When no other way is possible, sprout your seeds on your kitchen counter in jars or other containers. We use alfalfa sprouts almost daily. Alfalfa is known to contain trace minerals which may be lacking in other plants. The root system of field-grown alfalfa reaches down as deeply as fifteen feet into the subsoil, picking up minerals not present higher up, and these minerals are, of course, present in the seeds in the sprouts.

## **12.1 Do The Best You Can**

Grow as much organic food as you possibly can. Seek out and share with other organic growers. Import organically-grown nuts, seeds, and dried fruits from other areas. Keep trying to produce or obtain fresh organically-grown produce.

For the rest (if any) some compromises may be necessary. Get the best-quality food obtainable, wash in plain water, peel waxed fruits and vegetables, and do the best you can. Try to obtain foods grown on different soils, in different parts of the country, to insure obtaining a variety of trace minerals which may have been damaged or destroyed in certain areas: If you eat most of your food uncooked, you will still attain a higher degree of health than conventional eaters.

[Home](#) > [Lesson 49 - The Organic Garden; Avoiding Commercially Produced Foods - Why?](#) > 13. Harvest Of Pleasure And Health

## **13. Harvest Of Pleasure And Health**

I believe there will be a few who will dispute the environmental improvements that will accrue because of the deemphasis on chemicals and poisons, advocated by the organic gardener. If you learn about, and implement, organic gardening methods, you will also find them practical, convenient, agreeable, and economical.

And there is so much personal satisfaction in the creation of living plants in cooperation with the forces of nature—you come to regard your plants and trees as children whom you love and foster, and who respond by giving you their fruits.

What is more rewarding and thrilling than seeing the first seedlings, or the blossoms, or the fruits ready to harvest? But, best of all, the food you harvest will be flavorful and delicious, bursting with the nutrients you have helped to supply; and clean and free of residues of chemical fertilizers and poison sprays.

The, only way to obtain a full complement of all the vitamins, minerals, enzymes, hormones,

chlorophyll, carbohydrates, and other substances (known and unknown) in ideal combinations, is by eating the living food. Your harvest of organically-grown food will supply the needs of your body for optimal health.

[Home](#) > [Lesson 49 - The Organic Garden: Avoiding Commercially Produced Foods - Why?](#) > 14. Questions & Answers

## 14. Questions & Answers

### **Is it safe to mulch with grass clippings that have been treated with herbicides?**

It would be best to find out from your neighbors whether they are using herbicides before using their grass clippings. If you see dandelions in the grass, that is a good sign. However, the most commonly-used herbicide, "2, 4D," is not absorbed by grasses in amounts great enough to affect vegetables. Don't use suspect clippings in the green state. Either compost them or put them aside for a couple of weeks. Soil microbes usually break down the chemical weed killer in a week or two. If you know when the spraying has occurred, and several rains and a couple of mowings have occurred since the spraying, the residue should be gone. Of course, grass clippings that have had no spray are the best.

### **Since sprouting in soil produces sprouts of higher nutritional value than sprouting with water only, what is the best kind of soil to use?**

Seeds can be sprouted in soil, indoors or out. The sprouts will indeed be of higher nutritional value than the sprouts that are produced with the use of water only, especially if the soil is properly prepared. The soil should consist of one part fine compost, one part fine topsoil, and one part sand.

### **Is it best to wash the salt off of seaweed?**

*Organic Gardening* magazine, March 1980, page 20, says that it really isn't necessary to wash the salt off of seaweed, as the amount of salt that might cling to the seaweed is minimal. Dig the fresh seaweed into the soil to avoid leaching out of nutrients that will occur if you allow it to heap up and decay. *Organic Gardening* says that seaweed is nutritionally similar to barnyard manure, except that it contains twice as much potassium. It is also high in iron and zinc, and contains some iodine.

### **What is "Diatomaceous Earth?"**

It is composed of the fossilized shells of microscopic one-celled algae. It is a natural product, and kills insects mechanically. The shells break down into tiny, razor-sharp needles of silica, and the silica particles attack the wax coating that covers the insect. The insect gradually loses fluid and dies in about twelve hours. Diatomaceous earth is fine, dry dust, and is best applied when plants are wet, or it may be dissolved in water. In a five-gallon sprayer, place a teaspoon of liquid soap compound in a quart of warm water. Add one-fourth pound of diatomaceous earth, and top off with water. Keep solution agitated as you use it. Diatomaceous earth works against insects only when they are in their pupal, maggot, or grub stage. This substance can irritate your lungs, so wear a protective mask when using it. Don't use formulations which are mixed with pyrethrum and chemicals. If you can't find it locally, it can be ordered from [Golden Harvest Organics](#).

### What causes carrots to be bitter?

An insufficient or uneven supply of moisture or of nutrients will produce bitter carrots. Insects or disease can also cause bitterness. If you follow the instructions in this lesson, as to composting, mulching and watering, your carrots should be healthy and sweet.

### Is it advisable to grow vegetables or trees over or near a septic tank?

Root vegetables and leafy crops can become contaminated if grown near a septic tank. The roots of trees can damage the drainage pipes. Shallow-rooted plants would be less of a problem, but there would still be some risk of infection from any food plants planted over or near a septic tank. It would be best to plant somewhere else.

### Is soil-testing a foolproof method to determine the actual needs of the soil, or is one better off just feeding the soil with organic matter and thus building its fertility?

I grew many successful vegetable gardens without any soil testing. An article in the August 1982, *Organic Gardening* magazine ("Organic Discoveries," Jeff Cox, pp. 104-105) offers documentation of the fact that frequently these tests are relatively meaningless. Dr. William Liebhardt, Assistant Research Director at the Rodale Research Center, says that a reliable nitrogen soil test is just not available. Dr. Liebhardt sent the same soil to 69 major laboratories, and received analyses and fertilization recommendations that varied wildly. Measurements of organic matter varied almost as much as the nitrogen recommendations. The 69 laboratories' measurements of phosphorus, potassium and soil pH also fluctuated widely. Cox's opinion is the same as mine. Feed the soil, and let the soil feed the plants. He spoke with Dr. Roger Pennock, soil scientist at Penn State University, about the carbon-to-nitrogen ratio. Dr. Pennock said, "The end product of organic matter decay—soil humus—tends toward a perfect carbon-nitrogen ratio of ten to one. At this level, and up to about fifteen to one, nitrogen will be released to the plants as they need it." Finished compost has the 10 to one ratio, and is the perfect balanced fertilizer.

[Home](#) > [Lesson 49 - The Organic Garden; Avoiding Commercially Produced Foods - Why?](#) > Article #1: Vegetable Preferences

### Article #1: Vegetable Preferences

	Compatible Neighbors	Incompatible Neighbors
Beans, bush	Potatoes, cucumbers, celery, corn, savory, strawberries	Garlic, onion family
Beans, pole	Corn, savory	Garlic, onion family, beet, cabbage family, kohlrabi, sunflowers
Beans, misc.	Potatoes, carrots, cucumbers, cabbage family, corn, eggplant, squash, rosemary, nasturtiums, petunias, savory	Garlic, onion family

Beets	Onions, kohlrabi	Pole beans
Cabbage family	Potatoes, celery, beets, nasturtiums, mint, dill, sage, tansy, thyme, rosemary, garlic, onion family, radishes	Pole beans, strawberries, tomatoes
Carrots	Peas, lettuce, onions, leeks, chives, tomatoes, rosemary, sage	Dill
Celery	Tomatoes, bush beans, cabbage family, leek	
Cucumbers	Beans, corn, peas, radishes, nasturtiums, sunflowers	Potatoes, aromatic herbs
Eggplant	Beans, potatoes	
Lettuce	Carrots, radishes, cucumbers, strawberries	
Melons	Radishes	
Peas	Carrots, turnips, radishes, cucumbers, corn, beans	Garlic, onion family, potatoes, gladiolus
Potatoes	Beans, corn, cabbage family, horseradish (at corners of patch), flax, eggplant, marigold, green beans	Squash, cucumbers, pumpkin, tomatoes, sunflowers, raspberries
Soybeans	Helps everything—plant near corn	No enemies
Squash	Corn, radishes, nasturtiums	
Strawberries	Bush beans, lettuce, spinach, borage	Cabbage family
Sunflowers	Cucumbers	Potatoes
Tomatoes	Carrots, sweet basil, mint, chives, onions, parsley, dill, marigolds, nasturtiums	Kohlrabi, potatoes, cabbage family, fennel, nut trees
Turnips	Peas, shallots, leeks	

## Article #2: Companion Plants

Plant	Companions and Effects
Asparagus	Tomatoes, parsley, basil
Basil	Tomatoes (improves growth and flavor); repels flies and mosquitoes.
Beans	Potatoes, carrots, cucumbers, cauliflower, cabbage, summer savory, most other vegetables and herbs. Adds nitrogen to soil.
Beans(bush)	Sunflowers (beans like partial shade, sunflowers attract birds and bees), cucumbers (combination of heavy and light feeders), potatoes, corn, celery, summer savory.
Beets	Onions, kohlrabi.
Borage	Tomatoes (attracts bees, deters tomato worm, improves growth and flavor), squash, strawberries.
Cabbage family	Potatoes, celery, dill, chamomile, sage, thyme, mint, pennyroyal, rosemary, lavender, beets, onions. Aromatic plants deter cabbage worms.
Carrots	Peas, lettuce, chives, onions, leeks, rosemary, sage, tomatoes.
Catnip	Plant in borders; protects against flea beetles.
Celery	Leeks, tomatoes, bush beans, cauliflower, cabbage.
Chamomile	Cabbage, onions.
Chervil	Radishes (improves growth and flavor).
Chives	Carrots; plant around base of fruit trees to discourage insects from climbing trunk.
Corn	Potatoes, peas, beans, cucumbers, pumpkin, squash.
Cucumbers	Beans, corn, peas, radishes, sunflowers.
Dill	Cabbage (improves growth and health), carrots.

Eggplant	Beans
Fennel	Most plants dislike it.
Flax	Carrots, potatoes.
Garlic	Roses and raspberries (deters Japanese beetle); with herbs to enhance their production of essential oils; plant liberally throughout garden to deter pests (ex: near legumes).
Horseradish	Potatoes (deters potato beetle); around plum trees to discourage curculios.
Lamb's quarters	Nutritious edible weed; allow to grow in modest amounts in the corn.
Leek	Onions, celery, carrots.
Lettuce	Carrots and radishes (lettuce, carrots, and radishes make a strong companion team), strawberries, cucumbers.
Marigolds	The workhorse of pest deterrents. Keep soil free of nematodes; discourages many insects. Plant freely throughout garden.
Marjoram	Here and there in garden.
Mint	Cabbage family; tomatoes; deters cabbage moth. House fly repellent.
Mole plant	Deters moles and mice if planted here and there throughout the garden.
Nasturtium	Tomatoes, radishes, cabbage,, cucumbers, plant under fruit trees. Deters aphids and pest of cucurbits.
Onion	Beets, strawberries, tomatoes, lettuce (protects against slugs).
Parsley	Tomato, asparagus.
Peas	Squash (when squash follows peas up trellis). plus grows well with almost any vegetable; adds nitrogen to the soil.
Petunia	Protects beans; beneficial throughout garden.
Pigweed	Brings nutrients to topsoil; beneficial growing with potatoes, onions, and corn; keep well thinned.

Potato	Horseradish, beans, corn, cabbage, marigold, limas, eggplant (as trap crop for potato beetle).
Pot marigold	Helps tomato, but plant throughout garden as deterrent to asparagus beetle, tomato worm, and many other garden pests.
Pumpkin	Corn
Radish	Peas, nasturtium, lettuce, cucumbers; a general aid in repelling insects.
Rosemary	Carrots, beans, cabbage, sage; deters cabbage moth, bean beetles, and carrot fly.
Rue	Roses and raspberries; deters Japanese beetle. Keep it away from basil.
Sage	Rosemary, carrots, cabbage, peas, beans; deters some insects. Not with cucumbers.
Soybeans	Grows with anything; helps everything.
Spinach	Strawberries
Squash	Nasturtium, corn.
Strawberries	Bush beans, spinach, borage, lettuce-as a border.
Summer Savory	Beans, onions, Deters bean beetles.
Sunflower	Cucumbers
Tansy	Plant under fruit trees; deters pests of roses and raspberries; deters flying insects; also Japanese beetles, striped cucumber beetles, squash bugs; deters ants.
Tarragon	Good throughout garden.
Thyme	Here and there in garden; deters cabbage worm.
Tomato	Chives, onion, parsley, asparagus, marigold, nasturtium, carrot, limas.
Turnip	Peas
Valerian	Good anywhere in garden.
Wormwood	As a border, keeps animals from the garden.

Yarrow	Plant along borders, near paths, near aromatic herbs; enhances essential oil production of herbs.

[Home](#) > [Lesson 49 - The Organic Garden; Avoiding Commercially Produced Foods - Why?](#) > [Article #3: Nitrogen Fixation](#) by John Tobe

### **Article #3: Nitrogen Fixation by John Tobe**

Here is how nature provides nitrogen for plants in the soil.

Leguminous crops such as alfalfa, clover, etc., are probably, next to lightning, the most important sources of organic nitrogen.

While some of you may believe that the gods and nature have neglected the good earth and mankind, I want to assure you that this is not true.

It is fixed by natural phenomena and occurrence that all of the nitrogen required by the good earth is put into it by a simple, natural, trouble free way. It is only up to man to use it wisely.

It is my humble belief that the Lord did not ever intend mankind to do His work for Him. In truth, man is lucky if he can do his own work properly—never mind doing anything for the Lord.

Leguminous crops are properly established and divided through the entire earth's surface, including the deserts. This family not only contributes a wide range of forage plants but also plants used extensively for food, and, last but not least, as beautiful ornamentals. It consists of more than 430 genera and 10,000 species.

This family is probably one of the easiest of all to recognize because of the shape of the fruit which is invariably a legume or true pod, opening along tube sutures.

Many noted and respected authorities consider this family the most important family of plants in the horticultural world or any other world, says I!

When I talk to you about technical things, I can just feel I you drawing into that thick shell of yours so that you'll be impervious to my railing. But, says I, "How are you going to know and learn about nature's way if you don't listen?"

It is written that occasionally the road to knowledge gets a bit technical ... but bear up to it—there is much virtue and value therein.

The most important characteristic of this family is the fact all of them have roots or tubercles or nodules which certain soil microorganisms invade.

Here the bacteria obtains carbonaceous food from the plant and carries on the nitrogen fixation process, storing up the resulting nitrogeous food material. This, if not used by the plant itself, is added to the soil when a plant dies and its roots decay ... thereby becoming available to other plants.

Invariably leguminous crops leave the soil in much better shape when they die than it was when they first started to grow. That is why clovers, soya beans, vetches and alfalfa are treated as cover crops or green manures because they positively and definitely, without additional cost, increase the nitrogen content of the soil—apart from adding humus.

I'll just name a few members of this family at random: the mimosa, acacia, genists cytissus, laburnum, wisteria, robina, lupinus, clover, alfalfa, beans, peas, vetch.

The way scientists would describe nitrogen fixation is as follows:

"Gaseous nitrogen diffusing into the soil from the air is converted into useable nitrogen by the mechanism of the leguminous plants, combined with the bacterial action of the microorganisms living in its roots. This act of conversion is what is known as nitrogen fixation and by this means nature provides simple nitrogen to the earth for its crops."

Therefore, not only is this plant able to secure the nitrogen it needs even when there is insufficient nitrogen in the soil ... but these legumes actually add to that supply and as far as nitrogen is concerned, leaves the land more fertile than before they grew.

Animal manures are invariably rich in nitrogen and the reason is very simple and obvious ... because animal fare and forage is often heavy in leguminous crops and they contain large quantities of nitrogen.

There is one important factor that should interest horticulturists about this family and that is that the flowers are invariably very showy and some of our most important trees, shrubs and vines belong to this group.

Commit this to memory...this family of plants has the rare ability to absorb free nitrogen from the air.

While back more than 2,000 years ago they did not perhaps know what we know, and this is that these plants provided the much needed nitrogen to the soil, the Romans used them extensively for soil improvement.

*John Tobe is deceased, and "The Provoker," his publication in which this article appeared, is defunct.*

[Home](#) > [Lesson 49 - The Organic Garden; Avoiding Commercially Produced Foods - Why?](#) > Article #4: pH Preferences Of Some Plants

### Article #4: pH Preferences Of Some Plants

The chemical symbol "pH" is used to indicate acidity or alkalinity. On a scale of 0 to 14, pH values from 0 to 7 indicate acidity; values from 7 to 14 indicate alkalinity; pH 7, the value for pure water, is regarded as neutral.

#### Quite Acid (4 to 5)

Azalea	Holly
Gardenia	Ixora

#### Moderately Acid (5 to 6)

Fern	Pine
Orchid	Potato
Parsnip	Pumpkin

Persimmon, Japanese	Watermelon
------------------------	------------

**Acid. Near Neutral (6 1/2 to 7)**

Beet	Kale
Broccoli	Leek
Cantaloupe	Lima Bean
Chives	Marigold
Corn	Onion
Cucumber	Pea
Eggplant	Peach
Endive	Radish

**Slightly Acid (6 to 6 1/2)**

Allamanda	Oyster Plant
Avocado	Palm
Banana	Papaya
Bean Bottlebrush	Pecan
Citrus	Pepper
Copper	Philodendron
Croton	Pineapple
Dracena	Pittosporum
Fig	Poinsettia

Grape	Powderpuff
Gloxinia	Schefflera
Hibiscus	Shrimp-plant
Jasmine	Squash
Live Oak	Strawberry
Loquat	Tomato
Mango	Turnip
	Rutabaga

**Alkaline, Near Neutral (7 to 7 1/2)**

Alfalfa	Geranium
Cabbage	Lettuce
Carrot	Nasturium
Cauliflower	Petunia
Celery	Sweet Pea

The following is a partial list of available materials for "sheet composting" or compost piles, with some of their percentages of nitrogen, phosphorus, and potash:

	<b>% of Nitrogen</b>	<b>% of Phosphorus</b>	<b>% of Potash</b>
Activated Sewage Sludge	4.00-6.00		
Banana Skins		3.25	41.76
Blood Meal	7.00-15.00		
Bone Meal (Also contains potash and calcium)	5.00	22.00-35.00	
Cantaloupe Rind		9.77	12.21

Coffee Grounds	2.08	.32	.28
Corncoobs			50.00
Corn Stalks and Leaves	.30	.13	.33
Cottonseed Meal (May increase acidity of soil)	6.00-9.00		
Crabgrass, green	.66	.19	.71
Fish Scraps, Fish Meal, Fish Emulsion (May have pleasant odor)	2.00-10.00	1.50-8.00	
Granite Dust			8.00
Grapefruit Skins		3.58	30.60
Human Hair Clippings (Get from Barber Shop)	16.00-18.00		
Manure	3.00-4.00		
Oak Leaves	.80	.35	.15
Orange Culls	.20	.13	.21
Phosphate Rock		30.00	
Pine Needles	.46	.12	.03
Tea Grounds	4.15	.62	.40
Wood Ashes		1.00	4.00-10.00

## **Article #5: Dirt Cheap? Nonsense! It's Vital to Garden**

"As common as dirt!" "Dirt Cheap!" How many times have you heard those phrases? How many times have you watched an angry baseball manager bestow the ultimate humiliation upon a resolute umpire by kicking dust on his shoes?

In plain fact, the popular public image of dirt-dust-earth-mud-soil remains largely negative. In sharp contrast, all who have had more than a passing interest in planting and nurturing trees, shrubs, and food plants—centuries of professional farmers tilling millions of rolling rural acres and urban pot-bound house plant enthusiasts alike—have learned to place a high value on that vital, life-supporting medium, soil.

"Common?" Far from it! It can be as variable and complex as life itself. "Cheap?" Hardly! Placed in the proper perspective of materials most necessary to survival on this planet, soil becomes precious. Precious, yet misunderstood.

Soil is living and constantly changing material. It acts as a medium to hold the raw materials which trees and plants take up into their leaves and convert into food for their use through a process called photosynthesis. To function best, a soil should be made up of 45 percent mineral particles from disintegrated rock such as basalt, granite, sandstone or limestone; 5 percent humus from decaying organic matter; 25 percent water; 25 percent air; and a sprinkling of microscopic plant and animal life.

In general, basalt and granite-derived soils are shallow and tend not to be as rich as soils from sandstone and limestone parentage.

Sandstone-based soils are light, porous, have good aeration and are of medium fertility. Soils from limestone are high in clay, therefore heavy, usually poor in water and air content but can be fertile enough for trees. Most essential elements are present in large amounts in all soil, but the lack of one or more can result in poor tree and plant growth.

The ideal combination of ingredients in the right percentages occurs naturally in only a few fortunate places in the world.

Most people must start with the type and quality of soil that exists where they live. If it needs improvement they must gradually work with it, helping to move it closer to the ideal through the addition of sand, clay, or humus as individual conditions require.

A fairly deep hole dug in the yard, perhaps in preparation for planting a tree or shrub, will reveal soil layers of varying thicknesses. These may be noted as a visible change in color, structure or texture. The uppermost layer, the topsoil, should break up easily in the hand, yet feel slightly moist.

Topsoil does not have to be black in color to be a fertile medium for plants. The color as well as the fertility of a soil derives in part from the parent rock material that formed the soil and in part from the climate and other conditions under which it has been existing for milleniums.

Below the topsoil lies the first layer of subsoil. Often this is a hard ledge of material difficult to spade through. This accumulation of very fine iron particles or clay leached through from the topsoil above is called "hardpan" or "claypan." The National Arborist Association advises that this concrete-like layer can become impervious to the penetration of air, water, or even tree roots to the next layer of subsoil below, severely hampering normal, healthy tree development.

Heavily traveled areas of yard or garden otherwise having good soil texture may become sufficiently trampled so that the soil's structure is lost and air and water spaces are not large enough for root penetration. This condition is called "compaction." Simple cultivation will resolve the problem.

In these days of fast-rising developments and a new home construction a purchaser may be lucky or

unlucky in what the developer leaves him for topsoil. It can range from rich to poor to none! In rare cases the topsoil may be completely skimmed off the property, leaving the unsuspecting but hopeful gardener with a severe problem. Occasionally, the topsoil may have been trucked in from a distance and be far richer than the topsoil natural to the immediate area.

