A brief review of the process of digestion will help in understanding the food combining rationale. Gastric secretion is continuous (except during fevers, gastric inflammation, pain or strong emotions; fasting is indicated when any of these conditions are present). Of course, gastric secretion is unnecessary when no food is taken.

Hunger and the sight, smell, taste or thought of food stimulate gastric secretion. Usually about three pints of gastric juice is secreted every twenty-four hours and about half this amount is required to digest a hearty meal. If you eat more than two hearty meals daily, your account will be overdrawn.

As the process of digestion continues in the stomach and the food is mixed with the digestive juices, water (from the body's reserve supply) is added to the mixture in a process called hydrolysis. During hydrolysis, digestive enzymes separate carbohydrates into simple sugars, and proteins into their constituent amino acids.

Since digestion is a mechanical as well as a chemical process, some cellulose is an important part of the diet. Although cellulose cannot be digested by humans (no enzyme secreted by humans is capable of splitting cellulose), it serves as bulk in the propulsion of food through the digestive tract. Cellulose also provides the bulk needed in the efficient elimination of food residues. Juices and refined foods contain little cellulose. However, too large a quantity of cellulose is also undesirable. Therefore, we should use fresh fruits and, when using vegetables, strive to obtain the young, tender vegetables, as these contain smaller amounts of cellulose.

Food residues, fibrous materials and particles not thoroughly masticated proceed on to the colon. Peristalsis (wave-like muscular contractions) propels the food mixture back and forth in the stomach. Periodically, the most liquid portion of the mixture is discharged into the duodenum where it meets a very acid fluid. The resultant semi-liquid mixture, known as chyme, then proceeds further—into the small intestine—where it meets a very alkaline mixture of pancreatic juice, additional digestive enzymes and bile. (Bile is secreted by the liver and stored in the gallbladder to be used when needed, particularly for emulsifying fats).

The intestinal glands secrete a juice containing enzymes similar to pancreatic enzymes. Virtually all absorption should occur by the time the food passes through the small intestine, and the residue proceeds into the large intestine (the colon).

Through all these processes, the peristaltic contractions continue, longitudinally and circularly, and propel the chyme along the alimentary canal. As you can see, foods are not digested when they have passed out of the stomach. A large part of the work of digestion takes place in the small intestine. But the role of gastric digestion is an important one in preparing the food for the next stage in the digestive process.

Coffee, tea and other such toxic infusions cause a premature emptying of the stomach and thus cause foods to leave the stomach before gastric digestion is complete.

Digestion is governed by physiological chemistry, and this must be considered in the planning of meals that are compatible with the physiological limitations of the digestive glands and their secretions. This lesson will help in understanding the principle that the digestion of different foods requires digestive juices of different characters.

The study of the processes of digestion reveals the specific action of the digestive enzymes, the careful timing of their secretion and the adjustment of the strength and character of the digestive secretions to the character of the food upon which they are to act. Carbohydrate foods receive a juice rich in carbohydrate-splitting enzymes, protein foods receive protein-splitting enzymes, and so forth.

### **3.3 Starch Digestion**

Starch digestion begins in the mouth with the action of the enzyme ptyalin (alpha amylase) which converts (or else begins the process of converting) starches into sugar during mastication and insalivation. The salivary secretions accompany the food to the stomach and salivary digestion of starches continues in the stomach for a long time, if the food was eaten under correct conditions.

If ptyalin is the only agent in the body capable of initiating starch digestion (and this is not certain), or whether it is simply the body's first opportunity to initiate starch digestion, we must not disregard its importance. The chewing process in the mouth should mix food with saliva, but people have the tendency to swallow the mass too quickly to permit the enzyme to complete its action. This necessitates the continuation of the salivary action in the stomach.

It is important that starches be eaten dry, not moist. So, you should eat steamed or baked potatoes dry rather than in potato soup. The eating of liquids with starches promotes the tendency to swallow moist starch without thorough mastication, insalivation and emulsification, processes that are particularly needed for the digestion of starches. Drinking liquids or eating liquidy foods softens the food artificially and may also cause you to eat more food than if you had eaten it dry. Drinking at meals dilutes the digestive juices and also prevents thorough mastication and insalivation of the food.

If the ptyalin is destroyed or its action is inhibited and the digestion of starch is interrupted, the partially digested (and probably somewhat fermented) starch proceeds to the duodenum, where further starch-splitting enzymes are secreted. Starch that escapes digestion in the stomach may later be acted upon by pancreatic and intestinal enzymes, provided too much fermentation has not already occurred. It is also very possible that the interrupted gastric digestion may never be completed.

Ptyalin requires either an alkaline or neutral medium. Ptyalin is destroyed by even a mild acid. If fruit acids—or any acids—are taken with carbohydrates, especially with such as potatoes, beans, bananas or dates, digestion will be inhibited or prevented and fermentation may occur. Oxalic acid diluted to one part in 10,000 completely arrests the action of ptyalin. Significant amounts of oxalic acid are contained in rhubarb, spinach, Swiss chard, beet greens and purslane.

The acetic acid in a teaspoonful of vinegar can suspend salivary digestion. Tannic acid (in coffee and tea) inhibits starch digestion, as do drug acids. The combination of citric, malic and oxalic acids in tomatoes (which are released and intensified by cooking) interferes drastically with starch digestion.

People take oranges and grapefruit as part of a meal that includes cereal and/or bread, later complain that they feel great distress after such a meal and conclude that they cannot eat citrus fruit. Such a conclusion is based on their experience of a wrong combination—not of a wrong food. Fermentation frequently does occur as a result of eating acids with carbohydrates. All students of food combining know that this combination produces bad effects such as gas, sour stomach (hyperacidity) and contributes to great difficulty in digesting starches.

When foods are eaten in such incompatible mixtures, and the efficiency of digestive enzymes is

inhibited, it is subjected to decomposition in the digestive tract. If the digestive enzymes cannot perform their intended functions of breaking down and hydrolyzing the food (adding water from the body's reserve supply), bacterial decomposition may occur, resulting in fermentation and the production of alcohol and acetic acid. Sugar, particularly, will readily ferment into alcohol, especially when combined with acids or protein. Natural combinations of citric acid or malic acid or other natural fruit acids combined in the whole fruit with fructose (also called levulose or fruit sugar) do not cause fermentation unless eaten with starches.

*Alcohol, acetic acids and putrefying substances* are byproducts of decomposition.

*Putrefaction* may be defined as the decomposition (as opposed to digestion) of protein matter by microorganisms, producing malodorous and toxic substances.

*Fermentation* is the decomposition of sugar and starch, and their conversion by microorganisms into carbon dioxide, alcohol and acetic acids. Dr. Shelton says that digestion reduces food to the diffusible state without depriving it of its organic qualities, while fermentation renders food diffusible by reducing it to an inorganic and useless state. Digestion puts food in a solution, but fermentation disintegrates it.

A simple way to avoid production of these poisonous substances in the digestive tract is to learn, and implement, the Hygienic rules for food combining. They are perhaps of even greater importance than food selection. Persistent adherence to food combining principles has been known to reduce, or even eliminate, many digestive, nasal, skin and other problems, even in some people who have not changed to the Hygienic diet. It is obvious that elimination of incompatible food combinations is a giant step in the right direction. Efficient digestion and good health can be possible only when we eat in such a way as to offer the least hindrance to the work of digestion.

### **3.4 Protein Digestion**

The digestion of carbohydrates is so different from that of protein that, when they are mixed in the stomach, they interfere with the digestion of each other. Protein digestion starts in the stomach and acid enzymes are secreted when protein is eaten. Proteins require an acid medium for digestion so, upon ingestion, hydrochloric acid is secreted in order to activate pepsinogen; this immediately stops the digestion of starches.

Almost all foods contain some protein but, when we speak of protein foods in our study of food combining, we are referring to concentrated proteins like nuts and seeds, cheese, flesh foods, etc. (See Classification of Foods in Lesson No. 23 for help in identifying concentrated protein foods, concentrated carbohydrate foods, etc.)

The normal digestion, absorption and metabolism of protein requires thorough mastication of food, in order to break it down for propulsion through the digestive tract, and for action by the digestive enzymes. As previously indicated, hydrochloric acid and pepsin (and other acid gastric juices) are secreted for the initial phases of protein digestion in the stomach, and other enzymes, such as trypsin, continue the digestion in the small intestine in a slightly alkaline medium. Protein-digesting enzymes are also secreted by the pancreas.

Before the body can use proteins, they must be reduced to their constituent amino acids (the building blocks of protein). The body must break down the complex proteins in foods and synthesize its own protein out of the amino acids. Food combining rules are of major importance in the consumption of protein, since the complexity of this food element would seem to suggest that it be eaten only under ideal conditions.

Free hydrochloric acid to the extent of only 0.003 percent is sufficient to suspend the starch-splitting action of ptyalin. Only a slight further increase in acidity not only stops the action, but destroys the enzyme. All physiologists agree that even a mild acid destroys ptyalin. It has never been shown that saliva is capable of digesting starch without the presence of ptyalin.

The function of the gastric protein-splitting enzymes, such as pepsin, are prevented by an alkali. The physiologist Stiles says, "The acid which is highly favorable to gastric digestion is quite prohibitive to salivary digestion. The power to digest proteins is manifested only with an acid reaction and is permanently lost when the mixture is made distinctly alkaline. The conditions which permit peptic digestion to take place are, therefore, precisely those which exclude the action of saliva."

The presence of undigested starch in the stomach interferes with the digestion of protein. Physiologists have shown that undigested starch absorbs pepsin, which is necessary for the digestion of protein.

Dr. Richard C. Cabot of Harvard wrote: "When we eat carbohydrates, the stomach secretes an appropriate juice, a gastric juice of different composition from that which it secretes if it finds proteins coming down."

### **3.5 Combination Foods**

Single articles of food that contain starch-protein combinations (grains, legumes, and a few others) are less difficult for the body to handle than when two foods are eaten with opposite digestive needs. The body is able to adjust its juices, both as to strength and timing, to the digestive requirements of combination foods. The first response by the body is the releasing of an almost-neutral juice for digestion of the starch. After gastric digestion of starch is completed (about two hours), hydrochloric acid is secreted for digestion of the protein. The two processes do not go on simultaneously—rather, the secretions are minutely adjusted, in both character and timing, to the varying needs of the body to digest the complex food substance.

Such complex food substances are not ideal foods. They are usually cooked, and the fact that they require such complicated adjustments puts an additional strain on the body. Simple uncooked foods are easier for the body to process and offer the least hindrance to the work of digestion.

Beans: "Because of their complex character, beans, a protein-starch combination, tax the digestive powers more than simpler foods, but the gas, discomfort and other trouble that so commonly follow, eating them is not due so much to the beans themselves as to the company they keep. Baked beans are preferable to beans that are boiled and taken saturated with water. If taken thus relatively dry, well chewed and eaten in proper combinations, beans are readily digestible." This article about beans, which was published by Dr. Shelton in 1971, is evidently a somewhat revised opinion. In his Volume II of *The Hygienic System*, published in 1935, he suggested that beans should not be used.

I personally was formerly unable to tolerate lentils or beans of any kind, even when sprouted. I eliminated all legumes from my diet for about six months, after which I carefully experimented with small amounts, properly combined, until I seemed to build up my ability to digest them. Today I can eat sizeable servings of cooked or sprouted legumes (which I seldom do) and I have no problem with them.

### **3.6 Foods with Different Digestive Requirements**

When two foods are eaten that have different or even opposite, digestive needs, the precise adjustment of digestive juices to meet requirements becomes impossible. Eating proteins with carbohydrates (sugar or starch) produces the same abortive situation as combining acids with carbohydrates, since protein digestion requires the secretion of acid enzymes and juices. All acids, including those in food and the acid protein-digesting juices, destroy ptyalin, the starch-digesting enzyme.

Arther Cason, M.D., D.P.H., F.R.S.A. (London), writing in the April, 1945 issue of *Physical Culture*, mentions two groups of experiments made by him and his aides which showed that eating protein and carbohydrate at the same meal retards and even prevents digestion. He made control tests in which digestive rates were recorded, and a final analysis of the feces was made. He says, "Such tests always reveal that the digestion of proteins when mixed with starches is retarded in the stomach; the degree varying in different individuals, and also in the particular protein or starch ingested. An examination of

the fecal matter reveals both undigested starch granules and protein shreds and fibers, whereas, when ingested separately, each goes to a conclusion."

As indicated by Dr. Cason, there is an individual variation in the response to certain food combinations. This would seem to account for the fact that certain people exhibit overt symptoms from the use of certain food combinations, while others do not. However, the mere fact that overt symptoms are not observed is not proof, per se, that the food is being properly utilized.

Potatoes are said to be the least objectionable of any starch to be used with protein. Dr. Shelton is of the opinion that it is the rapidity with which potato starch digests that makes its combination with protein less objectionable than the combination of other starches with protein. Potato starch digests in ten minutes under ideal conditions and it would seem that the potato starch digests before the gastric juice can accumulate in quantity sufficient to interfere.

Even so, Hygienists have rarely been observed to use potatoes with nuts—either potatoes or nuts are so satisfactory as, an accompaniment to a salad that most of us would ask, "Why would we need both?"

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) >  
4. Food Combining Rules

## 4. Food Combining Rules

### 4.1 Acid-Starch Combinations and Protein-Carbohydrate Combinations

The preceding discussion leads up to the presentation of the first two food combining rules, which I consider to be by far the most important of all these rules and the ones which should be thoroughly understood and implemented at all possible times.

1. *Never eat carbohydrate foods and acid foods at the same meal.*
2. *Never eat a concentrated protein and a concentrated carbohydrate at the same meal.*

The purpose of this lesson is to help you to understand the reasons for these rules; Lesson No. 23 will help you to learn to implement them.

### 4.2 Protein-Protein Combinations

3. *Never consume two concentrated proteins at the same meal.*

Two concentrated proteins of different character and composition (such as nuts and cheese) should not be combined. Gastric acidity, type, strength and timing of secretions for various proteins are not uniform. Since concentrated protein is more difficult to digest than other food elements, incompatible combinations of two different concentrated proteins should be avoided. Some people with impaired digestions find it necessary to limit themselves to only one variety of nuts/and or seeds at a sitting, but other people may find, upon experimentation, that two or three varieties of nuts or seeds may be used at the same meal, if desired.

### 4.3 Protein-Fat Combinations

4. *Do not consume fats with proteins.*

Our need for concentrated fat is small and most protein foods already contain a good deal of fat. Most nuts contain about 10 percent to 20 percent protein, and about 45 percent to 70 percent fat. Avocados

contain about 1.3 percent protein (Florida varieties) to about 2.2 percent or a little more (California varieties) and 11 percent to 17 percent fat. Most other protein foods are high in fat, including cheese, eggs and flesh foods. The only protein foods not high in fat are legumes, skim milk cheese and lean meat.

Fat has an inhibiting influence on digestive secretion and lessens the amount and activity of pepsin and hydrochloric acid, necessary for the digestion of protein. The fat may lower the entire digestive tone more than 50 percent. Since most proteins already contain a good deal of fat, it would certainly be contraindicated to add more to the meal.

#### **4.4 Fats in Combination with Other Foods**

##### *5. Use fats sparingly.*

Fats also delay the digestion of other foods and, if used with starch, it will delay the passage of the starch from the stomach into the intestine. Fat not only inhibits the secretion of gastric juice—it also inhibits the physical actions of the stomach. Too much fat taken with a meal results in acid eructations and a burning sensation in the throat. When fats (avocados or nuts) are eaten with green vegetables, preferably raw, the inhibiting effect of fats on gastric secretion is counteracted and digestion proceeds quite normally. The use of fat (avocados) with starch is considered acceptable, provided a green salad is included in the meal.

*Avocados:* Though not a high-protein food, avocados contain more protein than milk. They are high in fat and the small percentage of protein they do contain is of high biological value. They are best used with a salad meal. Since they are so high in fat that they tend to slow down the digestion of foods normally requiring a shorter digestion time, they are perhaps only a fair combination with subacid and acid fruit. They are usually considered a poor combination with sweet fruit, especially *dried* sweet fruit. However, let us consider some recent work on this subject.

In an article on this topic, Dr. Vetrano says that exceptions may sometimes be made in combining avocados with fresh sweet fruit, such as bananas, but that avocados should not be combined with dried sweet fruit, unless it has been soaked overnight. She also says, "Eating avocados with salad enhances their digestion. The next best combination for the avocado is taking it with subacid or acid fruit. The fat in the food does not seem to interfere with the emptying time of the stomach and we have excellent results with this combination. The protein, which is about 2.1 to 2.5 percent, is not sufficient to interfere with the digestion of fruit. It is even better when lettuce leaves and celery are eaten with the fruit and avocado. By diluting the fats and the sugars with the lettuce, the emptying time of the stomach is not depressed.

Those who have weak stomachs with poor muscle tone would probably do better by taking avocado only with vegetable salads. If lettuce is taken with a sweet fresh fruit and avocado, even these digest well. It is probably best to never combine avocado with sweet dried fruit unless it is just a small amount of both eaten with a great deal of vegetables."

Since the avocado is low in protein, it may also be used with potatoes or other starch foods. Some people like to use avocado with the potato instead of using butter. However, I must reiterate, the best way to use avocado is with the salad.

Avocados should never be used with nuts, which are also high in fat, nor should they be used with melons.

The only fats we have considered here are nuts (a protein/fat food) and avocados (a low-protein/fat food). Other fats will be listed in the food classification chart in Lesson 23, but they are not recommended for regular use. Most of them should never be used.

## 4.5 Acid-Protein Combinations

### 6. *Do not eat acid fruits with proteins.*

Citrus, (tomatoes: see discussion), pineapple, strawberries and other acid fruits should not be eaten with nuts, cheese, eggs or meat. Acid fruits inhibit the flow of gastric juice. The digestion of protein requires an unhampered flow.

This is one rule that has given rise to some disagreement and controversy. Although Dr. Shelton includes in this rule the prohibition of citrus and tomatoes with nuts and cheese, he goes on to say that nuts and fresh cheese do not decompose when used with acids, but have their digestion delayed. He also says that acids do not inhibit the flow of gastric juice any more than does the oil of nuts or the cream of cheese.

Many Hygienists use tomatoes with nuts and believe they cause no problem. Citrus fruits present a different situation, due to the sugar in the fruit, which can ferment if its digestion is delayed by the nuts. Various experiments with the use of citrus fruits combined with nuts have produced differing results. Some Hygienists continue to use citrus with nuts.

If sweet oranges are used at the same meal with nuts, the precaution of waiting thirty to sixty minutes after eating the citrus is sometimes observed. Grapefruit might be better suited to combining with nuts, since it usually has a much lower sugar content.

Citrus fruit is best used alone but may be combined with other acid fruits; nuts are best used with salad.

Dr. Shelton modified this rule somewhat on Page 52 of *Food Combining Made Easy*: "Although green vegetables form the ideal combination with nuts, acid fruits form a fair combination with these foods and may be taken with them."

Dr. Percy Howe, of Harvard, says: "Many people who cannot eat oranges at a meal derive great benefit from eating them fifteen to thirty minutes before the meal."

Dr. Vetrano is convinced from her experience at the Health School that nuts should not be used with citrus fruit and she discontinued this practice some years ago.

A corollary of this same subject is the use of some subacid fruits with nuts or cheese-primarily tart or semi-sweet apples, although some other fruits which are usually considered subacid are sometimes used in this way. The same principles would apply as with the use of oranges with nuts, provided the sweeter subacid fruits, such as Delicious apples, are not used.

Such acid-protein combinations as sour salad dressings and acid fruit drinks used at conventional meals serve as a check to hydrochloric secretion.

## 4.6 Sugar with Starch, Protein and Acid Fruit

### 7. *Do not combine sweet fruits with foods that require a long digestive time-foods such as proteins, starches and acid fruits.*

The sugars in sweet fruit should be free to leave the stomach quickly, in perhaps fifteen or twenty minutes, and are apt to ferment if digestion is delayed by mixture with other foods.

Sugar-starch combinations cause additional problems.

When sugar is taken, the mouth quickly fills with saliva, but no ptyalin is present. Ptyalin is essential for starch digestion. If starch is disguised by sugar, honey, molasses, syrup or sweet fruit, the signals are scrambled and digestion is impaired.

Monosaccharides and disaccharides ferment more quickly than polysaccharides. (See definitions) No digestion of sugars takes place in the mouth or stomach; fermentation is inevitable if sugars of any kind are delayed in the stomach awaiting the digestion of starch, protein or acid fruit.

Sugar also has a marked inhibiting effect on the flow of gastric juice and on gastric motility. No other

food depresses the action of the stomach and the desire for food as does sugar.

#### **4.7 Starch-Starch Combinations**

8. *Eat but one concentrated starch at a meal.*

This rule is probably more important as a means of avoiding the overeating of starches than as a means of avoiding bad combinations. But it is true that starch foods may differ greatly. If two different starches are eaten together in small quantities, this is thought to not cause problems.

Slightly starchy vegetables may be combined with more starchy vegetables (e.g. carrots with potatoes), but not with combination foods (starch/protein foods) such as grains and legumes.

#### **4.8 Acid Fruits, Subacid Fruits, Sweet Fruits**

9. *Acid fruits may be used with subacid fruits.*

This is an acceptable combination, though some subacid fruits are rather high in sugar and the acid fruit may delay the sugar's normally quick exit from the stomach. However, there is no sharp line of division between the acid and subacid fruits. If combining subacid fruit with acid fruit, it is better to use only the less subacid fruit.

The acid fruits are those with the tart flavors, for example, citrus, pineapple, strawberries, and certain varieties of apples and other fruits. Tomatoes are also considered acid fruit (without the sugar content of other acid fruit). Tomatoes should not be combined with subacid fruit, nor any other kinds of fruit.

They are best combined with the salad at a meal at which no starchy foods are served. Do not use acid fruits with sweet fruits, as previously indicated.

Acid fruits are best used alone (a single variety), but if used in combination with other acid fruits, this is considered an acceptable combination.

10. *Subacid fruits may be used with sweet fruits.*

There is no sharp line of division between subacid fruits and sweet fruits. When using subacid fruits with sweet fruits, it is best to use the sweeter varieties of subacid fruit. The subacid fruits are those that possess a slightly acid flavor (but not tart), such as pears, certain apples, grapes, etc. Grapes, for example, can be acid, subacid or sweet. The sweet fruits are those that are rich in sugar and taste sweet—bananas, persimmons, sweet grapes, and so forth, and all dried fruit.

Some people prefer to eat bananas alone, but most people have no difficulty in combining them with subacid and other sweet fruit at a fruit meal. Dr. Shelton says, "While I have found that bananas combine fairly well with dates, raisins, grapes and a few other sweet fruits and with green leafy vegetables, such as lettuce and celery, I have noted that they digest best if eaten alone. This calls, to mind the fact that Tilden, also, after much testing of the matter, reached the conclusion that bananas are best eaten alone."

Dried sweet fruits should be used sparingly. Use but one kind at a meal, in small amounts, combined only with subacid fruit and/or fresh sweet fruit and/or with lettuce and/or celery. Overeating of dried fruits will often bring on symptoms similar to a "cold". The sugar concentration is naturally greater in fruits which have been dried. Some dried fruits, esp. dried apricots, should be soaked overnight to replenish the missing water. Dates are usually used without soaking, figs or raisins can be used either way. If they are rather hard, soaking will soften and improve them.

Dr. Vetrano recommends using as little soaking water as possible, soaking one side at a time, so all water will be absorbed, thus avoiding losing flavor and nutrients. It is important that the water used for soaking be distilled water.

Sweet fruits combine fairly well with subacid fruits, provided the subacid fruits are on the "sweet side," for example, use Delicious apples, not Macintosh or Jonathans, with sweet fruit.

It is best to have these fruits at a fruit meal combining only with lettuce and/or celery. Since fruits are usually high in acids or sugars, they do not combine well with other foods.

## 4.9 Fruits with Vegetables

11. *Do not combine fruit with any vegetables except lettuce and celery.*

It is best not to combine fruits with vegetables (especially cooked vegetables), proteins or starches because if such a combination of food is eaten, the digestion of the fruit will be delayed and subject to fermentation. Lettuce and celery, however, may be combined with any fruit except melon, and will cause no problem.

Dr. Vetrano says, "Taking green uncooked vegetables with a fruit meal is perfectly all right. Even though some charts state that subacid and sweet fruits combine fair to poorly with green uncooked vegetables, the feeding practices at the Health School indicate that these are good combinations, indeed, even enhancing digestion of the fruit in some conditions of impaired digestion."

## 4.10 Salads

12. *Salads combine very well with proteins or starches.*

Any nonstarchy vegetables may be combined with proteins or starch, except tomatoes, which should especially not be used with starches. The green leafy vegetables combine very well with most other foods. They are excellent food and should be used in the diet.

Lettuce and other green and nonstarchy vegetables leave the stomach with little change—they pass through the stomach rapidly unless delayed by oily dressings or foods that require a more thorough gastric digestion. Lettuce and celery are good combination with fruit because all of these foods require little gastric digestion.

However, even if these vegetables are held up in the stomach with other foods, as when using salad with nuts, there is no fermentation.