All trees and shrubs, however, do not find all types of soil to their liking, though one might assume they would if quoting the line from Joyce Kilmer's classic poem "Trees." "A tree whose hungry mouth is pressed against the earth's sweet flowing breast..."

But plants definitely do have preferences.

To avoid an unhappy union consult an expert, perhaps a local arborist, whose knowledge of both soil characteristics and individual tree needs will permit him to recommend a variety of trees that will find your particular soil "sweet flowing."

## **Article #6: Soil Test Secret To Success by Gene Austin**

The home gardener or landscaper is at a disadvantage unless he or she has, literally, done the groundwork.

That means fortifying and building up the planting soil with humus such as compost and peat moss and with the essential elements nitrogen, phosphorus and potassium, found in commercial fertilizers.

But the landscaper who wants to get the most out of those expensive trees and shrubs also will investigate whether the soil needs treatment for alkalinity or excess acidity—or whether, in some cases, he needs new soil.

Those \$2 words, alkalinity and acidity, and the related symbol, pH (hydrogen ion activity), place this story in peril of sounding like a high-school chemistry course, so "sweet" is hereby substituted for alkalinity, "sour" for acidity and pH is discarded, except to note that soil is measured on a pH scale and if your soil scores 7 on that scale, it's neutral.

Many well-meaning gardeners apply regular doses of ground limestone—a sweetener—to their lawns and gardens, in the belief that it will improve the soil. Unless the soil is fairly sour, it actually may be detrimental, since most plants grow best in a slightly sour or neutral soil.

A soil test is the way out of this dilemma, and is particularly important where major landscaping projects—such as a new lawn or a large vegetable or flower garden—are contemplated. In the case of these big projects, bringing in new topsoil may be a lot cheaper and easier than attempting to improve poor soil with additives.

Complete soil testing can be a do-it-yourself job. Kits are available for a few dollars but good ones are in the \$20 to \$50 range. The easiest way is to use the expert and inexpensive services of the Agricultural Extension Service in your county.

To get the most out of soil testing, and remove much of the element of chance from landscaping and gardening, several samples should be taken—one in the vegetable garden, a sample from a couple of points in the lawn, one from the area where fruit trees are grown, etc. Since testing is usually necessary only every four or five years, the cost is a real bargain.

Ground limestone—never slaked lime or quicklime—is used to correct sourness in soil and aluminum

sulphate or sulphur to reduce sweetness. Soil testing, however, also will determine the correct fertilizing needs in terms of nitrogen, phosphorus and potassium. The payoff here may be in hard cash as well as better plants, since either too much or the wrong kind of expensive fertilizer may be being used by haphazard gardeners.

While 5-10-5 (the numbers indicate the percentage of nitrogen, phosphorus and potash) is a good general fertilizer for many plants, lawns may require something much higher in nitrogen, such as a 24-4-4 formula. But only a complete soil test can determine the correct formula for a particular area.

If most of your plants are doing well and the complete test sounds like too much trouble, you can conduct a simple checkup for a few cents by buying a piece of neutral litmus paper at a drugstore. Press a bit of the paper against some moist soil after a rain—if the paper doesn't change color, the soil is neutral; if the paper turns blue, the soil is sweet; if it turns pink, sour.

*Knight News*

[Home](#) > [Lesson 49 - The Organic Garden; Avoiding Commercially Produced Foods - Why?](#) > Article #7: Pesticides—They're Killing Bugs—and the Land by Ronald Kotulak

### **Article #7: Pesticides—They're Killing Bugs—and the Land by Ronald Kotulak**

DENVER, Colo. — Millions of tons of chemicals dumped on plants to kill pests and germs contain heavy metals that are permanently destroying the productivity of the land, a federal agricultural scientist warned Monday.

The threat from the heavy metals has not been recognized before because little has been known about plant mineral nutrition, said Dr. John C. Brown, a soil scientist at the United States Department of Agriculture's plant stress laboratory in Beltsville, Md.

New research has disclosed that heavy metals such as copper, zinc, molybdenum and boron block a plant's ability to absorb iron from the soil, he reported at the annual meeting of the American Association for the Advancement of Science.

Iron is the single most important nutrient for plants. It is essential for the formation of chlorophyll.

"Based on our knowledge, we view this as a serious threat. The whole of agriculture is threatened," Brown said.

"If we don't stop the use of heavy metals, in 30 to 40 years from now we will destroy some of our most productive farmland," he added.

The danger from heavy metals already is showing up, he said. Citrus trees in Florida are suffering growth problems because the soil in many areas has been saturated with a fungicide containing copper sulfate.

In many areas of South Carolina, farmers are having difficulty growing cotton because of the widespread use of a bactericide containing zinc, he said.

Michigan farmers are having trouble with soybean because of high phosphate levels in the soil and in the Pacific Northwest chemicals containing arsenic added to the soil to kill pests are hampering plant growth, Brown said.

Once in the soil the heavy metals last indefinitely, permanently destroying the productivity of the land. Without adequate amounts of iron, the fruits of the plants are nutritionally deficient and the plants eventually die.

"The thing that bothers me is that we are still adding things to the soil that contain the heavy metals," he said. "If we don't stop it, we will have nothing left."

Most of the compounds are added to the soils without any basic understanding of how they affect the mineral nutrition of plants, which scientists only now are beginning to understand, Brown said.

We are not set up in agriculture to know what we are doing. We need to know what we are adding to the soil and how the soil is affected," he said.

Millions of dollars are being spent to develop methods of placing treated sewage on farmlands to increase their yield, said Brown. But the sewage contains high levels of heavy metals which eventually would make that farmland unproductive, he explained.

The Department of Agriculture needs more money so that it can establish regional laboratories that can analyze soils, plants and compounds intended to be added to the soil to avoid the danger of making the soils poisonous from heavy metals, he said.

*Chicago Tribune*

[Home](#) > [Lesson 49 - The Organic Garden: Avoiding Commercially Produced Foods - Why?](#) > Article #8: Pesticides—There Are Workable Alternatives To the Dusts, Sprays, and Oils by Joan Jackson

## **Article #8: Pesticides—There Are Workable Alternatives To the Dusts, Sprays, and Oils by Joan Jackson**

If there is a secret to garden defense, it is common sense. There are no easy answers about what is right—or best—to use in that defense.

While the pesticide-environment battle goes on, the backyard gardener fights his own private war, sometimes in unorthodox ways, to save his crops from insects and diseases.

Is there a happy medium between the shotgun gardener who tries to do too much and bombards his plants with dusts, sprays and oils at the first sign of invasion, and the purist who establishes his garden and then refuses to use any chemical means to protect it?

There are good pesticides—and bad ones. And there are alternatives that work—and ones that fail. A smart gardener weighs them all, experiments with some, and uses what works best.

The beneficial ladybug is probably the best known insect in the garden. This little beetle has done wonders for making poison-free gardening possible.

How do you keep your ladybugs from doing the "flyaway-home" routine? They will only stick around if there is enough to eat. You probably won't need ladybugs until summer, when the pest problem is at its worse.

Water your garden then in the early evening, carefully place a container of ladybugs about 15 to 20 paces apart at the base of the plant. In the morning, they will begin climbing the plants and sampling the insects (aphids are a favorite—one ladybug will eat 50 aphids for breakfast).

For the average backyard garden, one container of ladybugs should be enough. Where to find them? In the summer, they are sold commercially through garden supply stores.

Invite a creature into your garden. A toad or a frog, for instance, is a good friend to the gardener. Ninety percent of a toad's food consists of insects, most of which are harmful to the garden.

To encourage a toad to stick around, provide a modest shelter so it can rest out of the sun. Cut a small

entrance in a box or chip in an opening in the side of a flower pot, and bury it a few inches into the ground, preferably in the shade. You might even provide a shallow watering hole-pond; if not keep the shrubbery around your Toad Hotel damp.

Some people may feel squeamish about it, but picking off bugs by hand is a perfectly logical solution. If you squash or rub off pests as soon as you notice them, you may not need a pesticide later on.

Remember, many insects come and go with the season, and will come and go with little damage to your garden if you just let them alone.

If aphids are bugging you, give them a bath. A strong squirt of water will wash them off leaves; or you can rub them off by hand. Still got aphids? Then try a soap bath. Make a strong solution of soap—not detergent—(Ivory Flakes, for example) and water using three tablespoons of soap flakes to a gallon of tepid water.

Use your hose and sprayer to cover the infected plant with suds, wait a few hours, and then wash the plant off with plain water.

Lo, the beautiful marigold. It should be freely inter-planted with vegetables because of its pest-repellent properties. The gardeners say the French marigold and the tall odored American marigold seem to discourage many garden pests, especially nematodes and rabbits.

The marigolds exude substances from the roots which will rid the garden of nematodes if planted each year. The ones with the strongest odor are the most effective and have been reported to repel pests ranging from bean beetles to rabbits.

You could write a book about ways to get rid of snails—and you'd still have snails.

One way is to "go looking" for them late at night—about 10 p.m.—with a flashlight. Hand pick them and dispose of them.

Snails also are supposed to be beer lovers. All you need is a pie pan and some old beer. Make a depression in the ground and set the pan in it, so that the rim of the pan is even with the soil. Fill the pan with stale beer (that's the secret—the stale beer). The snails will crawl in and drown in the brew. Change the beer every few days.

Why is it that some gardens are plagued by a hungry horde of insects and others remain clean and bug-free? In gardening, an ounce of prevention is worth the time. The rules are simple:

- Keep your garden healthy without poisons by shaping up the soil with amendments and nutrients.
- Get rid of plants that are damaged by pests or are sick.
- Use seeds and plants that are disease or pest resistant varieties.
- Keep it clean. Rake up leaves and toss out fallen fruit and dead flowers.
- Water and fertilize regularly. It is part of the "keep 'em healthy" routine.
- Keep after the weeds. They offer a comfortable home for insects. For the same reason, the ground should be cleared of all crops once harvesting is completed.

## **Article #9: Containing Inhibits 'Raiders' By Gene Austin**

Home vegetable gardens are the targets of all sorts of four-footed and winged raiders, and everything

from beagles to buckshot has been tried at one time or another in the effort to foil them.

One reader, F. Thalken of Vineland, N.J., writes that last year rabbits ate everything in the family garden but the tomatoes, and equally plaintive tales are heard from others.

Except for a few animals that seem to defy all reasonable restraints—notably groundhogs, skunks and raccoons—fencing the garden or the parts of it containing the most vulnerable plants remains the surest solution.

Before discussing quick and inexpensive ways to fence, however, note should be taken of the various chemical and natural nostrums concocted in the battles against marauding animals and birds.

Mellinger's, a firm that advertises "1,000 horticultural items" and is located at 2310 W. South Range, North Lima, Ohio 44452, in case anyone wants to write for a catalog, devotes an entire page in its current sales book to such items as Squirrel Skram, K-Pels to protect shrubs from dogs, dog and cat repellent spray bombs, Roost No More to keep pigeons and starling away, rabbit and deer repellent, mole killer and snail and slug pellets. Try them at your own risk.

One gardener swears by a substance more readily available: cayenne pepper. Sprinkled lightly on rows while plants are small, it is supposed to solve the rabbit problem. Once plants have passed the tender stage they are not as attractive to rabbits.

A spray made of nicotine sulphate (2 teaspoons of 40 percent nicotine sulphate per gallon of water) is supposed to repel rabbits, if a garden supply dealer who stocks the chemical can be found.

Various plants also have been arrayed in the battle. Soybeans, planted all around the edge of a garden, are said to be so attractive to rabbits that the bunnies will touch nothing else. Wormwood, a smelly plant that some gardeners place throughout their plots, is supposed to deter raids by rabbits, groundhogs, raccoons and other freeloaders.

My own garden is located less than 200 feet from a wooded area with a full quota of wildlife, but I've been able to protect the vegetables adequately with temporary fences and other wire restraints. I also subscribe to the theory that fencing an entire garden is needless and expensive since many plants don't need protection.

Experience will have to be the guide in your area, but my own observation is that the plants most likely to be raided are young peas or seedlings of squash, melons, cucumbers, sunflowers and similar plants with large, edible seeds; corn when it becomes ripe; and ripe melons.

Corn and some large seeds often are victimized by crows and other birds, who will fish out seeds or pull up plants when they are only a few inches tall.

Plastic-coated fencing in the 48-inch size, or 24-inch if you can find it, makes fine protection for young plants and seedlings, including peas and beans, and just-planted corn and other vulnerable seeds.

The 48-inch fencing is cut into 24-inch wide strips about 6 feet long and bent down the middle to form a wire tent that will allow the plants to reach a safe size. The strips are easily stored in a small space by stacking them one on top of the other.

Temporary fences made of 24-inch chicken wire will protect larger bush beans and peas and also will help support the plants if you have only a couple of rows. Stakes cut for 2 or 3s and sharpened with a saw or hatchet will hold the fence, which can be put up in minutes with a stapling gun and disassembled just as quickly and rolled for storage.

Fences admittedly make cultivation of plants difficult, but if dried lawn grass is used for mulch between rows and around the plants, no cultivation will be needed.

Cages can be formed of pieces of chicken wire to protect melons when they near the ripe stage but ripe corn presents special problems. I have found stalks, chopped off near the ground and toppled and nothing but cobs left where the ears had been.

I've heard of one gardener who ties the tops of his cornstalks together with nylon fishline; when the maurader chews through the base of the stalk it doesn't fall and the animal departs, too discouraged to return (or so I'm told). I prefer to pick the corn as soon as it ripens and to write off any losses as philosophically as possible.

Fending off stray dogs and other pets may be the biggest problem with roses and shrubs. To protect them, make circles of 12-inch or 18-inch plastic-coated wire fencing. The circles should be approximately the same diameter as the shrub.

A simple way to get the right size circle is to measure or estimate the width of the shrub, then cut a piece of fencing 3 1/2 times that long. Hook the ends together by bending the wire ends together with pliers—the circle should slip down over the shrub and is easily removed for weeding or other work. Even cats don't seem interested in getting inside these circles.

If traps are resorted to, I recommend the box variety that doesn't injure the animal, which should subsequently be released in a woodland, not a residential area.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 1. The Benefits Of Biological Orcharding

### 1. The Benefits Of Biological Orcharding

It is often difficult and sometimes impossible to find natural, organically-grown produce in many locations. And what is available is usually higher priced than chemically-grown foods. Organic fruit growing, or biological orcharding as it is sometimes called, is the best way to obtain optimum quality fruits and nuts at an affordable price. By taking control of the production of our food we can be certain of obtaining high-quality, uncontaminated produce that will best satisfy man's nutritional needs.

Besides the obvious benefits of having a supply of fresh produce uncontaminated by chemical fertilizers and pesticides, you have the added health benefits of good exercise out in the fresh air while establishing and maintaining an orchard. You have the economic benefits that result from having your own food-producing trees and you have the psychological benefits of feeling "rooted" to a piece of land—a sense of responsibility for your own space in the ecosystem.

Biological orcharding benefits the ecosystem by producing a protective blanket of green over an earth that is rapidly being deforested. Solomon, supposedly a wise man, employed 70,000 men to cut down the cedars of Lebanon, an act that geologists say destroyed the food production resources of that region forever. Similar destruction is now happening in the tropical forests of South America, even though science has proven the loss as irreplaceable.

A permanent grove of trees is not like a cultivated field crop, and the differences become more pronounced and profound with the passage of time. A grove of trees managed biologically will in a

thousand years contain richer soil than it does today. A field cultivated conventionally in a thousand years will have no topsoil left at all and will have been maintained by tremendous outlays of chemical fertilizers and pesticides.

On the other hand, the grove is essentially self-fertilizing. The leaves fall to build rich topsoil through the interplay of soil microorganisms and humus. The tree roots feed on the nutrients released in the topsoil and also dig deep into the earth for minerals and water. The minerals find their way, via the leaves, back to the topsoil! Woodland can raise the water level and it acts as a reservoir of moisture as rain soaks and holds in the deep, permeable soil beneath the trees. While the trees produce their food and nourish a whole chain of plants and animals under and around them, there is a net gain in fertility. In cultivated fields, there is almost always a net loss. In nearly every instance, trees can produce more food than grain.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 2. Establishing An Orchard

## **2. Establishing An Orchard**

Every individual, whether he lives on a small city lot or a large country estate or farm, can provide some or all of his fruit and nut needs with an orchard. Even back-yard gardeners can enjoy many varieties of fruit on dwarf-size trees and miniatures. The range of tree crops you can grow in your area depends very largely on climate. Climate is more important than soil. You can always improve the soil by adding proper nutrients, but you can't do much about the climate.

Temperature and moisture are two factors which limit your orchard selections. Regarding temperature, your main problem in the North is too much cold weather and in the South your problem may be not enough cold weather to break the dormancy of certain trees. As for moisture, too much produces poor drainage in the soil and a high humidity contributes to fungal diseases. Of course, too little moisture means nothing will grow. The best climate for temperate-zone fruit culture is dry with adequate irrigation and with mild but not too mild winters. However, you don't have to live in an ideal climate to grow fruit and nuts. There are varieties established for every area. For assistance in choosing the proper varieties for your area, you should consult a local nurseryman or your county extension agent.

It is possible to experiment with varieties not usually grown in your area if you follow a few guidelines. Learn as much as you can about the requirements of the variety you desire and try to duplicate them as much as possible at your location. Mini-climates can be created around pools of water, next to walls, with the aid of greenhouses, etc.

For best success, plant varieties that are no more than one zone difference from yours (using cold hardiness zone maps from nursery catalogs or gardening books as a guideline).

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 3. Choosing Trees

## **3. Choosing Trees**

Diversity is the key for successful biological food production. Solid blocks of one variety of trees are open invitations to population explosions of pest bugs. A few trees of each of the varieties that you like are easier to care for and more likely to produce a crop of fruit every year.

Buying trees from nurseries is, in the beginning, the best way to get started, provided you get good healthy trees in varieties best suited for homestead production. A general principle is to buy from growers and suppliers who have a reputation to maintain. Healthy, well-grown trees may cost you more initially but will save you time and effort and will produce better in the long run. Choose trees with a well-shaped crown, a strong leading shoot, no damaged branches and a good, fibrous root system. The eventual size and vigor of fruit trees is an important consideration. This depends on the rootstock onto which they are grafted and a good nurseryman will be able to advise on the best rootstock for each purpose.

Nursery trees are sold in three categories. Bare root, container-grown, and balled-in-burlap. Bare root trees are only available during the dormant season, usually early spring in the northern areas and mid-winter in the South. Container-grown and balled-in-burlap trees can be set out anytime of the year though spring or fall are best. Trees planted in the fall have all winter to establish root systems before leaves start to develop and therefore will need less care and attention during the dry summer months.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 4. Pollination Of Trees

#### **4. Pollination Of Trees**

A good nurseryman will be able to suggest suitable cultivars to ensure pollination. Then you can be sure that your choices will have the best possible chance of giving you good yields.

Some simple rules for fruit pollination are as follows:

1. Some apples are self-fruitful but most horticulturists advise planting three varieties of apples and pears if you want to be 100% sure of pollinating all the trees. In apples, a Golden Delicious is probably the best way to ensure good pollination.
2. Some plums are self-fruitful including Stanley, Greengage, Shropshire Damson, and many of the old varieties plus Italian and other prune plums. Fewer of the Japanese plums are self-fruitful. Methley and Santa Rosa are.
3. You must have two varieties of sweet cherries for pollination. If you don't have room for two trees, graft two varieties on the same tree.
4. Sour cherries are self-fruitful, as are almost all peaches, apricots, and nectarines.
5. Southern- and eastern-type figs are self-pollinating but western Smyrna figs depend on a particular insect or mechanical pollination.
6. Persimmons are self-fruitful.
7. Some varieties of nuts are self-fruitful, others require cross-pollination. Some growers believe pollination between varieties produces a bigger and better-quality crop.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 5. Preparing A Site

#### **5. Preparing A Site**

The main considerations in preparing a site for your orchard are soil condition and drainage. The first thing you must put right in any area where it is a problem is drainage. Where the problem is not too severe, double-digging which breaks up any hardpan (compacted soil unimpenetrable by roots) and

aerates and introduces organic matter into the soil may be sufficient. On very heavy clay, you may need to aid drainage by digging a deep, stone-filled sump (a pit or reservoir serving as a drain for water) at the lowest end of the orchard with one or more lines of drainage tiles covered with six inches of gravel buried two feet deep leading to it. Other treatments for heavy clay are to dig coarse boiler ash, mortar rubble, coarse sand, etc., into the top-soil. And work in plenty of bulky organic matter, well-rotted compost, or coarse peat to increase the humus content and open up the soil structure.

The ideal soil for growing the widest range of fruit and nut trees is a medium loam combining the advantages of sandy and clayey soils and containing plenty of organic matter and minerals. Few gardeners are lucky enough to have such soil. However, any type soil can be improved through a program of organic soil conditioning methods.

To maximize soil fertility, large quantities of well-rotted manure, compost, and minerals are required. Sandy soils will benefit from the addition of coarse peat, clay, or even subsoil from excavations. Clayey soils must be thoroughly cultivated, and lime makes clay more workable by encouraging the formation of soil crumbs.

Nearly all soils are deficient in one or more minerals. These can be added in the form of rock phosphate, colloidal phosphate, granite dust, feldspars, ground glacial rock, and greensand. Natural rock fertilizers are slow working and long lasting. They do particularly well on acid soils and are more effective when combined with raw animal and/or green vegetable manures.

A healthy soil depends on adequate quantities of organic matter. While barnyard manure has long been used for this purpose, well-made garden compost is an excellent alternative. Apart from diseased material, all plant residues and kitchen wastes should be composted and returned to the soil. Various methods can be used to make compost, but all require good aeration, free drainage, adequate moisture, and a balance between dry coarse material and soft green plant tissues or animal manure. Dry material should be layered with soft plant material or animal manure and then watered. Bone meal or other natural fertilizers can be added to the heap to supply additional nutrients.

Another good way to increase the organic material in the soil is by green manuring. A quick-growing crop such as mustard, vetch, clover, or lupines is sown early and dug into the ground a few weeks before the orchard is to be planted.