Eating a large salad of fresh raw vegetables (three or four varieties) daily is an excellent practice. Dr. Shelton says, "A large bowl of salad each day is required by everyone."

## 4.11 Take Melons Alone

13. *Do not consume melons with any other foods.*

This rule has been somewhat under question in recent years. I personally have found that eating melons alone is an excellent practice, and have even found it advisable not to mix two different varieties of melon at the same meal.

Many people who have complained that melons did not agree with them have no trouble handling them when eating only melon at a meal. Yet, certain Hygienic professionals are offering some post-fasting people more than one variety of melon at a meal (even melons in combination with grapes or other subacid fruit) and some Hygienists follow this practice. If you want to experiment with these combinations, do it sparingly and carefully. But if you have a history of digestive problems, don't do it at all.

Melons are more than 90 percent liquid and leave the stomach quickly if not delayed and fermented by combining with other foods. Dr. Vetrano says, "Melons are best taken alone because the sugar and other nutriments are in a less stable form than the nutrients of other fruits. Orange juice may be kept in the refrigerator for an hour with little change in flavor, but if you refrigerate watermelon juice for only ten minutes, its flavor, color and composition markedly change. It decomposes much more quickly than other fruits. Consequently, if it is held in the stomach awaiting the digestion of other foods, it will

decompose (ferment) and cause a great deal of gastric distress. Eating watermelon with nuts can really be troublesome."

Dr. Shelton says, "Because of the ease with which melons decompose, they do not combine with any food, except, perhaps, with certain fruits. We always feed them alone, not between meals, but at meal time."

He also says, "It is probably a great misfortune that we do not always feel the direct effects of imprudent eating immediately following a meal. For example, there are large numbers of people who have discomfort, even great discomfort following a meal in which melons are eaten with other foods, but there are many others who do not. This latter group can see no connection between their life of imprudent eating and the breakdown of their health in later years. Their apparent impunity prompts them to defy all the same rules of life."

## 4.12 Sprouts

14. *Alfalfa sprouts may be combined as a green vegetable.*

Other sprouts should properly be classified in the same category as the original seed, even though the sprouting process has somewhat lowered the protein and carbohydrate content.

During the sprouting process, the carbohydrate and protein components of the sprouting seed tend to diminish, and the composition becomes more like a green vegetable instead of a legume, grain or seed. However, this is not uniformly the case. Sprouts which progress to the green leaf stage, such as alfalfa and mung beans, are high in chlorophyll, and alfalfa sprouts, particularly, may be freely combined as a green vegetable. Mung bean sprouts still retain enough of the property of legumes so that they are best eaten without other proteins or starches. These sprouts may be included in the low protein/starch category.

Lentils, soybeans, garbanzos and other miscellaneous beans and grains should be allowed to sprout only very briefly, until just a small sprout is showing—no longer than the seed, at most. The change in character is therefore much less than for those sprouts which are sprouted to the green leaf stage. Sprouts are high in protein in these early stages. They should therefore be classified, with some expectations, according to their original food categories, namely, as protein or combination protein/starch foods.

Sprouted sunflower seeds may, of course, continue to be classified as protein. In the case of lentil, soybean and garbanzo sprouts, they could be classified as low protein, since the starch tends to diminish and the protein remains in significant amounts in the early stages of sprouting.

I would classify sprouted grains as combination foods, their original category, to be combined as starch.

My experimentation with these sprouts, and my research on the subject, leads me to these conclusions as the best way to classify and combine them. More detailed information about sprouts and sprouting will be given in a future lesson.

## 4.13 Milk, Yogurt and Clabber

15. *Milk is best taken alone.*

This rule is included because it is one of Dr. Shelton's food combining rules, and because this lesson on food combining may be helpful to those still on a mixed diet. Hygienists do not drink milk. Adults do not need any kind of milk. Infants need their mother's milk; if this is not available, they need a substitute. (More about this in a future lesson.)

Dr. Shelton says that the use of acid fruits with milk does not cause any trouble and apparently does not conflict with its digestion. This would also apply to clabber (sour milk) or yogurt, which may be preferable to milk for adults.

Many adults (and some children) lack the enzymes lactase and rennin necessary for the digestion of milk. Lactase catalyzes the conversion of lactose (milk sugar) to the glucose and galactose which can be utilized by the body. Rennin is a milk-coagulating enzyme, which many adults no longer secrete.

This is also the reason that cheese is considered preferable to milk, although no dairy products are recommended for regular use.

The thymus gland, which also has a function involved in the digestion of dairy products, reaches its maximum development during early childhood, and usually degenerates and becomes vestigial in adults.

None of these products are recommended. If any milk products are used, they should be raw (unpasteurized) and should not be used on a regular basis. Yogurt cultures, particularly, can inhibit the body's own natural production of beneficial intestinal flora.

Dr. Shelton says that either sweet milk or sour milk (clabber) is a fair combination with acid fruit or subacid fruit, and that clabber is even a fair combination with dried sweet fruit.

Dr. Vetrano says that occasionally there are sick people with gastrointestinal problems who must temporarily be placed on milk, if they cannot take a fast of sufficient length for complete healing.

More information about the inadvisability of using fermented foods like yogurt, clabber or cheese will be included in a future lesson.

#### **4.14 Good, Fair, Poor and Bad Combinations**

When we say that foods are fair combinations, this means that they are permissible for those with unimpaired digestions. Good combinations are good for the weakest digestion.

Poor combinations should never be employed, unless, perhaps, they are used occasionally by people with the best digestions. Some combinations are so bad that no one should ever use them.

Examples of these precepts will be given in Lesson No. 23.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) >  
5. The Crux Of Food Combining

### **5. The Crux Of Food Combining**

If we want to eat several foods at the same meal, it would seem logical that trouble could be avoided, or at least minimized, by ingesting together those foods which are compatible; that is, those which require approximately the same conditions for digestion—including length of time, type of enzymes and digestive juices, and degrees of alkalinity or acidity.

When foods are eaten in incompatible combinations and fermentation results, alcohol is produced in the digestive tract, with the same consequences as imbibing it and with the same potential for liver damage.

The existence of such a still in your body may not be illegal, but it is certainly contrary to the laws of nature!

It is important to remember that all of the senses have a role in digestion. Seeing, smelling, touching, tasting—and even thinking about food—all help in sending the proper signals for the secretion of the digestive juices and their adaptation to the character of the food.

Complicated mixtures of food interfere with this process of digestion, make it less efficient and may cause digestive problems. When we compound the problem by adding seasonings, the true taste of the

individual foods is further disguised. This makes it extremely difficult for the digestive system to supply secretions that can cope with such meals and digestion is inhibited and impaired.

The glands react to the foods eaten to the best of their ability. They interpret the signals they receive and supply the best secretions they can muster to preserve the health and the integrity of the organism. When a saturation point is reached, due to continuous bombardment from intolerable food combinations, the ability of the overworked digestive system to make the necessary adaptations is reduced or destroyed, and disease is the result.

Optimal digestion requires that we eat in such a way as to offer the least hindrance to the work of digestion by making the best use of our knowledge of the chemistry and physiology of digestion and of the limitations of the human digestive system.

Raw, fresh, whole, ripe fruit; chlorophyll-, vitamin- and mineral-rich raw, leafy green vegetable, sprouted seeds and raw, unsalted nuts and seeds are essential and valuable—they are the best of foods. Eat them in accordance with food-combining rules, masticate them thoroughly, don't complicate them with oily dressings, and your body will easily accommodate this food program and progress toward optimal health.

People with serious digestive problems should consult a Hygienic professional and probably undertake the healing that only a prolonged, supervised fast can produce. Afterwards, they too can look forward to utilization of the Hygienic food program on their way to better health.

## **5.1 Dr. Shelton's Original 9 Food Combining Rules**

1. Never eat carbohydrate foods and acid foods at the same meal.
2. Never eat a concentrated protein and a concentrated carbohydrate at the same meal.
3. Never consume two concentrated proteins at the same meal.
4. Do not consume fats with proteins.
5. Do not eat acid fruits with proteins.
6. Do not consume starches and sugars together.
7. Eat but one concentrated starch at a meal.
8. Do not consume melons with any other foods.
9. Milk is best taken alone or let alone.

## **5.2 Food Combinations Discussed in This Lesson**

1. Acid-carbohydrate combinations.
2. Protein-carbohydrate combinations.
3. Protein-protein combinations.
4. Protein-fat combinations.
5. Fats in combination with other foods.
6. Acid-protein combinations.
7. Sugar with starch, protein and acid fruit.
8. Starch-starch combinations.
9. Acid fruits with subacid fruits.
10. Subacid fruits with sweet fruits.
11. Fruits with vegetables.
12. Salads with most foods.
13. Melons best used alone.
14. Sprouts—Combinations.
15. Milk, Yogurt, Clabber—Combinations.

## 6. Question & Answers

**I've heard that food combining is an individual matter. Why can't I ignore it unless and until I have symptoms?**

That's the rationale of many people, especially people who stay on conventional diets and eat junk foods. Is it better to avoid damage to your body, or would you rather wait until damage is done, and then try to correct it? Most people already have damaged their bodies long before symptoms appear. It would be much more prudent and sensible to take the best possible care, as soon as you can, of the only body you will ever have in this life, rather than to wait until the road back is long and arduous, and when you would probably have to start with a prolonged fast.

**You say an occasional deviation is not too important. How often is occasional?**

"Occasional", or infrequent, means different things to different people. A man once said to me, "I eat meat occasionally," and when I asked him how often, he said he eats it once a day. If you do something unwise even once a week, I would call that regularly rather than infrequently. Once a month is less frequently, of course, and might be tolerated fairly well by a healthy body. Actually, the degree of harmfulness of a dietary indiscretion depends on the extent of your deviation and the state of your health. Are you speaking of bending the food combining rules, or do you mean going to a restaurant and gorging on a conventional meal? And, what is even more important, can you afford to deviate? If you are having problems, you would be foolish to do things that can only make those problems worse. For most people who feel they can "afford" to "deviate" "occasionally", it would be best to save such deviations for occasions when they find themselves in unusual situations when such a choice is the lesser evil.

**You say not to have more than one concentrated food (protein, starch, sweet fruit) at a meal. Is it all right to have some meals without any concentrated food?**

Yes, an excellent choice for the first meal of the day (for most people) is melon or juicy fruit only. Yet, some concentrated foods, especially concentrated proteins, have a place in the food program (See Mono Diets, Lesson No. 23). Starch meals are less important, and dried sweet fruit should be used sparingly. Including concentrated protein foods (usually nuts and seeds) in some of the meals enables the body to obtain a balance of the nutrients it needs. (See sample menus, Lesson No. 23)

**I seem to lose weight on an all-raw-food diet, but hold a better weight if I eat some cooked food.**

Usually, persistent adherence to an all-raw-food diet eventually results in improvement of assimilation, and one gradually puts on, and retains, more weight. However, if you have a tendency to be thin, or if some impairments cannot be completely overcome, you may have to settle for a leveling off at a weight lower than you prefer. If you feel well, the best thing to do is ignore your weight. In some instances, for emotional or physical reasons, it may be advisable to use a small percentage of cooked food. But most people will be much better off if they can decide to stay with an all-raw-food diet. Those who are convinced that they maintain better weight, feel better or have more energy if they use some cooked starches,

legumes or grains, will probably be happier on an 80-90 percent raw-food diet.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) > Article #1: Skin problems? Tell me about them! By Richard Hill

## **Article #1: Skin problems? Tell me about them! By Richard Hill**

Perhaps I was vain, but having my face covered with red, or red and yellow oozing lumps made me a little self-conscious and depressed. The old platitude, "Beauty comes from the inside" sounded nice, but talking with people and FEELING their eyes on the big "honker" on my nose or that "headlight" on my chin didn't do much for my self-confidence, especially if I was talking to a girl I was hoping to impress. All this may sound like teenage trauma. But I was almost 27 years old and things were worse than ever. This wasn't my only problem. I was plagued with hay fever, migraine headaches, prostate trouble, poor vision and several other complaints. But my pizza-like complexion was my main concern and secret shame.

After 14 years of this "teenage" malady I was depressed and baffled. There was nothing I (or anyone else) could do for me. The slow but sure disfigurement I was stuck with was something I couldn't accept. Only fellow acne sufferers will understand my desperation and secret anguish. I've talked with many grossly fat people, asking if they would trade their excess weight for a chronic skin condition. So far not any would even consider it. And many of these people had contemplated suicide over their weight.

I really had given it my best shot. I had applied gallons of Clearasil, Oxy 5, 10 and 15, washed with Stridex, alcohol, witch hazel, distilled water and special skin soaps and cleansers. I washed many times a day. I was a voracious reader and tried every method and treatment I could find in those 14 long years. I was given various prescription drugs by dermatologists. The labels warned of dangerous side effects. Sometimes I would get temporary relief, usually not.

Next I tried health food store "cures." I developed a library and gathered glib knowledge from all the "experts" and their methods. I hunted down all the herbs (red clover, golden seal, cayenne, etc.) supposed to cleanse the system. I drank them from morning 'til night. I drank a half-gallon of carrot juice each day. It turned my palms orange, but did nothing for my skin. I did various other juice combinations. They did nothing. I stopped eating chocolate, nuts, fried foods, white sugar, white flour. I even gave up all fruits for a year.

I graduated from Clearasil and smeared my face with green, red and yellow clays, separately and in combinations. I took activated yeast every morning just before my vitamin ritual. I was assured my problem was a vitamin/mineral deficiency as well as an unclean system. I took megadoses of A, B complex, C (with bio-flavonoids and Rutin), D, E, folic acid, K, multi-minerals, chlorophyll, wheat germ oil, brewer's yeast, lecithin and protein powders, using my handy pocket pack. The few times I forgot caused me as much anxiety as the heart patient who forgets his nitro-glycerine.

Then I began to "fast." I took so-called "juice fasts," ones with products designed to clean out my colon. I took enemas of warm watery cold water, herb water and distilled water. I drank gallons of water to flush out my system. I tried "organic blood salts" and several other surefire cures. I was getting plenty of fresh, Los Angeles air and sunshine.

Next I got serious. I had said I'd pay a million dollars to solve my problem. Now I began to pay it on the installment plan to a young chiropractor into "natural healing." I got adjusted, x-rayed, diagnosed as having adrenal stress, given new vitamin/diet combinations. I took the glucose tolerance test and was diagnosed a hypoglycemic. (Since then I've never met anyone who took the test that was not so diagnosed!) This was the time I went on my no-sugar, no-nuts and no-fruit diet for a year.

I was as bad off as ever and switched to an older naturopath/chiropractor. He put me back on fruit, different vitamins and juices. When this didn't work he hit the problem with everything he had—more adjustments, x-rays, ultrasound, cold packs, hot packs and, finally, colonic irrigations with and without oxygen! I took these three times a week. It was expensive and embarrassing. But I was determined to get well or die trying. I was that desperate. After all the discomfort and expense my complexion was worse than ever.

I didn't give up hope. I returned to my library and came across a little book I hadn't paid too much attention to. It had seemed technical and too different. It was called *Food Combining Made Easy* by Dr. Herbert M. Shelton. Having nothing to lose, I tried this silly thing. Within a week my face started to clear up. It continued to get better. I stopped the colonics, adjustments, ultrasound and all the other things. Looking for more books by Dr. Shelton, I found *Fasting Can Save Your Life* at a health food store. I ordered more Shelton books from Natural Hygiene Press. I began to understand the basic ideas of Natural Hygiene and dove in with both feet. It was working where nothing else had. I gave away my vitamins and herbs, got back to 2 or 3 meals a day (from 5 and 6). I washed only with warm water.

I knew I had stumbled onto a new way of life and found people with no cures to sell. They had an understanding of the laws of life. They had a system where one can return to harmony with these laws and achieve total health. I made arrangements to fast under the supervision of Dr. Virginia Vetrano. I fasted at the Chateau Des Sages for 14 days. I listened to lectures and tapes and I learned more about Natural Hygiene. I wanted what these people had. I returned home with my skin more clear than it had been in 14 years. My hay fever and migraine headaches also were gone. At last my search was over and I reached the happy-ending.

I wish I could stop here saying everything was fine. But, I had more learning to do! I stayed with the Hygienic program for three months with never a pimple or snuffle. I thought I was "cured." I began to stay up late and "just this once" eat wrong food combinations. Within five months I was living worse than before I had discovered Natural Hygiene, junk foods and all. "Clear Skin!

Anything Goes!" I was headed for a fall and I fell hard. It wasn't easy to start back. But after some bad acne days, I was able to get back on the Hygienic Path. This was, in part, with the help of a certain anonymous group of overeaters. They gave me the tools to deal with the mental blank spot that precedes that first compulsive bite. Thanks to them I found my way back and everything cleared up again. I learned that I'm never "cured," but only healthy so long as I obey those Unbending Laws of Life.

I hope anyone with a similar, or any, health problem will take time to look into Natural Hygiene. I had to try everything else first. Maybe someone out there, who reads this, will be able to skip some disappointments and start in on a new, healthy life. I'll be glad to talk and write and answer questions for anyone who asks for help. This way, by passing the word along, I hope to pay back a little of the joy I have received through Natural Hygiene.

The above article is reprinted from *Naturally, the Hygienic Way*.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) > Article #2: The Hygienic Diet By Dr. Alec Burton

## **Article #2: The Hygienic Diet By Dr. Alec Burton**

I have never liked the term "The Hygienic Diet." It implicitly suggests a diet designed for everyone which is specific, inflexible and stereotyped. Hygienically, diet represents a means of affording the organism adequate nourishment and, in order to accomplish this, there may be a thousand different diets

which will provide the necessary materials of use in adequate proportions. Diet is merely a vehicle that provides the nutrients the body requires for the maintenance of its health and life. Diet does not cure disease. Diet per se does nothing. It is passive. It is acted upon by the organism. The purpose is to secure from it the necessary nutrients the body needs for growth, development, repair of wear and tear, reproduction and the maintenance of its functions. To speak as though diet performs some function by itself is erroneous. There is no such thing as an eliminating diet, implying in some way that diet is responsible for elimination. Elimination is a physiological process; it is performed by the organism, not by the food it consumes.

A diet should consist of those materials that are essential to the organism's survival. These may be broadly classified into proteins, carbohydrates, fats, minerals and vitamins. Providing that all of these are secured in adequate amounts, in a form which is usable, the organism will have the necessary materials to work with. If they are supplied deficiently or excessively, nutritional stresses will be incurred. To the extent that they are excessive or deficient, consequences will accrue depending upon the activity of the individual organism. Obviously there are considerable limits of toleration, varying from one individual to another. The organism can tolerate slight excesses and occasional deficiencies, at these times drawing upon its own nutritional reserves, but prolonged deficiencies and substantial excesses will incur consequences of malfunction.

The means whereby the various materials that the organism requires for its health and life are supplied are not of prime importance. Of first importance is the fact they are supplied. This does not mean that we can take refined and processed foods as being good sources of the materials that we require. What it does mean is that, providing the necessary materials are available to the organism in the diet consumed, free from noxious extraneous substances, in a form which naturally occurs, not tampered with by the food refiner and processor, the organism will be securing the necessary nourishment. It is important that we get away from the idea that specific foods and specific diets have healing properties or have special properties other than the mere presence of nutrients needed by the organism. The idea that we should take beet juice for anemia, cabbage juice for ulcers or parsley for the kidneys is a vicious reactionary hangover from the medicating superstition. Nor is it desirable that we study the analyses of various foods and select our diet according to some chart which indicates that a particular food is rich in a particular nutrient. This is not good nutrition. From this practice we may learn that wholegrain cereals are rich in iron but we may not discover that the presence of phytates renders the iron unavailable to the organism.

We should attempt to secure our nutrients from a wide variety of foods although obviously not at the same meal. Over a period of time, eat as wide a variety of foods as is practicable. Introduce new foods into the diet. I am speaking here of course of natural foods and by that I mean foods that are provided by the plant or tree in nature, i.e. fresh fruit and vegetables. In fresh fruits and vegetables, I also include nuts which are botanically classified as fruits. Some of the nuts which are in common use are not, strictly speaking, nuts. The peanut is a legume. However, if we select our protein from almonds, brazils, hazels, macadamias, pecans, pine nuts, pistachios, walnuts, etc., these will supply the essential amino acids required for growth, development, repair and reproduction. To avoid any argument about the importance of taking all of the necessary amino acids at the same meal, eat a variety of nuts, but be careful not to overeat. An amount of 3 to 4 ozs. daily is quite adequate. Some additional protein will be taken in the small quantities present in fruits and vegetables. In some cases this might be quite significant. It is desirable to keep one's diet simple, not to have a wide variety of foods at a single meal, but to limit the variety to perhaps four different types together with some concentrated food such as nuts for protein.

Many people can survive quite well on two meals a day. One fruit meal and one somewhat large salad meal together with protein. This does not mean, however, that one cannot have two fruit meals or two salad meals. It may be varied as desired. Two fruit meals may be taken one day and two salad meals may be taken another day. If one is on a 3-meal-a-day program, a fruit breakfast is usually the most desirable, but there is no real objection to a salad breakfast; For the remaining two meals, these may comprise a

further two fruit meals or two salad meals, or one fruit and one salad meal. Some protein with one of the meals is desirable and I usually recommend 3 to 4 ozs. of nuts. Basically the Hygienist is arguing that the natural diet of man is comprised of fresh uncooked fruits and vegetables (which includes nuts) and insofar as he deviates from this, he increases his chances of incurring trouble. Dairy products, cheese, yogurt, milk, eggs, butter, represent compromises and if taken at all should be used sparingly. Flesh such as meat, fish and fowl represent a departure from food normal to man. The arguments in support of this are involved and extensive and it is not appropriate for me to discuss them here, but it is incumbent upon me to state categorically that flesh foods do not constitute a part of the normal diet of man. Their use then represents a compromise. The extent to which one compromises, and by this I mean the extent to which one consciously and volitionally departs from what is accepted as the ideal, is the extent to which consequences will and must follow.

Among the most dangerous and health-impairing nutritional habits, I consider the following:

- Overeating
- Eating refined and processed food
- Eating foods that have been significantly chemically manipulated
- Excessive consumption of concentrated food

I personally view the diet containing a large proportion of fresh raw fruits and vegetables accompanied by 3 to 4 ozs. of concentrated protein as being the most satisfactory. The diet may have to be manipulated in various ways, in disease and during the process of recovery. What I am here discussing represents certain basic principles of dietetics which are generally applicable to the sound and healthy. The diet of the invalid may have to be modified considerably and frequently as their strength and weakness alternate, as the energy ebbs and flows, as the needs fluctuate from day to day. Considerable knowledge and skill is required in order to feed the sick adequately without imposing nutritional burdens which prove enervating and contribute to the misery of the sufferer. In acute disease it is relatively simple: abstain from food, i.e. fast. But in the case of the chronic sufferer, the problem is far more complex. Fasting may be employed, but there are limits to its practical nutritional reserves, and the extent of the toxemic load. Very few chronic sufferers are likely to recover during a fast. The fast merely provides a foundation for the reconstruction of health and in some cases it may require several fasts to provide this foundation, and the periods of feeding in between are most crucial. Progress may be inhibited if mistakes are frequent and serious. Correct feeding after the fast in recovery from chronic disease is an extremely critical and sensitive process requiring an accurate assessment of the nutritional needs and capacities of the invalid, and whilst there can be no mathematical accuracy applied to the provision of nutrients, it must always be kept clearly in mind that we do not nourish the organism by providing nutrients but by providing foods. The organism is constructed to ingest and digest foods and thereby assimilate nutrients. We do not secure health by feeding nutrients but by providing foods which contain nutrients. The difficulty is encountered in providing the right food in the proper proportion under the correct conditions, at a time when the organism is capable of using them.

People phone me and ask "Can I eat fried potatoes? Fat and starch are all right together?" Now there are two points I wish to stress here:

1. Combinations are a refinement of food reform, not a basic principle. The rules of food combining are subordinate to eating the right food, and
2. I did not make the laws of life and I cannot make any special dispensations.

Even if I say you can eat something does not make it either good or right. Some people try to persuade me to let them eat certain foods as though I am in some way responsible for physiological processes in relation to food. When I am asked these questions I often reply "What do you think?" Then they are forced to refer to their knowledge of Hygiene which usually compels them to accept the facts of reality.

People will argue that they are in some way special, the usual laws of life have to be "bent" a little in their case. These are all the subterfuges of compromise. There are only two types which are special,

male and female. There are special periods such as infancy, pregnancy and lactation, but this does not mean that lettuce and apples are good at one time and fish and chips at another. Such periods require modifications of feeding but not of food. The exception is infancy when the infant secures his fruits, vegetables and nuts through his mother. He is eating them indirectly instead of directly.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) > Article #3: Food Combining by Dr. Herbert M. Shelton

### **Article #3: Food Combining By Dr. Herbert M. Shelton**

Instead of confining himself to the compounds or combinations that are turned out by nature, man turns out compounds and combinations of his own, a thing that no other animal in nature does. The animal makes a meal on whatever his instincts demand at the time and does not fill up on many kinds of food at a meal. The general rule, to which there may be an occasional exception (I have failed to find one), is for them to get but one food at a meal. Even the most simple things mixed together are not as good as they would be if taken separately. For it is only thus that we can eat as little or as much of a particular food as the body demands.