The soil should never be left uncovered, especially on sloping sites, otherwise erosion will occur. You can use ground cover plants or a mulch of organic material such as ground bark, old straw, grass clippings, and/or leaves.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 6. Planting Trees

## **6. Planting Trees**

Trees that come bare root will benefit from being placed in a bucket of water for a couple of hours before planting. For optimum growth, trees should be planted in a large hole filled in with the best soil and rotted compost. Do not put a lot of fertilizer in the planting hole. Spread the roots of the tree out in the bottom of the planting hole in a circle over a mound of earth. Compact the soil firmly but gently around the tree roots taking care that the trunk is not left leaning to one side or the other. The tree should be set at the depth it was growing before, which should be obvious by a dark ring around the trunk above the roots.

In areas with high winds, it is a good idea to stake newly planted trees. This can be very simply done by placing a slated stake against the tree facing the prevailing wind. You can also stake the tree by using a

wire line covered with a rubber tube looped around the tree and attached to an upright post. Mulching with heavy rocks is also an effective method to help hold trees in place during high winds.

Fruit and nut trees need a lot of sunlight. They should be planted in an open area cleared of native trees, and they should be spaced far enough apart so they don't shade each other. Also, tall varieties should be planted on the north side of the orchard.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 7. Mulching

## 7. Mulching

No matter how you plant your trees, growing them successfully depends on mulch. Six inches of mulch will cover a multitude of planting sins. Even watering every day is not as effective as mulch. Mulching subdues weeds and grass under the tree that would compete for available water and nutrients. It helps the soil to conserve moisture during periods of drought and moderates the temperature of the soil around the tree roots. The mulch also begins immediately and continually to release nutrients to the tree. Mulching can supply most of the nutrition needed by a fruit or nut tree.

The type of mulch you use is mostly a matter of preference and availability. Any organic matter will do. Leaves are usually easy to obtain. Good results have been demonstrated from using old hay and on poor ground, straw mixed with manure is beneficial. Grass clippings are also a favorite of many growers.

Mulch should not be piled up too closely to the tree trunk. It is best to leave a few inches of air space between the mulch and the tree.

[Home](#) > [Lesson 50 - The Pluses In Orcharding: How To Get Started](#) > 8. Orchard Fertility

## 8. Orchard Fertility

Nitrogen (N) and Potash (K) are what fruit and nut trees need the most of. Phosphorus (P) needs are smaller but just as necessary. Other important nutrients include calcium and magnesium in addition to manganese, zinc, boron, copper, iron, and others.

Where land has been abused, or is naturally deficient in some trace element, nutritional deficiencies in your trees may occur. These deficiencies often show in the form of fungal diseases, though they can also manifest insect damage, hail damage, etc.

If mulch is not giving your trees enough of the important nutrients, other natural, slow-release fertilizers can provide them. Rock phosphate and bone meal will supply additional phosphorus, if needed. Wood ashes are an excellent source of potash, and they also contain high amounts of calcium. Manure is good for both nitrogen and potash. Bloodmeal, cottonseed meal, and soybean meal are slow releasers of nitrogen. In situations where you need both calcium and magnesium, dolomitic limestone or oyster shells can provide them. Granite dust and greensand are very slow-release forms of potash and are more effective when used with a high content of organic matter. Compost is one of the most desirable organic fertilizers of all. It contains all the important nutrients and trace elements.

The importance of a balanced nutrient supply cannot be overemphasised. The controversial argument of organic growers, that proper organic fertilization gives plants resistance to disease and pests has been

given more attention by conventional science in the last few years. There has been a steady increase in announcements by conventional science that a balanced, organic fertility program may indeed keep plants healthier and more resistant to bugs as well as promote more vigorous growth. The conclusions support the observations of organic gardeners for tens of years—organically-grown plants DO resist diseases and insect attacks better.

The English authority, E. R. Janes, in his book, *The Vegetable Garden*, wrote, "All gardeners should become health-minded and not worry too much about disease and pests. If it comes, act promptly and destroy the first specimen. Feed the soil so that plants are in sturdy health, because all the remedies in the world are useless if the underlying cause is repeatedly neglected."

[Home](#) > [Lesson 50 - The Pluses In Orchardring: How To Get Started](#) > 9. Pest And Disease Control

## 9. Pest And Disease Control

In a biologically-managed orchard, pest control should be limited to the use of integrated pest management techniques which include biological controls such as parasites, predators, and diseases. When insect damage is severe, organic growers can make use of certain nontoxic sprays such as dormant oil, rotenone, pyrethrum, ryania, pepper juice, and others (see previous lesson on organic gardening for more details). All insecticides should be used only in emergencies, and with caution, because of the possibility of upsetting the natural balance.

The main point in biological pest control is the greater the area under biological and integrated pest control, the greater that control can be. When one orchard under biological control methods is surrounded by nearby, sprayed orchards, it has less of a chance of attaining optimum good effects from biological management. The more growers who can be convinced to retreat from total reliance on toxic chemicals, the more effective the overall program will become.

However, at times you may need to intervene when pest damage is overwhelming. Some insects and types of controls are as follows: The Caribbean fruit fly may cause a problem with citrus. A small brown spot will appear on the rind, and you may find small worms inside the fruit. The papaya fruit fly does similar damage. The only control suggested is bagging the fruit. If you want to do this, use brown paper sacks, or cloth—not plastic which will cut off respiration. The fruit will still be able to ripen, since the ripening process proceeds through the leaves, not the fruit.

A program to exterminate Caribbean fruit flies in Florida has reduced damage from this pest. Millions of the flies have been captured and sterilized by irradiation. The sterilized flies are released to mate with wild flies, resulting in sterile eggs.

As mentioned in the previous lesson on organic gardening, "Neutral Copper" may be used in controlling certain plant diseases. If used properly, it will control diseases without poisoning the fruit.

Use neutral copper on fig trees only if rust (a fungus disease) becomes a problem (the leaves look like they are covered with a rusty powder). If there is just a little, simply ignore it.

Neutral copper may also give some control to fire blight on loquat trees if sprayed prior to blossoming, and again when the fruit is about the size of a pea. The symptoms of fire blight are drying up of blossoms, blossom stems, or fruit, when the size of small marbles. Remove and destroy diseased parts, then spray with neutral copper three times at two-week intervals.

If you find splitting bark, or gum running from the trunks of your trees, remove the loose bark, spray with neutral copper twice, seven days apart, then apply pruning paint. When the pruning paint wears off, repeat the process.

Ground-up sulfur rock is an organic fungicide. *Organic Gardening* magazine, August 1980, says it is the best organic fungicide available.

[Home](#) > [Lesson 50 - The Pluses In Orchardng: How To Get Started](#) > 10. Pruning

## 10. Pruning

Pruning is more of an art than a science. It is an act of cooperation or compromise between what you want the tree to do and what it wants to do. There is no "rule" of pruning other than the overall rule: approach each tree individually, and prune it in a way that enhances the natural form it wants to take. The most artful form of pruning may be none at all. Masanobu Fukuoka, the Japanese farmer who describes in his book, *The One-Straw Revolution*, his own orchard management techniques eschew all pruning in his citrus orchard which grows helter-skelter among other food and forest trees. According to Fukuoka, pruning is only necessary when man starts tampering with the tree.

Trees that are grafted onto other, different rootstocks, especially dwarfing rootstocks, will invariably need pruning. Most growers prune in late winter or early spring before buds begin to swell. Some additional light pruning may be done in summer. Normally, you want to prune when the tree is dormant, toward the end of winter in the North, earlier in the South.

### 10.1 General Pruning Guidelines

Cut as close as you can so as not to leave a stub, which can die and rot back into the trunk, providing a handy entrance for disease. On larger limbs, use a pruning saw to make flush cuts.

If you cut a branch partway back (called heading back), the buds behind the cut will grow more than they would have otherwise, develop more branchlets and spurs, and therefore thicken the growth. This will also stiffen the branch. Heading back can easily be overdone. If in doubt, don't!

Where two branches of about equal length form a Y, the branch cut back the least will grow the most, thus avoiding a weak Y-crotch.

In heading back a branch, always make a cut just above an outward-pointing bud, preferably on the lower side of the branch. This encourages low-spreading growth.

When heading back a central leader, cut back to bud so that there is no dead stub left when the bud grows out as a new leader.

Don't be in a hurry to cut lower branches from a tree unless you live in an area where snow drifts get heavy enough to weight and break them down. Cutting vigorous lower branches off too soon slows the growth of the tree.

Pruning tends to delay fruiting with the exception of skillful heading back of dwarf trees to induce fruit budding on spurs close to the trunk.

You only begin to understand pruning after you have lived with a few trees from planting to their heavy-fruiting years. In the meantime, the old-timers maxim, "Keep a tree just open enough so a robin can fly through without touching its wings," is about as good advice as any.

## 11. Thinning Fruit

Hand thinning is done primarily to develop extra large fruits. Apples and peaches will thin themselves to some extent (called Junedrop) and that usually suffices for busy people. If only a few trees are being maintained, supporting overlaid limbs with wooden props is an alternative to hand thinning the fruit. The home-grove grower should thin only to assure that his fruit is of good size and quality.

## 12. A Grove Of Trees To Live In

It is more important now than ever that man begin looking to tree-crop agriculture as a way to sustain both himself and the earth. As more and more people go hungry every year and more and more land is ruined due to poor farming methods and greed, it becomes eminent that changes must be started. Biological orcharding is a step in the right direction towards reforestation of our planet. Instead of a few people establishing groves of trees isolated from the concentrations of chemicals and toxins in our environment, perhaps the future could bring the whole landscape for human habitation into a pleasant grove of trees to live in and from.

## 13. Questions & Answers

### Are dwarf trees really worthwhile?

Standard trees have some advantages over trees with dwarfing rootstock. In fact, only in apples are the dwarf trees really satisfactory. In peaches, plums, cherries, apricots, etc., many horticulturists believe standard trees are better for home orchards. Rootstocks on standard trees are almost always stronger, more adaptable to a wider range of soils, hardier, and more drought resistant. However, dwarf trees usually bear earlier and require less pruning. Dwarfs are easier to pick and spray, unless the standard tree is kept small in which case the difference is minimal. You can keep a standard tree fairly small with intelligent pruning.

### Should the orchard site be tilled before planting?

Not necessarily. Some orchardists recommend deep tilling, lime, fertilizer, etc., a year ahead of time before planting an orchard and admittedly this is a good practice on certain types of soils. It cannot be practiced on a hillside or where erosion is a problem. Planting in sod can be successful and eminently more natural to the ecosystem. Trees should be mulched to the dripline and they can be fertilized with a light application of manure and minerals.

### I am 70 years old. Is it foolish for me to consider starting an orchard at my age?

No! Some of the best orchardists are elderly folks. They are usually livelier than many

young people and have a more positive outlook on life. Not only will you be contributing to your own health and welfare but you will be making a serious contribution to society as well.

### **Do trees need to be arranged in any particular way in order to be pollinated properly?**

No, you do not need to strive for perfect pollination. In an organically-managed orchard, an abundance of bees and other pollinating insects will do a fine job for you as long as the trees are reasonably close to each other.

[Home](#) > [Lesson 50 - The Pluses In Orchardring: How To Get Started](#) > Article #1: China Orders Citizens to Plant Trees, Or Else

### **Article #1: China Orders Citizens to Plant Trees, Or Else**

PEKING—The Chinese government Thursday ordered a gigantic tree-planting program in a major effort to stave off ecological disaster.

Every Chinese citizen is being told he must plant three to five trees annually, or face unspecified punishment. Planters must also tend the saplings to ensure the trees survival.

China's insatiable appetite for wood products contributes to the decline of its forests. But so have misguided farm policies.

*Knight Ridder News Service*

[Home](#) > [Lesson 50 - The Pluses In Orchardring: How To Get Started](#) > Article #2: Tree Culture—The Ecological Way to Restore the Earth

### **Article #2: Tree Culture—The Ecological Way to Restore the Earth**

America is, quite literally, floating out to sea! In many states, two-thirds of the topsoil has been destroyed through overcropping and erosion. Iowa, the foremost corn-growing state, exemplifies this national disaster. Areas of Oklahoma, Arkansas; Missouri, and other states are entirely bereft of topsoil—it's all gone! Only red clay remains. It is estimated that over 50,000 acres daily of American land is taken out of food production due to housing, mining, and soil exhaustion.

American farmers are exhausting our lands by plowing and subsequent loss of tons of topsoil from every cultivated acre each year. Much land is being exploited by crops (such as wheat, corn, and hay, which are exported or go to animals that are exported from the growing area) that remove much-needed minerals. This practice is fast depleting our greatest wealth—our topsoil. California lands are being lost so fast that many predict it will be a food importing rather than exporting state by 1990 to 2000. Its loss of land is frightful.

Tree culture, on the other hand, restores and builds up the soil. Most of the world's soil wealth was built on forest floors. About one inch of topsoil is added to a forest floor every 400 years. What nature built in 400 years, America's exploitative agriculture destroys in a single year!

Rebuilding America's soils is a number one priority. It is a herculean task, but it can be done. Restoration and maintenance can be accomplished scientifically by adding minerals as needed to give soil balance and then tree culture to maintain and enhance fertility.

Trees can build soil fertility while at the same time yielding tremendous quantities of fruit! A meat and grain agriculture destroys our topsoil wholesale. Its product is food that is pathogenic in the human dietary, while our frugivorous physiological disposition is excellently served by fruit. The former generates human fodder for our \$300 billion annual disease industry, while the latter—fruits—form the dietary basis for healthful, sickness-free living! When fruits are removed from the growing area, about 1% of the fruit represents minerals that must be replaced. Hence the export from an acre of soil of 10 tons of persimmons annually means about 200 pounds of minerals across the spectrum must be replaced. Ten tons of fruit will command a gross of about \$8-10,000, and the cost of organically replacing 200 pounds of minerals, including trace elements is a mere \$25-40.

The product yielded by fruit is astronomical compared with the grain and meat economy. It takes about four acres to produce a single beef animal over a period of two years. The "food" resulting therefrom on an annual basis per acre is about 75-100 pounds. This compares with 20,000 pounds or more of fruit. One destroys the soil, while the other builds it. One furnishes pathogenic fare, while the other is most healthful. One represents a suicidal course, while the other is the basis for the good life.

You can be instrumental in helping put America on the right ecological/humane track. The investment is small. You realize colossal increments, and the result is bountiful for America's health, too!

[Home](#) > [Lesson 50 - The Pluses In Orchardng: How To Get Started](#) > Article #3: Your Garden Needs Insects by Carl C. Webb

### **Article #3: Your Garden Needs Insects by Carl C. Webb**

The only controlled insect pollinator is the honey bee which is considered to be worth nine times as much for its crop pollination as for the honey and wax it produces.

This is no mean figure when it is not uncommon for a single hive of bees to produce 40 or more pounds of honey in one season.

Many other garden insects are of great benefit because both the quality and yield of many garden and field plants are influenced or dependent on insects for pollination.

My garden produce is grown without the use of any insecticides because I understand that 90% of insects are beneficial while only 10% can cause crop damage. If I spray to kill harmful insects, I am certain to kill the good ones along with them and soon I would have completely upset nature's delicate balance.

The lady beetle is well-known among gardeners and is a useful insect because of its intense hunger for other insect eggs and their young.

This insect is grown commercially in California and perhaps in other states, and is used on a wide scale by the grapefruit growers of Texas to control aphids on the trees.

Lady beetles vary in size and color.

Another effective predator upon other insects is the lace-wing, whose appetite for eggs and young of other insects makes it very beneficial. It is an attractive insect, light green in color, with a delicate lace design of the wing, which is the basis for its name. Protect these insects.

The young of the lacewing are so eager to feed on insects and eggs that the mother lays her eggs on a hairlike structure to elevate them so the first ones to hatch will not devour their unhatched brothers and sisters.

The praying mantis and the walking stick are two other helpful insects that deserve protection.

A number of tiny wasps are parasitic on harmful insects. In the North they work on infestations of alfalfa weevil, cereal leaf beetle, and the army worm. One of this type of parasitic insects works on the tomato hookworm. If a large tomato hookworm larva is seen to have a number of white egglike cocoons, do not molest it. Just let it remain so the new parasites can emerge and do good.

Do you see why it is important to be an informed organic gardener?

[Home](#) > [Lesson 50 - The Pluses In Orchardring: How To Get Started](#) > Article #4: Texas Could Feed Nearly Half the World by T.C. Fry

### **Article #4: Texas Could Feed Nearly Half the World by T.C. Fry**

Recently we published the statement that Texas could feed the United States with its vast agricultural capacity and that the United States could feed the whole world. This presumed, of course, that the world would be eating its natural biological diet.

That statement drew some exceptions from people who told us we were out of our minds and were publishing outright lies, exaggerations, and distortions.

Today I received the first issue of a new magazine, *Science 80*. And what did I find? More than two pages devoted to a new gardening/farming technology that promises better than the statement we previously published.

In Palo Alto, California, Mr. John Jeavons has been experimenting with organic intensive farming. He has found that only 2,800 square feet of land will produce in one four-month growing season enough food to sustain the average person for a full year. But if the growing season is twice that as it is in Texas, half that amount of space will do. (The Texas growing season varies from six months in the panhandle to all year in the Rio Grande Valley. Most of Texas has eight to nine months.)

Our world's population is about four billion. At 1,400 square feet of land per person, 30 persons could be fed per acre. Texas' 60 million arable acres, then, if devoted to organic intensive food growing through tree and plant cultivation could feed nearly half the world! No wonder one billion Chinese are so well fed!

This article is not written to praise the merits of Texas but to point out that the world could be well-fed with its present resources and to highlight a new method of agriculture that is staggering to the imagination.

Mr. Jeavons started building up some unpromisingly barren California soil by employing the biodynamic French intensive method, a method that has long been practiced in France and much of Asia, including China. This method requires few tools and little labor relative to the yield. "The most complicated machine required is a wheelbarrow."

One of the key features of the biodynamic/French intensive method is the elimination of row culture, as rows waste much growing space. Space devoted to actual growing can be doubled, tripled and even quadrupled. Further, by composting with organic materials, remineralizing with ground rocks and restoring the ecobalance by using insects, worms, and microorganisms instead of chemical fertilizers and pesticides, Mr. Jeavons again doubled, tripled and quadrupled the yields. For instance, his plot yields 16

times more zucchini squash than conventional methods! This greatly multiplied yield offsets conventional labor savings. Mr. Jeavons estimates that people who want to grow produce for a livelihood can work 40 hours per week for about eight months of the year and earn about \$10,000 to \$20,000! And, get this—on an acre or less of ground! But the biggest plus is ecological! Instead of, producing poisoned produce and land, we can grow more wholesome food on rich and highly-productive soil.

Perhaps you read of the Minnesotan who farmed over 1,300 acres of land conventionally and ended up with earnings of almost \$50,000 in a good year. He sold all but 50 acres of his land. This 50 acres he turned into an organic farming operation on which he consistently earned more money by organic methods than he had at anytime earned on his tremendous 1,300-acre farm. Further, he worked less for his increased earnings.

If the farmers of this country get off the chemical bandwagon and start working for themselves and their consumer clients instead of for the giant chemical companies that have made them their serfs, the health revolution will begin. (Mishandled soil is the first link in the long chain of practices that lead to disease, including degenerative disease.)

The biodynamic/French intensive method requires so much less water that land not presently arable may become usable. Mr. Jeavons uses one-eighth the water conventional farmers use even though he waters his plants lightly every day. Even though they employ sprays, conventional farmers lose 25 to 30% of their product. Mr. Jeavons loses only about 10% of his produce to pests because he has established ecological balance—pests have natural enemies. Where he does not have natural balance such as with snails and gophers, he employs manual gathering of the slugs and traps for the gophers.

Mr. Jeavons has contrasted the amount of land required for various types of agriculture based on different consumer diets. The biggest contrast is that one meat eater requires about 22,000 square feet of land for his diet intake whereas a fruitarian/vegetarian requires only 1,400 square feet, only one fifteenth as much land.

The average person can, by the methods Mr. Jeavons employs grow his total food needs (a 2,400-calorie diet) on just 28 minutes of labor a day.

To say that this *Science 80* article is a revelation is to put it mildly. Its portents are, I repeat, revolutionary for the health and well-being of everyone in the world!

If you'd like to learn more about biodynamic/French intensive organic farming, buy John Jeavons' book, *How to Grow More Vegetables*. You can also find helpful guidance if you subscribe to *Organic Gardening*, a wonderful monthly magazine published by Rodale Press.

[Home](#) > [Lesson 50 - The Pluses In Orchardng: How To Get Started](#) > Article #5: Fertilization of the Soil by Dr. Herbert M. Shelton

### **Article #5: Fertilization of the Soil by Dr. Herbert M. Shelton**

In 1950, I visited the Savage experimental Gardens in Nicholasville, Kentucky. It was late in the fall and the region had seen two heavy frosts. All the gardens in the area were destroyed—all, that is, except the Savage gardens. From these gardens an abundance of fine, tasty vegetables was still being taken and served. The Roy Health Home was serving these vegetables to its patients, and I enjoyed a few meals of fine vegetables fresh from the garden while there.

Why had the frost not damaged the gardens of Arthur Carter Savage, when it had destroyed all the other gardens for miles around? Mr. Savage explained that when he gets an abundance of minerals into the sap

of vegetables and trees, they have high resistance to cold. He gave it as his opinion that, if he had the funds with which to carry on the experiment, he could grow oranges as far north as Michigan. Assuming that he could grow the trees that far north, it is not probable that they would ever produce a crop of oranges as the season is too short. But the mere fact that the remineralization of the soil produces such remarkable resistance to cold as to lead one to think that orange trees could be grown that far north is a thing worthy of our closest attention and study.

Minerals constitute plant food. To state this differently, plants live on minerals. True they need carbon, which they extract from the air, converting this, by means of photosynthesis (with the aid of sunlight), into carbohydrates—sugars, starches, cellulose and pentosans. It is interesting to know that cotton fibers (cellulose) is made from sugar which, in turn, is made from a gas that floats in the air. The sugar of the sap of the maple tree or of sugar cane, and that from the date and banana, is made from the same carbon taken from the air by the green leaves of the plant, as is the fiber of the cotton plant. The plant is nature's great food factory.

Plants also require nitrogen and this is taken both from the air, where there is an abundance of it, and from the soil, where there exists another great storehouse. In the process of extracting nitrogen from the soil, the plant has the assistance of certain soil bacteria, with which it exists in a relation of perfect symbiosis, the plant supplying the bacteria with food substances in return for their assistance. Nitrogen in the soil is, in large measure, derived from the decomposition of organic materials. This decay is a bacterial process.

When plants decay, they return not only nitrogen to the soil, but minerals as well. It is thus, that when a forest has stood for ages on a tract of land, and returned to the soil the materials in its leaves and cast-off limbs, and the logs of dead trees, the fertility of the soil is built up, for trees strike their roots deep into the earth and bring up minerals from great depths. Such soil, when the forest is removed, is called virgin soil and is rich in minerals. Crops grown on this soil yield abundantly for the first two to four seasons, then the yield begins to fall off, due to depletion of the soil of minerals, and perhaps, also to some extent of nitrogen.

Ages ago man learned that by fertilizing his soil with animal manures and decaying vegetables (compost) he could restore a measure of fertility to his soils and thus maintain their fertility for a considerable time. He also discovered that he could not maintain a high degree of fertility in this manner indefinitely, for, in spite of the return of organic material to the soil, these did not return to the soil all that had been taken out, so that there was a gradual deterioration of the soil. He referred to the soil as "worn out". Compost fertilization has been dignified in recent years by being called "organic fertilization." It should be known, however, that among plants, only parasitic and saprophytic plants live upon organic matter. Other plants require that their food be reduced to soil before they do well upon it.

That compost makes poor plant food is demonstrated by the rank growth of plants on old, rotted-down haystacks and on cow lots, the vegetation of which animals refuse to eat. Fruiting plants grown on such compost heaps either do not produce fruit or the fruit fails to ripen. Oversized plants (plants afflicted with gigantism) are of poor structure and are deficient in food value. Trees, sugar beets, and other plants grown in overnitrogenized soils, that is, soil overdosed with manures and sewage, develop cancer. Tomatoes rot on the vine. Wheat turns yellow and dies after reaching four to six inches in height. Overcomposting with leaf mold and wood mold in the flower garden destroys the plants and flowers. All of these facts indicate that mineral rather than organic materials are the best foods for all normal plants.

The experiments of Hensel in Germany, Samson Morgan in England, and Lindlahr, Carque, and Savage in this country all indicate that remineralization of the soil is a superior means of soil fertilization. Does this mean, then, that the use of compost should be abandoned? It does not. It does mean, however, that we should conform more closely to the natural method in returning compost to the soil. Old Mother Nature deposits her compost on the soil in thin sheets and permits it to decompose upon, not within, the soil. The elements of the compost filter down into the soil with the water, when it rains, after they have been fully decomposed. This means simply that composting in nature is a slow and gradual process and

that the minerals of the compost are returned to the soil in a completely decomposed form. Composting that consists in adding partially decomposed compost to the soil and then turning it under, permitting the decomposition to take place in the soil, produces rank growth, poor food, sour soils, and the foods thus produced smell of decay. When the Grahamites founded the world's first health store in Boston in 1836, they sold fresh fruits and vegetables to those who desired to eat healthfully. They followed the rule laid down by both Graham and Alcott, that all such foods, to be acceptable by the store for sale to their patrons, must either be grown on virgin soil, of which there still remained an abundance at that time, or the compost must have been thoroughly decomposed before adding it to the soil.

In writing on the subject of "organic fertilization" during recent years, I have pointed out that our organic materials partake of the deficiencies of the soils upon which they are grown; hence, returning these to the soil does not adequately fertilize our already markedly depleted soils. If we take materials from one tract of land and add them to another tract, we merely rob one tract of land of valuable substance in order to build up another. This process of "robbing Peter to pay Paul" cannot be kept up indefinitely without depleting both tracts. Also, as we never return to the soil all that we take from it, organic fertilization alone can never do more than slow down the rate of soil depletion. It can make our soils last longer, but it can never build them back to their pristine fertility. This statement is intended to mean that they cannot do this universally. It is obvious that if we draw organic materials from a wide area and add them to the soil of a small tract, they can rebuild the soil of this small tract to a high fertility, but we lack sufficient surplus soils from which to continue to draw in order to maintain the fertility of the smaller tract.

Remineralization comes to our rescue at this point. Soil is disintegrated rock. In the rocks of earth, and we have a superabundance of these in our hills and mountains, exist sufficient rock, if pulverized and added to the soil, to maintain the fertility of our soil for untold ages. This was the program employed by Hensel, Morgan, Lindlahr, and Carque. This is the program now employed by Savage. These rocks are often abundantly supplied with the trace elements that are so often lacking in our soils, hence lacking in the compost derived from these soils.

When I asked Savage if he used organic fertilizers on his garden soils he replied that he used a very small amount. Then I asked him what he did about earthworms. I have never seen any real reason why we had to go into the business of raising earthworms and shipping them over the country to be added to soils. The soils that I knew were always, except in droughts, abundantly supplied with earthworms. Savage replied that he found no need to import earthworms; that when he got enough minerals into the soil, he always had an abundance of earthworms.

It is minerals and not earthworms that we remove from the soils in harvesting our crops. The few earthworms that are taken from the soil to serve as fish bait make little detectable difference in the earthworm population of an area. A fertile soil supplies an ideal condition in which these worms live and multiply. Doubtless, the added minerals in the organic material that they help to work over and return to soil enable the worms to thrive and grow as they do the higher forms of life.

Hardier, healthier plants, more abundant yields, stronger bones and harder, stronger teeth of the animals grown on remineralized soils all indicate the superiority of this form of fertilization. Powdered rock, however, is not good plant food. It must be prepared for the use of the higher plants by bacteria and pioneer plants, and this takes two to three years. The presence of organic material seems to facilitate this work of preparation; hence the need for a small amount of organic fertilizer in addition to minerals. This avoids the common overcomposting that is practiced. We are so bent on production, production, and more production (for it is out of production that we derive our profits) that we overcompost to force production, just as we overfeed our hens on rich fare to force egg production, without any thought of the deterioration of the food value of our product as a result. We are as reckless in our handling of plant nutrition as we are in handling our own nutrition.

I do not say that organic fertilization should be abandoned, or that it is always an evil; I say that, alone, it is inadequate; that it is being overdone and that compost is being added to soil prematurely. I have

repeatedly urged that we make a more thorough study of plant nutrition and the valid needs of plants, to the end that we may raise better food crops. This does not seem to me to be an unreasonable demand.

[Home](#) > [Lesson 50 - The Pluses In Orchardng: How To Get Started](#) > Article #6: The Green Revolution

## Article #6: The Green Revolution

The time is rapidly approaching when, if one does not have a plot of ground on which to raise one's own food, one will be unable to get anything that is suitable for eating. That time has just about arrived. Foods are grown on soils that are improperly fertilized; they are sprayed with poisonous insecticides; they are pulled too green and shipped long distances to market; they are held for some time before they are eaten. They are processed, conditioned, colored, flavored, preserved, cooked, canned, and in many ways rendered less and less suitable for human consumption. Fruits are becoming so poor that one hardly knows the taste of good fruit any more.

We have had a revolution. Farms have been industrialized. They have grown so large and are attended by machinery of such cost that the small farmer is out in the cold. In simple English, the industrial revolution has struck the farm with a vengeance. Conditions are growing worse and bid fair to get much worse before any serious attention to the problems this presents will be given to the matter of correction by the powers that be. Something is needed by the health seeker in the meantime to make it possible to live a healthful life.

A partial answer is the proposed "green revolution" suggested and pushed by the forces of decentralization headed by Ralph Borsodi and Mildred Loomis. The green revolution is being pushed through a recently founded publication entitled *The Green Revolution*. It is a move to lure the suckers of *suburbia* away from their rat holes in the cities and back to old mother earth, to the end that they may have a hand in the production of their own food.

The Green Revolution calls to people to get away from the murky atmosphere of the fume-laden cities and out into the wide open spaces and to get their hands dirty in the rich, humus-fertilized soil of their own garden and orchard. Out where the air is pure, the sun shines and the countryside is green. It may be a resurgence of the "back to the land" movement that was started in the early days of this century. As such, it is for the intelligent few and not for the herd thinkers, who are content to rot in *suburbia*. Give them a television set, a cigarette, a glass of beer, and a hot dog and they are happy and maudlin, while looking forward to that bright day, when, at the age of sixty-five (which few of them will ever reach), the state will take over and grudgingly dole out, from the social security funds that are wasted in a thousand other ways, to them a bare subsistence so that they can retire.

For the intelligent, for the aspiring, for the man and woman of grander view, the green revolution offers a way of escape from the hum-drum existence of city life; it offers a healthier way of living and a higher enjoyment of life. How should a human being live? Certainly not the cramped and confined life of boredom, *stimulation*, and *tranquilization* of the cities, where his greatest thrills come from turning on the television set and watching two slaves pound each other's feeble brains out in the prize ring. Out under the stars, out where the sun shines, out where the flowers bloom, the trees grow and the grass is green is the place for man.

The Green Revolution is not vegetarian, but it will provide the vegetarian and the fruitarian with an opportunity to live his life in a better way than he now lives it. It does not condemn cruelty to animals, and one of its pioneers has opened a rodeo pen at the gate of his ranch. Rodeos are hotbeds of cruelty. They belong to a bygone period of our country and represent an anachronism, but suburbia's mobs are thrilled by their sights.

Today's farm machinery and big farms are driving people from the land and into the cities where they work in the factories. Automation is rapidly robbing them of jobs in the factories. A new feudalism is in the making. Can we reverse this trend by getting back to the land and staging a green revolution? Perhaps not. Man rarely turns back until he has followed each trend to its bitterest end. But for the intelligent members of our population a little land with garden, orchard, and flowers will enable them to live in spite of the mounting evils that we call civilization.

Nostalgia? Perhaps. But not one that it is impossible to do something about. A big tract of land and a warehouse full of machinery are not essential to the life of the green revolution. A few fertile acres, a few simple and inexpensive tools, a little time each day devoted to the tasks of gardening and orcharding and life takes on new meaning while the body is better nourished. What a difference there is between the screech of brakes, the honking of horns, and the sound of sirens in the city and the song of birds in the country! What a difference there is between the life of the cave dwellers of the big cities and the dwellers in a homestead in the great outdoors! It is the difference between being in paradise and in the abodes of the damned.

The Hygienist can take an active part in the green revolution and do so in strictest harmony with the eternal principles of Hygiene. The green revolution should cover the earth as waters cover the seas, but I suggest for the Hygienist a warm climate where fresh food can be had through the whole year. South Texas, Florida, southern California, Arizona, New Mexico, along the southern regions of the Gulf states—these regions offer nearly ideal locations for the Hygienist. It was in the South that Dr. Trall expected Hygiene to flourish in its greatest perfection. He even toured the South in search of a location to establish a Hygienic colony. The Civil (?) War brought that green dream to an unsuccessful end.

[Home](#) > [Lesson 50 - The Pluses In Orchardng: How To Get Started](#) > Article #7: A Case for Tree Crop Agriculture by Mark Chass and Don Weaver

### **Article #7: A Case for Tree Crop Agriculture by Mark Chass and Don Weaver**

We are trying to alert people to act on nature's imperative while there is still time and resources. The earth's soils must be completely remineralized and our mode of producing food entirely revamped. Otherwise we'll destroy our beautiful earth and what terrestrial life remains, including ourselves.

Humans must either work towards purifying and replenishing our earth and themselves or expect a tremendous crisis in our ecosystem due to intolerable toxemia and malnutrition. Whether glaciation, ozone depletion, oceanic death that leads to oxygen depletion, massive earth upheavals and quakes, magnetic field reversals, excessive carbon dioxide or other calamitous events occur; whether any or all of these come to pass, our path is presently fraught with doom and will steadily worsen so long as we continue to be led by and grovel at the feet of exploitative minds.

This being the core of our convictions, we hope you can see the importance of reaching and bringing together people who are interested in rebuilding our ecosystem, and in conserving rather than exploiting our resources. The quality of human life is foremost in our minds and we don't wish to see our brethren in life's journey plunged deeper into the disastrous course that prevails. We abhor the unchecked tide of earth destruction that is leading to catastrophic world upheavals: unbearable weather, glaciation, mass starvation, and other evils with which we are running a collision course.

The unimaginably great capacity of this earth for being a paradise beyond our wildest dreams and our inherent potential for beauty, goodness, and exalting joys makes our quest all the more urgent.

This is why we seek your cooperation, why we ask your attention and care to this message, and why we

ask you to extend your area of awareness and coverage to all facets of human existence. Our total well-being depends on the well-being of our entire ecosystem on which we depend.

The one most powerful, widespread and growing destroyer of our environment is agriculture. In all its ramifications, today and throughout history, it has changed untold millions of square miles of virgin land into neat square fields of overcultured and overdomesticated plants and animals. Its requirement of raw materials is so huge that when all is added up, we humans are net losers. Not only do we suffer nutritionally, but the earth suffers even greater and the situation is like a time bomb set to destroy us. Until we realize that our thinking is creating and perpetuating this artificial environment and consequent destruction, we will severely limit our potential and destroy much of the planet we live on. We are doing nothing significantly different or better than our ancestors and, in many ways, we are doing much worse. A vision entirely new and fresh must be brought into our daily lives.

This article will bring to light and confront directly the root causes of humanity's critical and unprecedentedly urgent global crisis in virtually all realms of existence. Most specifically it will question our approach to the problem of securing nourishment from the soil by agriculture. The authors have learned that it is too late for any more fragmented or half-hearted solutions to the rapidly accelerating environmental crisis. This article will outline a sane and beneficial course for meeting our most pressing problems of living here and now and in the unlimited future. Fundamentally, this is a call for a worldwide movement towards a biologically-oriented culture and a nonirrigated and noncultivated tree crop agriculture. This is the only long-term approach nature can afford and accept of humanity. The survival of all life as we know it is at stake. One can sense that the land has changed from its original design and unhampered course. Where are the great valley oaks of magnificence that once provided shade and food for humans and animals? Where are the riparian zones that used to extend for great distances from free-flowing rivers, even in rather arid central valleys? Why is the water table dropping, forcing ever deeper wells and more dams? Why are fruits and vegetables becoming more and more unnutritious and tasteless at the same time disease is becoming more rampant? Why is the weather so unusual and causing unseasonal floods, frosts, and decreased yields even though the USDA still claims that harvests have never been better? Possibly the most obvious change is the declining quality of our air and water, even in remote areas. Even the rain is becoming toxic as it washes poisons from the skies.

To understand this situation a little more clearly, the authors did extensive research and found quite a bit of evidence that documents the change in our earth's fragile skin over the last 6,000 years of recorded history, a very short time in the course of our existence. In his classic book "Man and Nature" written over a hundred years ago, George Perkins Marsh states, "There is good reason to believe that the surface of the inhabitable earth, in all climates and regions which have been the abodes of dense and civilized populations, was, with few exceptions, already covered with lush forest growth when it first became the home of man." In fact, one can go to areas of past civilizations and realize that, because of misuse and incorrect vision of nature, the forests were destroyed. Marsh adds: "Ancient historical records . . . prove that large provinces, where the earth has long been wholly bare of trees, were once clothed with vast and almost unbroken woods when first made known to Greek and Roman civilizations." In *Losing Ground* by Erik Eckholm and the Worldwatch Institute, the author states, "The bare hills that characterize the Mediterranean today provide little hint of the extensive woodlands that once existed. By the end of the Classical Age, deforestation in the lowlands around the Mediterranean was acute. The clearance of farmlands, grazing herds, and wood gathering for fuel and construction all contributed to this condition. The region's dry climate and nimble goats discouraged natural forest regeneration, even in centuries when the pressures of civilization slackened." It was common for builders of that area to cut down as many as 2,000 mature oak trees to build a single sailing ship.

Eckholm also presents us with a most interesting picture of the extent of natural forestation in recent history. For example, the area now known as the United States was, at the time of European colonization, approximately one-third forest. Mexico, now largely arid and desert-like, had an extensive tree mantle on over half of its surface prior to European influence.

Another method of land alteration is fire. Fire became an important tool for the developing agriculture

and domestication of grazing animals. Brush, young trees, and mulch material are all destroyed by fire. Overgrazing prevents their return and accommodates erosion. Complete generations of successional plants are eliminated. When the older trees eventually die there are no replacements and an evergrowing wasteland takes over. This can be seen in many areas of California where the land is used for grazing. Further complications arise when the unprotected soil begins to be washed away adding to the silt burden of our streams and rivers which disrupts and destroys river and ocean environments. The Eel River in Northern California carries more silt from eroded hillsides than the Mississippi River which drains a manifold larger area.

The advent of agriculture and the domestication of grazing animals, most notably goats, Sheep, and cattle, was, and still is, a major cause of deforestation. One can see that if land once under cultivation and grazing is left alone, a spontaneous nature will soon cover it with herbacious plants and eventually a dense forest. Marsh even believed that forests would soon cover many arid areas of Arabia and Africa "if man and domesticated animals, especially goats and camels, were banished from them. Young trees sprout plentifully around springs and along the winter water courses of the desert. A few years of undisturbed vegetation would soon suffice to cover such points with groves, and these would gradually extend themselves over soils where now scarcely any green thing is seen."

For centuries man has based his agriculture on clearing, plowing, cultivation and irrigation of annual crops. Only in a few rare instances are there people who have, because of necessity or enlightened vision, based their sustenance on perennial tree crops. J. Russel Smith in his book "Tree Crops" describes cultures who eat most of their food from tree produce and who allow their animals to self-feed themselves on the fruit and nut drop of the trees. Plowing and cultivation have taken their toll on Earth's fertility. The soil is bared of its covering of leaves, broken and loosened by the mechanical action of implements, deprived of its Fibrous root hairs which hold it together, dried and pulverized by sun and wind and at last exhausted of its vitality. The face of Earth is no longer a sponge but more often a growing dust bowl.

The practice of irrigation has also become a major factor in today's crisis. Pumping deep wells lowers the water table for indigenous species of plants. The volume of water is tremendous. In California and Arizona 85% of all diverted water can be attributed to irrigation and this irrigation is both wasteful and even unnecessary. Rivers are diverted, dams are built, and the fresh water cycle drastically altered. The great rivers of the world have been reduced to a predictable flow, at least temporarily. Since the irrigated fields are so saturated with water-soluble chemicals from fertilizers, pesticides and herbicides, the water runoff has become laden with toxic compounds deadly to all life. This water must be treated before it can become of acceptable quality for further irrigation or usage. This is now occurring to the Colorado River where it enters Mexico loaded with chemicals from U. S. farms. In Nebraska ground water is so loaded with chemical nitrates from nitrogen fertilizers that it is infesting potable water supplies of the area. Physicians are now diagnosing nitrate poisoning in children of the area.

Historically nothing was much different. The Sumerians in the fertile Tigris-Euphrates valley in 4,000 B.C. had a complex irrigation system. However, the water left so much dissolved salt in the soil that it ruined the soil permanently. We witness an ominous recurrence in the California desert. Areas all through the U.S.A. are losing valuable cropland due to irrigation. Irrigation experts say all that is needed is a very costly underground drainage system which would drain the salts from the uppermost levels of the soil; but this is not the answer, obviously. All irrigation water contributes to an unbalance of the soil that might well be called "mineral-poisoning." Salt may be characterized as a "junk mineral" that destroys. This has its consequences too. We really do not realize how we are disrupting the natural order just from the way we grow our food which, in itself, is an apparent innocent and innocuous endeavor.

In some cases stream flow becomes so low from diversion that water temperature rises past the point at which fish can spawn. Many of the dams built in recent years to supposedly help conditions are silting up quicker than expected from up river erosion. This not only shortens their effective time of usage, but also has disastrous effects on fish and other life in the water as well as irrigated land downstream.

Farmlands are covered by the rising waters behind the dam. Farmlands below the dam are deprived of the supplies of fertilizing silt which would normally be deposited by the river but still receive certain of the deadly soluble salts. An example of this is the Aswan dam which backs up the waters of the Nile River. The Nile's silt had kept the soil along its banks fertile for ages.

When water is backed up behind dams everything changes. The water's chemistry, kinds and numbers of indigenous flora and fauna, the salinity, the water's pressure on surrounding hills and on earth faults are all altered. Incredibly, a world-wide recognition of the immense problems entailed has not yet occurred. More and more dams are being built to supply the world's suffering agricultural systems with water.

All of these situations culminate in the fact that the amount of oxygen producing biomass on the earth and in the oceans is decreasing. In many areas the vegetation remaining is so mineral deficient, with a resultant decrease in water storage capacity in the plant's tissues, "that it is on the verge of bursting into flames." The minerals tied up in our forest trees and grounds have been exported from the forest for so long by logging practices that widespread forest destruction by fire becomes ever more ominous.

Mineral depletion is also causing our agricultural soils to dry out, ready to be blown away in another dust bowl. When crops are harvested and shipped off to supermarkets, the soil loses its ability to replenish itself. The plants would usually return to the soil, decompose and nourish the next cycle of growth. Since none of our excrement returns to the soil either, the soil loses again. The only thing receiving minerals is the ocean where everything seems to be ending up, not only to the detriment of the land but the ocean itself.

The latest insanity of soil depletion concerns the burning of biomass to generate electricity. This practice not only pollutes our atmosphere but it burns vegetation, crop residues and forest slash. It thereby removes vital carbon and minerals necessary to the soil life cycle. Without these vital humus-to-be components, soil microorganisms cannot exist. Without these necessary organisms upon which new plant life becomes stunted due to malnourishment. It becomes susceptible to insects and diseases. Animals and people cannot thrive on these plants—they likewise become stunted, malnourished and diseased. Modern farmers respond to this situation with massive chemicalization to stimulate plant growth and insecticides to destroy the pests that thrive on such plant life.