We are prone to follow custom and acquired habits in our eating practices and to ignore (commonly we do not know) the inhibiting effects of a variety of conditions and circumstances upon the process of digestion. Much of the alleged scientific defense of customary eating practices is but a lingering survival of ideas formed when little was known of the process of digestion.

It was long thought that the gastric juice was the only solvent of aliment. The office of the saliva was unknown and the other digestive juices with their several enzymes were unknown long after Beaumont discovered the work of the gastric juice. Thus it came to be held that the action of the gastric juice was the same on all articles of diet. It was thought that in some manner, not then understood, bile did aid in the digestion of fats and oils.

The British health reformer, Andrew Combe, accepted the view of Beaumont that saliva is lacking in alimentary solvent. (These solvents are today called enzymes). "The agent of chymification," said Combe, "is the gastric juice." It should be noted at this point that Graham took the opposite view. He held that saliva does contain a ferment or solvent. It is a strange thing that at this late date when the importance of the work of the salivary amylase, *ptyalin*, in the digestion of starch is well known, medical writers, in attempting to discredit Graham, list his differences with Beaumont as one of his mistakes. They are determined not only to discredit Graham, but also to discount the importance of salivary digestion. Recently I read the statement that "digestion begins when food has been swallowed." Physiologists, physicians and gum-willies all seem to be determined to minimize the importance of salivary digestion. Even the importance of chewing of food in the mouth, which is a part of the digestive process, is negated.

In the effort to defend modern eating customs a number of imaginary activities are pictured as going on in the stomach. Beaumont showed long ago that the gastric juice quickly becomes intimately mixed and blended with the food in the stomach by the motions of the stomach. These continuous motions are in two directions—*transversely* and *longitudinally*. It is now customary to deny that the gastric secretion is quickly mixed with the food ingested. This denial is necessary if food combining is to be discredited. Indeed, all enzymic limitations are ignored in the effort to combat the Hygienic heresy that certain combinations of foods may be digested with greater ease and efficiency than others.

In his *Air, Food and Exercise*, Rabagliati tells of witnessing the vomiting of a salad at 5 A.M. in about the same condition it was eaten at 7:30 the preceding evening. He mentions that the salad "had rather too

much vinegar on it." Acids not only destroy ptyalin and thus stop starch digestion, but they also inhibit the secretion of gastric juice and retard protein digestion. It is the part of dietetic wisdom to avoid eating acid foods (vinegar is not a food, but a poison), with protein. Because acids destroy ptyalin, it is well to avoid eating acid foods with starches.

An acid gastric juice is required to digest proteins. An alkaline medium is required for the work of ptyalin. For these reasons, protein foods and starch foods should not be eaten together. If a natural protein-starch combination, such as beans or cereals, is eaten, the body can so adapt its digestive juices to the digestive requirements of such a food that it is digested without too much trouble. If an artificial protein-starch combination is eaten, this adaptation cannot take place. Because of their complex character, beans, a protein-starch combination, tax the digestive powers more than simpler foods, but the gas, discomfort and other trouble that so commonly follow eating them, is not due so much to the beans themselves as to the company they keep. Baked beans are, of course, preferable to beans that are boiled and taken thoroughly saturated with water. If taken thus relatively dry, well chewed and eaten in proper combinations, beans will be found to be readily digestible.

A test meal of soup, beef-steak and potatoes remained in the stomach for three hours. The same meal with sugar remained for five hours. Sugar, like acids, has a marked inhibiting effect upon the flow of gastric juice and upon gastric motility. The meal of soup, potatoes and steak was sufficiently difficult of digestion, but when the sugar was added, it became more so. In our regular eating habits we ignore, or do not know these simple facts. We tend to eat as those around us eat and we refuse to listen to the voice of those who seek to instruct us in the art of better eating. Perhaps this is the reason that it has been said that our people's favorite dessert is baking soda. I think that Alkaseltzer has now supplanted baking soda as an after-meal tid-bit, largely due, no doubt, to the fact that few homes use soda any more, since little home baking is now done.

When we were children, our mothers would not permit us to eat sugar, candy or cookies before a meal. As she expressed it, "it spoils the appetite." The fact is that no other food depresses the stomach and the desire for food as sugar does. The so-called "energy break" in mid-morning and mid-afternoon, when sugar or candy is taken to renew lagging energies, is no different from taking a coffee-break for the same purpose. This practice of taking sugar has been dignified with the high-sounding title: "The Scientific Nibble," but it is a fallacy. It is certainly a mistake to eat sugar, syrups, cakes, candies, pies, sweet fruits or honey with proteins.

Fat, like sugar and acid, also inhibits the secretion of gastric juice and the physical actions of the stomach. Too much fat taken with the meal results in acid eructations which leave a pungent, burning sensation in the throat. Fat inhibits gastric secretion. We have a great army of gastric invalids who overeat on butter and other fat, take sugar or acids with proteins and then are told by their physician that they do not have sufficient hydrochloric acid. The physician gives them hydrochloric acid to take and tells them that once this acid has been "lost" it cannot be regained. How does the physician know? Has he ever tried removing the cause of gastric hypo-secretion? Has he ever tried restoring the patient to health to see if his glands will function normally? Has he ever tried correcting the patient's eating and living habits? The answer to all of these questions is the same. He has never made such attempts. He has been content to palliate the symptoms of his patient and leave causes untouched.

People often consult us who are taking hydrochloric acid upon the advice of a physician, who has explained that there is no possibility of them ever regaining the tone of the stomach and that they will have to take the acid the rest of their lives. They are fully convinced that this is true and it is no easy task to disabuse them of the fallacy. It is true, of course, that if they have taken the acid for a prolonged period, the practice itself has resulted in so much deterioration of the gastric glands that secrete hydrochloric acid, that the chances of full recovery are greatly reduced. The practice should never be started in the first place and only the grossest kind of ignorance or criminal indifference to a sick person's welfare will ever prescribe such a treatment for the sick.

Fruits, because of their peculiar combinations, are best eaten at a fruit meal and not combined with

starches, fats or proteins. As a rule they are abundant in either acids or sugars, hence do not combine well with other foods. As they undergo very little digestion in the mouth and stomach they should not be held up in the stomach awaiting the completion of gastric digestion of other foods.

There is no sharp line of division between the acid and subacid fruits. Neither is there a sharp line of demarkation between sub-acid fruits and sweet fruits. The gradations between these classes of foods are almost imperceptible. The acid fruits are those with the most tart flavors—lemons, grapefruit, oranges, pineapple, sour apples, tomatoes, and similar fruits rich in acid. The sub-acid fruits are those that possess less acid flavors—pears, sweet apples, apricots, fresh figs, some grapes, sweet peaches, cherries and nectarines. The sweet fruits are those that are rich in sugar (sweet in taste)—persimmons, bananas, figs, dates, raisins, sweet grapes, mangoes and papayas. The avocado is a fat.

Tilden recommended eating the banana alone. He especially enjoined milk with this fruit, but said that it does not seem to go well with any other food. Although bananas do not give any special difficulty in digestion, if eaten with other sweet fruits, such as dates or sweet grapes, the same cannot be said for melons, which should be eaten alone. It is probably a great misfortune that we do not always feel the direct effects of imprudent eating immediately following a meal. For example, there are large numbers of people who have discomfort, even great discomfort following a meal in which melons are eaten with other foods; but there are many others who do not. This latter group can see no connection between their life of imprudent eating and the breakdown of their health in years. Their apparent impunity prompts them to defy all the same rules of life.

[Home](#) > [Lesson 22 - The Principles Of Digestive Physiology Which Decree Correct Food Combining](#) > Article #4: Protein-Starch Combinations by Dr. Herbert M. Shelton

### **Article #4: Protein-Starch Combinations by Dr. Herbert M. Shelton**

At frequent intervals, some chemist or physician comes forward with the announcement that there is nothing to the idea that people have better health if they do not combine starch and protein foods in the same meal. They are sure to tell us that laboratory experiments show that digestion is carried out almost as quickly where these foods are combined as where only one is taken at a time. They are likely to add that experiments with certain patients verify this opinion of theirs.

We have in these announcements, two groups of men invading a field and posing as authorities therein, to which they are alien. Chemists know nothing of feeding man or animal. They should stick to chemistry. Physicians are not trained in dietetics. They know nothing of feeding the well and the sick. They are trained in the black art of poisoning the sick. I will not say that they should stick to this practice, but I will say that they should cease trying to pass themselves off on the public as authorities in fields outside their own.

Of what value are their laboratory experiments? Very little. A laboratory is not a human being. It is not a human digestive tract. The laboratory experiment cannot be substituted for the actual work of digesting a meal. Even feeding test meals and pumping out the stomach contents, or viewing the stomach through the X-ray is not a satisfactory approach to the solution of the problems involved in the heterogeneous and haphazard mixtures of foods commonly consumed at a meal.

What can be learned from feeding one meal to a subject, or even from feeding a few such meals to a few subjects? One such meal may not bring any distress to the subject. Indeed, we see many people eating such meals regularly for years before they develop discomforts therefrom. But the constant repetition of heavy protein-starch meals taxes their digestion to the limit and, sooner or later, results in discomforts and diseases galore.

Dr. Tilden once pointed out that nearly all such experiments are carried out by physicians and chemists who use the potato as the starchy part of the diet, and, he adds, "I have often stated, the potato is the least objectionable of any starch to be used with protein, on account of its potash content." My own view is that the potash content of the potato is not concerned in the matter at all. Potato starch digests in ten minutes under ideal conditions. I am of the opinion that it is the rapidity with which the potato starch digests that makes its combination with protein less objectionable than the combination of other starches with protein. It seems to be that the potato starch digests before the gastric juice of the stomach can accumulate in such quantity as to materially interfere with the digestion of the starch. Whatever the true explanation, the fact still remains that potato with protein, though objectionable, is less so than some other starchy foods with protein.

The man who has fed thousands of patients, old and young, and has had an opportunity to study the effects of diets and food combinations upon the health and diseases of these people is in a far better position to judge the accuracy of the contention that protein-starch combinations are not conducive to good digestion and good health, than are the chemists who feed nobody and the physicians whose great work is that of poisoning the sick.

Those of us who have made these observations know well that correct food combinations result in an immediate improvement in health by lightening the load the digestive organs have to carry. We know that we see better digestion and less fermentation and putrefaction. We see more comfort and less distress. There is less gas and little or no odor to the gas.

I do not believe that such experiences are worth anything if they cannot be explained by correct principles. Unless they can be explained by the facts of physiological chemistry, particularly the chemistry of digestion, we may be only deluding ourselves. On the other hand, if our rules of food combining are soundly rooted in physiology, they are worthy of more than a passing notice.

It is frequently objected that nature, herself, combines starches and proteins and if nature does, we may do so also. This objection is not valid. It is based on the untenable assumption that everything in nature is *designed* or *intended* for food. The great representative examples of protein-starch combinations in nature are cereals and legumes. These are the very foods that are most prone to decompose in the digestive tract when eaten. Neither of them constitute the best of foods and neither of them is readily digested. While a diet of cereals or a diet of legumes is inadequate in several ways, there is reason to believe that some of the inadequacies that result from such dietaries are results of the failure of digestion, a failure that is probably the result of the protein-starch combination.

Physiologically, the first steps in the digestion of starches and proteins take place in opposite media—starch requiring an alkaline medium, protein requiring an acid medium in which to digest. The enzyme *ptyalin* (salivary amylase) that initiates starch digestion is active in an alkaline medium only and is destroyed by a mild acid. On the other hand, *pepsin*, the enzyme that initiates protein digestion is active only in an acid medium. If starches and proteins are eaten together, the acid gastric juice destroys the ptyalin and puts an end to salivary digestion of starch. That the presence of the undigested starch in the stomach interferes with the digestion of protein is shown by the presence of undigested protein in the stools. Physiologists have shown that undigested starch absorbs pepsin and this will surely interfere with digestion of protein.

If a food that is a natural protein-starch combination is eaten alone, the body is capable of modifying its digestive juices and timing their secretions in such ways that digestion can go on with a fair degree of efficiency. But when a starch food and a protein food are eaten at the same meal this precise adaptation of the digestive secretions to the character and digestive requirements of the food is not possible. There is a marked and important difference between eating a food that is a natural protein-starch combination and eating two foods, one a protein, the other starch.

When starches and proteins are eaten together, there is a fermentation and this results in fouling the whole digestive tract. Fermentation means irritation and poisoning. If starch is eaten without protein, the gastric (stomach) secretions will not be acid, or will be so weakly acid that they will not interfere with

salivary digestion. In this case here will be no fermentation, except from other causes, such as overeating, hurried eating, other wrong combinations, eating when fatigued, worried, angry, fearful, grieved, etc., eating immediately before beginning work, eating when in pain, fever or when there is inflammation, etc. The causes of indigestion are legion.

When the artificial protein-starch combination is eaten, not only undigested starch, but undigested protein will be found in the stools. The presence of undigested starch and protein in the stools is of far greater importance in determining the digestibility or indigestibility of a food combination than is the emptying time of the stomach. "Research" workers have found that the protein-starch combination delays the digestion of protein four to six minutes. This would seem to be unimportant, and I believe it is unimportant. If this brief delay in protein digestion represented all there is to the matter, we could forget the whole thing and continue to eat haphazardly. But starch digestion is important, also. Then there is the fact that the delay in emptying time of the stomach is no criterion of the completeness with which gastric digestion of protein has been done.

Physiologists resort to a number of "dodges" to escape the obvious implications of the facts of the physiology of digestion. A fine example of this is contained in *Physiology* by V.H. Mottram, professor of physiology at the University of London. He says that when the food in the stomach comes in contact with the gastric juice no salivary action is possible. He says: "Now gastric juice digests protein and saliva digests starch. Therefore it is obvious that for efficient digestion the meat (protein) part of a meal should come first and the starchy part second—just indeed as by instinct is usually the case. Meat precedes pudding as being the most economical procedure."

Why should it make any difference what order in which we consume the various foods at a meal? Mottram explains it in this way: "the distal end of the stomach is that in which the churning movement that mixes the food with gastric juice takes place ... But the food in the quiescent end is still under the influence of the saliva, while the food in the motile end comes into contact with the acid gastric juice and no salivary action is possible."

This means that if you eat your protein first so that it will be down in the lower end of the stomach and consume your starch last so that it will be in the upper part of the stomach, the protein will be digested below while the starch is digested above.

Assuming that there is any absolute demarkation between the food in the different parts of the stomach, and this assumption would be false, it is still not true that people in general, either instinctively or otherwise, consume their proteins and starches in this manner. Perhaps in England it is customary to eat meat at the beginning of a meal and pudding at the end, just as we have a similar practice of taking a dessert at the end of a meal in this country; but it is likely to be the practice there as here of eating bread and meat together. When the average man and woman eats flesh or eggs, or cheese, he or she takes bread with the protein. In eating hamburgers, sandwiches, hot dogs and similar dietetic abominations, it is certainly not the custom to consume the protein first and then, at the end of the "meal" eat the bun or other bread. The protein and starch are eaten together and are thoroughly mixed in the mouth in the process of chewing before they are swallowed.

For good digestion, let us eat our proteins and starches at separate meals.

## **Article #5: Basic Considerations In Food Combining By Virginia Vetrano, B.Sc.**

The Hygienic rules of food combining are based on certain facts of the physiology of digestion that are well-known to the orthodox biologist and physiologist. Although these specialists in science never make any effort to make a practical application of their knowledge to the everyday task of living, the known limitations of the digestive enzymes make it important that some consideration be given to these in our eating habits. What I have to say in the remainder of this article is based squarely upon the current teachings of standard physiologies, as I learned them in my studies of science prior to my graduation, but a few weeks ago, from the University.

The human digestive tract is divided into three cavities: the mouth, the stomach and the intestines. Each of these cavities possesses its own characteristic digestive juice or juices with which to do the digestive work of the particular cavity. Thus the work of digestion may be divided into three steps or stages, the work of each cavity preparing the food for the advanced work of the next. Although physiologists and biologists tend to think of salivary and gastric digestion as relatively unimportant, many facts, which I shall discuss in a future article, indicate that the efficiency and satisfactoriness of intestinal digestion depend upon the thoroughness with which salivary and gastric digestion have been carried out. With this thought in mind we shall begin our studies of the digestive processes.

Digestion is essentially a process whereby large molecules are broken down into smaller molecules by the process of *enzymatic hydrolysis*. Hydro (water) lysis (to loosen), means to loosen up by water, or to cleave large molecules into smaller ones by adding water. The organic catalyts (enzymes) are necessary to speed up hydrolysis. Without enzymes, very high temperatures and strong chemicals are necessary to produce hydrolysis, but these destroy food values. In the stomach hydrolysis occurs in comparatively low temperatures and in a short while. The thesis is that it takes a year or more to hydrolyze foods without enzymes. Unfortunately the end-products are never really the same. Thus we see that enzymes are of primary importance in digestion.

Without chemical digestion, the animal organism would derive no benefit from foods. The food must be reduced to the size necessary to pass through the mucous membrane of the intestine and it must be changed into substances that can be assimilated and used by the organism, such as simple sugar, resulting from carbohydrate digestion; glycerol and fatty acids, derived from the fats of our diet; and amino acids, derived from proteins. Without good digestion we rob ourselves of many important elements and permit decomposition and putrefaction which cause various and sundry troubles.

Enzymes are organic catalyts composed of complex protein; hence, the requirement of amino acids for their synthesis. (A catalyst is a chemical agent that, when added to reacting chemicals, greatly speeds up their reaction and may be recovered practically unchanged at the end of the reaction.) The vitamin molecule is also said to form part of the enzyme molecule. There are extracellular enzymes (exoenzymes), such as the digestive enzymes, and glycogenase, found in the liver, is an example. Exoenzymes are secreted from the cells that produce them, and they perform their activities outside the cell. Endoenzymes do their work inside the cells that produce them.

Each enzyme is specific in its action; by this is meant that it acts upon one class of food only (fats, carbohydrates or proteins) and upon no other, or upon one class of products of previous enzymic activity. Indeed, each one of the different sugars requires its own specific enzyme. They perform their work best at body temperature.

Each enzyme is capable of acting only in a medium of a certain pH. The pH of a substance is the measure of its acidity or alkalinity. An alkaline substance is one in which the hydroxyl ions (OH) are in excess of the hydrogen ion (H). If the hydrogen ions are in excess, the substance is acid. If the hydroxyl and hydrogen ions exist in equal concentrations, the substance is neutral. For convenience, the

physiologist expresses the concentration of hydrogen ions with the chemical symbol pH. Measuring the relative concentration of hydrogen and hydroxyl ions with the potentiometer, substances with a pH of seven are neutral, becoming increasingly acid as the pH falls from seven to one and increasingly alkaline as the pH rises from seven to fourteen.

Enzymes exist in an inactive form designated as proferment or zymogen, within the cells that produce them. Some may remain inactive until activated by *activators* (an inorganic activator) and *kinases* (organic activators). Others are converted into active enzymes at the moment of secretion. There are also coenzymes, where the action of an enzyme is dependent upon the presence of another substance as in the case of the dependence of pancreatic lipase upon bile salts. It was formerly thought that bile has an antiputrefactive action, but it is now thought that the greater amount of putrefaction of proteins and carbohydrates in the absence of bile is due to the fact that fats are not digested off the food, thus protecting them from the digestive juices. This allows the foods to undergo bacterial decomposition, the end-products of which are toxic. The above should indicate the importance of not eating fried foods and of not saturating your bread, potatoes, and other starch with butter, margarine, oil or other fat.

Food, upon being received in the mouth, is subjected to comminution and insalivation and is thus reduced to a soft mass known as a bolus. The first enzyme with which the bolus comes in contact is *ptyalin* or salivary amylase. This enzyme begins starch digestion, changing the starches to dextrine and maltose, if given sufficient time to continue its action in the stomach. I shall speak more of this later. The bolus acquires a neutral or slightly alkaline reaction that is essential to the continued action of the salivary amylase. If the saliva is distinctly acid, it immediately stops salivary digestion and the first step in converting starch into usable sugars is arrested.

After food has been masticated and insalivated, the bolus is sent through the esophagus to the stomach where gastric juice is poured out in large quantities (an average of 1.5 to 2.5 liters a day). It is a thin, colorless fluid with a definite acid reaction (pH of 0.9 to 1.7), containing protein, mucin, inorganic salts, about five percent hydrochloric acid, and the enzymes pepsin and gastric lipase. If no protein is eaten, the juice is almost neutral in reaction.

Shortly after food enters the stomach, contractions begin in the middle region, passing down to the lower end called the *pyloris*. These actions thoroughly macerate the food with the gastric juice, forming the thin liquid mass now called *chyme*. The fundus or upper end of the stomach exerts pressure on the food in it so that it constantly pushes the food further into the more active or prepyloric and pyloric end of the stomach. In thin way, all the contents of the stomach become a liquid chyme and are thoroughly mixed together. There can be no separation in the stomach of one part of the meal from the other. A blender also has the churning action only at the bottom but shortly after the motor is turned on all the contents are thoroughly and evenly mixed. The churning motion in the lower part of the stomach, the addition of an enormous amount of fluid, plus the constant pressure of the fundus, (which the blender lacks) upon the food is more than enough to ensure the thorough maceration of the food.

As previously stated, the enzymes of the stomach are pepsin, and gastric lipase. Pepsin, which initiates protein digestion, requires an acid medium in which to work. It is secreted as the zymogen pepsinogen and rendered active by the hydrochloric acid of the gastric juice. Pepsin is active only in the presence of hydrochloric acid and the hydrochloric acid may be destroyed by alkali such as baking soda, etc. Pepsin hydrolyzes proteins through several stages into proteoses and peptones, which are inabsorbable and must undergo further hydrolysis in the intestine by other proteolytic (protein splitting) enzymes.

The stomach enzyme, gastric lipase, asserts its activity upon fats, breaking them up into fatty acids and glycerols, but the action of this enzyme is inhibited by an acid medium. Physiologists believe that fats undergo little or no digestion in the stomach because of the acid gastric juice, but Hygienists have shown that, with proper combinations, fats can be digested in the stomach. The very fact that a fat-splitting enzyme is contained in the gastric juice, indicates that it is there for a purpose and, if in a medium of the right pH, it will exercise its properties. Fats and proteins are a very bad combination since proteins require a very acid medium for digestion and this would inactivate gastric lipase. Fats also inhibit gastric

secretion, it is thought possibly by the production of a hormone called enterogastrone. But where fats are eaten with green vegetables, preferably raw, the inhibiting effect of fats on gastric secretion is counteracted and protein digestion proceeds quite normally.

Salivary digestion or the action of ptyalin or salivary amylase upon starches occurs while chewing and swallowing food and for a brief time after it gets into the stomach. This is not sufficient time to complete salivary digestion. Unless starch-protein combinations are avoided, salivary digestion of starch is not completed. We have learned that pepsin, that acts on proteins, needs an acid medium in which to work, and salivary amylase, that digests starches, needs an alkaline medium. Then, if protein foods, such as nuts, cheese, etc., are eaten with starches, such as potatoes or bread, the gastric secretion will be acid because of the presence of the protein food, and will speedily bring to a halt all starch digestion in the stomach. The starchy food will be left incompletely digested until it reaches the small intestine for further hydrolysis, providing it has not undergone fermentation and decomposition. It must be remembered that it is during this waiting period, because of the temperature of the stomach, that fermentation and decomposition are most likely to occur. The end-products of bacterial decomposition are always poisonous.

When a starch is eaten alone, that is without protein, as for example, a potato, a gastric secretion, the pH of which is practically neutral, is poured into the stomach, and salivary digestion will combine in the stomach uninhibited. Other acids besides hydrochloric acid destroy salivary amylase. Free acids of fruits, such as those of oranges, grapefruit, pineapples, tomatoes, lemons, limes, sour apples, sour grapes, sour berries, etc., and the acid of vinegar as well as drug acids, destroy salivary amylase. The eating of acid fruits and the taking of vinegar-containing dressings suspends salivary digestion. The drinking of orange or tomato juice with the starchy breakfast cereals that conventional eaters consume, is hazardous.

Salivary and gastric (stomach) digestion, if carried out properly, prepares the food for intestinal digestion, where enzymes of the *succus entericus* (the secretion of the intestinal glands) and the pancreatic juice and the coenzymes of the bile take over. In the intestine, the end-products of hydrolysis are reached and the food is ready for absorption, which also takes place in the intestine.

*Succus entericus*, the intestinal secretion, contains four or five enzymes and has a marked alkaline reaction. The enzymes are as follows: *enterokynase*, which activates *trypsin* (the protein-splitting enzyme of the pancreatic juice); *erepsin*, which completes the work of *pepsin* and *trypsin*, hydrolyzing peptides to their constituent amino acids. The hydrolyzing enzymes of the *succus entericus* hydrolyze disaccharides, which are double sugars, into monosaccharides, which are simple sugars such as *glucose* and *fructose*. Without the hydrolyzing enzymes, to convert disaccharides to monosaccharides, the disaccharides would be eliminated by the kidneys because as such they are non-usable by the tissues.