Furthermore, since photosynthesizing plants are our source of oxygen, we are really disturbing the whole oxygen-carbon dioxide balance of our biosphere with our unwise activity. Along with the increased burning of fossil and organic fuels, carbon dioxide levels are expected to double in the next forty years—nothing less than a disastrous situation! To relate this to agriculture, overoxidation of humus by tillage exposure also increases carbon dioxide in our atmosphere. Tillage exposure permits the oxidation that releases carbon to the air and, simultaneously, decreases the carbon storage the humus provides in the soil mantle. The harvests of the forests, which conduct more photosynthesis worldwide than any other form of vegetation, the extension of agriculture onto soils high in organic matter and the destruction of wetlands all speed the decay of our precious humus heritage. The worst aspect of this trend is the destruction of the tropical rainforests. Most of these will be gone in 20 years if the present trend continues. In Brazil alone in 1975, 62,000 square miles of forest were cleared. For what? Primarily for cattle grazing for beef ' production. Satellite mapping indicates this is happening throughout the world's tropical zones. All over the world, in fact, forests have been removed and replaced with grasslands for domesticated animals and animal food crops. As amply attested to, these lands are due to become deserts without their protective forest covers.

Forests account for 90% of the carbon held in vegetation and contribute more than 60% of the net primary production of biomass. In contrast, all cultivated land on Earth accounts for only 8% of net primary production and stores only 1% of the carbon. This represents a tremendous loss from forest to cultivation and is adding to our atmosphere's carbon dioxide imbalance at breakneck speed. These observations have come as quite a surprise to many agriculturists and foresters since they assumed that modern agricultural and forestry practices were establishing a good carbon balance. Secondary and managed forests compared to untouched climax forests still represent a loss in carbon balance such that

increased carbon dioxide is still being released to our atmosphere. German foresters have shown that yields decrease with succeeding timber harvests because more and more minerals and carbon are removed with each cycle without replenishment.

So now we have an increase in atmospheric carbon dioxide, a decrease in terrestrial and oceanic biomass, and an acute mineral shortage in plants and people. All of these play an important role in Earth's weather machine and the changes, often disastrous, that we now witness. Excess carbon in the air as a result of mineral depletion causes a cooling in Earth's mean temperature. Earth has slowly been cooling since 1950. Observation of glaciers reveals that they are now extending their mass after thousands of years of retreat due to a warm and stable climate. Glaciation is Nature's response to conditions such as are being created by our unwise exploitation of the earth's resources. Increase in the ice pack forces the earth's tectonic system to release the pressure from added land mass through earthquakes and volcanic activity, both of which are noticeably increasing of late. The glaciers give soils mineral replenishment and help restore long-term balance by grinding the rocks they dislodge and push along. The new minerals begin to accumulate, plant growth and vitality return, remove excess carbon dioxide from the atmosphere and thus bring warmer, more stage temperatures. With this the glaciers retreat and volcanic activity subsides. South Pole drilling exploration confirms this since dust layers were found intimately associated with past glacial periods. During the onset of glaciation, however, (and we are now in the beginning stages of a new ice age), the weather will, become more turbulent and erratic with an increasing subsequent loss in food production and starvation for many people. The wearing out of the soil initiated this process. We are now losing three billion tons of soil per year from U.S. croplands alone! Only 8% of the world's soil can still be cropped by current methods. This situation worsens with each passing year. An accelerating downward spiral has been initiated. The practice of exporting huge quantities of food amounts to a soil loss just as much as if it were washed out to sea.

Obviously, we must stop the burning of fossil fuels and crop residues. We must also reduce our consumption of wood which includes paper products, lumber and firewood. Many Third World countries have an acute firewood shortage and are resorting to burning dung for fuel. Their soil will become even less productive without dung as fertilizer. Most importantly, we must change over to an agriculture based on nonirrigated and noncultivated tree crops. We must again subsist on our natural diet of unfired foods. This system utilizes the same approach nature observes in the growth and maintenance of all living creatures. Under the natural order, forests grow to tremendous proportions and vitality. In contrast to the natural order, humans are the only ones that use fire to alter foods before ingestion. Nature had going a beautiful system of recycling and conserving carbon and minerals as a basic and for the welfare of her creatures as an adjunct.

Plentiful microorganisms in the soil can supply up to 97% of the tree's needs through symbiotic atmospheric assimilation. The remaining 3% of the trees' needs are met by the minerals in the soil. Trees produce abundant crops. Each year millions of bushels of fruit and nuts drop to the ground. With more nursery and selection work many of our native trees could be supplying us with luscious fruit and nuts of extraordinary high quality. This would also help save trees from needless destruction by farmers who, because of a meat-demanding populace, cater to it by growing grain and animals. Midwest farmers are now cutting down tree windbreaks to make room for new irrigation systems and massive machinery that require big stretches of even and unbroken ground.

So our first task on our depleted lands is to remineralize their soils as quickly as possible. Deep rooted weeds do part of the job, but time is critical now. Glacial gravel, granite, porphyry and gneiss, all rich storehouses of minerals, should all be ground into fine particles and added to the soil in amounts of up to ten tons per acre. Especially should applications be heavy on land where overgrazing and logging have taken place in order to provide the basis for rapid development of microorganisms. Soil carbon must also be preserved. Dr. Julius Hensel did extensive research in Germany in the late 1800s on stone dust fertilizers and found the plants to be remarkably free of disease and the produce of very high quality. We must, therefore, resupply our soils with the complete spectrum of elements in their balance as found in the mixed rocks of Earth. Hensel used no animal manures in his experiments, thus fixing minerals as the

primary deficiency of our soils.

Tree crops supply us with highly-nutritious, complete, and balanced foods. Under nonirrigated and noncultivated practices, nutrients are either available or unavailable and in high concentrations or scarce in respect to the heat and rainfall, of a, given area. These concentrations fulfill the biological requirements for the animals and people living in that area.

Calcium, for example, is more prevalent in tropical fruit than in temperate fruit. Calcium helps the body to stay calm and cool, a much needed factor in warm climates. Phosphate is more prevalent as the weather cools and helps the body to stay warm. These and other elemental concentrations help the body to thrive in the same environment that grew the plants. This seems to imply that food from a particular climate and soil is not suited for people of other climates and soils. While not necessarily so, importation and exportation of foodstuffs and fertilizers would largely cease with optimal recycling programs on a local level. Each geographical area would supply most of its own food, shelter and other needs that draws upon soil resources. Our needs can be met like the needs of the other animals without excessive technology and as nature provides it. All our needs are provided for in nature.

Ripe fruits and nuts as they come from the tree and vine are still the most delicious and palatable foods for the small and the large, for the strong and the weak, for the healthy and the sickly. Fruits and nuts offer us sound health and great vitality. It has been scientifically shown that fruits and nuts furnish the basis of superb health. They do not cause anything but the most wholesome intestinal processes while in the intestinal tract. They do not cause health-robbing putrefaction or fermentation in normal amounts eaten under normal conditions. These facts solve the problem of human excrement. It may be added to the soil without vitiating it in any way. Besides the feline family, humans are the only animals that bury their feces. A person on a fruitarian diet can sustain himself or herself on a fraction of an acre. Little labor and very low input of materials are required. This makes possible true self-sufficiency. A fruitarian learns about the true nature of bodily processes, the true causes of disease and assumes full control and responsibility of and for his or her health. Coldness and heat become more tolerable as the body becomes pure and its system achieves physiological balance. Hunger and appetite take on new meanings as the body's innate intelligence emerges to again dictate our eating habits.

Upon the fruitarian diet, a clarity of perception and a joy in understanding add to individual strength and integrity. A fruitarian finds that the body, if intake is not cooked, assimilates a larger proportion of nutrients than on a conventional diet. Less food is required. This not only helps to relieve some of the pressure on the world's food production, requiring as little as 5% of the land meat eaters require, but it also gives fruitarians immensely greater survival ability should environmental conditions become harsh—something we're bound to see more and more of.

The state of most tree nursery practices is in equally as poor a situation as our agriculture. Commercial fruit and nut trees are grown on soils that have been heavily fumigated, chemically fertilized, sprayed with insecticides and overwatered. These trees lose a great deal of their feeder roots when they are dug up by machine from nursery stock. Covered with plastic film or other material to reduce water loss during storage and shipment, these trees undergo considerable transplant shock and have difficulty in adjusting to unnatural farming practices.

Natural tree culture requires more work and attention to grow healthier and more productive trees. Wild and original rootstock, seeds, or seedlings must be used to assure hardiness.

There are countless varieties of fruits, some of which would help to extend the fresh fruit season to year round in most of the world. Slightly more than 100 years ago there were over 1,000 varieties of apples grown in this country. Some of them would remain on the tree ripening until early spring, unaffected by intense freezes. More intensive planting can also be done. Two or three tier agriculture is common in some countries. Trees occupy the highest level with vines growing among the lower branches. Around the trees and vines, melons, berries, or other food crops ideal to the human dietary can be grown. In the partly shaded areas that are cooler, shade-tolerant plants can grow.

The widespread adoption of tree crop agriculture and nutrition is urgently needed. Slight modification in present practices is not sufficient. A thoroughgoing revolution is the only answer. More dams, more implements, more chemicals, more cookbooks, and more of the same solve no problems. Rather they lead us deeper into the crisis. Humanity cannot continue on this self-destructive course. The holistic health movement must recognize its total dependence on our soils. All the yogas, nerve treatments, manipulations, drugs, or whatever can't substitute for nutrients, clean air, and other factors for which the body is starved.

We all realize that it is our own false sense of need that compels us to overconsume food, water, and other materials. This dictates a system of agriculture to supply these false or fancied needs. Surely this is bringing us to destruction.

So look around. Find out where your food and needs are coming from. What had to happen that your meals could show up on your table? Be concerned for the quality of your air and water, of the foods and clothing you use. This is very vital to your health and, if posterity is to be, then it is especially important to our children's welfare.

There are some pilot programs being started by our group which we will be demonstrating in a village atmosphere. These will stress tree crop agriculture and the fruitarian diet. We have already been on this diet for 19 years between us. We feel alive, alert, and well-nourished. We will be happy to communicate with anyone of similar motivation and commitment who has concern for human well-being.

The time for right action is now. Catastrophies are in the making. Just a few more degrees drop in Earth's mean temperature will trigger glaciation that will force all remaining life back to the equator where it all began eons ago. Every day of procrastination and lack of interest brings us closer to this and other irreversible processes of human and Earth destruction.

Can we make the required change in our thinking and practices to reestablish biological health and stability? We must do so if we want humanity, as well as all other life, to survive on this planet.

## Lesson 51 - Chemicals In The Household Environment

### 1. Introduction

#### 1.1 The Unhealthiest Place To Live

Over half of your life is spent inside your home. Yet it may be the unhealthiest place you can be. Chemicals, pollutants, and toxic substances can surround you in your house and can create a number of health problems. You may never realize how dangerous household chemicals can be until it is too late. This lesson tells you about the most common household pollution hazards and how you can avoid them for better health.

You may think that you are safe in your own home. After all, the air pollution is on the freeways, and the poisoned waters are in the industrial rivers. But the foul air and water are also in your home, and much of it is brought in by your family. Here is one area where a natural and hygienic lifestyle can provide immediate benefits to all family members.

#### 1.2 The Household Chemical Problem

Just for a start, look around you and count the various chemicals found in your house. Over the course of a year, the average home will contain *forty-five* aerosol sprays, another two dozen nonspray chemical cleansers, several insect killers and repellents, paints and paint thinners, spot removers, room fresheners, natural gas leakages, and so on.

Inside your house alone are more chemicals (in floor polishes, oven cleansers, detergents, etc.) than were found in any major chemistry lab of a century ago! Worse yet, we do not understand anything about these chemicals, how they should be used, and the toxic effects that accompany their use.

Labels list dozens of unpronounceable and unrecognized chemicals in all sorts of household products. It is foolish to believe that all are harmless and that they can be safely used.

An experienced homemaker cannot handle most chemicals properly. For example, one woman dragged her small oven outside to clean it. She did not, quite rightly, want the fumes from oven cleaners in her house. Unfortunately, while spraying the oven outside in the wind, the spray blew back into her eyes and permanently blinded her.

Housewives and children are allowed to handle dangerous chemical compounds that experienced chemists would not touch unless they had on protective gloves. Not only that, but the toxins and pollution from these common household products can eventually poison all the members of a family

without their knowledge.

A family in a rural area had a problem with flies in their house while they were eating. To combat the problem, they hung a "No-Pest" insecticide strip over their table to keep the insects away. After a few weeks, three of the four family members were hospitalized for acute pesticide poisoning. The anti-pest strip they had thought was safe had nearly killed them with its "fallout" over their food.

Besides the sheer quantity of new chemicals in the home environment, another problem arises from the multiple use of these products. For example, cleansers may be mixed or other chemicals may be used together. When combined, these household chemicals can produce deadly byproducts. This combination of one or more household chemicals produces what is called a *synergistic* effect which means that the total effect of the mixed chemicals is greater than the individual chemicals used separately.

Homemakers do not actually have to even mix various cleansing agents, etc., together to create this dangerous synergistic effect. Simply having the vapors from one cleaning lingering in the air which may then combine with other chemical vapors can have a toxic effect on the individuals. In fact, within the average American home, at least once a day two aerosol sprays are used within a half hour of each other. These sprays can combine in your house to form toxic fumes.

We often improve our diet and our health, but we may neglect the source of potential health problems: the chemicals in our own home. This lesson identifies the more common household chemicals in use, and how you can avoid them by adapting a new lifestyle along the teachings of Life Science.

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > 2. The Chemicals In Your Home

## **2. The Chemicals In Your Home**

Dangerous household chemicals are usually disguised in common products. Everything from underarm deodorants to frying pan spray contains toxic ingredients. Almost all of these chemical products can either be completely eliminated by following a healthy, hygienic lifestyle or by using a more natural substitute. This portion of the lesson lists most common household chemicals and how you can avoid them.

### **2.1 Aerosol Sprays**

The first living creature to die from an aerosol spray was a mosquito in 1942. Since then, much more than just insecticides have appeared in spray cans. Antiperspirants, feminine hygiene sprays, underarm deodorants, oven cleaners, spot removers, floor wax, varnish, and anti-fogging agents have appeared in thousands of aerosol and spray products.

Aerosol sprays are a major source of air pollution within the home. The sprays spread out into the surrounding air and make it unfit to breathe. This is especially true in closed spaces (like the bathroom) where the sprays are used most often.

A study by Du Pont Laboratories revealed that the amount of freon propellant in front of the faces of users of hair spray and deodorant to be dangerously high even when these rooms were heavily ventilated by an exhaust fan. You can imagine the serious injury that results from years of breathing these fumes in an enclosed house.

The particles and chemicals in aerosol sprays are often so small that they can penetrate the lung tissue and be directly absorbed into the bloodstream. Thus, a chemical which might be relatively harmless if used externally quickly becomes an internal poison when sprayed in easily inhaled particles.

Just how harmful are these fumes from the aerosol sprays? Dr. William Good of Montrose, Colorado, made a study of 200 people. The only thing these people had in common was that they were all heavy users of sprays in their homes. Without exception, every person in the group had precancerous lung cell changes.

## **2.2 Hair Today—Gone Tomorrow**

Perhaps the most dangerous of all these sprays is the hair spray. These sprays are always used in closed quarters (like the bathroom or beauty parlor). They are emitted near the face, and the air breathed is heavily contaminated.

The hair spray itself contains shellac, starch, and plasticizers which may be toxic enough to form enlarged lymph nodes. The FDA reported on twenty-three women who were daily users of hair spray. All of their X rays showed precancerous lung changes. After six months of stopping the use of hair sprays, fifteen of the women completely recovered.

Hair sprays also contain silicone which is damaging to the eyes and cannot be washed away by the natural eye fluids. An irritation of the cornea often develops in users of hair sprays.

Of course there is no valid reason to use hair sprays except for reasons of "beauty" or appearance. Freshly-washed and combed hair should be enough to make a healthy person truly beautiful, but if you are attached to having "set" hair, then you should use a setting gel or lotion instead of a spray.

These gels and lotions also contain noxious fumes and chemicals, but the danger is less than when using hair sprays. The sincere health seeker, however, will abandon all such artificial hair care products. Clean air is healthy and attractive. A more natural manner of wearing the hair will end the need for all such artificial products.

## **2.3 Does Your Nose Smell—Or Do You?**

Americans stink. At least that's what the advertisers would have us think. Underarm deodorants, antiperspirant sprays, feminine hygiene deodorants, air fresheners, and room sprays are aggressively promoted and advertised. But how necessary are such odor disguisers, and more importantly, how safe are they?

Most anti-odor sprays and chemicals are totally unnecessary concoctions that serve no purpose. The most blatant example of this is the feminine hygiene deodorant sprays. In a trade magazine for such spray manufacturers, an article states: "Such is the American way of advertising and persuasion that even the best smelling ladies began to feel insecure and wonder if they were offending—and so another new market was born."

While these feminine sprays may make the manufacturers rich, they also contribute to health problems. The sprays are irritants and often contain talc that is contaminated by asbestos, a known cancer-causing agent. Many gynecologists have reported cases of vulvar irritation by their patients who used such sprays.

Sprays are also used to fight bad breath and other body odors. All of these contain chemicals which are both breathed and deposited directly on the skin. Underarm sprays, for example, work by actually clogging the sweat pores with an aluminum chloride compound.' Mouth sprays kill all bacteria in the mouth, including the so-called beneficial variety.

Besides these sprays, there are also foot deodorizers and hair fresheners. Evidently most people stink greatly or think they do because the amounts of spray and roll-on deodorants sold is enormous.

Why do people smell bad and feel that they must use some chemical to deodorize their bodies?

Basically, an improper diet is the cause of all body odors in almost every case. Foods of animal origin (meat, eggs, milk, etc.) are poorly assimilated and full of foul-smelling toxins. When these foods are

eaten, the waste products are eliminated from the skin and an unpleasant odor results. When all animal foods, junk foods, and sugar are eliminated from the diet, all body odors eventually disappear.

A Natural Hygienist or a person who follows the suggested Life Science diet will never experience bad body odors. Unpleasant odors from the body indicate that something is wrong in the diet or lifestyle. Covering or hiding these odors with sprays and chemicals does not correct the underlying problem which causes these smells.

If body odor is a problem, then frequent washing is the best short-term solution and an improvement in the diet is the only long lasting answer. Spraying and applying chemicals to every body orifice can cause irritation and damage. The person concerned about his health and well-being will quickly abandon all such products.

## **2.4 Home, Sweet Home?**

Next to American bodies, the smelliest place may be the home. Cooking odors, cigarette smoke, furnace emissions, and bathroom odors seem to permeate our households. Many people try to remove these odors with air fresheners, such as sprays, wicks, candles, cakes, etc.

All of these air fresheners work in one of four ways: 1) They use one odor to cover another; 2) They coat the nasal passages with an oil film; 3) They deaden the sense of smell with a nerve chemical; or 4) They deactivate the unwanted odor (such as through charcoal absorption).

Actually, very few deodorizers work by actually removing the odor. Most simply contaminate the air with another foreign substance, and certainly do not "freshen" the air. Many times an artificial fragrance is released that simply smells stronger than the offending odor. These fragrances often irritate the eyes and air passages.

More remarkable are the air fresheners that do their work by temporarily "killing" or deadening the sense of smell. This is sort of like blinding yourself to avoid seeing an unpleasant sight. One such air freshener, advertised for use in the "nursery," contains carbolic acid which causes serious burns and tissue destruction when applied to the skin.

There is one safe and recommended air freshener: an open window. A healthy lifestyle will also mean that most household odors will never even occur. For example, cooking and grease odors are common in meat-eating households. Cigarette, cigar, and pipe smoke are also common contributors to the foul air problem. A nonsmoking household that follows a predominantly raw food diet will never experience most of the household odors that plague many Americans. A well-ventilated house will also mean an end to odors. Even in the winter, the house should be opened briefly to allow a healthy exchange of air between the inside and the outside.

## **2.5 How Clean Is Your Kitchen?**

The most dangerous and physically harmful of all household chemicals are the cleansers—oven cleaners, detergents, scouring powders, toilet bowl cleaners, bleaches, drain cleaners, and so on. Most of these chemical cleaners are not needed; indeed, many safe substitutes exist. Many people continue using these harmful household chemicals simply because they are not aware of their dangers.

## **2.6 Oven Cleaners**

"Danger: May cause burns to skin and eyes. Irritant to mucous membranes. Danger—contains lye. Keep out of reach of children. Do not get on exterior surfaces. Keep away from electrical connections. If taken internally or sprayed into eyes, call physician."—from the label of "Easy-Off Oven Cleaner."

Oven cleaners harmed over 3,000 people in one year alone. Their sprays contain powerful chemicals that drift around the kitchen and penetrate the skin, eyes and lungs. Worse yet, these dangerous, unpleasant

chemicals are hidden by added fragrances so they are more likely to be breathed in.

And such cleaners are totally unnecessary. True, ovens can become the filthiest area of any kitchen. But if the diet is changed so that meat is eliminated and all cooking is curtailed, then the oven will not become dirty or require an extensive cleaning. If cooking does occur, any splattering should be cleaned up as soon as the oven cools. Only when stains and drippings are continually reheated and baked does a strong cleaning agent become necessary.

Better yet, eliminate the messy oven. The hygienic or Life Science diet advocates a 100% raw food diet. Some people even sell their stove or use it as a counter area when they adopt the all raw diet. Even if cooking is still used at times, it should be in the form of steaming or occasional baking. Such conservative food preparation practices eliminate the dirty oven, the harmful cleaners, and the hours of work spent in cooking and cleaning.

## 2.7 Other Household Cleaners

Drain cleaners are similar to oven cleaners. They too have a high percentage of lye and they attack waste and grease buildup from food disposal. Drain and toilet cleaners account for about 10,000 injuries every year. Worse yet, if the drain remains clogged after the cleanser is poured in, then a dangerous caustic solution develops which gives off toxic fumes.

Bleaches are often used in the house, and great care must be taken not to mix bleaches with other cleansers. In November 1975, a 68-year-old Maine woman mixed bleach with ammonia to remove egg stains from a window. When she brought the pail of mixed bleach and ammonia into the house, the fumes killed her. The woman's niece discovered her and tried to give mouth-to-mouth resuscitation. She was also killed by the fumes in the house.