Maltase acts upon maltose, and dextrine, which are products of the salivary digestion of starches. Two other hydrolyzing enzymes are *sucrase*, which hydrolyzes *sucrose* to *glucose*, and *fructose*, and *lactase*, the milk sugar enzyme. *Sucrose* is cane sugar, but it is also found in vegetables, the juices of many plants and some fruits. Most fruits contain the monosaccharides glucose and fructose. (If combined properly, fruits are the easiest of foods to digest, because their sugars are already in an assimilable form, needing no further hydrolysis. They need only to be absorbed and used.) *Lactase* acts upon milk sugar (lactose), hydrolyzing it to *glucose* and *galactose*.

Other constituents of the *succus entericus* are *nuclease*, which hydrolyzes the nucleic acid components of nucleoproteins and *secretin*, which is a hormone that I need not discuss in this short article.

Bile serves many important functions in the small intestine. It is an alkaline fluid, pH about 6.8 to 7.7, consisting of water, bile pigments, bile acids, bile salts, cholesterol, lecithin and neutral fats. Secretion of bile in the liver is continuous but it enters the duodenum only when chyme is present. Bile may be considered a coenzyme of pancreatic lipase as pancreatic lipase combined with bile splits fats more rapidly than it does alone. Bile helps in the absorption of fatty acids by combining with them, making them more soluble, hence more easily absorbed. Bile is needed in facilitating absorption of many fat

soluble vitamins, especially vitamins D, E and K. Bile has many other functions not concerned with digestion.

The pancreatic fluid enzymes are *trypsin*, pancreatic *amylase* and pancreatic *lipase*. *Trypsin* hydrolyzes proteins into proteoses, peptones and polypeptids and, given enough time, under favorable conditions, will continue its action until the necessary amino acids are reached. The more efficient and complete peptic digestion has been in the stomach, the more likely will *trypsin* and *erepsin* be able to complete the hydrolysis of proteins. Normally, proteins should be hydrolyzed into proteoses and peptones by gastric digestion. Under favorable conditions, proteins may be passed into the intestine without peptic digestion. Physiologists think that the enzyme trypsin of the pancreatic juice can initiate protein digestion and may reduce these proteins to proteoses and peptones, polypeptids, dipeptids and, finally, amino acids. It is reasonable, however, to think that thorough peptic digestion of proteins before they are expelled from the stomach assures the completion of their hydrolysis in the intestine, thus avoiding putrefaction.

The Hygienist does not agree with the thought of physiologists that salivary and gastric digestion are unimportant. The thoroughness with which enzymes do their work depends upon the amount of time they have in which to work. Obviously, therefore, thorough peptic digestion of protein will shorten the time required for the completion of protein hydrolysis in the intestine.

The several enzymes of the pancreatic and intestinal juices that complete the digestion of proteins, carbohydrates and fats in the intestine, function only in an alkaline medium. The chyme from the stomach is acid, but bile from the liver and the pancreatic juice, both of which are alkaline, quickly provide an alkaline environment for the action of the enzymes in the intestine. We need not concern ourselves with combinations, as they relate to intestinal digestion, except to point out that the best preparation for intestinal digestion is good salivary and gastric digestion. Food combining is, therefore, of greatest importance as it relates to salivary and gastric digestion.

Dr. Vetrano recommends using as little soaking water as possible, soaking one side at a time, so all water will be absorbed, thus avoiding losing flavor and nutrients. It is important that the water used for soaking be distilled water. If any water remains after soaking the fruit, you can drink the water.

Sweet fruits combine fairly well with subacid fruits, provided the subacid fruits are on the "sweet side," for example, use Delicious apples, not Macintosh, or Jonathans, with sweet fruit.

It is best to have these fruits at a fruit meal combining only with lettuce and/or celery. Since fruits are usually high in acids or sugars, they do not combine well with other foods.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 1. The Food Combining System

### **1. The Food Combining System**

Most of the food combining rules were first set down long ago by such Hygienic pioneers as Doctors John H. Tilden and William Howard Hay, and they have been tested in practice by modern Hygienic doctors and many thousands of lay people. This empirical testing has resulted in some modifications of the original food combining principles. Other modifications continue to be evaluated as "gray" areas and are studied and tested.

What is needed by neophytes and old-timers alike is accurate, up-to-date information, clarification, simplification and a common-sense approach—a way to eliminate confusion and anxiety.

This lesson discusses meal-planning principles and their application. You will be given all the details you will need in order to learn to apply these principles. This lesson will also lead you through numerous examples of the correct application of each of the food combining rules that were discussed in Lesson 22.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 2. Planning Meals

## 2. Planning Meals

Meal planning advice is intended merely as a guide to enable the individual to work out his own menus. The object is to understand the principles of food combining so that you (and your students) will be independent and never at a loss, no matter where, in preparing meals from the foods at hand.

Food availability varies with location, season, climate, altitude, soil and market factors. If you know how to combine your foods correctly, you may usually select compatible combinations anywhere—at the market, at the home of a friend or relative, or even at a public eating place. An intelligent adult should learn these principles and learn to apply them. Soon the practice becomes habitual—almost automatic.

We will start with an outline of how to plan your daily food program.

If you have Dr. Shelton's book, *Food Combining Made Easy*, you will notice (pp. 55-57) that his daily menus usually include a breakfast of fruit, a starch meal for lunch, and a protein meal for dinner. He even includes such items as lamb chops and eggs on some of the menus (simply to show how to combine animal products, if you use them).

My daily menus (in this lesson) will also include three meals, even though it is best to eat only two meals on most ( days. Many people do better with two meals daily, some do better alternating between two and three meals (two meals one day, three meals the next, etc.).

On days that you eat two meals, you may use the menus as a guide, selecting two meals each day from the variety offered. I would suggest selecting one fruit meal and one salad meal, being sure to include enough protein foods, according to your needs.

My menus will not advocate the use of a starch *and* a protein every day. My recommendation is to have some concentrated protein most days, and salad every day. Some people get along quite well with concentrated protein every other day, others need some every day. The amount of concentrated protein you need depends on how much you take at each sitting, your tolerance, and the efficiency of your assimilation. How much concentrated protein you need also depends on whether you are eating all raw food.

The proteins to be found in almost all vegetables and many fruits, though usually not concentrated, are of high biological value when eaten unchanged (without cooking), and are an important source of dietary protein. People on all-raw-food diets may need less concentrated protein, but it is an individual matter. Your own needs may best be ascertained through personal experimentation.

On the other hand, people who eat some cooked starches and cooked combination foods should realize that these are supplementary sources of dietary protein, and that it may not be necessary to also use concentrated proteins on every day when concentrated starches or combination foods are used. Again, this is an individual matter.

But four ounces of nuts or seeds at one meal, a serving of brown rice at another meal, and a serving of dates at a third meal on the same day, may easily result in overburdening the body with too many concentrated foods, and too much protein.

How much concentrated protein you need is also dependent on another extremely important factor. How active are you? How much regular vigorous exercise are you getting? Everyone should make it a point to use the body energetically every day. People who engage in little physical exertion need less food, particularly less protein. Sedentary people who consume more food, especially more protein, than their bodies are capable of metabolizing efficiently, are incubating future serious pathological problems.

I find that I personally need to take some concentrated protein almost every day. I usually can eat only two ounces of nuts and/or seeds at a sitting, supplementing my protein needs at other meals with other lower protein foods, such as large green salads and avocados. I use alfalfa sprouts with almost every salad meal, and sometimes use lentil and mung bean sprouts.

My recommendation includes a program that does not utilize concentrated starches or combination foods (whether raw, sprouted or cooked) more than four or five times weekly. You will note that the menus which include some cooked food indicate cooked foods not more than four times weekly. It is hoped that cooked foods will gradually be de-emphasized even more.

I am not, by any means, saying that Dr. Shelton's fruit-starch-protein daily menus may not be applicable to some people, nor am I saying that some people may not use more fruit and less concentrated foods than are included in these menus. I am simply offering suggested alternatives, determined through research and practical experience of many years and by many people.

Study the daily menus in this lesson, compare them with Dr. Shelton's and others, if you wish and determine, by experimentation, which daily meal plan is best for you.

## **2.1 Your Daily Food Program**

*Breakfast:* Starting with breakfast, you have three ways to go, with many variations of these three basic choices. The first choice—the best choice for most people—is the "no-breakfast plan." That would mean you would be eating only twice daily.

The second choice is a light breakfast of one kind of juicy fruit—citrus or melon or any subacid fruit, such as grapes—no dried fruit. *Fresh fruits are the best choice for the first food of the day*—one or two varieties. They should be eaten whole, uncooked and unjuiced. Eat until pleasantly satisfied, not stuffed. Three to five oranges, or a grapefruit and two oranges, or one-eighth of a medium watermelon, or a medium cantaloupe or honeydew melon, or one pound of grapes, should be maximum amounts for an all-fruit first meal of the day. Most people would want less.

The third breakfast choice is for people who find that they do better with a more substantial breakfast. This is preferred by some men (and also a few women), and especially by individuals who will be away from home during the day and will perhaps be unable to obtain good food conveniently. This plan might also be preferred by those who find that they feel better if they eat some protein early in the day—notably, people who might have the problem of low blood sugar (hypoglycemia). However, many people who have had hypoglycemia (or have been diagnosed as hypoglycemics) have successfully progressed to the two-meal-a-day plan.

This more substantial breakfast might consist of citrus or other acid fruit, such as pineapple or strawberries followed by raw, unsalted nuts and/or seeds. It might be advisable to wait thirty minutes or longer before eating the nuts, to allow the sugars in the fruit a chance to leave the stomach. This is a precaution often taken by people with impaired digestions. Maximum amounts of fruit in such a meal should be about half the quantities used when eating only the fruit. Two to four ounces of nuts and/or seeds may be used. Lettuce and/or celery would be an excellent addition to this meal.

This type of more substantial breakfast, or brunch, might be more advantageously used around noon, rather than early in the morning, if the circumstances permit, and if you are willing to postpone eating until after you have done something to "earn" your meal.

*Luncheon:* Now we get to luncheon, where we again have multiple choices. Even if you have not eaten breakfast, you might prefer to have a lunch of juicy fruit or melon. If you choose melon (most people do better with melon only, only one kind) eat as much as you want, but stop before you are

uncomfortably full. Some people have no problem when combining more than one kind of melon, or combining melon with certain subacid fruits. (See Lesson 22.)

If you decide on a mixed fruit lunch, this is an excellent and satisfying meal, if you are careful about the combinations. You should not use acid fruit with sweet fruit; for example, don't use oranges and bananas at the same meal. Your mixed fruit lunch could consist of grapes, peaches, apples or other fresh subacid fruit—one or two varieties (two or three pieces)—plus one or two bananas and/or one-half of a medium avocado. It is better to choose either the bananas or the avocado. Lettuce and celery also make an excellent addition to this meal, especially if you are including avocado.

If desired, you could also have a small serving of figs, dates, raisins, soaked dried apricots, or other dried fruit, *if you have not had avocado*. Or you could occasionally have acid or subacid fruit, lettuce and celery, and four ounces of cheese, if you use it. If you do use cheese, use it sparingly and rarely. Actually, lettuce and celery may be used with almost any fruit meal, but I would not recommend their use with melon.

Another type of luncheon, especially if you have had a fruit or melon breakfast, would be a salad meal. You could have as much salad as you want, consisting of one or more dark green varieties of lettuce: Romaine, Boston, Bibb, leaf, or any garden lettuce (not pale iceberg head lettuce), plus tomatoes, cucumber, celery, or any nonstarchy vegetables, along with or followed by avocado or nuts or seeds.

*The Evening Meal:* Now we get to the evening meal, where the choices are almost infinite. Much depends on what you have already eaten. If you have already eaten your fill at breakfast and lunch, you need very little additional food, perhaps none.

If you ate a citrus and nuts breakfast, and a salad and avocado lunch, you might want a mixed fruit supper. If you had a fruit or melon breakfast and a salad and nuts lunch, you might want a salad and avocado supper. If you have not yet had any nuts that day, you could have salad and nuts for supper.

If you are still using cooked food, it is better to eat it in the evening, after the day's work is done, when you may rest and relax, and accomplish better digestion. Many people have a tendency to overeat of the cooked food—so eat a large salad first; this may help you to eat more conservative amounts of cooked food. Try to avoid second helpings, and stop before you feel stuffed. In any event, it is preferable to eat raw food before cooked food, juicy food before dry food, and easy-to-digest food before foods that need more time for digestion (such as starches, proteins and fats).

## 2.2 Sequence of Eating

It is true that all the food will be mixed in the stomach, but the so-called "Ideal Order of Eating" is helpful to some extent.

*Eat raw food before cooked food.* Raw foods contain live enzymes, which influence digestive efficiency; cooking destroys all enzymes. Moreover, the consumption of raw foods stimulates gastric enzyme secretion, which is necessary to initiate good digestion. Besides, the more raw foods eaten as the first course, the less cooked foods will be eaten.

*Eat juicy foods before dry foods.* During the process of digestion, hydrolysis occurs—that is, the combining of the food with liquid from the body's reserve supply. Juicy foods contain some of their own liquid, which facilitates the initial processing of the food mixture. (Do not take water with dry foods as an alternative—this causes problems—see Rules for Drinking.)

*Eat easy-to-digest foods before foods, that require a longer digestion time.* The digestive process starts while the meal is being consumed, and the most liquid portion of the food mixture, the chyme, leaves the stomach at intervals. Thus, some of the easy-to-digest foods may be processed and leave the

stomach before the end of the meal. Even if this does not occur, if the concentrated foods are eaten last, you may possibly eat less of them, which would be an advantage for many people, especially those who have a tendency to overeat of the concentrated proteins and starches.

An exception may advantageously be made in the case of eating salad alternately with nuts, rather than consecutively. Many people find that eating the salad along with the nuts actually aids digestion, and also eliminates the dry or thirsty feeling that sometimes follows the eating of nuts after the salad. Do not use the tomato or lettuce to moisten the nuts to help get them down. The nuts must be thoroughly chewed.

Dr. Vetrano's article on the "Sequence of Eating" indicates that she does not attach importance to the sequence of eating concentrated foods and less concentrated foods. You might want to experiment to determine your own preference.

When combining several fruits at a meal, it is a good idea to eat the sweetest variety last. (Oranges after grapefruit; bananas, persimmons, dates, figs, after grapes, plums, apples etc.) If you follow a sweet fruit with one that is less sweet, the comparison actually seems to make the less sweet fruit usually taste acid or sour.

On the other hand, I sometimes like to eat a small amount of subacid fruit after the sweet fruit to dilute the excessively sweet taste at the end of the meal. Either way, there is no food combining principle involved—please yourself.

If you sometimes would like to eat fruit in combination with a mixed vegetable meal, the best way would be to eat the fruit first, and then, if possible, delay at least fifteen minutes before eating the other foods, starting with the salad.

As previously indicated, exceptions to this arbitrary "eating order" are not serious. After all, it does all go into the same stomach, and is quickly combined into a mobile mixture, the chyme.

## **2.3 Rules for Drinking**

Drink no beverage except pure water, only when thirsty, and not with meals, as drinking at meal time dilutes the digestive juices and retards digestion. Most beverages commonly consumed are loaded with harmful substances, interfere with the digestion and assimilation of foods, and may be addictive and destructive of vital organs.

No particular amount of water is necessary; thirst is the best guide. Hygienists usually drink very little water because no spices or seasonings are used, and there is so much liquid in foods as provided by nature. If thirsty, one may drink ten to twenty minutes before meals, one-half hour after a fruit meal, two hours after a vegetable or starch meal, and four hours after a protein meal. It is best to sip water, not gulp.

If one ignores the feeling of thirst that sometimes follows a meal and resists the impulse to drink, the thirst may soon disappear, having been satisfied by digestive secretions, and good digestion will be accomplished (since the digestive juices will not have been diluted). If very thirsty, and you feel that you must drink, try a few sips, instead of gulping large quantities of water. Drinking water with meals, or directly after meals, causes the stomach to dilate, and may lead to chronic indigestion, gastritis, ulcers, or even cancer.

*Juices:* Foods should not be juiced for use as a beverage, but should be eaten in their whole state. If exceptions to this rule are occasionally made, it should be with the full awareness that this fragmented food does not contribute anything "extra" to your health or nutrition, and is definitely a compromise of Hygienic principles.

In fact, this bombardment of the body with concentrated portions of fragmented foods may actually cause unpleasant, even serious problems. If carrot juice is consumed in large quantities, it may cause carotinemia and discolor the skin—the liver cannot handle too much of it. I have seen yellow palms (a symptom of carotinemia) that, fortunately, disappeared when the juicing habit was discontinued (prior to irreversible damage).

If you do insist on using juices, it would be best to follow the following guidelines: Never use large quantities of juiced foods and don't use them as part of your regular food program. If you use juice occasionally, four to six ounces of vegetable juice may be taken twenty to thirty minutes before the evening meal at which a salad and, perhaps, some cooked food are eaten. Fruit juice—preferably fresh-made at home—may occasionally be used prior to a fruit meal. However, keep in mind that juices, either fruit or vegetable, are not beverages but fragmented foods.

The only time juices are indicated as part of a Hygienic program is when breaking a fast (though many people do very well in breaking a fast on whole fruit) or, very judiciously, as a temporary elimination diet. See Dr. Vetrano's article "Mono-Eliminating Diets". More details about the inadvisability of juicing foods will be given in a future lesson.

*Pure water:* The only beverage which should be used when thirsty is pure water. Avoid chlorinated city water, if you can. Don't drink fluoridated water; do whatever you must to avoid it. Using fluoridated water in cooking is even worse, as it concentrates the fluorides, causing the water to be even less safe for use. Osteoporosis can occur from drinking fluoridated water. Sodium fluoride inactivates magnesium and some amino acids, and inhibits enzyme activity. Never drink artificially softened water because the miscellaneous inorganic minerals and impurities have been replaced by salt.

Minerals in water inhibit the absorption of the water. The minerals are inorganic substances and must be eliminated by the body. They are usually suspended particles of dirt and stone. These inorganic minerals are usable only by plants, which convert them to organic minerals, thus usable by man.

Professor Henry Sherman, in his book *The Chemistry of Nutrition*, says he doesn't like to refer to such elements as calcium and iron as minerals, which may imply that they come directly from the mineral kingdom.

He says that these elements are usable by humans only when they occur organically in plant tissues—as complex, organized structures within the plant. This is the way in which these elements are adaptable to animal life, and this is the way we can make the best possible use of them.

Pure water from a rock spring is excellent; fresh rain water (if it could be gathered unpolluted) and distilled water are best. More detailed information about water, beverages and drinking are given in another lesson.

## **2.4 Modifications**

People with efficient digestions can withstand modifications more freely; people with impaired digestions need to utilize as ideal an eating pattern as possible.

## **2.5 Cooked Foods**

No cooked food could even come close to the nutritional value of foods which are used as they grow in the garden and orchard. If you do use some cooked foods, choose the best available and prepare them conservatively and correctly. Lessons 24, 25 and 26 will help in the selection, storage, preparation and serving of foods for the best nourishment. This lesson will simply provide a preliminary outline of foods which may be cooked.

The variety of acceptable cooked foods is quite extensive. It includes such meals as broccoli and lentils, or green beans and steamed or baked potatoes, or eggplant casserole, vegetable chop suey, a mixed vegetable casserole, or thick bean or vegetable soup. Baked parsnips, beets and carrots have a delightful sweet taste and need no seasonings. You may select globe artichokes, cauliflower or sweet corn—the choices are many.

Plain steamed vegetables need no seasoning if they are not overcooked; most vegetables cook in ten minutes or less. Casseroles may require some seasoning, but we use no salt or pepper. Season with parsley, celery or sweet bell pepper. Recipes for casseroles will be included in the lesson on food preparation.

The best way to use whole grains is to sprout them.

Even those people who cook some of their vegetables should try to use as many as possible in the raw state. Try young sweet corn or sweet potatoes uncooked. Ground (Jerusalem) artichokes are delicious raw. Raw young sweet peas or edible pod peas are delicious uncooked. In fact, the edible pod peas are a gourmet delight. Of course, all meals that include some cooked food should be preceded by a large raw salad.

*Individual needs:* The foregoing suggestions for meals including uncooked and cooked foods are generally applicable to people not suffering from serious pathological problems. This program may have to be adjusted in various ways to provide for the nutritional needs and capacities of those whose health is impaired. It is not necessary or advisable to try to conform to a "blueprint" program. Certain people may have emotional needs, or other reasons, for requiring other foods.

We must think in terms of careful consideration of the needs of the individual. It is important to see each person in relationship to his emotional as well as his physical needs, and in relationship to his total life situation.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 3. Daily Menus

### **3. Daily Menus**

#### **3.1 Salads**

Eat as much salad as you want—but don't stuff yourself. Use one or two varieties of lettuce from among the dark garden varieties, such as Romaine, Bibb, Boston, leaf or any garden lettuce (except iceberg). Endive or escarole may be included as a variety of lettuce, if it is not bitter. In addition to the lettuce, choose two or three salad vegetables from among the following: celery, cabbage, cucumber, sweet pepper, or any young, tender greens (kale, turnip, dandelion, collard). Broccoli flowerets and leaves are particularly good salad vegetables. Cauliflower flowerets are also very good in the salad. Green beans, peas, chayote, zucchini or yellow summer squash are good choices when young and tender. Raw carrots or sweet potato may be used except with a protein meal; tomato may be used except with a starch meal.

### 3.2 Four Weeks of Menus

### 3.3 Two Weeks of All-Raw-Food Menus - First Week

	<i>Breakfast</i>	<i>Lunch</i>	<i>Supper</i>
<i>Sunday</i>	Strawberries	Salad Raw sweet corn (young/tender) Raw carrots Alfalfa sprouts	Salad Tomatoes Raw broccoli Macadamianuts
<i>Monday</i>	Oranges	Salad Wheat or rye sprouts Avocado	Salad Tomatoes Alfalfa sprouts Almonds
<i>Tuesday</i>	Papaya	Lettuce Blueberries (or other subacid berries) Persimmons Fresh or dried figs	Salad Raw turnips Alfalfa sprouts Lentil sprouts
<i>Wednesday</i>	Cantaloupe	Lettuce, celery Pears Sweet plums Soaked dried apricots	Salad Tomatoes Raw zucchini squash Cashews
<i>Thursday</i>	Kiwi Fruit Filberts	Watermelon	Salad Alfalfa sprouts Edible pod peas Raw cauliflower or carrots Avocado
<i>Friday</i>	Fresh ripe pineapple	Salad Alfalfa sprouts Raw cauliflower Jerusalem artichokes Avocado	Lettuce Peaches Papaya Bananas
<i>Saturday</i>	Casaba melon	Lettuce Grapes Apricots Dates	Salad Tomatoes Alfalfa sprouts Pecans

### 3.4 All-Raw-Food Menus - Second Week

	<i>Breakfast</i>	<i>Lunch</i>	<i>Supper</i>
<i>Sunday</i>	Honeydew Melon	Lettuce, celery Jonathan apples Plums Avocado	Salad Tomatoes Alfalfa sprouts Pecans
<i>Monday</i>	Fresh ripe pineapple	Salad Tomato Alfalfa sprouts Sunflower seeds	Lettuce, celery Pears Grapes Dates
<i>Tuesday</i>	One grapefruit Two oranges	Salad English peas Raw broccoli Avocado	Salad Tomato Alfalfa sprouts Brazil nuts
<i>Wednesday</i>	One or two grapefruit Pecans	Watermelon	Salad Raw chayote Alfalfa sprouts Mung bean sprouts
<i>Thursday</i>	Mangoes	Lettuce Cherries Bananas Dried soaked apricots	Salad Edible pod peas Coconut
<i>Friday</i>	Strawberries	Salad Alfalfa sprouts Raw sweet potato Raw cauliflower Avocado	Salad Tomato Raw broccoli Filberts
<i>Saturday</i>	Grapes	Lettuce Peaches Fresh figs Persimmons	Salad Tomato Alfalfa sprouts Almonds

### 3.5 Menus Which Include Some Cooked Food - First Week

	<i>Breakfast</i>	<i>Lunch</i>	<i>Supper</i>

<i>Sunday</i>	Watermelon	Salad Tomatoes Eggplant casserole With cashew nut topping or Mixed vegetable casserole with sesame seeds	Lettuce, celery Apricots Cherries Bananas Raisins
<i>Monday</i>	Grapes	Salad Alfalfa sprouts English peas (raw) or Lentil or mung bean sprouts Avocado	Salad Tomatoes Raw broccoli Pecans
<i>Tuesday</i>	Honeydew melon	Lettuce Red Delicious apples Persimmons Bananas	Salad Alfalfa sprouts Lentils with steamed yellow squash
<i>Wednesday</i>	Grapefruit Filberts	Watermelon	Salad Edible pod peas (raw) Alfalfa sprouts Avocado
<i>Thursday</i>	Fresh ripe pineapple	Salad Young tender raw kale Wheat or rye sprouts Avocado	Salad Green beans (raw or cooked) Raw carrots Steamed or baked potato*
<i>Friday</i>	Oranges Lettuce Avocado	Lettuce, celery Grapes Persimmons Dates	Salad Tomatoes Alfalfa sprouts Sunflower seeds
<i>Saturday</i>	Kiwi fruit Almonds	Casaba melon	Salad Alfalfa sprouts Vegetable chop suey Brown Rice

\* Sweet potatoes may be eaten raw, but white potatoes should not. It is advisable to dextrinize the starch in white potatoes, by cooking, to render them suitable as food.

### 3.6 Menus Which Include Some Cooked Food - Second Week

	<i>Breakfast</i>	<i>Lunch</i>	<i>Supper</i>
<i>Sunday</i>	Honeydew melon	Salad Globe artichokes (raw) Steamed broccoli Alfalfa sprouts	Lettuce, celery Strawberries Cashews
<i>Monday</i>	Raw fresh pineapple	Salad Tomatoes Raw yellow squash Macadamia nuts	Celery McIntosh apples Plums Avocado
<i>Tuesday</i>	Grapefruit Almonds	Lettuce Cherries Peaches Dried figs	Salad Alfalfa sprouts Vegetable stew with garbanzo beans
<i>Wednesday</i>	Strawberries Oranges	Salad Edible pod peas Sweet potato Avocado	Salad Tomatoes Alfalfa sprouts Pecans
<i>Thursday</i>	Kumquats Winesap apples	Lettuce, celery Grapes Bananas Soaked dried apricots	Salad Alfalfa sprouts Steamed or baked butternut squash Green beans (raw or cooked)
<i>Friday</i>	Cantaloupe	Salad Alfalfa sprouts Avocado	Salad Tomatoes Raw broccoli Almonds
<i>Saturday</i>	Grapefruit Oranges	Lettuce Golden Delicious apples Fresh figs Bananas	Salad Alfalfa sprouts Kasha (Buckwheat groats) or (Wild rice casserole) or (Millet casserole)

### 3.7 Recap of Concentrated Foods in Sample Menus (Number of Times Used Each Week)

	<i>Raw Food Menus</i>		<i>Menus With Some Cooked Food</i>	
	First Week	Second Week	First Week	Second Week
Concentrated Protein/Fat (Nuts and Seeds) Use 2 to 4 oz.	5	6	5	5
Combination Foods Starch/Protein (Coconut, Lentil Sprouts, Lentils, Mung Bean Sprouts, Rice, Wild Rice, Kasha, English Peas, Garbanzo Beans)	1	3	4	2
Starch foods (Jerusalem Artichokes, Globe Artichokes, Corn, Carrots, Potatoes, Sweet Potatoes) Use 1/2 to 3/4 cup	3	2	1	3
Fat/Protein (Avocado) Use up to 1/2 Medium Size	3	3	4	3
Concentrated Sweet Fruits (Dried Fruits) Use sparingly, e.g. up to 8 dates	3	2	2	2

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 4. Mono Meals And Mono Diets

## 4. Mono Meals And Mono Diets

Primitive man, in his pristine life in the forest, probably ate one food at a time, depending upon the availability of the food. Eating only one food at a meal is known as a monotrophic meal. If all meals over a period of time consist of a single food, such as oranges or grapes or watermelon, this would be called a monotrophic or "mono" diet.

### 4.1 Advantages of Mono Meals

There are advantages to the use of monotrophic meals, and it is recommended that at least the first meal of the day be a mono meal and preferably be of one kind of juicy fruit or melon. Obviously, the

digestion of a mono meal would not be subject to the adaptation problems that are sometimes experienced (even to a minimal degree) when so-called compatible foods are combined. For instance, even when several subacid fruits are combined, there may be subtle or overt differences in degrees of alkalinity or acidity, or in liquid or sugar content, or in digestion time. Most fruits lend themselves very well to monotrophic meals. It would be advantageous to program at least one mono meal daily—for the first food of the day.

## **4.2 Mono Diets Not Recommended for Regular Use**

I do not endorse the use of a monotrophic diet for extended periods or regularly for several days every week, nor do I endorse the regular or extended use of a diet consisting of all monotrophic meals, i.e., each meal consisting of a single food, e.g., one kind of melon for one meal, grapes for another meal, romaine lettuce for another meal, alfalfa sprouts for another meal. I do not believe this would be conducive to optimal nutrition, nor do I believe that all types of Hygienic foods lend themselves optimally to this usage. For example, romaine lettuce and nuts or seeds combine well; this combination has been observed to produce more efficient digestion of both foods.

Several days on a mono diet, followed by several more days on monotrophic meals, immediately following a prolonged fast—or, perhaps, during a flareup of digestive problems—may prove to be very beneficial. But people who implement diets consisting of all mono meals usually concentrate on fruit and neglect nuts and green leaves. This can be damaging, even disastrous. Such a practice may ultimately result in protein deficiencies and other serious pathological problems.

Dr. Herbert M. Shelton says (*The Hygienic System, Volume II, Orthotrophy*, Page 223): "As there are no pure frugivores, all frugivores eating freely of green leaves and other parts of plants, man may, also, without violating his constitutional nature, partake of green plants. These parts of plants possess certain advantages, in which fruits are deficient. Actual tests have shown that the addition of green vegetables to the fruit and nut diet improves the diet."

In the June 1976 issue of Dr. Shelton's Hygienic Review, Dr. Shelton says: "If man is a frugivore, as we have tried to demonstrate, then his natural diet should consist of fruits, nuts and green vegetables. The inclusion of tender, succulent green leaves, stems and flowers should not be considered a violation of his constitutional nature, as practically all animals in nature consume green foliage of one kind or another. For example, the frugivora consume large amounts of wild celery and other leafy plants along with their fruits and nuts. At times, even the carnivora consume large amounts of vegetation. Green leafy plants may be regarded as a wild card throughout nature. Whatever else an animal eats, whatever else it is specifically adapted for, some green leafy food is invariably included in the diet.

"Besides being specifically adapted to his digestive mechanism, fruits are also appealing to man's visual, olfactory and gustatory senses. They require no cooking, no dressing, no seasoning, no utensils, and hardly any cultivation, considering the abundance of wild fruit trees. Could any other food be more natural for us? With the addition of nuts and green vegetables, the fruitarian diet is as nutritionally sound as it is biologically correct."

Green leafy vegetables are more abundant in alkaline minerals than fruits. They are an excellent source of calcium, iron and other valuable minerals. They are rich in vitamins and contain small amounts of protein of the highest quality and biological value. They are the richest source of chlorophyll, such as only green plants can provide.

The analysis of chlorophyll shows it to be almost identical with the blood hemoglobin, except that the blood contains iron and chlorophyll contains magnesium. Increasing the amount of green leafy vegetables in the diet has been known to aid the body to correct secondary anemia.

The scientist, Frans Miller, wrote, "Chlorophyll has the same fast blood-building effect as iron in animals made anemic." The regenerative effect of crude chlorophyll from green leaves (not pure chlorophyll) was demonstrated through numerous scientific experiments in this country and abroad. (See Viktoras Kulvinskas article on chlorophyll.)

Green leaves convert sunlight into food by a process called photosynthesis, aided by the green pigment chlorophyll. Photosynthesis is the production of carbohydrate, in the presence of carbon dioxide, water and light. Since only green plants can do this, they are the most important things on our planet,, because they make possible the continuity of life.

Dr. Virginia V. Vetrano says (Dr. Shelton's Hygienic Review, January 1975, Page 116): "The Hygienic doctor has always advocated that some vegetables, particularly leafy vegetables, be eaten along with the fruit and nut diet, mainly because of the protein content in leafy vegetables. Most individuals have a difficult time adjusting to eating only nuts for protein and take an insufficient amount of protein at first; proteins of high biologic value are easily supplied by adding green vegetables to the diet."

Dr. Vetrano has also repeatedly advocated the regular use of nuts in the diet—in fact, they were served at the Health School every day. She is convinced that this source of concentrated protein is a necessary part of the daily diet. She says that whole nuts should be used, but that freshly-made nut butter or ground nuts can and should be used, if an individual does not have good teeth. (Dr. Shelton's Hygienic Review, February 1976, Page 135).

Dr. Shelton had many young people come to him during the time that Arnold Ehret's dietary system (*The Mucusless Diet*) was in the heyday of its popularity. These young people had been on his low or no (concentrated) protein diet for several years or longer and were suffering from weakness, ease of fatigue, and transverse and longitudinal ridges in their fingernails. After studying their problems for a while, he came to the conclusion that the problem was nothing more than a protein deficiency. He fasted them for three days, added protein to their diets, and they all recovered. (Dr. Vetrano, Dr. Shelton's Hygienic Review, October 1974).

I myself have repeatedly encountered individuals who, for as long as six months to a year after a fast, were becoming weaker and more enervated with each passing day—even having fainting spells. In every case, they had been convinced that concentrated proteins (nuts and seeds) were unnecessary, even inadvisable. When they added nuts and seeds to their diets, spontaneous and continuous improvement followed in every case.

Dr. Burton says (See his article "The Hygienic Diet" in Lesson 22): "I personally view the diet containing a large proportion of fresh fruits and vegetables, accompanied by three to four ounces of concentrated protein (nuts and seeds) as being the most satisfactory." He says we should attempt to secure our nutrients from a wide variety of foods, though, obviously, not at the same meal.

True that protein deprivation has to be prolonged and extreme in order to produce obvious signs of its inadequacy. Dr. Burton also makes the point that the varying needs and capacities of individuals must dominate in establishing requirements.

Eat a variety of Hygienic foods. Overeating of citrus and other fruits may be more easily avoided if it is thoroughly understood that a meal program which includes a variety of Hygienic foods, including fruits, nuts and seeds, green leafy vegetables, and sprouted seeds, is the best road to optimal nutrition.

It is not difficult to fall into the trap of the overeating of fruits. They are the most delightful of foods. They are also among the finest and best of foods, if properly used.

In many respects, I empathize and even tend to agree with those who maintain that the delights and nutritional value of fruits are unsurpassed. If, in addition, nuts, seeds and sprouts, and chlorophyll-rich

green leaves are not neglected, optimal nutrition would be assured.

Dr. Esser really brings it all together with this sage observation: "Fruits and nuts are the perfect foods for man, but in the civilized areas of the world it is virtually an impossibility to obtain a sufficiently rounded supply for perfect nutrition and health. Therefore it is necessary to supplement them with vegetables. It will be found that vegetables are delicious and succulent."

I know it was a great relief to me, after my 29-day fast, when I was (after almost two weeks on fruit juices and fruits) at last given something to eat that was not sweet. When I was permitted to have at least one salad meal every day, with nuts or avocado or coconut or raw sweet corn, my improvement, weight gain and energy multiplied.

*Recap:* Monotrophic fruit meals are excellent; a total, diet of monotrophic meals is not advisable. Since the usual monotrophic meal consists of one kind of fruit or melon, it would seem that at least one meal daily (or, at the very least, one meal every second day) should consist of several salad vegetables and a protein (or possibly a starch).

But keep it simple! The less complex our food mixtures, and the simpler our meals, the more efficient will be our digestion, and the better our health. Few foods at a meal, with sufficient variety of different types of foods over the period of several meals to insure that the body gets all the nutrients it needs, is the ideal Hygienic food program.

*Relationship of the diet to the acid-alkaline balance of the body:* In general, the diet should consist of at least 75% alkaline-reacting foods and 25% or less of acid-forming foods. Most foods with high protein content are acid-forming. Adherence to a varied Hygienic diet, and to the other principles of Natural Hygiene (especially regular, vigorous exercise) will enable your body to adequately monitor its own acid-alkaline balance, since there is a buffer action in the organism which serves to maintain an equilibrium between alkalinity and acidity. Minerals play an important part in the regulation of this function.

Animal proteins, which contain sulfur, uric acid and other acid end-products, tend to leach the tissues of their alkaline salts. These alkaline salts (minerals) are particularly needed by the cells to buffer and render such end-products less acid, and thus less irritating to the cells and tissues.

The alkaline properties of vegetable and nut proteins help to maintain the acid-alkaline balance of the body. Thus, correct eating (and exercise) are the keys in maintaining the acid-alkaline balance. Eating vegetables helps to maintain your acid-alkaline balance. If only fruits are eaten, the balance tends to swing to the alkaline side eating only proteins swings it to the acid side. Bananas are neutral if you are in good health, but otherwise they are slightly alkaline.

### **4.3 Monotrophic Diets as "Elimination Diets"**

"Elimination diets," which can be mono-diets, are often referred to under the misnomers "juice fasts" or "fruit fasts." Diets that are not stressful on the body and allow it to better perform its eliminative functions are sometimes useful when urgent symptoms require the temporary cessation of normal food intake, and it is not possible to go to bed and fast. However, the substitution of a long-term juice or fruit diet, when a fast is indicated, may be unwise and wasteful of the body's energy, because this does not accomplish the striking long-term benefits of the fast with nothing but distilled water. Nevertheless, a temporary juice diet or fruit diet may be indicated in some cases. If serious problems exist, a professional Hygienist can help to make this choice or decision.

There are other types of "elimination diets" (some not monotrophic) that are sometimes prescribed where a fast must be postponed, or should not be undertaken at the particular time.

"Elimination diets" are low in proteins, carbohydrates and fats. This causes the cells to use stored reserves to meet their requirements. During such a diet, the body can eliminate toxic matters and accumulated wastes, but never as efficiently or thoroughly as it would during a fast. The fast is always more efficacious in eliminating toxic wastes than is any kind of elimination diet. Greater benefit can be expected from one week of a complete fast than from two or three weeks of an elimination diet.

Further, a mono diet (the use of one food only—such as citrus, grapes or watermelon) may result in the production of imbalances in the body. During a total fast, the body is better able to monitor its own nutrition in a more balanced manner from the use of nutriment stored in the body.

A total fast increases metabolic efficiency. For example, the process of energy release from glucose (stored as glycogen in the liver) which is at 25% efficiency when eating, is increased to 45% efficiency when fasting (according to Dr. Alec Burton).

On a monotrophic diet, there is often a tendency to feel hungry and unsatisfied, while, during a total fast, hunger pangs usually disappear.

As you can see, the uses of monotrophic diets are limited. (See Dr. Vetrano's article "Mono-Eliminating Diets".)

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 5. Application Of The Food Combining Rules

## **5. Application Of The Food Combining Rules**

You will note that the discussion of a particular food combining rule will frequently overlap and dovetail with other food combining rules, since they are all closely interrelated.

Since starch digestion begins in the mouth with the action there of the enzyme ptyalin and requires an alkaline or neutral medium—while protein digestion begins in the stomach, where acid enzymes are secreted when protein is eaten—the first two and most important food combining rules seem obvious.

### **5.1 Carbohydrates with Acids or Proteins**

1. *Never eat carbohydrate foods and acid foods at the same meal.*
2. *Never eat a concentrated protein and a concentrated carbohydrate at the same meal.*

Carbohydrates include starches, sugars and cellulose. Lesson 22 demonstrated in great detail how incompatible combinations such as protein with carbohydrates reduce and inhibit the efficiency of digestive enzymes and subject the foods to decomposition in the digestive tract.

Some illustrations of combinations at the same meal which can produce this abortive effect are:

- Potatoes or other starchy vegetables with tomatoes or other fruit
- Starchy vegetables with nuts or other concentrated proteins
- Grains or legumes with tomatoes or other fruit
- Grains or legumes with nuts or other concentrated proteins

This means that when people eat meat and potatoes together, or a meat sandwich, they are not only consuming foods that cause problems when eaten separately (meat, bread), they are also compounding

the problem by ingesting them at the same meal with foods that require different conditions for digestion.

Tomatoes (acid fruit without the sugar content of other acid fruits) may be used with the vegetable salad or with any green or nonstarchy vegetable. They may also be eaten with protein/fat foods like nuts, cheese and avocados.

This seems to contradict Food Combining Rule No. 6, prohibiting the acid-protein combination. However, in actual practice, most Hygienists do use tomatoes with nuts and avocados rather freely. Both Dr. Shelton and Dr. Vetrano have come to consider these combinations acceptable and even desirable.

But Food Combining Rules Nos. 1 and 2 are extremely important, and there is general agreement among Hygienic professional and lay people that acids should not be used with starches nor with foods which combine concentrated starches with concentrated proteins (grains, legumes).

Since soy beans are higher in protein and fat, but lower in carbohydrates than other beans, there might be some possibility of combining them with tomatoes. I have experimented with this combination and have rejected it for my own use.

Any meal which includes cooked starches, or any cooked food, should begin with a large green salad. If you do use cooked foods, you should *always* use some raw food at the same meal, preferably as the first course.

Foods in the slightly starchy category, such as carrots, are best used with starchy vegetables like potatoes. When eating starch/protein foods, such as rice or beans, it is best to use green or nonstarchy vegetables only. Green and nonstarchy vegetables contain very small amounts of proteins and carbohydrates, and thus will not further complicate the digestion of the combination foods.

## 5.2 Some Examples of Percentages of Protein and Carbohydrate Content Of Various Categories of Foods

		<i>Protein Content</i>	<i>Carbohydrate Content</i>		
Concentrated Protein Foods:	<i>Almonds</i>	18.6%	19.5%		
		<i>Sunflower Seeds</i>	24%	19.9%	
			<i>Cashews</i>	17.2%	29.3%
Starch/Protein Foods	<i>Brown Rice</i>	7.5%	77.4%		
		<i>Wild Rice</i>	14.1%	75.3%	
			<i>Fresh Coconut Meat</i>	3.5%	9.4%

Starchy Vegetables	<i>Yam</i>	2.1%	23.2%		
		<i>Potato</i>	2.1%	17.1%	
Mildly Starchy Vegetables	<i>Winter Squash</i>	1.4%	12.4%		
		<i>Carrot</i>	1.1%	9.7%	
Nonstarchy Vegetables	<i>Cauliflower</i>	2.7%	5.2%		
		<i>Summer Squash</i>	1.1%	4.2%	
		<i>Romaine Lettuce</i>	1.3%	3.5%	
Sweet Fruits	<i>Banana</i>	1.1%	22.2%		
Subacid Fruits		<i>Dried Date</i>	2.2%	72.9%	
	<i>Apple</i>	.2%	14.1%		
		<i>Peach</i>	.6%	9.7%	
Acid Fruits	<i>Orange</i>	1.0%	12.2%		
		<i>Pineapple</i>	.3%	13.7%	

*Composition and Facts About Foods*, by Ford Heritage, lists the protein and carbohydrate content of most common foods. You need not become an expert on these fine points, unless that is your desire. The food classification and food combining charts in this lesson will be adequate to help you to become enough of an expert in the food combining system to enable you to plan properly combined meals, and to teach others to do the same.

### 5.3 Examples of Menus That Do Not Violate Food Combining Rules No. 1 and 2

1. No Carbohydrate with Acid
2. No Carbohydrate with Protein

*Carbohydrate Menus* (No Acid or Protein)

*Protein Menus* (No Carbohydrates)

Bibb lettuce  
Celery

Romaine lettuce  
Celery

Cucumber  
Sweet potatoes (raw or cooked)  
Water chestnuts

Tomatoes  
Raw broccoli  
Pecans

Romaine lettuce  
Sweet pepper  
Edible pod peas  
Sweet corn (raw or steamed)

Boston lettuce  
Sweet red pepper  
Tomatoes  
Kale (raw or steamed)  
Sprouted sunflower seeds

Boston lettuce  
Raw carrots  
Brussels sprouts (raw or steamed)  
Potatoes (steamed or baked)

Young, sweet cabbage  
Cucumber  
Alfalfa sprouts  
Tomatoes  
Cashews

Celery or cabbage  
Raw turnips  
Green beans (raw or steamed)  
Raw yellow squash  
Cooked rice

Ruby leaf lettuce  
Celery  
Raw zucchini squash  
Soy bean sprouts

## 5.4 Examples of Menus That Violate Food Combining Rules No. 1 and 2

1. No Carbohydrate with Acid
2. No Carbohydrate with Protein

Boston lettuce  
Sweet pepper  
\*Tomatoes  
\*Sweet potatoes

NO-NO! (Acid with starch)

Bibb lettuce  
Celery  
\*Peaches  
\*Sweet corn  
\*Almonds

NO-NO! (Starch with protein, fruit with starch, fruit with protein)

Romaine lettuce  
Celery  
Broccoli NO-NO! (Acid fruit with starch)  
\*Oranges  
\*Jerusalem artichoke

Cabbage  
Cucumber  
\*Tomatoes NO-NO! (Two combination starch/protein foods; acid with combination  
\*Lentil sprouts foods)  
\*Rice

Leaf lettuce  
Celery  
\*Dates NO-NO! (Sweet fruit with Protein)  
\*Pecans

Cabbage  
Celery  
Alfalfa sprouts NO-NO! (Starch with protein)  
\*Potatoes  
\*Sunflower seeds

Bibb lettuce  
Cucumber  
Sweet pepper NO-NO! (Protein with combination starch/protein food)  
\*Millet  
\*Cashews

Ruby leaf lettuce NO-NO! (Starch with combination protein/starch food)  
Cabbage  
Yellow squash  
\*Acorn squash

\*Soy beans

## 5.5 Protein-Protein Combinations

3. *Never consume two concentrated proteins at the same meal.*

Gastric acidity, and type, timing and strength of secretions for various proteins are not uniform. Therefore, do not combine nuts with cheese, nor any of the following concentrated protein foods with each other: nuts, avocado, soy beans, cheese, eggs, flesh foods.

Alfalfa sprouts, which are considered a green vegetable, may be used with a concentrated protein.

For optimal digestive efficiency, only one variety of nuts or seeds should be used at a sitting, but, if digestive problems are not a factor, it may be possible to eat two or three varieties together without harm. Some personal experimentation in this area is indicated. You may desire to combine one variety of seeds with one variety of nuts, or not to use high-fat nuts like brazils or macadamias by themselves. I have had good results in combining such high-fat nuts with lower-fat nuts or seeds. It might also be useful to combine expensive nuts like macadamias or pignolias with lower-priced nuts or seeds, in order to be able to afford the indulgence and variety of including the higher-priced nuts in the diet.

Some high-fat nuts are:

Macadamias	71.6% Fat
Brazils	66.9% Fat
Pecans	71.2% Fat

Some lower-fat nuts and seeds are:

Almonds	54.2% Fat
Pignolias	47.4% Fat
Sunflower seeds	47.3% Fat
Pumpkin seeds	45.8% Fat
Sesame seeds	52.2% Fat

Do not combine cashews with other nuts; the cashew is a part of the cashew apple and is not a true nut. It has a higher carbohydrate content than true nuts, having 29.3% carbohydrate and 17.2% protein. By contrast, for example, the almond has 19.5% carbohydrate and 18.6% protein.

Actually, the cashew is the pistil of the cashew apple. The whole raw cashew has within its shell a thick caustic liquid. In preparing cashews for marketing, they are "parched" to dissipate the acid, and then shelled. While not exactly "raw", they have not been subjected to the "roasting" (deep-frying) given "roasted nuts", and are considered good Hygienic food. They are combined in the same manner as nuts

and can be eaten with a salad.

Peanuts, of course, are not nuts. They are combination starch/protein foods, and are combined as starch.

If you experience any problems in learning to eat and digest nuts, it would be best to use only one variety at a sitting. Start out with small quantities, one to two ounces, and use only with salads. If you do have problems with nuts, experiment and find those you handle best and use mostly those. You will eventually build, up your nut-digesting ability and be able to use more varieties.

Most people have no problem with sunflower seeds. Those who do can begin by using them slightly sprouted. Just soak overnight, drain and let them progress until just a small sprout is showing. Complete sprouting instructions will be given in Lesson 26, Preparing and Serving Foods.

Although the pecan is a high-fat nut, it is easy to chew and seems to agree with most people. Cashews are also easy to chew and most people enjoy the sweet taste.

Almonds are valuable nuts, and have a somewhat alkaline reaction, whereas other nuts have the acid reaction commonly found in protein foods. However, they are hard and more difficult to masticate thoroughly. Problems may be avoided by thoroughly masticating and insalivating these nuts.

It does not seem necessary to give examples of menus which do or do not violate Food Combining Rule No. 3. It should suffice to repeat: eat but one protein food at a meal, and do not combine nuts, avocados, soy beans, cheese, eggs or flesh foods with each other.

## 5.6 Protein-Fat Combinations

### 4. *Do not consume fats with proteins.*

For the conventional eater, this means do not use cream, butter or oil with meat (any flesh foods), eggs, cheese or nuts. For the budding or experienced Hygienist, the fat foods are avocados and nuts. Of course, nuts are also a principal protein food. Avocados also contain small amounts of excellent protein. Since the Hygienic "fat" foods are really protein/fat foods, it would certainly be inadvisable to add more fat to the meal. You learned in Lesson 22 that fat has an inhibiting influence on digestion. We have also emphasized that we do not use two proteins at the same meal. So, it is obvious you would not use nuts and avocados at the same meal. This would also apply to cheese, if you use it—do not use cheese with avocados or nuts.

However, in implementing the "no protein-fat combination" rule, it must also be borne in mind that you should not use cream, butter or oils with protein foods, whether they are protein/fat foods (which most of them are) or whether they are among the few low-fat protein foods (legumes, skim milk cheese, lean meat).