Toilet bowl cleaners are either the in-bowl or in-tank variety. The in-bowl cleaners contain extremely strong acids and release fumes. The in-tank cleaners are almost ineffective, according to Consumer Reports, in either removing stains or odors.

Scouring powders contain a bleaching agent and a coarse polishing agent. Over 22,000 people in 1973 received hospital treatment for injuries associated with scouring powders and other caustic cleaning agents.

What's left to help you clean your house? Well, first remember that most cleaning should be mechanical and not chemical. Dirt, dust, and stains can usually be removed with a simple and harmless detergent and some work. All in all, almost every chemical household cleaner can be replaced by a combination of one or more of these simple and inexpensive products: soap, baking soda, vinegar, borax, and ammonia. With the exception of ammonia (which has noxious fumes), all of these are totally harmless when used by themselves to aid cleaning.

Here are some ideas on how to use these substances as a substitute for the expensive and toxic household cleaners:

*General surface cleaning:* Several tablespoons of vinegar dissolved in a bucket of water. Baking soda may be used to scour surfaces.

*Bleaching:* Use borax instead of chemical bleaches. It whitens without harming the fabric, regardless of color or weave.

*Utensil cleaning:* A diluted solution of ammonia (caution) can be used for really greasy pots and pans. Of course if you are following a correct diet, you will not have "greasy" utensils at all.

*Oven cleaning:* Again, this should not be needed on a proper diet. If it does require cleaning, use baking sodas a scouring powder and ammonia to cut through the grease. Always be careful to avoid breathing ammonia fumes.

*Drain Cleaning:* Slow drains can be opened by pouring hot water down them, and then adding about a

half cup of washing soda. Wait a minute, and then flush again with hot water. A small plunger can be used to unclog and loosen the drain.

## 2.8 Whiter Than White And Other Laundry Lies

Detergents and soaps are the most bought-and-used item of any product in the grocery store—including milk, bread, or any other food. They also cause more poisonings than any other household product. During 1975, for instance, over 1,300 laundry soap detergent and dishwasher product poisonings occurred.

Part of the problem is that many consumers do not understand the difference between ordinary soap and synthetic chemical detergents. Ordinary soap is relatively harmless, and has been used for thousands of years. The new detergents, however, are all chemical products from the last thirty years.

While soap is just soap, detergents are often soap along with foam boosters, perfumes, enzymes, cleaning agents, fillers, and optical brighteners.

A person who rubs just a few grains of synthetic detergent into the eye can receive corneal burns and severe eye damage. Ingestion of these products cause serious harm to the upper digestive tract. Clothes washed in some detergents become permeated with artificial perfumes and other irritating fumes.

Enzyme detergents are thought to cause dermatitis (a skin condition) and flulike and asthmatic conditions from breathing the air with detergent dust.

These steps can be taken to reduce harm from such cleaners: First, try to use ordinary soap or an organic cleaner instead of the chemical detergents. Don't overuse detergent—most people, according to a Consumer's Union survey, use at least twice as much detergent as is required. Don't mistake detergent for soap—never wash the skin with detergents and keep away from the mouth. To help with soiled clothes, prewash them with washing soda and then use common soap.

## 2.9 Other Sources Of Household Chemicals And Pollutants

It may seem that chemicals are all through the average household. In almost every room, some synthetic chemical compound can be found: mouthwash in the bathroom, dishwashing liquid in the kitchen, air freshener in the bedroom, a small gas leak in the living room, furniture polish in the dining room, paint thinner in the garage, and so on.

You may find it difficult to eliminate every chemical compound in your home, but you should start asking yourself if it is really needed or if a safer substitute can be found. This is a quick overview of other dangerous household chemicals:

**Tobacco Smoke:** Smoke from cigarettes contains over 3,000 chemical compounds. Although the dangers of smoking are covered in another lesson, it should be pointed out here that tobacco smoke can quickly and completely pollute the entire house even if only a single cigarette is smoked in one room. Smoking is bad enough outside, but inside a home it can be deadly to smoker and nonsmoker alike. If you live with smokers, you have three choices: 1) Stop living with them; 2) Complain long and loud until they stop; 3) Continue as before, but isolate the smoking to one room only and keep this room ventilated, even in the winter.

**Insecticides and Pesticides:** Many people routinely spray their house for roaches and other insect pests. The fumes from these sprays can linger for months, and be breathed continually by the inhabitants of the house.

The solution to the insect and pest problem in the home is to first make the house an unattractive spot for such creatures. Keep all areas clean, and learn that there may be a needed compromise in insect control and total eradication.

There are many ways of controlling insect pests naturally in the home. (Insecticides and pesticides for

the garden are discussed in a separate lesson.) Remove all gathering places for roaches, etc., from around the house and yard. Eliminate mosquito breeding grounds, or stock nearby ponds and lakes with larvae-eating fish. If pesticides must be used to control insects in the house, obtain the dry powder type that releases no fumes.

There are many natural ways to keep the insect population under control in your home. Another bonus of following the chiefly raw food Life Science diet is that insect populations tend to decrease when there is no cooked food leftovers or spills around the kitchen.

**Heating Emissions:** Although not a chemical pollutant, another source of household pollution is the heating system. This is especially true of people who use gas, coal or wood heat. The fumes from these types of heaters continually fill the room. Often the unlit gas heaters and ovens emit unburned gas into the room. No house should remain "air tight" during the winter. If the house is very well insulated, then a window should always be cracked to allow an exchange of air.

**Other Pollutants:** There are many other sources of pollution in the home. Noise pollution is often ignored, but excessive levels of noise around and in the house has detrimental health effects.

Low-level radiation from microwave ovens is also a source of "pollution" in the house, and such devices are best abandoned. If cooking is to be used, then gas or electric is safer than the microwave oven.

Dry-cleaning fluids, spot removers, lead paint, paint thinners, solvents, glues, and many other chemical compounds in the home can be dangerous if used improperly.

By simplifying your life, you will eliminate the need for all such chemical products. Here's how you can benefit by adopting a Life Science way of living in your home.

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > 3. The Benefits of Natural Living in the Home

### 3. The Benefits of Natural Living in the Home

Most people see the immediate benefits that a natural diet and lifestyle can bring them. It is usually only later that this new way of life is completely introduced into the home. Here's a category description of how a Life Science regimen can improve your home living:

**Personal Hygiene:** The first thing you will notice after changing your diet and lifestyle is that you will no longer need 99% of all the personal hygiene care products sold. You can eliminate all underarm deodorants, all mouth-washes, all feminine sprays, all antiperspirants, and so on. Why? Because your body will always smell clean and fresh when you eat a simple diet of chiefly fruits, vegetables, nuts, seeds, and sprouts.

**Kitchen Cleaning:** When you change your diet to a predominantly raw one, your kitchen cleaning days will be over. No more greasy pots, pans, or ovens. You'll never need those harsh kitchen cleansers again.

**Air Fresheners:** When you eliminate cooking and smoking, your air will always smell clean in your home. Open windows and doors will ensure that you have a pleasant and healthy environment, free from obnoxious odors.

**Other Ways:** As you simplify and improve your life and diet, you will also want to make these changes in other areas. You will find that you need or want very few household chemicals or cleaners in your home. You'll search for safer and more natural ways to clean and upkeep your house. You'll discover the value of a natural way of living that will eliminate all dangers of household pollution and poisoning.

As a student of Life Science, you already know the vital importance of having a clean body, mind, and diet. Now you should become aware that a clean and natural home is simply another way of expressing these new found values. Leave the chemicals behind in your "new" home, and keep your living environment healthy and pollution free.

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > 4. Questions & Answers

#### 4. Questions & Answers

**After reading this lesson, I'm too scared to use any type of cleaner! Aren't you exaggerating about the dangers of these chemicals? We never hear anything bad about them on television.**

Certainly the risks of household cleansers and other chemicals in the home are much less than many other unhealthy practices. Yet prolonged use of these common chemicals do indeed lead to serious health problems, especially in the respiratory tract. Unintentional poisonings from such chemicals are very high, particularly among young children. You should not be afraid to clean, but you should rely more and more on simple *mechanical* cleaning—that is, use some armwork and physically remove the dirt. Don't depend upon chemical compounds to do your cleaning for you. Many years ago, about the only household cleanser available was soap and water. Homes have stayed remarkably clean by just using such simple and relatively natural ingredients. The simple truth is that most household chemicals are "convenience" items, just like there is now "convenience" (or "fast") food. What you gain in convenience is more than offset by dangers to your health in these products. By all means, clean your home, but don't chemicalize it!

**Here's another source of chemicals in the home you didn't cover: cosmetics and toiletries.**

While attention was given to hair sprays and deodorants, perhaps not enough mention was made about these other chemicals that so many people put on their faces and bodies. Almost all cosmetics are either made from animal products or they are tested on animals in cruel ways (such as blinding rabbits to test eye shadow, etc.). Not only that, but almost all cosmetics contain chemicals which can harm the skin after years of use. Men, too, are guilty of using such things as aftershave lotion, cologne, and so forth. All of these substances contain irritating ingredients that are harmful when breathed or applied to the skin. The best makeup is a clear, smiling face. Reduce or eliminate these "personal" chemicals that so many people put on their bodies.

**So many new houses are unsafe to live in because of their internal pollution. Could you comment on that?**

The new home owner must be very careful nowadays about the building and insulation materials used in a home. Much insulation has asbestos fibers and other particulants which can cause lung cancer in those that breathe it day in and day out. Many plywood sidings are impregnated with formaldehyde, and these fumes are slowly released into the new house over a period of months. Recently, thousands of people have been forced out of their new homes because of toxic fumes that emit from the building materials used in construction of the house. These problems can be avoided by always having an open source of ventilation (a heat pump works well in the winter for this purpose) and carefully investigating the types of material used in the insulation and siding.

## Article #1: Radiation in Your Kitchen by Mike Benton

Do you want to live next door to a nuclear power plant? A stupid question, right? But think about this:

Over *five million* homes have their own little boxes of radiation sitting right in the kitchen. They're called microwave ovens.

Now comparing a microwave oven to a nuclear plant may seem silly. After all, a microwave oven doesn't even give off the same type of radiation as an atomic energy source or an x-ray machine. The radiation from a microwave oven is about like what you get from radar or what is called *low-energy nonionizing* radiation.

But that microwave oven sits in many a house. It's used day in and day out. It's a constant source of low-level radiation that penetrates through the house. Is the microwave oven dangerous? Yes!

A microwave oven is like a fallout shelter in reverse: It's a tight little box that is designed to keep the radiation in. If you have a perfect, tight box, then the radiation won't get out. But a microwave oven is *not* a perfect, tight box. Radiation does leak out, especially around the door and the seals of the oven.

There are government standards for "acceptable" leakage rates for microwave ovens. In other words, microwave ovens can leak a certain amount of radiation and still be considered safe.

*There is no such thing as a safe dose of radiation.* Dr. Karl Morgan, a researcher on the effects of radiation on human health, stated: "From 1960 to the present, an overwhelming amount of data have been accumulated that show there is *no safe* level of exposure and there is no dose of radiation so low that the risk of malignancy is zero."

## How Microwaves Can Harm Us

Microwave ovens *do not* make the food cooked in them radioactive. Food cooked in a microwave oven is no more nor less harmful than any cooked food. Any time heat is applied to food, destruction of nutrients and alteration of food chemistry occurs. Consequently, microwaved food is not better for you just because it is cooked for a shorter time. Microwaves destroy food *faster* than conventional cooking methods, but they do not destroy food *less*.

The main reasons for recent concern about microwave ovens are:

1. Microwaves can interfere with the normal operation of certain heart pacemakers, as well as other electrical and electronic items.
2. The thermal effect of exposure to these waves may harm sensitive body cell tissue or organ function.
3. Microwave radiation can cause eye damage and cataracts and is suspected of causing other ailments, including nervous exhaustion.
4. Low-energy, nonionizing radiation may also be capable of causing detrimental health effects not fully understood or recognized as such.

## Nobody Really Knows How Dangerous They May Be

There are safety standards for microwave ovens, and consumers feel safe that they are buying, government-regulated equipment. What is not generally known is that the Soviet Union, which has done more research on microwave radiation than any other country, has an acceptable radiation level for the public that is *one thousand times* stricter than U.S. levels.

Not only that, but the biophysicist, Dr. A.H. Frey, has discovered that the human nervous system reacts

to microwave exposure that is 300 times *below* the government standards for microwave ovens.

Older microwave ovens frequently leak more than new ones. Improper servicing, cleaning, and general wear cause radiation leakages to increase. If someone you know has a microwave oven, there are several steps you can take to minimize irradiation leakage:

- Never insert objects around the door seal.
- Examine the oven for shipping damage or damage through normal use.
- Do not tamper with or inactivate the oven safety interlocks.
- Frequently clean oven cavity, door and seals with mild detergent. Do not use scouring pads, steel wool, or other abrasives.
- Stay at least an arm's length away from the oven when it is in use and keep your eyes away from the door.

### **But Why Have One At All?**

Microwave ovens are unnecessary conveniences. They were developed so foods could be cooked in a hurry. Just like TV dinners, precooked convenience foods, and fast foods, microwave ovens exist because people are too lazy or too unaware to provide good nutrition for themselves and their families.

So what if you can cook a frozen chicken in four minutes? Do you need to eat a chicken, frozen or otherwise? The truth is that the best foods to eat require no cooking and little preparation.

Fresh fruits, vegetables, seeds, nuts, and sprouts do not need to be microwaved, boiled, baked, or fried. They're delicious as they are, ready to eat. If any cooking is to be done to food, it should be light steaming which destroys as few nutrients as possible. You can't even steam for food in a microwave.

Like fast foods, microwave ovens are "fast cooking" and they are associated with the same sort of convenience orientation. For superior health, you should eat as few cooked foods as possible. And you certainly should not have a leaky box of radiation sitting in your kitchen!

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > Article #2: World's Most Polluted Place: The American Home!

### **Article #2: World's Most Polluted Place: The American Home!**

#### **"My, Is It Stuffy in Here!"**

Most of us are keenly aware that America's air, especially in and around large cities and industrial complexes, is seriously and dangerously polluted. Most of us are aware that even the upper atmosphere is becoming so dangerously polluted as to pose a threat to plant and animal life.

Many of us are aware that the average American home is a hotbed of pollution and stands first as a source of aerial pollution. Further, it is only beginning to dawn on researchers that pollution in the home is a source of much disease and misery for our populace.

The relation of polluted air to such respiratory diseases as pneumonia, colds, bronchitis, asthma, sinusitis, and a long list of other diseases, many nonrespiratory in nature, has been only casually noted.

However, researchers are already indicting such pollution as a contributing cause to many human ailments if, indeed, not the primary or only cause.

Certainly little aggravates an ailing person more than aerial pollutants, for they not only make suffering more severe but so hamper the body's healing efforts as to prolong recovery.

If there is any right we must value and treasure above all others, it is the right to breathe pure air. We must not inadvertently deny ourselves the benefits of pure air by our own acts.

If you doubt that the air in your home is polluted, note the difference between it and outside air! You can tell it instantly upon passing from one to the other—even if the outside air is polluted. The air in homes has the pollution of the outside air plus that added in the home.

The primary source of polluted air in American homes is smoke, mostly from tobacco, but from sundry other sources too. Smoke has its tars, carbon dioxide, carbon monoxide, and many other poisons.

If this is not the case in nonsmoking homes, then human aerial excreta is usually the primary source of pollution! Trapped in closed houses are the wastes of our breathing. These contain carbon dioxide, carbonic acid, and yet other waste products. They are deadly to man and beast alike in concentrations such as they become in closed homes.

There is a whole catalog of pollution sources in homes. Not only is pollution BAD in itself but it is usually found in a situation that would be bad WITHOUT the pollutants! For the air in which pollutants are found is usually "stale" air, a term for air that has been seriously deoxygenized. Air that has been breathed in, in which combustion has occurred, has been heated from whatever means, or in which cooking has been conducted, is not only possessed of considerably less oxygen but also is possessed of considerable pollutants as a result.

Consider these sources of pollutants in the home:

- Air from the outside that is polluted to start with
- Tobacco smoke
- Furniture polishes
- Detergents
- Cleansers
- Aerosol cans of all descriptions
- Chlorine from tap water and bleaches
- Cosmetics (none are good!)
- Deodorant sprays
- Insect repellents
- Insecticides
- Powders
- Air sweeteners and deodorants
- Hair sprays
- Lotions and "perfumes"
- All drugs and "medicines"
- Preservatives emanating from foods during cooking
- Volatile oils
- Byproducts of frying food
- Ammonia
- Wastes from combustion of anything burned
- Human aerial excreta
- Alcohols and drinks
- Condiments and other irritants used in foods
- Byproducts of cooking, brewing, boiling, breathing, etc.
- Chemicals of all descriptions exposed to our air

- Antiseptics

Perhaps the most deliberate and criminal of pollution practices is smoking. Many babies are born nicotine addicts and, if reared in an atmosphere filled with smoke of their parents, may become addicted to nicotine without ever having smoked a cigarette.

If "fouling our nests" aurally is not bad enough there are other deleterious forms of pollution in the home, notably noise pollution from inside and outside (it's so bad as to be inescapable in most cities) and x-ray emissions from fluorescent lighting and from television.

Perhaps it is stale polluted air in homes that is largely the cause of more respiratory ailments in winter than in the summer.

In any event, we should be on guard against pollution as much as is commensurate with our circumstances. We should breathe air as fresh as possible as much as possible.

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > Article #3: Typical Compounds Found In Cleaning Agents

### Article #3: Typical Compounds Found In Cleaning Agents

Name	Where Found	Purpose	Dangers
(Lye), potassium hydroxide, sodium hydroxide	oven and drain cleaners	chemically attack and dissolve organic matter	extremely dangerous to all parts of body, especially eyes
Ammonia	oven and window cleaners, wax removers	chemically attack and dissolve organic matter	strong concentrations attack skin, eyes, lungs
Sodium tripolyphosphate	coffeepot cleaners	water softener and building agent	strong concentrations attack skin, eyes, lungs
Sodium phosphate	cleaners, scouring powders	water softener and building agent	strong concentrations attack skin, eyes, lungs
Sodium silicate	dishwashing detergent	water softener and building agent	strong concentrations attack skin, eyes, lungs
Sodium metasilicate	dishwashing detergent	water softener and building agent	strong concentrations attack skin, eyes, lungs
Sulfuric acid	commercial drain cleaners	chemically attack and dissolve organic matter	extremely dangerous to entire body

Hydrochloric acid	drain cleaners, toilet cleaners	remove stains and deposits	extremely dangerous to entire body
Phosphoric acid	denture cleaners, metal cleaners and polish	remove stains, dissolve rust	extremely dangerous to entire body
Sodium hypochlorite	bleach chlorine	remove color, disinfect	dangerous to entire body; never mix with anything other
Calcium hypochlorite	bleach chlorine	remove color, disinfect	dangerous to entire body; never mix with anything other
Sodium perborate	Oxygen bleach, denture cleaners	remove color, disinfect	dangerous to entire body; mildly toxic
Sodium dodecylbenzene sulfonate	detergent	dissolve grease and oil	continued contact removes protective oil from skin

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > Article #4: Typical Potential Household Hazards In A Retail Merchandise Catalog

#### **Article #4: Typical Potential Household Hazards In A Retail Merchandise Catalog**

1. Tree fertilizer spikes
2. Insecticides for tree fogging devices
3. Carbon dioxide cartridges for bikes
4. Chain lube spray for motorcycles
5. Lithium grease
6. Gear grease
7. Brake fluid
8. Motor oils
9. Engine flush liquid
10. Auto-body repair
  - a. aerosol spray can primer
  - b. cream hardener
  - c. epoxy repair kit
11. Batteries
12. Fire extinguishers
13. Polyurethane wood finish spray
14. Epoxy spray enamel

15. Wood stain
16. Masonry coating
17. Crack stop
18. Concrete etching acid crystals
19. Antiskid sand additives
20. Heavy-duty cleaners
21. Paint remover
22. Acrylic latex caulk
23. Brush cleaner
24. Mildew wash
25. Swimming pool chemicals
26. Water conditioners
27. Toilet bowl cleaner
28. Portable toilet antifreeze (propylene glycol)
29. Propane torch kits
30. Silicone
31. Rug shampoo
32. Laundry detergents
33. Boat supplies
  - a. polyester materials
  - b. epoxy materials
  - c. epoxy marine enamel
  - d. semi soft point (cuprous oxide)
  - e. water repellents

[Home](#) > [Lesson 51 - Chemicals In The Household Environment](#) > Article #5: In-Depth Home Survey

## **Chemicals In The Household Environment: In-Depth Home Survey**

Answer each of the following questions with "YES," "NO", or "UNCERTAIN". Some of the questions do not pertain exactly to chemicals in the house, but to all sources of unhealthy pollution (such as noise pollution, motor vehicle products, etc.) At the end of the survey, you will be able to rate your home for its safety.

Are the following aerosol sprays found in the home:

1. Hair sprays, tints or dyes?
2. Underarm deodorants?
3. Antiperspirants?
4. Shaving cream?
5. Feminine "hygiene deodorant"?
6. Medicines?
7. Is the home insulated with asbestos products?
8. Are there asbestos caulking materials around the home?
9. Are caulked surfaces sanded in the house?
10. Are air vents or ducts lined with fiber glass?
11. Are home repairs made with asbestos shingles?
12. Are loose asbestos materials stored around the house?
13. Are spot removers or dry-cleaning materials used in the home?

14. Are aerosol fabric finishes used?
15. Are antistatic agents used?
16. Are gloves worn when using spot removers?
17. Are aerosol spray starches used?
18. Do members of the family wear extremely flammable clothing?
19. Does dust accumulate in various parts of the house? (Be honest).
20. Is vacuum cleaner in poor running order?
21. Do sweeper bags become overfilled?
22. Are air-conditioner filters left unattended?
23. Are collector screens in clothes driers neglected?
24. Does drier vent fail to reach the outside?
25. Does ragweed grow near the house?
26. Is the ash chute unattended?
27. Is there a coal, natural gas, or heating oil furnace?
28. Has it not been checked this year?
29. Is there a gas stove without an exhaust hood? Was the pilot light for water heater or kitchen stove checked today?
30. Is there an attached garage?
31. Do family or neighbors ever warm up cars (let them idle) for long periods on cold mornings?
32. Is the house near a heavily traveled highway?
33. Does the refrigerator or air-conditioner leak coolant?
34. Is there a kerosene stove, lantern, or camping stove in the house?
35. Is there a fireplace which occasionally emits smoke in the house?
36. Are glowing charcoals ever carried indoors?
37. Is trash burned in the backyard?
38. Is aerosol floor polish, wax, or cleaner used?
39. Are aerosol furniture polish and wax used?
40. Are metal polish and cleaners used (silver, aluminum brass, and copper) without gloves?
41. Is rust remover kept around the house?
42. Are tarnish-preventing materials used?
43. Is aerosol rug cleaner or tack-down material used?
44. Are there open garbage bags at the kitchen counter?
45. Are garbage cans left open?
46. Are garbage cans left uncleaned especially during hot weather?
47. Is "junk" mail permitted to be sent to the house?
48. Is a garbage service used instead of mulching?
49. Do neighborhood pets get into the garbage?
50. Does garbage stand overnight in the kitchen?
51. Is a garbage disposal unit used?
52. Is an automatic trash compressor used?
53. Is there a failure to defrost and clean out the refrigerator often?
54. Are rotten and stale vegetables and fruits left in the storage room?
55. Is paint (oil-based) used for artistic work at home?
56. Is the hobby area poorly ventilated?
57. Are rocks polished without the use of a facial aspirator?
58. Is film developed in the house?
59. Is pottery baked at home?
60. Are home photographic, painting, and etching supplies stored outside a chemical hood?
61. Are wood lacquers in furniture finishing used?
62. Is metal work such as sculpting, welding, or etching done at home?
63. Are fast-fixing glue and cement kept in the house?
64. Are insecticides stored in the household?

65. Have any of these ever spilled?
66. Are garden pesticides used?
67. Are rooms used within three days after fumigation?
68. Are pesticides ever used before reading the instructions?
69. Are herbicides used?
70. Is the house unclosed when neighborhood trees are sprayed?
71. Is petroleum-based fly spray used in place of pest sticking paper?
72. Are doors and windows unscreened?
73. Is No-Pest Strip used?
74. Are mothballs stored where small children can get to them?
75. Are aerosol insect repellents used?
76. Are aerosol air fresheners or room deodorizers used?
77. Are aerosol disinfectants used?
78. Are germicides and disinfectants near where children are playing?
79. Is there a failure to aerate rooms after use?
80. Is the family overly germ-conscious?
81. Are strong soaps used in kitchen or laundry?
82. Are detergents used?
83. Are brighteners used?
84. Are laundry soap or detergent overused (beyond instruction amounts)?
85. Are soaps and detergents beyond the reach of infants?
86. Are rubber gloves not worn when using strong soaps?
87. Are there spilled laundry soaps and detergents in the house.
88. Is indoor lead-based paint present in the house?
89. Is lead paint removed without proper ventilation?
90. Is any of the paint cracking, peeling, and chipping?
91. Is a blowtorch used for removing the paint?
92. Are there old lead-based paint cans around the house?
93. Are unglazed pottery mugs for coffee, tea, fruit, juices, or soft drinks used?
94. Do children habitually play within fifty feet of a heavily traveled highway or where dirt is contaminated with leaded gasoline emissions?
95. Is gasoline stored in the house or garage?
96. Are aerosol antirust or lubricants in the house?
97. Are there waste oil cans in the house?
98. Is oil changed near the house?
99. Are commercial deicing agents used?
100. Has leaded gasoline been spilled on carport or in garage?
101. Is antifreeze kept away from children?

Are the following used at home:

102. Typewriter?
103. Hairdrier?
104. Loud vacuum cleaner?
105. Stereo?
106. Radio?
107. Television?
108. Electric mixer?
109. Power drill? .
110. Leaf chopper?
111. Children's toys?
112. Power chain saw?
113. Power lawn mower?

114. Metal garbage cans?
115. Lathe?
116. Vibrator?
117. Motorcycle?
118. Do persons have a habit of making phone calls late at night?

Are the following in the reach of children:

119. Oven cleaners?
120. Glass cleaners?
121. Bleaches?
122. Toilet bowl cleaners?
123. Scouring powders?
124. Are ammonia and bleach or acid cleaners ever mixed in the home?
125. Are rubber gloves worn when working with cleaners?
126. Are a large variety of cleaning agents purchased?
127. Are aerosol drain cleaners used?
128. Are aerosol oven cleaners used?
129. Are large amounts of plastic furnishings used around the house?
130. Is the family unaware of toxic emissions from burning plastics?
131. Does the car have a film (from plasticizers) on the windows?
132. Are furnishings made from PVC (polyvinyl chloride)?
133. Are PVC containers used for food products?
134. Are antifungicide paints used which contain mercury?
135. Has spilled mercury ever come from a broken thermometer?
136. Are mercury-treated seeds around the garden supplies?
137. Is there liquid mercury in the house?
138. Is an old microwave oven used?
139. Does the microwave oven work improperly?
140. Do any family members sit quite close to a TV set?
141. Are there ultraviolet lamps in the house?
142. Is the house near high-tension electric wires?
143. Are black lights in the home?
144. Do members oversunbathe?
145. Is the home near locations containing powerful transmitters or defense electronic equipment?

Are the following stored in the house:

146. Paint solvents?
147. Paint thinners?
148. Paint removers?
149. Lighter fluid (charcoal or tobacco)?
150. Butane lighter containers?
151. Kerosene?
152. Are aerosol paint products used?
153. Are oily rags stored around the house?
154. Are there open cans of petroleum-based solvents with paint brushes?
155. Are cement solvents used?
156. Is the house aerated after painted until fumes decrease slightly?

Is Smoking allowed in the following:

157. Bedrooms?
158. Bathroom?
159. Living room?

- 160.Kitchen?
- 161.Recreation area?
- 162.Do smokers fail to honor nonsmoker rights?
- 163.Is the house not aired out after smoking and parties?
- 164.Is marijuana smoking permitted in the house?
- 165.Are aerosol utensil coating materials used?
- 166.Is the household ignorant of the use of utensil coatings by teenagers for sniffing?
- 167.Are there any poisonous plants in the house?
- 168.Are any in the reach of children?
- 169.Are fertilizers kept around the house?
- 170.Is the drinking water below standards for purity?
- 171.Is hot water used for cooking purposes?
- 172.Do drinking water pipes contain asbestos?
- 173.Do they contain lead?
- 174.Do they contain PVC (polyvinyl chloride)?
- 175.Is the house near a heavy industrial area?
- 176.Are the gutters dirty or downspouts blocked?
- 177.Are pool cleaners stored around the house?
- 178.Are water-conditioners kept around the house?
- 179.Is there a water-purifying device in the house?
- 180.Do the toilets ever back up into the bathtub?
- 181.Does the water have a cloudy look when taken from the tap?

Are the following around the house:

- 182.Lye and other corrosives?
- 183.Fireworks?
- 184.Matches?
- 185.Aerosol medicines such as decongestants and anti-fungus agents?
- 186.Are medicine cabinets unlocked or within reach of children?
- 187.Are medicines stored near food?
- 188.Are any old unmarked medicine bottles around?
- 189.Are any members of the household habitual users of drugs?
- 190.Are fire extinguishers left unchecked from year to year?
- 191.Is salt used to melt snow on walkways and drive?
- 192.Has there been a cutoff Christmas tree in the house this year?
- 193.Are aerosol decorative materials or cocktail chillers used?
- 194.Are there rats or other rodents in or near the house?
- 195.Are dogs, cats, or other large pets allowed indoors?
- 196.Do children play near dog or cat litter or in pet pens?
- 197.Is the pet ever infested with fleas or ticks?
- 198.Is there a protective screen on chimney to prevent bug and rodent entry?
- 199.Are there bird nests in rafters or bird droppings near the house?
- 200.Do the children have pet turtles?

## Answers

Your Score: Count up the total number of "YES" answers. Some of these questions might not apply to you at all, but of all the questions answered, use this scoring:

### Number Of Yes Answers To The Survey:

1. 80 or more: A very high chance for chemical contamination problems now exist.

2. 60 to 80 YES answers: Too many chances for chemical contamination probably now exist in your house.
3. 40 to 60 YES answers: A moderate chance for household pollution—initiate a clean-up action.
4. 20 to 40 YES answers: A relatively low chance for pollution in your home.
5. LESS than 20 YES answers: Congratulations!

## Lesson 52 - Chemicals In Our Air

- [1. Introduction](#)
- [2. The Deadly Chemicals In Our Air](#)
- [3. Clean Air: How Can We Get It?](#)
- [4. Questions & Answers](#)
- [Article #1: The Breath of Life By Dr. Herbert M. Shelton](#)

### 1. Introduction

The monument had stood in the Egyptian sands for over 35 centuries. "Cleopatra's Needle" it was called, and it had thousands of beautiful carvings and drawings all upon it. Somehow the ancient monument had survived the raging desert sands and hot Egyptian sun for over three thousand years.

In 1880 the monument was transferred to downtown New York. A hundred years later, the monument had eroded away so that all the drawings upon it had completely disappeared. What the sandstorms of Egypt for 3500 years could not do had been accomplished by the polluted air of New York City. The ancient drawings had been eaten away by the sulfur oxides in the dirty city air.

The chemicals in the air today are equally destructive of human health and life, and with every breath you take, you are taking in chemical compounds that never even existed a few years ago.

Air pollution and the chemicals we are forced to breathe should be an area of great concern to the health seeker. Much more important than the food we eat is the air we breathe. After all, you only eat about three times a day. You breathe about fifteen times every minute. Clean, pure air is one of the primary requisites for superior health. This lesson discusses the chemicals that are now in our air supply, and what we can do about them.

#### 1.1 The Sea of Air

A philosopher once said, "The fish shall be the last to discover water." He meant that it is often hard to see clearly what is often taken for granted. Humans take the air they breathe for granted, and we always assume that each morning we can wake up and take a nice, deep breath of life-giving air. Some day that might not be the case.

Almost all life on earth is supported by a layer of air less than two miles thick. Without this protective layer of air, the earth would reach a daily high temperature of 230 degrees, and drop to an overnight low of 300 degrees below zero.

Right now, we have about six thousand billion tons of air on this planet. We won't run out of air, but we may run out of *breathable* air in the near future. Almost all of our air is either nitrogen (78%) or oxygen (21%). A gas called argon makes up 95% of the remaining atmosphere, and carbon dioxide takes up another 3% of the remaining air. Less than two-hundredths of a percent of our atmosphere contains other gases, such as helium, neon, methane, ammonia, hydrogen sulfide, and carbon monoxide.

Yet in that small percentage of other gases lies the pollution problem. Only a very small amount of dangerous gases and chemicals need to be present in the atmosphere to affect all of us greatly.

## **1.2 Nature's Balance**

Naturally occurring air is never completely clean. There has always been foreign matter in the atmosphere in the form of volcanic ash, pollen, spores, salt particles from the ocean, and even cosmic dust from the upper atmosphere. These particles actually serve a useful function in the play of nature by acting as a stimulus for rain and precipitation.

The foreign particles fall to earth with the rain and the air is cleaned. Meanwhile, plants are busy recycling carbon dioxide into oxygen, and the giant oceans are recirculating and cleaning the air all over the planet.

But then the balance was upset. With the coal-burning industries of the nineteenth century, abnormally large amounts of foreign particles and gases escaped into the air. The rain could no longer clear the air completely, and the oceans became polluted. The oxygen-producing forests and fields were leveled and made into concrete sites for buildings.

More garbage was being dumped into the air than nature could handle. Finally, the whole atmosphere all over the globe became contaminated, dirty, and unhealthy.

## **1.3 What Is Air Pollution?**

Air pollution is defined as substances or radiations in the atmosphere which harm living organisms or their environment. Normally, as we have seen, the atmosphere is self-purifying. However, when a high concentration of unnatural wastes is discharged into the air, then the atmosphere becomes overburdened and polluted.

Eventually the pollutants in the air may be precipitated from the atmosphere when it rains. When this occurs, the pollution falls onto the land or water, and contaminates this part of our environment.

## **1.4 What Causes Air Pollution?**

Air pollution is caused in one of three ways: surface friction, vaporization, and combustion.

Friction is a minor cause of air pollutants. Such things as sawing, drilling, and grinding various materials release airborne particles which may find their way into your lungs eventually. For most people, friction is not a major source of pollution unless they are workers in a mine, mill, or other industry that releases small particles into the air.

Vaporization occurs when a liquid becomes a gas. A good example is paint thinner. When the can is opened, certain fumes escape as vapor into the atmosphere. Gasoline also undergoes vaporization, as do paints, glues, and other chemical compounds. This is only a major source of pollution when a nearby industry is engaged in making these products, or is working with rubber or plastic which can also vaporize.

Combustion is the real villain as the cause of air pollutants. Combustion is simply the burning of a solid or liquid into a gas. For instance, your car works on combustion by turning gasoline into various hot gases.

When combustion occurs, heat and light are usually released. Unfortunately, other chemicals and gases are also released into the atmosphere. Some of these chemicals are harmful, and are the major factors in polluting our air.

In fact, a quick study of the air pollution problem is really just a description of these chemicals and how they get into our atmosphere.

## 2. The Deadly Chemicals In Our Air

Many of the pollutants in our atmosphere have unfamiliar and scientific names, yet they are not difficult to understand. Each major chemical pollutant is discussed below as to the possible harm it can do us, where it comes from and how we can prevent it from becoming more widespread.

Here's a list of the more common chemicals that pollute your air: sulfur dioxide, carbon monoxide, nitrogen oxides, hydrocarbons, ozone, lead, and asbestos.

### 2.1 Sulfur Dioxide: The Gas From Hell

"If smells like hell around here," a worker complained to his boss. What he was talking about was the choking, sulfur fumes that came from the worker's plant. Sulfur dioxide does indeed remind you of the "fire and brimstone" odor. If you breathed a deep lungful of the gas, it would feel like thousands of razor blades in your lungs.

Sulfur dioxide is one of the deadliest air pollutants, and it accounts for about 18% of all air pollution. Sulfur dioxide has been implicated in cases of asthmatic attacks, eczema (a skin disease), breathing difficulties, and paralysis and corrosion of the respiratory organs.

As soon as sulfur dioxide rises to a concentration of only one-five *millionth* of the atmosphere, deaths increase rapidly.

Coal-burning plants and industries account for almost 85% of all sulfur dioxide pollution. Residential use of coal and fuel oil makes up another 10% of the sulfur dioxide release. The problem of sulfur dioxide pollution is the most serious in areas of the northeast where coal burning is the most widespread.

No one, however, can escape the harmful effects of sulfur dioxide because it is spread all over the earth in "acid rain." Acid rain occurs when the particles of sulfur dioxide are carried through the air and combine with water particles and fall to earth. Along with the water in the rain, you also get the acid waste products of sulfur dioxide.

Crops that are especially susceptible to sulfur dioxide and acid rain are wheat, barley, oats, cotton, alfalfa, buckwheat, and white pine. In fact, within a twenty-mile radius of a plant that emits sulfur dioxide in Tennessee, over 90% of all the white pine trees have been killed.

These sulfur compounds also enter the streams, rivers, and lakes after they fall from the air. As a result, many fish and aquatic plants quickly die.

As an individual, you can help control this type of air pollution by using another form of heating besides coal and fuel oil. If you must use these fuels to heat your home, insist that you receive a *low-sulfur* content coal or fuel. By simply converting to a lower sulfur content of coal, the problem could be greatly eased. At the same time, you should push for stronger regulations about the amount of sulfur dioxide industries can release into our air.

### 2.2 Carbon Monoxide: A Totally Manmade Gas

A jellyfish can belch carbon monoxide. Other than that, man is the only creature that can create this deadly gas. Carbon monoxide is the killer behind automobile gas poisonings that occur in closed garages. This gas in the exhaust fumes of cars is often fatal to unsuspecting drivers.

Over one-half of the total air pollution in this country comes from carbon monoxide. And you are responsible, because 80% of all carbon monoxide comes from the exhaust pipe of the automobile.

Carbon monoxide is extremely dangerous. It is almost certain that you have been poisoned by this gas at least once in the past week if you drive in heavy traffic. Tests have shown that traffic jams can produce

enough carbon monoxide from the idling cars to cause headaches, irritability, dizziness, and nausea.

People who must work near heavy traffic areas often breathe in enough carbon monoxide so that their mental processes are slowed down to about one-half what they should be in clean air. Many driving accidents are now thought to be caused by carbon monoxide leaking from the car and poisoning the driver in the car.

For some people, driving a car isn't enough pollution. They must also smoke cigarettes, which also give off carbon monoxide. Heavy smokers may have as much as 5% of their blood hemoglobin permanently combined with carbon monoxide. When this occurs, the tissues suffer a low level of oxygen starvation and destruction. Even the carbon monoxide from a single cigarette in a closed car can create headaches in all the passengers.

Every gallon of gasoline that you burn in your car releases three pounds of carbon monoxide into the atmosphere. The solution to this sort of pollution is simple: restrict and limit all driving and strive for a more fuel-efficient car.

During the days of the Vietnam war protests when hundreds burned their draft cards, science-fiction writer, Ray Bradbury, said: "The students who are burning their draft cards are fighting the wrong enemy. This war will eventually end, but the more serious and deadly war, the one against air pollution, will never be won until we end our dependence on the polluting automobile. If these protestors want to perform a really radical and earth-saving act, they should be burning their *drivers' licenses* instead of their draft cards."

### **2.3 Nitrogen Oxides: The Smog Triggers**

The sun in the midday sky was only a watery disk. Cars drove slowly with their lights on. It was noon in Los Angeles, but the smog made the city look like a smoky, evening battleground. Nitrogen oxides had combined with other gases from the heavy traffic to form a dense layer of smog that blocked the sunlight.

Nitric oxide and nitrogen dioxide are the two most damaging of the nitrogen pollutants. Nitric oxide is very similar to carbon monoxide, and reduces the oxygen carrying capability of the blood. Nitrogen dioxide irritates the eyes, nose, bronchial tubes, and lungs. High concentrations of this toxic gas prove fatal.

Gasoline motor vehicles are the major source of nitrogen oxide pollutants. Coal and natural gas burning account for the second largest class of nitrogen oxide pollutants.

Again, the most effective way to control this form of air pollution is by reducing dependency on the gasoline engine, and finding safer energy alternatives than coal burning.

### **2.4 Hydrocarbons: The Urban Air Pollution**

Hydrocarbons are often emitted in the exhaust from automobiles and from industrial smoke stacks. The major cause of hydrocarbon pollution is the processing and use of petroleum products. Consequently, hydrocarbon pollution is highest in urban areas.

About 13% of the entire annual output of air pollutants is in the form of hydrocarbons. Most of the hydrocarbon compounds are carcinogenic—that is, they "contribute to the causes of cancer.

One of the major hydrocarbon pollutants is *benzopyrene*. This toxic gas is also found in cigarette smoke, and is suspected as a cancer catalyst. Worldwide studies have proven that benzopyrene specifically produces lung cancer. Many city residents breathe in about as much of this gas daily as is contained in seven cigarettes.

Some cities are much worse. For example, the benzopyrene level in New York City and Birmingham, Alabama, is such that the average resident takes in as much of this poisonous gas as is contained in the

equivalent of about fifty cigarettes daily! Studies have also shown that the person who both smokes cigarettes and lives in polluted urban air is the most likely to have cancer.

## **2.5 Ozone: From Out of the Blue**

Ozone is a clear, blue gas that exists naturally in the far upper regions of our atmosphere. Man, however, has increased the ozone content at the lower levels by emitting large amounts of nitrogen dioxide pollutants which in turn cause the creation of additional ozone.

At low levels, ozone poisoning results in chest pain, coughing, and eye irritation. Continuous exposure to small amounts of ozone has shortened the lives of laboratory animals. Ozone destroys such crops as grapes, spinach, lettuce, and alfalfa. It even attacks textile and rubber, causing them to deteriorate.

Ozone poisoning may also be a problem with those that work around electrical equipment and apparatus. Ozone has a sharp, almost "clean" type of smell. It may also be found in various air fresheners and sprays.

## **2.6 Better No Lead Than Dead**

Chances are good that you are suffering from a low level of lead poisoning, particularly if you live near areas where automobile exhaust is a problem.

Lead affects the central nervous system. Headaches, dizziness, insomnia, weakness, anemia, and loss of appetite are some of the symptoms of chronic lead poisoning. The greatest danger of lead pollution is that it changes the shape of healthy red blood cells and makes them brittle. Residential areas where lead fallout is high also have a correspondingly high incidence of heart failure and disease.

Lead is a cumulative poison. That means it can build up in your system over a number of years. Lead is in both the air and water supply. Over urban areas, there is twice as much lead in the rainfall as is set by the government for drinking water standards.

Most of the lead, however, is not in the water but in the air. Airborne lead is caused chiefly by burning gasoline that contains lead. About two-thirds of all lead in gasoline is exhausted into the atmosphere.

In fact, since the introduction of lead-containing gasoline in 1924, the average person now carries around in his body *100 times* as much lead as did people who lived before 1924.

Our cars that use lead gasoline have made the atmosphere over *1,000 times higher* in lead content than it would have naturally. The annual lead fallout over this country is over 500,000 tons a year. Eventually, these large amounts will upset the mineral balance of the oceans and produce massive lead poisonings.

The solution? Immediate suspension of sales of all leaded gasoline. The lead in the gasoline our automobiles burn is the major cause of the lead problem. If you want to help, always use unleaded gasoline in your car. It's worth the extra effort for the sake of the environment and your health.

## **2.7 Asbestos: Fibers In Your Lungs**

Asbestos is found in pipe and electric insulations, brake linings, and, unfortunately, the human lungs.

Asbestos fibers pollute our air and often find their way into sensitive lung tissue where they become embedded. The mechanical irritation of these fibers harms the lungs and are believed to contribute to tumors in the lungs.

Asbestos is also often found in many building materials, all the way from the roofing of a house down to the floor tiles, and in the insulation in between.