## 5.7 Menus That Do Not Violate Food Combining Rule No. 4 No Fat with Protein

Boston lettuce	Sweet, young cabbage
Celery cabbage	Cucumber
Cucumber	Sweet pepper
Pecans	Alfalfa sprouts
	Cheese

Romaine lettuce	Kale
-----------------	------

Cucumber  
Celery  
Tomato  
Avocado

Cucumber  
Celery  
Soy pecan sprouts

## 5.8 Menus That Violate Food Combining Rule No. 4

Cabbage  
Tomato  
Celery  
\*Avocado  
\*Pecans

NO-NO! (A fat/protein with a protein/fat)

Boston lettuce  
Celery cabbage  
Tomato  
\*Cheese  
\*Walnuts

NO-NO! (Two protein/fat foods)

Leaf lettuce  
Kale  
Cucumber  
Celery  
\*Cooked soy beans with  
butter added

NO-NO! (Fat added to high protein combination food)

Romaine lettuce  
Sweet pepper  
Broccoli  
\*Cheese  
\*Avocado

NO-NO!(A protein/fat food with a fat/protein)

## 5.9 Fats in Combination with Other Foods

### 5. Use fats sparingly.

Too much fat taken with a meal results in discomfort and digestive problems. The best way to use fats, in moderation, is with raw green vegetables. If fats are used with other foods, adding raw green leafy vegetables to the meal will help to counteract the inhibiting effect of fats on gastric secretion.

In Lesson 22, it was pointed out that the use of avocados (low protein/fat) with starch is considered fair, provided a green salad is included with the meal. Nuts (high protein/fat) are not used with starch. The best way to use avocados or nuts is with the salad meal.

We also concluded that, while the use of avocados with subacid or acid fruit is ordinarily considered only a fair combination, it has been found that including salad vegetables, especially lettuce and celery, in the avocado/fruit meal enhances its digestion, and it becomes a quite acceptable combination.

### **5.10 Menus, That Do Not Violate Food Combining Rule No. 5 Fats with Other Foods**

Bibb lettuce	Leaf lettuce
Celery cabbage	Celery
Cucumber	Cucumber
Tomato	Potato (steamed or baked)
Avocado	Avocado

Romaine lettuce	Peaches
Celery	Apples
Sweet pepper	Lettuce
Alfalfa sprouts	Celery
Avocado	Avocado

In the above menus we are using avocado only as an example of the correct combining of fat. We are not using nuts (high protein/fat) as examples of fat with other foods, because when we combine nuts with other foods, their protein content is our primary concern. As for other fats (butter, oil, etc.), they do not really belong in a list of Hygienically correct menus.

### **5.11 Menus That Violate Food Combining Rule No. 5 Fats with Other Foods**

Cucumber	
Green beans	
*Steamed potato with butter	NO-NO! (Two foods high in fat)
*Avocado	

Bananas	
*Dates	NO-NO! (A fat/protein with dried sweet fruit—this would be somewhat better if lettuce and/or celery were included.)
*Avocado	

Carrots	NO-NO! (Two foods high in fat)
---------	--------------------------------

Buttered cooked sweet  
corn  
Avocado

Salad with oil dressing  
Rice NO-NO! (Two foods high in fat)  
Avocado

## 5.12 Acid-Protein Combinations

### 6. Do not eat acid fruits with proteins.

There is some variation in practice as to the use of citrus or other acid fruit with nuts. Dr. Vetrano has discontinued this practice, but it is still used by other Hygienic professionals and lay people. Those with digestive problems should certainly avoid this combination. The student should carefully re-read the text of Food Combining Rule No. 6 (in Lesson 22) for an understanding of this subject.

Those with unimpaired digestions can probably decide on an individual basis whether they should experiment with this combination. The choices would be (a) no citrus with nuts, (b) eat citrus, wait one-half hour to one hour before eating the nuts, and (c) eat the citrus and nuts together. The best practice is (a), because it is not good Hygienic practice to eat a meal in "relays."

If you do use citrus and nuts at the same meal, it would be a good idea to include some lettuce and/or celery.

The same reasoning would also apply to other acid fruits, such as pineapple, strawberries, tart apples, etc. The less sugar they contain, the less objection there is to combining them with nuts.

The same reasoning would apply to the use of citrus or other acid fruits with other protein foods, such as avocado or cheese.

People who use eggs or flesh foods should avoid the use of any fruit at the same meal. The use of these foods causes enough problems without also adding the extra problems of combining the fruit acids and sugars with the flesh foods.

Sour salad dressings and acid fruit drinks are bad with any meal, but are particularly bad with protein meals because they check hydrochloric acid secretion.

## 5.13 Menus Illustrating Food Combining Rule No. 6 Acid Fruits with Proteins

### Good Combinations

Lettuce  
Celery  
Tomato  
Brazil nuts (or other nuts, or avocado, or cheese, if you use it)

## **Fair Combinations**

Lettuce  
Kiwi fruit  
Almonds

Lettuce  
Grapefruit  
Avocado

Somewhat tart oranges, pineapple, strawberries or apples, combined with nuts, avocado or cheese would also be fair combinations.

## **Bad Combinations**

Very sweet oranges, pineapple, strawberries or other fruit, combined with nuts, avocado or cheese would be bad combinations (too much sugar with protein).

## **5.14 Sugar with Starch, Protein, Acid Fruit**

*7. Do not combine sweet fruits with foods that require a long digestion time—such as proteins, starches and acid fruit.*

Sugar with protein, starch or acid leads to fermentation, a sour stomach and discomfort. When protein or starch foods are combined with sugars, they may remain in the stomach almost twice as long as is normal. Use sweet fruits only as indicated in Food Combining Rule No. 10.

The same principle applies to the use of any sugar, honey, molasses or syrup, which are especially prone to ferment if used with mixed meals. Of course, these types of sugars should not be used at all—with anything. Refined sugar robs the body of B-vitamins and throws a "monkey-wrench" into the digestive machinery. The other "sweeteners" are almost as bad. A future lesson will discuss in detail the harmfulness of sweeteners.

## **5.15 Menus That Do Not Violate Food Combining Rule No. 7**

Sweet Fruits with Foods Requiring a Long Digestion Time

Lettuce  
Grapes  
Bananas

Lettuce  
Sweet mangos  
Persimmons

Celery  
Cherries  
Delicious apples  
Dates

Celery  
Lettuce  
Pears  
Peaches  
Raisins

## 5.16 Menus That Violate Food Combining Rule No. 7

Sweet Fruits with Foods Requiring a Long Digestion Time

Jonathan apples

Strawberries  
Bananas      NO-NO! (Acid fruit with sweet fruit)

Plums

Oranges  
Dates      NO-NO! (Acid fruit with sweet dried fruit)

Sweet corn

Persimmons  
Figs      NO-NO! (Starch with sweet fruit)

Apples

Raisins  
Pecans      NO-NO! (Protein with sweet fruit) (Many people have said they like to eat this combination, but it should be avoided, as it is quite incompatible.)

## 5.17 Starch-Starch Combinations

8. *Eat but one concentrated starch at a meal.*

This rule may be important principally as a means of avoiding overeating of starches, but it is a good rule to follow. Never combine a concentrated starch with a combination food (starch/protein food) such as grains or legumes. Never combine two combination foods at the same meal (such as rice with beans).

Slightly starchy foods may be combined with concentrated starches but not with combination foods. Potatoes with carrots, green beans and a large green salad is a good combination (if you are using cooked food). Brown rice would be better combined with broccoli, yellow squash and a salad.

Two mildly starchy vegetables may be combined if no concentrated starch is used, e.g., globe artichokes and carrots, or beets and edible pod peas.

## 5.18 Menus That Do Not Violate Food Combining Rule No. 8 One Concentrated Starch at a Meal

Ruby lettuce

Carrots

Celery

Raw Broccoli

Celery cabbage

Cucumber

Edible pod peas

Globe artichoke

Sweet corn (raw or cooked)

Cabbage

Sweet pepper

Cucumber

Green beans (raw or cooked)

Potatoes

Bibb lettuce

Celery

Cauliflower (raw or cooked)

Yams (raw or cooked)

Romaine lettuce

Celery

Sweet pepper

Cauliflower (raw or cooked)

Butternut squash

Boston lettuce

Cucumber

Water chestnuts

Parsnips

### **5.19 Menus That Violate Food Combining Rule Nr. 8 One Concentrated Starch at a Meal**

Bibb lettuce

Sweet pepper

Kale

\*Sweet corn

\*Potatoes

NO-NO! (Too much starch—unless corn is young, green and freshly picked)

Celery cabbage

Cucumber

\*Cauliflower

\*Acorn squash

\* Jerusalem artichokes

NO-NO! (Too much starch)

Leaf lettuce

Celery

Broccoli

\*Sweet potatoes

\*Rice

NO-NO! (Starch with combination starch/protein food)

Cabbage  
Celery  
Cucumber  
Zucchini squash1 NO-NO! (Starch with combination starch/protein food)  
\*Potatoes  
\*Chestnuts

## 5.20 Acid Fruits, Subacid Fruits, Sweet Fruits

9. *Acid fruits may be used with the less sweet subacid fruits.*

Tomatoes should not be used with subacid fruits. The acid fruits are those with the tart flavors (see Food Classification Chart in this lesson). The less sweet subacid fruits are some grapes (those which are neither sweet nor sour), some varieties of apples, most mangos, and any fruit on the subacid list which is not really sweet.

## 5.21 Menus Illustrating Food Combining Rule No. 9

### Good Combinations

Lettuce  
Oranges  
Apples  
Celery  
Pineapple  
Peaches (if not sweet)

Lettuce  
Strawberries  
Plums (if not sweet)

### Bad Combinations

Tomatoes  
Bananas NO-NO! Acid with sweet fruit

Grapefruit  
Sweet cherries NO-NO! Acid with sweet fruit

Oranges  
Delicious apples NO-NO! Acid with sweet fruit

## 5.21 Acid Fruits, Subacid Fruits, Sweet Fruits

10. *The sweeter subacid fruits may be used with sweet fruits.*

The sweeter subacid fruits are any fruits on the subacid list that have a marked sweet taste. See Food Classification Chart for a list of the sweet fruits. Dried sweet fruits should be used sparingly—one kind at a meal—and in small quantities.

## 5.22 Menus Illustrating Food Combining Rule No. 10

### Good Combinations

Lettuce  
Delicious apples  
Bananas

Lettuce  
Pears  
Persimmons

Celery  
Sweet grapes  
Dates

Celery  
Papayas  
Figs

### Bad Combinations

Tart apples  
Bananas                      NO-NO! (Acid with sweet fruit)

Tart mangos  
Dates                         NO-NO! (Acid with sweet fruit)

Tart grapes  
Persimmons                 NO-NO! (Acid with sweet fruit)

Tart peaches  
Figs                            NO-NO! (Acid with sweet fruit)

## 5.23 Fruits with Vegetables

11. *Do not combine fruit with any vegetables other than lettuce and/or celery.*

Lettuce and celery combine well with all types of fruit except melon. It is best to use two to four

varieties of fruit at a fruit meal, plus lettuce and/or celery. These green leafy vegetables may even enhance digestion of the fruit.

#### Menus Illustrating Food Combining Rule No. 11

##### **Good Combinations**

Lettuce  
Celery  
Sweet grapes  
Pears  
Bananas

Lettuce  
Sweet apples  
Sweet cherries  
Fresh figs

Celery  
Papayas  
Sweet peaches  
Persimmons

##### **Bad Combinations**

Broccoli  
Yellow squash  
Apples  
Dates

NO-NO! (Fruits with vegetables other than lettuce and celery)

Lettuce  
Pears  
Sweet corn  
Bananas

NO-NO! (Fruits with vegetables other than lettuce and celery)

Lettuce  
Blueberries  
Green beans  
Potatoes

NO-NO! (Fruits with vegetables other than lettuce and celery)

## **5.24 Fruits with Vegetables**

*12. Salads combine very well with either proteins or starches.*

Green leafy vegetables combine well with most other foods. They are excellent food and should be used in abundance. Do not combine any vegetables with melon.

with the use of melons with subacid fruits should do so very carefully, testing one subacid fruit (in small amounts) at a time. (See Dr. Vetrano's comments on this subject.)

### 5.27 Sprouts

14. *Alfalfa sprouts may be combined as a green vegetable.*

Other sprouts should be classified somewhat in the same category as the original seed, even though the protein and carbohydrates are less concentrated. (Review the discussion of sprouts in Lesson 22.)

#### Classification of Sprouts for Purpose of Food Combining

Alfalfa seeds, sprouted	Green vegetable
Mung beans, sprouted	Green vegetable protein/starch (combine as starch)
Grains, sprouted, sprouted	Mildly starchy combination foods
Sunflower seeds	Protein
Soy beans, sprouted	Protein
Lentils, sprouted	Protein

### 5.28 Menus Illustrating Food Combining Rule No. 14

#### Good Combinations

Tomato	Celery
Lettuce	Cucumber
Alfalfa sprouts	Avocado
Nuts	Mung bean sprouts

Cabbage	Lettuce
Sweet pepper	Celery
Broccoli	Cauliflower
Sprouted soy beans	Green beans
	Sprouted wheat

#### Bad Combinations

Lettuce	NO-NO! (Protein with combination food)
Cucumber	

Sprouted mung beans\*  
Nuts\*

Celery  
Sweet Pepper  
Sprouted rye\*  
Nuts\*  
NO-NO! (Protein with combination food)

Cabbage  
Celery  
Sprouted sunflower seeds\*  
Potatoes\*  
NO-NO! (Protein with starch)

Lettuce  
Tomatoes\*  
Lentils, sprouted\*  
Rice\*  
NO-NO! (Acid and protein with combination food)

## 5.29 Milk, Clabber and Yogurt (Not Recommended)

*15. Milk is best taken alone.*

This rule is included because it is one of Dr. Shelton's food combining rules, and because this lesson may be helpful to those still on a mixed diet. Please review the text in Lesson 22 on Food Combining Rule No. 15. I hope you will decide not to use milk, clabber or yogurt.

I am not including menus for the best ways to combine these foods, but will simply say they are best used alone, but are a fair combination with acid or subacid fruit.

## 5.30 Good, Fair, Poor and Bad Combinations

- Good combinations are good for the weakest digestion.
- Fair combinations are permissible for those with unimpaired digestions.
- Poor combinations should only be used by people with the best digestions, and then rarely (or they may lose their distinction of possessing the "best" digestions).
- Bad combinations are so bad that no one should ever use them.

## 5.31 Examples

### Good combinations

Golden Delicious apples  
Thompson seedless grapes  
Lettuce and celery  
Bananas

Lettuce  
Cucumber  
Sweet peppers  
Alfalfa sprouts  
Nuts

### Fair Combinations

Jonathan apples  
Pears  
Lettuce  
Avocado  
(Avocado with fruit)

Lettuce  
Cabbage  
Green beans  
Potatoes  
Avocado  
(Avocado with starch)

### Poor Combinations

Cherries  
Lettuce  
Avocado  
Soaked dried apricots  
(Avocado with dried sweet fruit—the fact that it has been soaked and that lettuce is included with the meal improves it somewhat.)

Celery cabbage  
Cucumber  
Mung bean sprouts  
Nuts  
(It would be better to use alfalfa sprouts with nuts.)

### Bad Combinations

Grapes  
Avocado  
Bananas  
Dates  
(Concentrated fat with too much concentrated sugar.)

Lettuce  
Celery  
Cabbage  
Rice  
Potatoes  
(Starch with combination starch/protein food)

## 5.32 Discrepancies

You may detect discrepancies if you compare the different food charts and classifications of foods as interpreted by various authors and professionals. For instance, you may see butternut or acorn squash listed by one author as starchy, and mildly starchy by another author.

If you are really concerned about it, you can refer to *Composition and Facts About Foods*, by Ford Heritage, or *Composition of Foods*, Department of Agriculture Handbook No. 8. You can then make your own decision.

Sweet potatoes with 26.3% carbohydrates, yams with 23.2% carbohydrates and potatoes with 17.1% carbohydrates are all considered starchy foods. Carrots with 9.7% carbohydrates and beets with 9.9% carbohydrates are considered mildly starchy. Winter squash (butternut, acorn, etc.) has 12.5% carbohydrates. Would you classify it with the 17.1% potatoes or the 9.9% beets? It's not too important, since starches may be used together, if desired, provided the total quantity of starch at the meal does not exceed, say, 15% of the meal.

Cauliflower, with only 5.2% carbohydrates, is listed by some as mildly starchy, yet its carbohydrate content is less than that of broccoli or brussels sprouts.

Another case in point is the coconut. Dr. Esser classified it as protein, but Dr. Shelton combines it as starch. It is actually a combination food, and is usually combined as a starch. But when we look it up in the food charts, we find that fresh coconut contains 9.4% carbohydrate and 3.5% protein; dried coconut contains 23% carbohydrate and 7.2% protein.

By comparison, almonds contain 19.5% carbohydrate and 18.6% protein; pecans 14.6% carbohydrate and 9.2% protein; these, of course, are classified as protein foods.

Brown rice contains 77.4% carbohydrate, 9.6% protein; fresh lima beans contain 22.1% carbohydrate and 8.4% protein; these are combination foods, and are combined as starch.

It seems to me that the coconut, with three times as much starch as protein, should be combined as starch. But, since fresh coconut only has 9.4% carbohydrate, perhaps the idea that its starch content is unimportant is a valid one. What do you think? My own method is to think of it as a combination food, and I don't use tomatoes or other acid fruits with coconut—it seems the safest interpretation.

If you see other such discrepancies, you may either disregard them and use the food either way, or, if you are uncomfortable about it, get a reference book and look it up. It can be a great satisfaction to resolve such discrepancies in your own mind by tracking down the correct information.

You may also occasionally come across an error in food combining charts; for example, on page 321 of *The Hygienic System, Volume II*, in one place starch is said to be a bad combination with subacid fruit and in another place on the chart, it is said to be a fair combination. I would say that the use of any fruit with starch would be contraindicated.

The food combining charts in this lesson are as accurate as I could make them, and I hope they will be helpful to you and your students.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 6. Trying Too Hard

## **6. Trying Too Hard**

### **6.1 Take It Easy!**

*Don't try so hard that you become nervous and anxious.* Do the best you can. Avoid the worst combinations (dates or bananas with nuts, potatoes or grains with tomatoes, or grain with nuts) and everything else will gradually fall into place.

Occasional indulgence in incorrect food combinations is no cause for anxiety, even though it is not ideal—a healthy body can cope with occasional exceptions. It is what we do daily, habitually, that will

make the difference.

*Don't make food the focal point of your life.* Above all, the student should not become overly preoccupied with food. Eat your meal and forget it. Let your friends eat their foods and don't give them a lecture at the dining table. You may have to parry their questions about your eating habits by explaining that you don't like to enter into these discussions at mealtime, but will be happy to answer their questions afterwards.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 7. Your Social Life

## **7. Your Social Life**

If you take a moderate attitude, the enjoyment of dining out, entertaining or eating at a friend's home need not be eliminated from your life. Sometimes, with good planning, little or no compromise will be necessary.

Do your best at home, and partake, somewhat selectively, when with your friends. Even if you decide to "go all the way" in Natural Hygiene for optimal health, and never make exceptions at home, it is not necessary to act superior and critical when in company. You can partake enough not to be too conspicuous without really hurting yourself. Just be alert not to carry your indulgences too far, or to lose sight of your goal. You might even find that your friends respect you and are interested in your desire to cooperate with the needs of your body.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 8. Your Family

## **8. Your Family**

As for your family, their participation in proper food and good food combining is up to them. You can make better food available, but don't try to force them to eat anything or to eat in a particular way. They may gradually want to follow your example, or they may never do so. It's not all that hard to provide simultaneously for your needs and theirs. It's certainly worth the effort if it's going to improve your health.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 9. Looking Forward

## **9. Looking Forward**

As you progress in Natural Hygiene, your understanding and application of Hygienic principles will become increasingly synchronized, and you will find it easier today than yesterday, and easier

tomorrow than today!

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 10. Food Classification Charts

## **10. Food Classification Charts**

### **10.1 Proteins**

#### **Nuts**

Pecans  
Almonds  
Brazil nuts  
Filberts or hazelnuts  
English walnuts, butternuts, heart nuts  
Black walnuts  
Macadamias  
Pistachios  
Pignolias (Pine nuts)  
Indian nuts  
Beechnuts  
Hickory nuts  
Cashews

#### **Other Plant Proteins**

Soy beans (fresh, dry or sprouted)  
Sunflower seed sprouts  
Lentil sprouts  
Garbanzo sprouts

#### **Low Protein**

Avocados (may also be classified as a fat and as a neutral fruit)  
Olives  
Milk (not recommended)

#### **Green Vegetable Proteins\*\* (Combine as Starch)**

Peas in the pod  
Lima and other beans in the pod  
Mature green beans in the pod  
Mung bean sprouts\*

\* Mung beans sprouted to green leaf stage—green vegetable starch/protein

\*\* Classified as starches for purposes of food combining

## **Seeds**

Sunflower seeds  
Sesame seeds  
Pumpkin and squash seeds

## **Animal proteins (not recommended)**

Cheese (raw milk or unprocessed)  
Eggs  
All flesh foods except fat

## **Starchy proteins \* \* (not recommended) (Combine as starch)**

Beans:

Peas  
Lentils  
Peanuts  
Chestnuts

All grains:

Wild rice  
Rice  
Buckwheat  
Millet  
Wheat  
Rye  
Barley

## **Sprouts (contain significant amounts of protein, especially in early stages)**

Soy sprouts (Combine as protein)  
Lentil sprouts (Combine as protein)  
Sunflower seed sprouts (Combine as protein)  
Alfalfa sprouts (may be combined as green vegetable)  
Mung bean sprouts\*  
All seed, bean & grain sprouts  
Combine seed & bean sprouts as protein —except alfalfa  
Combine grain sprouts as mildly starchy

\* Mung beans sprouted to green leaf stage—green vegetable starch/protein

## **10.2 Starches**

### **Starchy proteins (Classified as starches for purposes of food combining)**

Peanuts  
Chestnuts  
Coconuts  
Dry beans

Dry peas  
Lentils  
Peas in the pod  
Lima & other beans in the pod  
Mature green beans in the pod

All grains and all foods containing grains:

Wild rice  
Brown rice  
Buckwheat groats  
Millet  
Oats  
Wheat  
Rye  
Barley

### **Starchy vegetables**

White potatoes  
Yams and sweet potatoes  
Mature corn  
Jerusalem artichokes  
Parsnips\*  
Salsify (Oyster plant)\*

Mildly starchy vegetables

Carrots  
Globe artichokes  
Beets  
Rutabaga  
Edible pod peas  
Winter squash (acorn, butternut, hubbard, banana, etc.)\*  
Pumpkin\*  
Water chestnuts  
Sprouted grains

\* Parsnips (17.5% starch) and salsify (18%) are sometimes listed as mildly starchy or even nonstarchy vegetables, but since they contain as much starch as the potato (17.1%) they should properly be classified as starchy.

Winter squash (12.4%) and pumpkin (6.5%) are shown on some charts as starchy, but their starch content is quite a bit lower than potatoes (17.1%). I would consider them mildly starchy (or you could consider winter squash as borderline).

\* Cauliflower is sometimes listed as mildly starchy, but with a starch content (5.2%) lower than broccoli (5.9%) and Brussels sprouts (8.3%), it properly belongs in the nonstarchy category.

### **10.3 Nonstarchy and green vegetables**

Lettuce  
Celery

Cabbage (young, sweet)  
Celery cabbage  
Cucumber  
Cauliflower\* (see \* above)  
Escarole (if not bitter)  
Sweet pepper  
Broccoli  
Rappini (similar to broccoli)  
Brussels sprouts  
Kale  
Collard greens  
Dandelion greens  
Turnip tops  
Mustard greens (if young and mild)  
Okra  
Kohlrabi  
Turnips  
Eggplant  
Green corn (if not mature, and if eaten less than 2 hours after picking)  
Green beans (young & tender)  
Zucchini (and all other summer squash)  
Yellow crookneck squash (and all other summer squash)  
Chayote  
Bok choy  
Alfalfa sprouts

**Use seldom if at all— too high in oxalic acid (a calcium antagonist)**

Spinach  
Swiss chard  
Beet tops  
Rhubarb

**Should not be used— contain concentrated acids & irritants**

Bitter cabbage  
Endive  
Escarole

**Contain mustard oil**

Irritant foods (unless very young and sweet)— should not be used often or in large quantities

Parsley  
Watercress  
Chives  
Scallions  
Onions  
Leeks  
Radishes

Garlic  
Mature mustard greens

## **10.4 Fats**

Fats delay digestion—may take up to four to six hours. The need for fat is small, and the best sources are whole foods like nuts and avocados.

### **Recommended fats**

Edible (protein/fat foods) seeds, nuts and avocados

### **These fats are not recommended**

Not recommended, though used occasionally by some Hygienists.

Butter  
Cream

### **All oils**

(Oils are used occasionally by some Hygienists, but are not recommended. Use unrefined cold-pressed oils, preferably stable oils like olive and sesame oil, less likely to be rancid. Oils are fragmented, concentrated foods, and are best omitted)

Olive oil  
Sesame oil  
Sunflower seed oil  
Corn oil  
Peanut oil  
Cottonseed oil  
Safflower oil

### **All meat fats (not recommended)**

Butter substitutes (not recommended)—oleomargarine and the hard white hydrogenated "vegetable" shortenings commonly used in frying and baking are particularly pernicious substances, which the body is not equipped to handle.

## **10.5 Sweet fruits**

Fresh:  
Bananas  
Persimmons  
Thompson grapes (seedless)  
Muscat grapes  
All sweet grapes  
Fresh figs

Dry:  
Dates  
Figs

Raisins  
Prunes  
Apricots  
Peaches  
Apples  
Cherries  
Bananas  
Litchi "nuts"  
Carob  
All dried fruit

Some unusual or tropical fruits not listed— sweet taste is a good indication of its classification.

### **10.6 Subacid fruits**

Sweet apples (Delicious)  
Sweet peaches  
Sweet nectarines  
Pears  
Sweet cherries  
Papayas  
Mangos  
Apricots  
Fresh Litchi "nuts"  
Sweet plums  
Blueberries  
Raspberries  
Blackberries  
Mulberries  
Huckleberries  
Cherimoyas  
Some grapes (neither sweet nor sour)  
Some unusual or tropical fruits not listed.

### **10.7 Acid fruits**

Oranges  
Grapefruit  
Pineapples  
Strawberries  
Pomegranates  
Lemons  
Kiwi fruit  
Kumquats  
Loquats  
Carambolas  
Loganberries  
Gooseberries  
Cranberries (not recommended—they contain benzoic acid)

Limes Sour apples Sour grapes Sour peaches Sour nectarines Sour plums Sour cherries

Tomatoes—acid fruit, without the sugar content of other acid fruits. Used with vegetable salad or any green or nonstarchy vegetables, but not at a starch meal. May be used with nuts or cheese, but not with meat, milk or eggs. Some unusual or tropical fruits are not listed—acid (or sour) taste is a good indication of its classification.

## 10.8 Melons

Watermelon  
Honeydew melon  
Honey balls  
Cantaloupe  
Muskmelon  
Casaba melon  
Crenshaw melon  
Pie melon  
Banana melon  
Persian melon  
Christmas melon  
Nutmeg melon

## 10.9 Syrups and sugars

Brown sugar  
"Raw" sugar  
White sugar  
Milk sugar  
Maplesyrup  
Cane syrup  
Corn syrup  
Honey

None of these substances are recommended.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > 11. Questions & Answers

## 11. Questions & Answers

### **How many mildly starchy vegetables may be used with a concentrated starch?**

Preferably only one, e.g., potatoes and carrots. However, if no concentrated starch is used at the meal, two (or perhaps even three) mildly starchy vegetables might be used together, e.g., globe artichokes, carrots and water chestnuts, together with a large green salad.

### **What percentage of a meal should be of concentrated proteins or starches?**

A small percentage, say 10 or 15%.

**If I want to eat home-made bread, cake or pie occasionally, how should they be combined?**

Cake or pie is such a conglomeration of ingredients, there is no way to properly combine them.

**I have an 85-year-old mother who lives with me. How far should I go in trying to convince her to accept the Hygienic food program and food combining?**

You can't (and shouldn't try to) force anyone at any age to eat your way. You should not nag elderly people to change their ways. If she is receptive to gentle persuasion, that is fine, but arguing about what foods she should eat may do more harm than good.

**Why is it that conventional foods stay with me longer, and what can I do to feel more satisfied for a longer period of time between meals, so I can resist snacking?**

First of all, to have foods "stay with you" is undesirable. When you eat a conglomeration of foods that are difficult to digest, you have given your body a lot of work to do to try to get rid of the mess. No wonder you don't feel like eating again for a long time! Food mixtures that take many hours to digest are apt to ferment and cause problems. When I first changed to a properly combined Hygienic diet, I noticed the "empty" feeling at certain times, but I soon came to realize that it was a good feeling to know that gastric digestion has been efficiently accomplished, and that the stomach would now have chance to relax and rest before it would have to deal with the next meal. The "empty" feeling doesn't necessarily signal the need for food.

Of course, it is unusual to feel "empty" very soon after a protein meal. My digestion has improved so much that I am delighted when my stomach feels empty 3 1/2 or 4 hours after eating nuts and a raw salad. In my earlier years of Hygienic eating, it took five or six hours or longer to achieve that happy state of "emptiness."

It is true that for those who feel more satisfaction and less desire for unwholesome foods after a meal that takes longer to digest, it might be advisable to have a protein meal at noon instead of in the evening. A properly combined protein meal will not cause the complicated problems common in digesting conventional meals, but it does remain in the stomach and intestines much longer than fruit or starch meals, thus giving people a satisfied feeling and preventing them from snacking on junk foods or sugars between meals.

In recent years, Dr. Vetrano served the protein/fat meal (nuts) at noon at the Health School. (See article, "Protein Meal at Noon," by Dr. Virginia Vetrano, in this lesson.) I personally prefer to defer eating foods which require long digestion time (proteins or combination foods or starches) until the evening meal. During the day, when I am most active, I don't like to have a "full" feeling. In fact, when I am scheduled to give an afternoon lecture, I usually don't eat at all until after the lecture. Sometimes I might eat the orange or a small piece of melon a couple of hours before the lecture. When I am scheduled for an evening lecture, I might eat a light fruit meal a couple of hours beforehand.

When I eat a meal which includes protein or a combination food or starch (following a large salad, of course), I prefer to be able to relax and rest afterwards, if at all possible. I find this works best for me.

I do make some occasional exceptions to this rule, depending on my program for the day. If I am going to be away from home in the evening and unable to have my leisurely evening meal, I might eat a protein meal before leaving home, as my noon meal. Sometimes I simply take a bag of salad and some nuts with me.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > Your Probing Mind By Dr. Virginia Vetrano

## Your Probing Mind By Dr. Virginia Vetrano

### "Mono-Eliminating Diet"

*What are your feelings about a "mono-eliminating diet, " e.g. oranges or grapefruit?*

An "eliminating diet," mono or otherwise, is useful when for some reason a genuine fast cannot be taken. Bear in mind that the fast is always more efficacious and more rapid in permitting the body to rid itself of toxic wastes than any kind of eliminating diet. One week of a complete fast is probably more beneficial than two or three weeks of an "eliminating diet."

It is often thought that one can do the "eliminating diet" on his own, bypassing the service of a *Hygienic* doctor. While I am not trying to make people more dependent upon doctors for everything, I am trying to stress the fact that most people have insufficient knowledge of their condition and the "elimination diet," and often damage themselves by the improper application of *Hygiene*. Many people come to me after having placed themselves on an "eliminating diet" and carrying it out for too long. Many people tend to vascillate back and forth from one type of "eliminating diet" to another; and from stuffing to underfeeding so long that real deficiencies are produced and health is not regained. They do themselves much harm and come to me suffering with the same problems for which they started the diet, as well as suffering with deficiencies. The pathetic thing is now they are too thin to fast for speedy recovery of their health and too sick to eat. What do you do with them? They've gotten themselves in real trouble and have actually made themselves sicker and unable to be helped by the Hygienic doctor until they carry out his or her instructions in Hygienic living and have eaten properly for a year or more.

Juice diets, and the orange or grapefruit diet may be used judiciously with beneficial results, but these should not be carried out for months at a time, nor should a person go three or four days out of every week on a juice diet over a long period of time. He will become weak, and run into deficiencies.

### Protein Foods

*Is it true that the food I eat today is not digested, assimilated and put to use until several hours later? Why then does eating nuts early in the day give me a protein kick and in general help me to feel more*

*satisfaction and less desire for unwholesome foods?*

Eating protein foods, especially nuts, satisfies for many physiological reasons. One of them is probably because of their high fat content. Fat seems to be used for energy longer than carbohydrates before being stored by the body. Sugars and starches are absorbed and gotten out of the small intestine and circulation quickly, and then rapidly converted into glycogen in the liver. Perhaps, with nothing in the intestines to be absorbed, hunger is again manifested. Proteins take quite a bit longer for digestion and absorption, and perhaps this is another reason why they satisfy more. Once they have been absorbed through the digestive epithelium, however; the amino acids are readily taken up by the cells. In spite of this, they still satisfy and prevent people from desiring junk foods or sugars between meals. This is one of the main reasons that we began serving the protein meal at noon instead of in the evening at the Health School.

## **Sequence of Eating**

*In what order should you eat foods?*

Formerly it was thought by a few Hygienists that it was necessary to eat the least concentrated food first and the most concentrated food last. The reason for this was that the foods were supposedly layered in the stomach, and it was thought best not to mix them; to permit the juicier foods to be evacuated from the stomach first. It has been shown, however, that food does not stay in layers in the stomach, and the pyloric valve does not open with each peristaltic wave so that food will become mixed in the stomach even if you eat the most concentrated food last. For instance, let us say that you eat some subacid fruit first. The pyloric valve stays tightly shut for fifteen minutes after the beginning of a meal, then it begins to open and pass a tiny bit of food to the duodenum. Each time there is a contraction of the stomach, the food is pushed forward toward the pylorus (the lower end of the stomach). As the valve opens only occasionally and not each time the peristaltic wave pushes food toward it, the food is pushed toward a closed valve. The food cannot get out of the stomach at the valve, so it streams back toward the upper end of the stomach, thoroughly mixing with the food eaten last. Even if some food empties from the pylorus when it opens, only a small amount is evacuated and the rest is propelled backward to be thoroughly mixed with the contents of the upper stomach. Eat your foods in proper combinations, and you won't have to worry about the sequence in which you eat them. Food becomes mixed in the stomach regardless of sequence of eating.

It is wise, however, to remember to chew your foods well, and separately. That is, do not use a tomato or lettuce to moisturize nuts to help get them down. Chew your nuts well, and alone; swallow them. Between mouthfuls of nuts you may eat some salad foods. Never use the moisture of the less concentrated foods to help liquify nuts or other concentrated foods. The salivary glands will secrete sufficient moisture of the proper kind for this purpose and your foods will be better digested.

Sometimes it is wise to eat the least sweet fruit first when eating three fruits at one meal, otherwise the last part of the meal may be less tasty. If you eat dates first, for instance, and then take apricots, which are less sweet, you may not enjoy them as well after the very sweet fruit because of the unavoidable comparison of sweets.

## **Melons**

### *Why do you eat melons alone?*

Melons are best taken alone because the sugar and other nutriment are in a less stable form than the nutrients of other fruits. Orange juice may be kept in the refrigerator for an hour with little change in flavor, but if you refrigerate watermelon juice for only 10 minutes, its flavor, color and composition change. It decomposes much more quickly than other fruits. Consequently, if it is held in the stomach awaiting the digestion of other foods, it will decompose (ferment) and cause a great deal of gastric distress. Eating watermelon with nuts can really be troublesome.

One should not take watermelon with other more concentrated fruits. The more concentrated the food is, the longer it takes to propel it from the stomach, and if the melon is held in the stomach mixed with the other fruit, then it also will be held in the stomach for a longer period of time. Watermelon must be evacuated from the stomach as rapidly as it would be if eaten alone. If eaten with foods that slow its evacuation time from the stomach then it will ferment in the stomach and cause trouble.

### *Can you eat watermelon seeds?*

Watermelon seeds can be saved and eaten if desired. There is some nutrient inside the hard shell, but the shell itself is composed of indigestible cellulose, and I do not think it wise to consume so much cellulose. In wild nature, animals would not normally try to chew something so hard and indigestible. Primates eat the fruits and spit out the hard seeds. Man, unfortunately, has the ability to analyze foods, consequently he discovered nutrients in the seed, so he tries to eat the seed, forgetting that most of the watermelon seed is indigestible, and may serve only to irritate the lining of the gastrointestinal tract. Many seeds of fruits are poisonous; they contain benzaldehyde and cyanide.

## **Nuts with Acid Fruits**

### *Why is it not advisable to take nuts with acid fruits?*

We no longer serve nuts with acid or subacid fruit mainly because of the sugar content in the fruit. When fruit is held in the stomach awaiting the digestion of nuts, it has a tendency to ferment, and cause digestive troubles. The sugar content of organically grown citrus fruit is very high, and high concentrations of sugar inhibit gastric secretion thus also interfering with protein digestion. It was formerly thought that the citrus didn't interfere with protein digestion but with greater study, observation and reflection, thoughts have changed.

Acid fruit such as tomatoes and grapefruit may not be deleterious, because of their diminished sugar content. Even if one eats the citrus thirty minutes prior to taking nuts, in most cases, there will still be a great deal of fruit in the stomach. The pyloric sphincter stays tightly shut for approximately 15 minutes after a meal begins. After fifteen minutes, the stomach begins gradually to evacuate, and then not rapidly. The food gets mixed in the stomach. If you desire nuts in the morning for breakfast, then it would be best to take them at least one hour after finishing your citrus or other fruit.

## **Beverages**

*What kind of beverage do you suggest besides water?*

Many years ago Dr. Shelton pointed out that water is the only drink. All other substances are either food or poison. If you are thirsty, you should drink pure water. If you are hungry, you should eat. If you are thirsty it doesn't mean you must eat a piece of watermelon, unless you are hungry at the same time. Drink only when thirsty and eat only when hungry. Poisonous soft drinks, coffee, tea, and other un nourishing beverages, and other poisonous fluids should never be used to quench a thirst. Pure water is best.

## **Dried Fruits**

*Are there any subacid dried fruits?*

The sugar concentration is naturally greater in fruits which have been dried. Some fruits that are considered subacid are considered as sweet fruits, after drying, unless they are soaked to replenish the missing water.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > Article #2: Proteins In Your Diet! By Dr. Alec Burton

### **Article #2: Proteins In Your Diet! By Dr. Alec Burton**

*This short thesis on proteins is intended to clarify some of the confusing issues at present dominating the so-called science of nutrition, and especially to present to hygienists a rational view of the importance of protein and its indispensability to normal health and well being.*

It has been of considerable interest to me to study the various diets offered by the numerous food reformers over the past two decades. Many of these diets have had nothing more than enthusiasm to support them and several have been completely impractical. One of my chief aims is to present a program which will have a genuine practical application based on sound physiological principles. I have frequently been identified with a movement which stresses the need for protein. I do not wish to reject this identification but to elaborate its basis.

My argument is not as some have supposed, that a high protein diet is desirable, but that an *adequate* amount of protein is necessary. Few, if any, students of the subject would quarrel with this, although much current argument revolves around the term 'adequate'. There is considerable disagreement among nutritionists as to the optimum protein requirements and when one consults the literature on the subject, it is distressing to find so many assumptions replacing facts.

Some discussion has also arisen as to whether there is such a condition as protein deficiency. Those of us with experience of fasting are aware of the fact that the organism can maintain nitrogen needs throughout an extensive period without food. This seems inconsistent with the well-publicized statement that the body does not store protein, and in the sense in which it stores carbohydrates as glycogen in the liver and muscles, and fat in the organs and cutaneous tissues and elsewhere, this is probably correct. But as tissue structures are broken during the fasting process, materials (amino acids)

are made available for utilization. It is true that protein deprivation has to be prolonged and extreme in order to produce obvious signs of its inadequacy, and even here it is not necessarily only a problem of protein.

The complex physiological processes involved in digesting, absorbing and assimilating the materials ingested is such that it is unwise to make predictions about the effect of an isolated food element. Rather, the hygienist is inclined to study the total impact of food on the organism and strive to relate the theoretical concepts of nutrition to a practical situation. It is necessary to dissociate ourselves from nutrients in feeding our patients and deal with foods that are complex parcels of numerous nutrients. In addition the hygienist has always, stressed the need to consider the feeder. In nearly all diets and nutritional studies, the individual variations of those consuming the food is overlooked. Notable exceptions to this exist, but only in a general way, such as the dietetic control of the diabetes, diets for obesity, the regulation of diet in phenyl-ketouria and so on. This maneuver is not so much a consideration of individual needs and capacities as a therapeutic approach to disease, that is, treating symptoms. Such an action may be justified on practical grounds but it has serious theoretical inconsistencies and is objectionable philosophically because it does not radically solve any of the most crucial problems.

Because of the serious deficiencies of generalizations, hygienists are often reluctant to make specific extensions of their principles. Consequently, at this point, I should absolve myself from apparent infallibility in the pages that follow wherein I have made categorical statements concerning qualities and quantities of food. There is always the individual consumer, whose ever varying needs and capacities must dominate his requirements. Hygiene, in its proper role of education, should teach us to respect our limitations and learn our needs, so that we can adequately supply them. What I have suggested should remain a tentative generalization requiring individual modification.

An inadequate diet may be a temporary necessity. By this I mean that food, and particularly protein which is more difficult to digest than many other food elements, should be consumed within individual capacities rather than according to charts, tables and graphs. There are times when the organism will be unable to utilize satisfactorily an adequate amount of a nutrient, and less will suffice. A consequent loss of weight and possibly energy may result, but this could conceivably be even greater if the extra food is forced into a reluctant feeder. Fasting usually, but not always, involves some loss of weight (this may be disputed, but the apparent contradiction involves fluid changes and not flesh). It is a procedure employed in special circumstances; it is most effective when the desire for food is lacking, when there is a diminished capacity to use food. The feeder must therefore learn to balance his diet and balance his intake. As we no longer live in a natural environment, one that would supply all our needs selected according to inherent demands, some knowledge of food and feeding is essential, if we are to maintain health and vigor. Man's success or failure depends upon the use of his rational faculty. He can choose to respect his bodily (mental, emotional and physical) needs and supply them, or he can ignore them and suffer the consequences.

Conventional nutritionists argue that protein must be eaten with a carbohydrate, otherwise the amino acids derived therefrom will be broken down by the liver (de-amination). This is called the 'protein sparing' effect of carbohydrates. If this is true, (and the experiments the claim is based are highly suspect), only a small quantity of carbohydrate is necessary. As indicated earlier, we do not eat nutrients and an examination of analyses of vegetable proteins reveals that they contain sufficient carbohydrates to provide the required conditions to prevent deamination. Animal proteins, on the other hand, do not. Their carbohydrate content is negligible.

Proteins combine best with nonstarchy vegetables. They should not be eaten with concentrated carbohydrates, either starch or sugar, nor with concentrated fats. Their use with fruit is not generally advocated.

Hygienists are almost unanimous in their agreement that nuts represent the best source of protein for man. It is a fact that people have developed tremendous muscular strength and vigour on an exclusively vegetarian diet. There are no special properties in animal foods which confer superiority over vegetable sources of nutrients. It may be categorically stated that vegetable proteins, especially nuts, have the following advantages over animal products:

1. They are generally eaten raw; uncooked proteins are superior.
2. They do not contain toxic end products of metabolism, as is inevitable with meat and fish.
3. They are generally much fresher. No matter what precautions are taken, flesh decomposes after the death of the animal, and meat is usually many weeks old before it reaches the table. Some putrefactive poisons are inevitable.
4. The present method of raising animals domestically leaves much to be desired. Most animals are unhealthy and have to receive regular treatment from veterinary scientists. At present, nuts are subject to few contaminating influences, far less than our other fruits and vegetables.

The grains and cereals do not represent any part of the natural diet of man. They are not essential to life and health and should certainly be omitted from the diets of infants and young children. Where they are included, they should be eaten whole, unprocessed and dry. The habit of eating cereal products with milk or other fluids such as juices is objectionable and conducive to fermentation. If they are included in the diet, thorough mastication is essential.

Cereal proteins are almost invariably incomplete and should not be used.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > Article #3: Food Combining By Dr. Herbert M. Shelton

### **Article #3: Food Combining By Dr. Herbert M. Shelton**

An intelligent reader who has done much personal experimenting with foods and diets writes me as follows:

"It is surprising that of all the foods I've eaten, I find the banana the best and the least troublesome. Of course I'm talking about the ungasped banana. The gasped ones do give me some trouble, even such easily digested foods as the orange, apple, grape, etc., if overeaten, will cause distress. I realize one should not overeat on any food, but I do find that the ripe banana even if eaten to excess does not seem to do me any harm. Also, the banana seems to be a complete meal all by itself. It eaten with other foods, it can cause trouble. It really can't be appreciated unless eaten alone. Even if combined with sweet fruits (dates, figs, raisins, peaches, grapes) it is not digested as well as when eaten alone. It seems to be a good food for both the hard laborer and sedentary worker. I am praising this fruit because by most people it is looked upon as 'monkey food' and of little importance as far as nourishing the body. I don't know how long one can live on the fruit alone, but I think with the addition of some nuts or seeds and some leafy vegetables one could probably maintain good health. This should be a comparatively simple diet; not too expensive. Since I do not have the facilities for cooking and preparing elaborate meals, "I think this could be the type of diet I can live on."

This reader's experience verifies my own. While I have found that bananas combine fairly well with dates, raisins, grapes and a few other sweet fruits and with green leafy vegetables, such as lettuce and celery, I have noted that they digest best if eaten alone. This calls to mind the fact that Tilden, also,

after much testing of the matter, reached the conclusion that bananas are best eaten alone. Tilden's view, like that of the writer of the foregoing letter, was based upon tests made with the ungasped banana. Gassed bananas do not ripen and can hardly be said to form desirable additions to man's diet.

The green banana is an almost insoluble starch; the ripe banana (ungasped) is a predigested sugar. It is quite probable that it is this sugar that makes a poor combination with other foods. As the gassed banana does not ripen, but rots instead, while still in the starch stage which is practically insoluble, it would seem quite natural that it should give trouble in digestion, even if eaten alone.

The banana, which contains about 1.30 per cent protein, is abundant in most of the minerals required by the body and is rich in vitamins. Dr. Carlos Arguello, of Nicaragua, introduced me to a native strong man, while I was visiting in his country a few years ago, who stated that he lived largely on bananas, eating them in large quantities and that he found that they sustained him in health and strength as none of the other foods did. He had one advantage over those of us who live in the United States; namely, he could get his bananas tree ripened and fresh from the banana tree. This is an advantage of considerable importance.

[Home](#) > [Lesson 23 - Application Of Food Combining Principles](#) > Article #4: Chlorophyll And Hemoglobin By Viktoras Kulvinskas

#### **Article #4: Chlorophyll And Hemoglobin By Viktoras Kulvinskas**

For ages men have puzzled over the question - "What makes grass green?" About a century ago, chemists named the green pigment in growing plants chlorophyll.

A certain belief evolved about this green fluid. The fact that herbivora build hemoglobin (blood cell pigment) on a diet composed of leafy greens invites the hypothesis that derivatives of chlorophyll may be used in making hemoglobin. A Dr. Abderhalden, in his textbook, suggests that blood pigment might be made from plants.

Added to this biological relationship is the chemical similarity between chlorophyll and hemoglobin. This was suggested by Verdeil in 1851, though on the basis of invalid evidence. It was substantiated in 1879 by Hoppe-Seyler, who showed a similarity between hematin and chlorophyll derivatives.

Willstater's work between 1906 and 1913 identified chlorophyll as an unstable water soluble magnesium compound characterized by ester groups of methyl and phytyl alcohol. He further showed both chlorophyll and hemoglobin to be closely related; both had some pyrrole fragments.

The years of research that were stimulated by Verdeil's hypothesis culminated in the series of brilliant investigations by Hans Fisher, for which he was awarded the Nobel Prize in 1930. He and his co-workers finally established the correct structure of hemin, part of the hemoglobin, by synthesis, and showed the true relationship to chlorophyll. They observed that the chlorophyll molecule closely resembles hemin, the pigment which, when combined with protein, forms hemoglobin. The latter is present in the red corpuscles of the blood, and by carrying oxygen to the tissues, makes the production of energy and life feasible. One of the major differences between chlorophyll and hemin is that chlorophyll contains magnesium, while the hemin molecule contains iron for the central atom. Note, hemoglobin is one of the most important constituents of cells; it makes up three quarters of the solid content. Owing to the close molecular resemblance between chlorophyll and hemoglobin, it was

believed by Frans Miller, another scientist, that chlorophyll is nature's blood-building element for all plant eaters and humans. He writes: "Chlorophyll has the same fast blood-building effect as iron in animals made anemic." This has led to a great deal of controversy.

What exactly is anemia? According to Webster's dictionary, anemia is a condition in which there is a reduction of the number of red blood corpuscles or the total amount of hemoglobin in the blood stream or both. Thus, anemia is an excellent vehicle for the study of the relationship between food and hemoglobin count.

The first scientist to demonstrate the regenerative effect of chlorophyll on animals was Dr. Emil Burgi, who, in 1916, observed that rabbits rendered anemic by bleeding recovered more rapidly when chlorophyll was added to their diet.

Scott showed that a diet of milk, white bread and chlorophyll rebuilt blood faster than bread and milk. Scott and Delor noted that iron-and-copper-free alfalfa extract relieved milk induced anemia.

Patek and Minor, in clinic study with a rare type of anemia caused by pigment scarcity, observed a small positive increase in hemoglobin concentration on intravenous injection of chlorine derivative. Dr. Fisher in Germany announced that for some time he had been using chlorophyll in the treatment of anemia with promising (although by no means conclusive) results.

In another clinic study, Dr. Patek used fifteen adult patients with chronic hypochromic anemia. They were given chlorophyll and allied substances, and were placed on house diets free of meat and eggs, whereas the diet was adequate in all other respects. The crude chlorophyll was a tar-like substance extracted from alfalfa leaves. It was found that chlorophyll alone was not effective. When chlorophyll and its derivatives were administered, there was an increase in hemoglobin and improvement in the sense of well being.

Other workers have reported curative effects of chlorophyll and its derivatives in a wide variety of anemias: protein deficiency, hemorrhagic, phenyl hydrazine poisoning, pernicious, hypochromic of unknown etiology and "experimental nutritional anemia" of unidentified character. Some of the reports are based on clinical studies, while others are the results of animal experimentation.

J. Howell Hughes and A.L. Latner, from the Department of Physiology, University of Liverpool, in a highly discriminative experiment, finally resolved the question of the blood regeneration capacity of chlorophyll. Rabbits were made anemic by daily bleeding, reducing the hemoglobin level to two-fifths of the normal value. The rabbits were split into two groups. The experimental received in diet chlorophyll in oil, the control only oil.

They performed five experiments. Three were with varying degrees of pure chlorophyll, one with large doses of crude chlorophyll (unrefined), and one with magnesium-free chlorophyll derivatives. The following is a summary of their findings.

1. Pure chlorophyll in large doses has no effect on the speed of hemoglobin regeneration after hemorrhage. It seems large doses are toxic to the bone marrow.
2. Very small doses of pure chlorophyll markedly increased the speed of hemoglobin regeneration to approximately its previous level.
3. Crude chlorophyll is effective even in large doses. Hughes concludes: "It seems, therefore, that the animal body is capable of converting chlorophyll to hemoglobin." This is in agreement with Zin, who, however, showed the effect of chlorophyll injection on the red blood cell count of animals not rendered anemic.

Thus we see how chlorophyll can aid in rebuilding the bloodstream. Without correcting all the causes of anemia, the chlorophyll results are temporary in nature and not consistently workable with every

individual. If, however, the individual was to be placed on organic live foods and on one of the richest crude forms of chlorophyll, then the results are always the same, and the anemic condition disappears. Rev. Ann Wigmore, in clinical studies, has proven this many times.

[Home](#) > [Lesson 24 - Selection And Storage Of Most Wholesome Foods, Part I](#) > 1. Changing To A Nutritionally Superior Diet

### 1. Changing To A Nutritionally Superior Diet

#### 1.1 Raw Food

It is relatively simple to plan an optimally nutritional diet. For optimum nutrition, eliminate the denatured foods, and enjoy the greatest possible variety of raw fruits and vegetables, as they are seasonably available, plus approximately two to four ounces of raw, unsalted nuts and seeds per day, in addition to sprouted seeds and grains.

If you persevere in adhering to this all-raw food diet, you will eventually achieve the highest pinnacle of health possible for you. Those who are willing and able to quickly progress to an all-raw food diet from the plant kingdom will have amazing and seemingly miraculous health improvement and potential for longevity.

#### 1.2 The 80% Raw Food Diet

If you are not yet willing or able to change to the all-raw food diet, a good start is the 80-90% raw food diet. If you have been a conventional eater and now concentrate on the use of uncooked foods to this extent, you will achieve a radical improvement in your food program, and, consequently, in your health.

As indicated in Lesson 22, an 80% raw food diet is not difficult to achieve. It can be appetizing, interesting, varied, satisfying and economical. The best plan is never to eat cooked food more than once a day, as part of one meal. Try for more and more days on raw food only.

### 1.3 Body Chemistry

The English poet, John Dryden, said, "We first make our habits, and then our habits make us."

As indicated in Lesson 22, the body chemistry is largely determined by the food that is eaten. When the diet is altered and the new diet maintained for a given length of time, the enzymes, body fluids and glandular secretions become increasingly adapted to the influences and requirements of the new food—just as they necessarily adapt to the junk foods that are eaten. *The important difference is that the adaptation to the junk foods involves health deterioration, while the readjustment to a nutritionally superior diet is in the direction of improved health.*

If you live on a conventional diet, which by all the recognized standards is said to contain enough nourishment, that diet will still fail to support normal physiology. The percentage of raw food is usually very small and, except for the fresh fruits and vegetables (usually a very small amount), practically everything in the conventional diet has been denatured.

Long-term storage of food, careless handling in shipping, and the refining, preserving and cooking processes destroy delicate and tender vital food factors and flavor. These altered foods become dull, flat and insipid, requiring seasonings to make them palatable. A future lesson will discuss in detail the destructive effects of all these processes.

The addition of vitamins to such diets will not render them adequate. Humans have not learned to create living substances. They cannot synthesize living substances in the laboratory, only chemical imitations. Neither can they extract them, in the kitchen or in the laboratory, without greatly impairing or destroying their food value. A more comprehensive discussion of the futility of the use of food supplements to replace missing elements in food and the actual harm that they can cause, will be given in a future lesson.

### 1.4 Organically Grown Food

A plausible argument has been offered that foods which are not organically grown are deficient in vitamins and minerals, and therefore we should take supplements. The superiority of organically grown foods is undeniable, but this problem cannot be solved, or even palliated, by taking nutrients out of their proper context.

Furthermore, whether or not an orange is organically grown, it still contains Vitamin C—the orange cannot be grown without it. It is true that the total nutritional value is impaired by the use of the chemicals, yet it is not totally destroyed.

But, as to the argument that commercially grown foods are practically devoid of nutrients—that is not biologically possible. Fresh, good-tasting food must contain substantial quantities of nutrients, regardless of how it was grown.

You should certainly make Herculean efforts to grow your own fruits and vegetables to the greatest extent possible. For whatever food you cannot grow yourself, you should try to secure as much organically grown as possible. For the rest, you should obtain the freshest, best quality obtainable, and you will achieve far better health than conventional eaters, plus a "serendipity" bonus: Dr. Burton says that Hygienists can save up to 30% on their food bills and up to 74% on their medical care bills. This lesson will help you in your quest for the best food available.

### 1.5 The Vegetarian Diet

Some people have misgivings about changing to a vegetarian diet. They may be worried about complete proteins, essential amino acids, or obtaining all of the amino acids at every meal. These are groundless concerns. All nuts, except the hickory, contain complete proteins, with all the essential amino acids—verified through experiments by Cajori, Kellogg and Berg. In addition, a generous supply of raw green

leafy vegetables, sprouted seeds and grains, and raw fruits, will assure an adequate supply of all nutrients needed in the diet.

These nutrients are stored in the body and utilized by the cells as needed. If the body were not capable of storing nutrients, we could not fast for lengthy periods. Nowhere in Nature is there any evidence of the necessity for complicated maneuvering to obtain all of the essential amino acids at each meal.

You may be concerned about Vitamin B-12 and fearful that, on a preponderantly vegetarian diet, you might become a victim of pernicious anemia. But the fact is that more meat eaters than vegetarians suffer from this affliction. Pernicious anemia appears to arise, not from a shortage in the diet, but from impairment of the ability to absorb B-12. Study after study has revealed that this deficiency is due not to dietary inadequacy, but to failure to absorb the vitamin from the intestinal tract.

Putrefactive bacteria can destroy friendly bacteria, thus inhibiting the synthesis and absorption of B-12. Putrefaction in the digestive tract can be caused by the ingestion of flesh foods, bad food combining or overeating of concentrated proteins.

A more exhaustive analysis of the myths surrounding Vitamin B-12 will be given in a future lesson. In this lesson, it is simply desired that you establish in your mind that the foods recommended for your selection are the best of all possible foods.

A future lesson will deal at length with the destructive effects of flesh foods.

For the present, in order to establish in your mind the advisability of omitting flesh foods from your shopping list, a few points on this subject will be made.

The best protein foods for humans are raw, unsalted nuts and seeds. Dr. Hoobler, who did some research at Yale University, proved conclusively that the protein of nuts and seeds provides greater nutritive efficiency than that of meat, milk and eggs. *And of course, nuts and seeds have the distinct advantage over animal foods of being delicious in their fresh, raw state.*

John A. Scharffenberg, M.D., Director of Community Health Education at San Joaquin Community Hospital, Bakersfield, California, has marshaled the scientific evidence against flesh foods in his book, "Problems with Meat."

A meat-based diet is deficient in natural carbohydrates and fiber, high in saturated fat and excessive in protein, resulting in bone degeneration and greater work for the kidneys and liver. It can lead to calcium and vitamin deficiencies and a shortened life span.

Dr. Lendon Smith, M.D., from Portland, Oregon, incorporates in his writings many of the same ideas Hygienists have been advocating for years. On the Phil Donahue show (WTSP-TV, September 8, 1980) he recommended using nuts, seeds and legumes instead of meat. He said a bowl of lentil soup has as much good protein as a beefsteak. In fact, he emphasized that meat is not a good food, and his family does not use it more than once or twice a month. He said milk causes many problems and that people should eat as much raw food as possible—raw fruits, vegetables and nuts and seeds. He advised that foods processed by humans should be avoided, and he specifically mentioned the lack of nutritional value of boxed cereals. He declared that when a person gets sick, there is always a diet, component in the cause, and he advocated fasting one to four days for alleviation of minor problems.

It is true that it is possible to experience a protein deficiency on a poorly-planned diet. An adequate supply of protein in the diet is indispensable to normal health and well-being, and a protein-deficient diet will certainly not contribute to your health and longevity. But an adequate diet is not dependent on animals for food, nor is it necessary to play a numbers game with amino acids at each meal. My book, *"The Happy Truth about Protein,"* gives more details on this subject.

In fact, humans are dependent on the plant kingdom for their nourishment. If they do not get it first-hand by eating plants, they get it secondhand by eating animals that have eaten plants.

A study by the Washington, D.C.-based Environmental Defense Fund revealed that the breast milk of

vegetarian women contained significantly lower levels of pesticide residues than that of meat-eating women. This could have a relationship to the ability of the fiber in the plant foods to help in the removal of pesticides from the body. Another reason for lower pesticide residues in the bodies of vegetarians is the fact that plants contain lower levels of pesticides than do flesh foods.

Vegetables and nuts contain about 1/7 the pesticide residues of flesh foods, fruits and legumes about 1/8 as much, and grains about 1/24 as much. This is due to the *concentrating* factor, as the contaminant goes through the additional link in the ecological chain, and the animal concentrates the pollutant in its body.

Actual tests in Great Britain have shown the pesticide level to be highest in meat-eaters, lower in lacto-vegetarian (that is, vegetarians who use dairy products) and lowest in total vegetarians.

The Environmental Protection Agency did a study (about 1979) with laboratory rats, showing that dietary fiber helped remove pesticides from their bodies. The study pointed out that fiber is not just an inert substance that provides "roughage," but has some qualities that are just coming to light.

This particular study showed that pectin (a form of fiber found in fruits and succulent vegetables) could significantly affect the body's metabolism of at least one pesticide—lindane. (Organic Gardening, July 1979)

The best source of dietary fiber is whole foods. The use of a fragmented food, such as bran, in an attempt to add supplementary fiber to a deficient diet, only causes more problems. It is not in a form readily acceptable by the body without stress, may cause a loss of vital mineral elements, and its action is similar to that of a laxative, ultimately resulting in inhibition of the body's ability to act for itself.

An intelligently planned vegetarian diet has none of the disease problems associated with the use of meat, and provides a dependable source of all the nutrients, including protein.

If you eat a generous amount of raw food and include approximately two to four ounces of nuts and seeds daily, as well as sprouts, greens and fruits, you cannot help but get an adequate supply of protein, vitamins, minerals, enzymes, hormones-and chlorophyll, such as only green plants can supply. And this is a foolproof diet that will contribute to health improvement and longevity.

[Home](#) > [Lesson 24 - Selection And Storage Of Most Wholesome Foods, Part I](#) > 2. Let's Go Shopping

## 2. Let's Go Shopping

Even those who have a sizeable organic garden must track down and purchase many of the foods they require. When the weather is warm, take along a picnic cooler with ice for transferring perishable food. Much damage can result from alternately cooling, warming, and again cooling your produce. It is even a good idea to carry a cooler when the weather is cold if your car is heated.

Your greatest concern will be produce—good quality fruits and vegetables. It is sometimes possible to locate organically grown produce, but if not, get the freshest, best quality obtainable and you will still come out ahead, as there will be much less waste. Sometimes you can, just by trying and not giving up, locate individuals in your own area who are growing organically for their own use and have some surplus to share. If your local health food store has a bulletin board, you might try to reach these local growers by expressing your interest there in contacting them.

It is not always practical to have fresh produce shipped in from distant cities, but there are some instances when it is advisable to do this. If you live in a climate where the growing season is short, produce can be shipped by air freight from California but the transportation cost may be greater than the cost of the food. If you join with other people and buy in bulk quantities, it might be more economical.

Even when buying food locally, you may find that starting a food-buying co-op would be very worthwhile if this enables you to buy direct from a wholesale food distributor in your area.

You can grow some of your own food. I once grew lettuce in a large crate on the porch. You can find some local sources of organically grown food. Locally grown produce, in season, is always the best—fresher, better-tasting because it is not picked prematurely, and more economical. You can at least obtain organically grown nuts and seeds from distant shippers, and sometimes from your local health food store.

For that portion of your food that you cannot obtain organically grown, just get the best quality obtainable, selected, stored and eaten in accordance with Hygienic principles, and, as previously indicated, you may rest assured that your health will be far better than that of those on conventional diets.

Shop around and find the stores or produce departments that do the best job in your area. Get friendly with the produce people and they will cooperate with you in your efforts to locate the best produce, especially when they learn that you do all your major purchasing in the produce section. You might even be able to persuade the owner of a produce business to keep his eyes open for organically grown food from local farmers who come to the wholesale produce markets, or even to locate organically grown produce in distant cities, and have it shipped in to sell at retail. We developed such a source in our area in Florida and enjoyed a plethora of organically grown produce for five years—last year the man retired, and we are still trying to replace him.

In season, shop the transient roadside truck merchants—early in the morning, before the sun has done its wilting job on the produce. You will probably have to shop the supermarkets for some of your produce. Most produce managers will allow you to break open the pre wrapped packages of produce and select the best, especially if you are a good customer. Sometimes, if you ask, they will bring out fresher produce from the refrigerator and allow you to select directly from the crates.

This lesson will continue with information on how to judge and select your produce and other foods. You will not need to be greatly concerned about additives in packaged, frozen or canned foods, because you will not be using these items. If you do buy anything that is packaged, frozen or canned, be sure to read the labels and don't buy anything that contains chemicals.

[Home](#) > [Lesson 24 - Selection And Storage Of Most Wholesome Foods, Part I](#) > 3. Fruits

### **3. Fruits**

Fruits are the most delightful of foods. They are also of great nutritional value because they possess most of the essential minerals and vitamins necessary for optimal health.

A variety of fresh fruits are available throughout the year. Fortunately, bananas are always in season. They are a staple part of the Hygienic diet, being high in nutritional value and even containing 1.1% protein, about the same as mother's milk. Most other fruits have a season in which they are most economical and flavorful.

Good watermelons start coming in May. Pineapples and strawberries are also in season at the same time, and the oranges and pears are still available and reasonable in price.

In June, a plethora of fruits appear: a variety of all kinds of melons, peaches, cherries and berries. As oranges and pineapples dwindle—around July—the grapes, nectarines and plums come in. All through the summer, you have a veritable horn of plenty of many varieties of fruit.

Then, in the fall, the apples are in season, along with the citrus and pears, while the grapes are still available.

The information in this lesson about the peak seasons of specific fruits and how to choose them wisely will help you not only to get the best for your money, but also the best for your health and nutrition.

Since the average diet is too high in protein, adding fruit to the diet is beneficial. A fruit diet is "cleansing" because it is lower in protein. This results in the cells drawing upon the body's store of nutritional reserves, and initiating the elimination of the accumulated wastes and poisons, much of which are the by-products of the over-consumption of protein. The fruit, though, is not itself cleansing; it merely causes less burdening of the body than most food, and allows the body to do its own "cleansing."

Fruits contain large percentages of sugars and free acids that are favorably utilized by the body, unless consumed in greater amounts that can be processed efficiently.

Claims are made that certain fruits have "curative" or "magical" properties—that such fruits as apples, apricots, papayas or grapes will "cure" what ails you. Hygienists know that food is used for its nutritional value, not for some hoped-for special influence on the body. Apples, apricots, papayas and grapes are excellent fruits and should be used, along with other varieties of fruits, as they become seasonally available.

### **3.1 How to Judge and Select Fruits**

#### **General Suggestions:**

1. Buy in season when quality is highest and prices lowest.
2. Don't buy more than you will use before they perish. The sooner you use your ripe fruit, the more flavor and nutritional value it will contain.
3. Don't buy damaged fruit unless damage is slight and you will use it immediately.
4. Handle displayed fruit carefully so you don't ruin it for others.
5. Fruit should be eaten when ripe—not green or overripe. Some fruits may be purchased green and ripened at home. This information will be included under specific fruits.

The trouble with many fruits available today is that they are picked while still immature and thus never have a chance to develop properly to their full potential of taste and nutritional value.

The season for marketing fruit has been overextended, and out-of-season, expensive and tasteless fruit is often available. Don't buy fruits out of season.

Unfortunately, most fruits are grown in soil that is fed chemicals to increase productivity, and the fruit is sprayed with chemical pesticides. The thick rind of pineapples, melons, bananas, mangos and avocados gives the underlying flesh natural protection against most of the chemical sprays. For other fruits, you cannot do much more than give them a thorough washing and scrubbing, and hope for the best. Peel them, if you like. If you must peel your fruit, don't cut too deeply; try to discard the thin skin only. The greatest concentration of nutrients is just under the skin.

Grapes and cherries have no protection against high levels of chemical residues. Don't eat large quantities of these fruits unless organically grown, and don't eat them every day, in season.

Apples, pears and plums are commonly waxed to give them a glossy look—it is best to peel them.

Fruit is most luscious if it is picked from the tree when it is just at the peak of its ripeness. Wherever you live, try to have and nurture some of your own fruit trees. No store-bought fruit can approach freshly picked ripe fruit for flavor and quality.

Whenever possible, buy fruit from the farmer—you may get fruit almost as good as you could grow yourself. You might even be fortunate enough to find a local organic fruit farmer.

Most people are dependent on markets for most of their fruit. It is necessary to cultivate the ability to judge the ripeness and quality of the fruit you buy. This ability will come with experience, though the best of us can sometimes still be misled.

There are several things to check. First, if it's fresh, it looks fresh, not wrinkled or blemished. The color should be characteristic of the ripe fruit. If it is misshapen, it is usually inferior in taste and texture, and there will be more waste. Medium sizes are generally better than very large or very small.

Ripe fruits, regardless of whether they belong to the acid, subacid or sweet classification, possess a certain sweetness, and, in most instances, it is possible to judge ripeness by appearance, fragrance, touch, and, of course, taste.

Unripe fruit is highly indigestible and usually quite unpalatable. It may contain starch and other carbohydrate substances which are distasteful and unwholesome. Overripe fruits may be even worse. When decay begins, the sugar is changed to carbon dioxide, alcohol and acetic acid (fermentation) and the fruit rapidly deteriorates in wholesomeness, nutritional value and taste. It loses water and becomes spongy, mealy and insipid.

Fruit is potentially alkaline, that is, it produces an alkaline ash after it has passed through the process of digestion. If the fruit is of poor quality, or unripe or overripe, especially if it is fermented, it produces an acid reaction in the body and its absorption creates many unpleasant symptoms, such as nervousness and insomnia, as well as digestive and "allergic" problems.

If fruit doesn't taste right, discard it. It is better to "waste" some food than to waste your health.

Since vine-ripened fruit is too soft to withstand much handling en route from farm to supermarket, most fruit bought in the market was picked when mature (we hope!) but not yet ripe. Most of the fruit available in supermarkets is not intended to be eaten immediately, but needs a day or two at room temperature to fully ripen. Problems in attaining proper ripeness occur when fruit is picked before it is fully mature. Usually, an indication of the beginning of the ripening process is a signal to pick the fruit for marketing.

Most ripe fruits have lost all traces of hard spots, but are not mushy. Many ripe fruits exude a delightful, but delicate fragrance. As a rule, you should buy fruits which are almost ripe, and eat as soon as flavor peak is reached (or refrigerate when ripe and eat as soon as possible thereafter).

Bananas, avocados and some other fruits may be purchased green and ripened at home. Fruits which are to be ripened at home may be "displayed" on trays on the kitchen counter during the day, and put into brown paper bags at night, to shelter them from insects. To accelerate ripening of very hard fruit, put it in a brown paper bag with an apple or banana (day and night). Apples and bananas emit a kind of natural ethylene ripening gas.

Most fruits will be discussed specifically in this lesson. When available, varieties of specific fruits are listed, no attempt is made to list every variety grown. For such complete listings, see Rodale's *How to Grow Vegetables and Fruits by the Organic Method*. Some exotic tropical fruits which are not generally available in the marketplace are omitted, principally because no first-hand information is available about them, other than that which is included in Dr. Esser's Dictionary of Man's Foods and other reference books which give no marketing information.

### **Specific Varieties of Fruits (alphabetically):**

#### **Apples**

The peak season for apples is October through March. The principal varieties of eating apples include Golden Delicious, Red Delicious, Pippin, Golden Grimes, McIntosh, Jonathan and Winesap. The peel is rich in vitamins, but, if purchased in the supermarket, it will probably be waxed and contain pesticide residues. In fact, I myself never use commercially grown apples. It is my understanding that more pesticides and chemicals are used on apples than on any other fruits, and that the tree itself is poisoned, so that any insect that bites the apple will die. The human who eats the apple will survive, but I choose not to eat such apples.

Winesap, McIntosh and Golden Grimes apples are available in the fall, Jonathans and Delicious in the winter. Delicious apples are the sweetest.

Apples should be firm and crisp with bright and shiny skin. Color is a sign of maturity in apples—high color indicating maturity—and only apples picked when mature will have good flavor and texture. Apples that yield to pressure on the skin will have soft, mealy flesh. Bruised areas are usually a sign of rough handling or exposure to frost.

The apple is an excellent food, nutritionally speaking. It is also one of the most practical, since it can be shipped and stored for many months, though, of course, long storage results in some loss of nutrients.

## **Apricots**

The peak season for apricots is June and July. Apricots are a nutritionally excellent food but they have a very short season and a very short life. Look for (but you will seldom find) plump, juicy-looking apricots, with a uniform golden-orange hue. When ripe, they will yield slightly to gently pressure. If the fruit is hard, pale yellow or greenish yellow, these are indications that it was packed too soon and will never progress to the proper ripeness and delicious taste. They will simply become mushy or rot.

Larger apricots tend to ripen more quickly. Avoid fruit that is green at the stem end. Apricots are ripe when they turn from yellow to orange.

Once I found a crate of "just-right" large apricots at the wholesale market in Tampa, in time to be served at a Hygienic luncheon for the members of our local American Natural Hygiene Society chapter. That was about seven years ago, but I still remember the luscious taste. It is almost impossible to find such apricots in the markets, unless you happen to be in the right place at the right time, and know enough to recognize and quickly acquire them. Apricots are rarely found in the markets at their best, because of premature harvesting.

Ordinarily, we must settle for sun-dried, organically grown soaked apricots, which are an acceptable substitute, and much better than the disappointing "fresh" apricots usually available. Buy dried apricots from Jaffe Brothers or at a health food store. Dried fruit sold at supermarkets has usually been treated with sulphur dioxide or hydrogen peroxide, to preserve the fruit and retain the bright color. These substances destroy the value of the food and cannot be washed off, since the chemicals are absorbed into the fruit.

Experiments conducted by dr. H. W. Wiley, formerly chief chemist of the U. S. Department of Agriculture, demonstrated that the use of sulphurous acid in food is always harmful. It degenerates the kidneys, retards the formation of red corpuscles, and destroys the vitamins in the fruits.

## **Avocados**

California avocados are available all year, with a slight peak in December through June. Florida avocados are available July through March. California avocados have a thinner skin and are more buttery and less watery than Florida varieties; they also have a better flavor and contain perhaps twice as much protein.

It is very important to eat the avocado when just ripe, when it has a buttery consistency and a mild flavor. When unripe, it is hard and practically inedible. It is best to buy your avocados hard and firm, so that ripening conditions can be controlled. Ripen at room temperature in a tray on your kitchen counter—this usually takes two or three days. When there is a slight yielding to gentle pressure on the skin, it is time to enjoy them. Dark avocados are somewhat soft to firm when ripe—if very soft, with black spots, they are usually rotted. Green avocados are softer when ripe (while still retaining their characteristic green color).

Select avocados of uniform color and free of cracks. Irregular brown markings have no effect on the inside of the fruit. Don't buy avocados with dark, sunken spots in irregular patches or cracked surfaces,

which indicate decay. By law, avocados cannot be picked before a date that is supposed to insure that the fruit will be mature before being harvested, so commercially grown avocados should always ripen properly. With careful handling, they do ripen properly most of the time, although sometimes you get a "bad batch" which darkens and rots.

Fortunately, the thick, tough skin of the avocado affords some protection against chemical sprays, though it is true that the roots of the tree itself are bound to absorb chemicals from the fertilizers and sprays. The rule for avocados is the same as previously indicated: Use organically grown fruit whenever you can get it—otherwise, do the best you can. But, with avocados, at least the flesh has not been exposed to poisonous sprays.

An interesting fact about the avocado: An acre of land will yield a larger amount of food when planted to avocados than it will when planted to any other tree crop known at present. (Dr. William L. Esser)