Construction workers, electricians, plumbers, and many industrial workers need to be concerned about the asbestos pollution in their working environment.

Homemakers are not immune to the asbestos problem either. Even such a harmless-looking product as talcum powder has now been discovered to contain asbestos fibers. When this powder is used, asbestos particles enter the air and lungs, as well as being deposited on the skin.

## 2.8 Air You Can See: Particle Pollution

Although not purely chemicals, another form of air pollution is solid particles. You've seen this type of air pollution yourself. In a ray of sunlight, you've probably seen tiny moving particles of "dust." Such dust contains spores, pollen, molds, ash, soil, soot, and dozens of other solid compounds.

In a large city, every breath you take has about 70,000 solid particles in it. Even "clean" country air has about 40,000 solid particles in each breath of air.

Generally, these airborne particles of pollution remain in the air for only a few days. Occasionally, however, the lighter particles may drift for weeks and hundreds of miles from where they were released.

These particles come from everywhere: from fires, from industries, from farming, and from cars. In Los Angeles alone, one survey estimated that 50 tons of rubber particles from spinning tires are released into the air every day!

These airborne particles can make the sky hazy and shut out needed sunlight. For example, after volcanic eruptions which release a large amount of solid particles, the temperature often drops for a period of weeks. Solid particles in our air also cause irritation to the lungs and eyes, and produce what are often mistakenly labeled as "allergies."

If temperature inversions occur or the wind blows the wrong way, these particles can gather in one part of an area and actually darken the daytime sky. When such conditions occur, deaths due to pollution rise by as much as 50%.

[Home](#) > [Lesson 52 - Chemicals In Our Air](#) > 3. Clean Air: How Can We Get It?

## 3. Clean Air: How Can We Get It?

One of the primary requisites for a healthy and long life is clean and pure air. Unfortunately, this is one area that we sometimes have little control over. We can always choose the food we want to eat and decide when to exercise or fast, but the air we have to breathe is what is given us.

This does not mean, however, that we are helpless in obtaining pure air. Here are some practical suggestions that will help you live in a cleaner environment:

1. Demand strict enforcement of all existing air pollution laws. Push for stronger standards and increased funding for air-quality control organizations.
2. Reduce your fuel consumption and automobile dependency. *Use unleaded gas.* Drive less, and have your car checked to see if it is emitting high levels of pollutants.
3. Allow no smoking in your personal environment, and work for antismoking ordinances in public places and business areas.
4. Try to live in a low-urban environment. Have your home away from heavily traveled roads and highways. Make sure that home gardens are at least 100 feet from any street. The further you live from traffic congestion, the healthier you will be.
5. If you live where the air quality is low, take trips and vacations to where the air is clean and your lungs can have a chance to detoxify.
6. Follow a nontoxic diet as suggested by Life Science. This will allow your body to better cope

with the effects of pollution.

7. Exercise away from heavy traffic areas. Do not run alongside cars while jogging, and save all heavy exercising for as unpolluted an area as available to you.
8. Purchase products which produce little pollutants in their manufacture. Some of the worse pollutants are plastic industries and petroleum companies. Try to restrict the use of all such products.
9. Start to re-green your city and area. Plants and forests are our first line of defense against air pollution. You can help by setting out trees in your yard and city. Actively work to preserve all existing "green" areas in towns and cities.
10. Watch the fuel you burn for heating. Low-sulfur coal fuel oil can slow pollution down. Have your home furnace or heating system checked for maximum efficiency so that fewer byproducts are produced in the heating of your home.

Fighting air pollution is not hopeless. Already the quality of the air has somewhat improved since the early 1970s. However, our air has not become so much better than we can grow lax. Industries are continually petitioning for relaxed air standards, and it is up to the public to see that the antipollution laws are instead strengthened and enforced.

Every day of your life, you draw in 20,000 breaths. You have the right to expect that not a single one of these breaths should endanger your health. The air and atmosphere are our common heritage and resource, and we must insure that they stay clean for us and our children.

[Home](#) > [Lesson 52 - Chemicals In Our Air](#) > 4. Questions & Answers

#### 4. Questions & Answers

**I'd like to know more about air filters and cleaners that I can use in my home. Specifically, what about negative ion generators? Are they good in cleaning up the air, and are there any worthwhile machines to filter out cigarette smoke?**

Air cleaning machines and ion generators do not solve the air pollution problem. The chemicals are still in the air that we breathe even after being filtered through these machines. Air-cleaning devices, however, have been effective in eliminating particles of dust, pollen, and smoke from the home and business.

Before buying or using one of these air-cleaning machines, you should first investigate very carefully how they work. Some of these devices may have harmful chemicals in the filtering mechanism they use, so make sure that you are not creating another problem when you use such machines.

Negative ion generators are very popular and are widely advertised. The verdict is still out on these machines, but caution is urged. All negative ion generators emit ozone as well as negative ions. Make sure that any ion generator you might buy has a very low level of ozone emission. Many people also report a difficulty in sleeping when one of these generators is in the bedroom. Evidently the negative ions have a stimulating effect on the organism, and this may prevent a deep sleep or rest.\

If you must work in a smokey or dust-filled environment, however, an air-filtering device or ion generator might be more beneficial than harmful and should be carefully investigated.

## **I want to move where there isn't any air pollution. Where should I go?**

I would suggest the moon. There is no air there, nor any pollution at this point. Seriously, there is now no place on earth that does not have an air-pollution problem. Air pollutants have been found in the Antarctic air where there are no cars nor industries. There are definitely worse places to live than others, however. If you live in the nation's top twenty urban areas, you'll be worse off than many of your country cousins. It's not just urban density, however, that determines the quality of your air. You also have to consider the terrain and weather conditions. Some cities produce an awful lot of pollution, but the prevailing winds simply blow the poisons downwind to another town or state. Generally, however, you would do well to avoid cities that have heavy industries, like petroleum, plastic, or chemical plants. Coal-burning areas are always worse than locales that do not use coal as a major fuel source.

You cannot, however, run away from air pollution. It will follow you no matter where you live. The ultimate solution to air pollution is not to remove yourself from it, but to remove the pollution from the air. It is an uphill fight, but it can be won if you make your voice heard.

[Home](#) > [Lesson 52 - Chemicals In Our Air](#) > Article #1: The Breath of Life by Dr. Herbert M. Shelton

### **Article #1: The Breath of Life by Dr. Herbert M. Shelton**

Man is a child of nature. He is an outdoor animal. Normally he lives amid the beauties of nature, his skin bathed in the morning dew, kissed by the sun, soothed by the gentle zephyrs of Spring and his body fed by the luscious fruits and vegetables all around him, while his spirit is cheered by the songs of birds and the beauty and fragrance of myriads of gorgeously colored flowers. The open air is his home and he who lives in it is fortunate indeed.

Like fish on the floor of the ocean, we live in a sea of air that is much deeper than the hydrosphere in which aquatic animals live. There is always an abundance of much needed oxygen, if we but permit it access to our lungs. The air is self-purifying, so that, while impurities are ceaselessly being discharged into it, these soon find their way to other levels and leave the air fit to breathe. Pent-up air, that is, air that is confined in closed rooms, and air that is held in congested and gas-laden cities quickly becomes unfit for breathing. Such air, if breathed habitually, helps to produce disease; whereas, pure is one of the basic essentials of good health. This is often denied, but we shall continue to insist that pure air is absolutely essential to excellence of health and to the highest beauty and that, on the contrary, impure air tends to the production of poor health and the deterioration of beauty.

Modern city life, with more than sixty-five percent of our population residing in the cities, denies fresh air to the people as certainly as did the closed windows and doors of the houses of our grandparents. It is not that there is no air in the cities, but that it is so badly polluted with smoke, fumes, dust, etc., that it is actually unfit to breathe. The carbon monoxide from the exhaust of automobiles is but one of the air-polluters of modern life. Nitric and sulphuric acids, lead oxides and lead carbonates are among the contaminating elements found in the air of cities. The soot of soft coal is often one-half coal tar and this must help to produce lung cancer as surely as do the tars of tobacco smoke. The particles of carbon (soot) in smoke-filled air accumulate in the lungs and become imbedded in the air cells, gradually changing the lungs from their normal pink to one of sooty blackness. Indeed, this coating of carbon becomes so thick that one wonders how the individual breathes at all. As we become more and more a

manufacturing nation and chemistry continues to pollute the air of the cities, they will grow progressively more and more unfit for human beings to inhabit. There are urgent reasons, other than atom and hydrogen bombs, why we should inaugurate an immediate program of decentralization designed to ultimately do away with all cities.

The body's need for oxygen is constant, hence it is not possible to stop breathing for more than a very brief time. It is impossible to hold the breath for more than a minute or so. If the breath is forcibly cut off for a longer period than this death, death from lack of oxygen quickly occurs. It is estimated that approximately eighty-five percent of the oxygen we need is derived from the air we breathe, ten percent from water and five percent is taken in from the air through the skin. Dr. Tilden held that we get some oxygen from the foods we eat, perhaps from the water in these. There are reasons to doubt that we breathe with the skin. I question that we extract oxygen from water.

Other than an adequate supply of fresh air, the essential of good breathing is an adequate respiratory mechanism; sound lungs, a chest of sufficient size to house lungs large enough to deliver sufficient oxygen to the blood, normal chest movements in breathing and normal passages from the nose to the lungs. If the chest is too small it is not only out of harmony with the rest of the body, hence ugly, but it fails to meet the functional needs of the organism. If we begin early enough and persist in our efforts the chest may be developed in almost everybody to the required size.

The motility of the chest is often only slight, due in most instances, to a lack of use. The motility of the chest may be determined by measuring its expansion. In measuring chest expansion it is common to place the tape just beneath the arms. A truer measure of chest expansion may be obtained by applying the tape over the lower ribs, just beneath the breasts. The chest should be fully contracted and then expanded to its limit. The difference between the two measurements thus obtained gives us the chest expansion. This does not always measure chest capacity, as much of this depends upon the action of the diaphragm.

Air does not require to be forced into the lungs; it has to be forced out. When the chest expands, a vacuum is created and the air automatically flows into this. Normally the activities of the chest in breathing—inspiration and expiration—are automatically adjusted to the needs of the body; these activities increasing when more oxygen is needed or there is more carbon dioxide to expel, and decreasing when there is decreased need for oxygen or decreased production of carbon dioxide. Many things do, however, lower the functioning power of the respiratory system and cause use to function on a lower physiological level.

Impaired respiratory function reduces the amount of oxygen that is taken into the blood and that is carried to the tissues (anoxia) and the amount of oxygen in the blood (anoxemia). Some of the inhibiting factors are external and are supplied by the individual himself; others are internal and are commonly of the individual's own making. Let us briefly consider these in order.

Cramped positions of sitting and standing that prevent the normal excursions of the chest and diaphragm, tight belts, corsets, foundation garments and other articles of apparel, that constrict of the chest and abdomen and prevent normal chest and diaphragmatic movements, hamper the intake of sufficient oxygen to meet the needs of the organism. Under such conditions, the body is forced to reduce its other functions to a level commensurate with the support provided by the respiratory system. Instead of vigorous function, feeble function is our lot.

Nasal obstructions (adenoids, nasal polyps, thickened nasal membranes, catarrh, bent or broken septum, traumatic and congenital distortion of the nose, small nasal passages, etc.), spasm of the bronchi (as in asthma) tumors that block the respiratory passages, pleurisy, adhesions, tuberculosis of the lungs, water in the lungs, as in advanced heart disease, pneumonia, a cold, smallness and deformities of the chest limit the amount of air that may be taken in at each respiration and the amount of carbon dioxide that can be expelled at each expiration.

Free nasal passages are not only essential to the ingress of adequate oxygen, but also to the normal

conditioning of the inspired air for its entrance into the lungs. The air must be warmed or cooled, moistened or dried, as the case may be, in its passage from the outside to the lungs. If the nasal membrane is swollen and congested, for example, it will not only hinder the intake of air, but it will fail to properly condition the air. Dust and dirt must be filtered from the air, as it passes into the air passages and down to the lungs. This fails if the nose is not normal. Thus it becomes apparent that a well-formed, efficiently functioning and fully healthy nose is as necessary to good breathing as a well-developed chest and sound lungs. If the respiratory mechanism is normal, if the air is pure, if there are no external and positional interferences with the mechanism of breathing, this function will be automatically and subconsciously adjusted to the varying needs of the body for oxygen, so that conscious attention to the process is unnecessary.

### 1. Solar Energy

#### 1.1 What Is Solar Power?

The sun is expected to emit radiant energy for another four billion years, the only perpetually renewable energy source for our planet. Obviously, it is time to learn how to use the massive amounts of energy the sun gives us each day. Three processes by which the sun's radiation can be used are *heliochemical* (photosynthesis, photography), *helioelectrical* (manmade devices that convert solar radiation into electricity), and *heliothermal* (devices that absorb solar radiation on blackened surfaces and convert it to heat).

All energy on earth originally came from the sun. All of our hydrocarbon fuels such as coal, oil, and natural gas were originally produced by the action of sunlight on vegetation.

Light is a form of electromagnetic energy. Energy is the capacity to do work, and power is the rate at which energy is generated or used (measured in watts or kilowatts). The amount of power we can get from any solar device depends on the amount of sunlight it intercepts and on the efficiency of the energy conversion device. Solar energy intercepted by an area the size of a small tennis court would supply the energy needs of an average household. The radiant energy in sunlight must be converted into some form of energy that is easier to use, such as electricity—the solar cell is just such a device.

The photovoltaic effect, where electricity is produced when certain materials are illuminated, was first noted in 1839, and the photovoltaic effect, where electricity is produced when certain materials are illuminated, was first noted in 1839, and the photovoltaic cell is probably the first solid-state electronic device ever invented. Its use has been slow because of the abundance of hydrocarbon fuels like coal, oil, and natural gas. Photovoltaics were first used in selenium cells to measure light levels (as with the light meter used in photography). The space program uses photovoltaic cells because conventional batteries will run down, but solar cells will continue to deliver electric power as long as sunlight is available.

## 1.2 Advantages of Using Solar Power

The basic reason for using solar energy is that it is a renewable, limitless energy source that promises freedom from dependency on nonrenewable energy sources, thus freeing humankind from the threat of war over dwindling natural resources.

Solar power is clean, nonpolluting, and safe. Once the basic systems are installed, the sun is free; and since power is produced locally, on the spot where it is to be used, transportation of fuels and distribution of power aren't necessary. Solar electricity can be brought to remote locations that are too far away for bringing power lines, for example. Solar research can be carried out in small laboratories with inexpensive equipment.

Solar energy usage will create jobs—about four times as many as nuclear power. It is labor-intensive, that is, about half the money that goes to building a solar space or water-heating system goes to paying the wages of the people building or installing it. A solar-based economy would put more people to work than a fossil/nuclear one. (It also employs people from a wider range of abilities, whereas nuclear power plants, aside from preliminary construction workers, use mostly professionals. Most jobs at nuclear plants will be for security personnel.) Solar power is community-based, but nuclear power is centralized and monopolized by certain monied interests. Tax credits can be received for certain home-improvement and energy conservation installations.

## 1.3 History of Solar Power

The concepts behind solar energy use are not new, by any means. Legend has it that in 212 B.C. Archimedes set fire to an attacking Roman fleet by turning a "burning glass" composed of small, hinged square mirrors so as to reflect concentrated sunlight onto the ships. For years scientists argued about whether this was myth or fact, but in 1747 a Frenchman proved that it could have been done by burning wood from a distance of 200 feet with an array of 168 small flat mirrors, and then melted lead at 130 feet and silver at 60 feet. In the same century, an optician in France built polished iron solar furnaces that could smelt iron, copper, and other metals. Another inventor used two lenses to achieve a temperature close to 1750° Fahrenheit—far beyond any temperature attained by man up to this time.

In the 1800s came many models of solar-powered engines and solar steam engines. In 1871, a solar still in Chile provided 6,000 gallons of pure water a day for forty years. In 1880, a solar engine was built in France that ran a printing press.

Of course, foods have been sun-dried for ages, using solar power *without* the need for technology. In the early 1900s, solar ovens appeared.

Solar water heaters were known in southern California and other states in the 1920s and 30s. After World War II, solar sciences flourished in Europe and a boom in solar water heaters began in Japan and Israel. Heaters were installed by the 100,000's in Japan.

Here in America, the military picked up interest in solar power. The navy wanted solar battery power supplies for buoys and other installations. The Air Force had small solar-powered radio transceivers for aviators' survival kits. The Army used solar panels to transmit radio signals and put smaller units in helmet radios for soldiers.

These are but a *few* of the many experiments in solar power undertaken through the centuries, and one would need to read a whole book to go into greater depth. The point is, that many inventors have long trusted in the power of the sun, and their greatest obstacle has probably always been the apathetic lack of interest by their fellow men in using the sun's power. In fact, there is an interesting analogy that serves as a parallel to the solar/nuclear industry. When Thomas Edison was first working on his experimental light bulb, the gas company did all it could to discredit this inventor calling his work foolishness. They wanted, of course, to preserve their energy monopoly as gas suppliers to all those gas lamps! When Edison finally perfected his *light bulb*, not only did he change the future of the human race, but he also

showed the gas company who was *foolish*. It is certain that the nuclear power industry would rather have people remain ignorant of solar power and its grand potential for as long as possible. They would rather have people perceive it as "futuristic," when the truth is that much can be done now in solar energy, and its use and history are as *old* as the sun itself.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 2. Nonrenewable Resources

## 2. Nonrenewable Resources

### 2.1 History of Their Use

For centuries before the Industrial Revolution, people relied on the chemical energy of plants and animals and the natural forces of wind and water to provide the necessities of life. As more efficient ways were discovered to use these energy sources, changes took place in the way people lived. After the 18th century when power devices were found that could convert steam and, later, fossil fuel into work, energy consumption grew and people underwent rapid social changes. There were switches from wood to coal and from whale oil to petroleum. Then came the internal combustion engine; electricity; steam, gas, and water turbines for generating power; and then the nuclear age.

The trend has been away from *dispersed* natural forces available for large numbers of people to *limited reservoirs* of intensive chemical energy (fossil fuels) controlled by a few corporations. People have become more dependent, in that they've lost more control over their energy resources.

On a global scale, there are two main patterns of energy consumption:

1. About 80% of the world's energy comes from fossil fuels, about 20% from dung and vegetable wastes, and about 1% from water power (mostly hydroelectric), and minor amounts from nuclear, solar, geo-thermal, and wind power.
2. About 75% of the world's energy is consumed by a few rich countries representing less than 30% of the world's population. (The U.S. has about 6% of the world's population, yet it uses 35% of the total energy.)

Energy consumption is *encouraged* because it is said to reflect growth, though unemployment often increases despite or because of increased usage. Much money is spent to increase energy production, but there should be more interest in energy *conservation* and use of renewable resources. Nonrenewable resources like fossil fuels are limited and destined to be exhausted. If people make themselves *totally* dependent on dwindling supplies, the threat of war over what's left becomes a horrible specter.

Today many of us in the United States draw on what would be the equivalent of 70 mechanical slaves to "enjoy the good life." The first waterwheels produced about 1/2 horsepower, with later versions producing 70 horsepower. Cars can have several hundred, aircraft engines thousands, and a rocket engine for spacecraft may produce more than 20 million horsepower. Electric power plants generate millions. Much of the world suffers from hunger and malnutrition (70,000,000 people face starvation yearly), so if we and our fellow human beings are to have any quality of life, we should cut down on our energy consumption and look to new sources of *renewable energy for power*.

## 2.2 Disadvantages of Nonrenewable Energy Sources

Aside from the fact that nonrenewable energy sources are in limited supply, the main reason for not using them is the pollution, health, and safety risks involved. Some say there are "three environmental time bombs"; toxic chemical pollution, carbon dioxide (CO<sub>2</sub>) buildup, and acid rain.

The buildup of CO<sub>2</sub> in the earth's atmosphere is often referred to as "the greenhouse effect." By burning fossil fuels and cutting down forests, people have caused an increase of carbon dioxide in the atmosphere, which can cause temperatures to rise on a world level. A few degrees difference may not seem important, but on a world scale it can have a dramatic effect. (Some say there would be increased melting of polar ice caps, for one thing.)

As coal, oil, and natural gas are burned worldwide, smokestacks of electricity—generating plants, industrial boilers and smelters release sulfur dioxide (SO<sub>2</sub>) and nitrogen oxides. Nitrogen oxides also come out of auto exhaust pipes and slowly escape from chemical fertilizers. These emissions have resulted in "acid rain" which damages vegetation and wildlife and can corrode metals. Fish are being destroyed in sensitive areas, and acidifying soils can result in increased leaching of some trace elements, a slowdown of the organisms that break down the contents on the forest floor, and reduced organic nitrogen. For decades, acid rain has eaten into structures like steel bridges and statues. Not only is acid rain destructive, but winds carry the emissions from factories and exhausts into other countries as well. There are no boundaries for air pollution. Some beautiful areas in Scandinavia are getting acid rain from Europe's industrial belt and in some lakes, fish have been virtually eliminated. Canada gets its share of America's acid rain. In an unprecedented lawsuit in 1981, Maine Attorney General, James Tierney, said he was considering suing the federal government and other states because of drifting air pollution that caused acid rain. He wanted laws concerning sulfur dioxide emissions strengthened, and states with weak laws held liable.

No one yet knows for sure what acid rain might do to *humans*. Dry, airborne pollutants are largely associated with respiratory diseases. One estimate in 1975 suggested that "acid sulphates from fossil fuel emissions are responsible for 7,500 to 12,000 deaths a year." This can't be proved, of course, since so many factors influence peoples' health that one particular cause of death is always difficult to pinpoint, (as in cases of radiation exposure).

## 2.3 Water Pollution

Forty-three percent of America's community drinking water systems are reporting violations of federal health standards. In addition, 13,600 of the nation's 65,000 systems have inadequate treatment facilities. People often aren't aware of any dangers in their water. In 1980, of 146,000 violations recorded, public notice was made in 16,000 cases. In 1981, New Hampshire officials warned 14 communities that traces of arsenic had been detected in their public water supplies. Virtually every stream, river, and lake in the country is polluted. There is runoff from fertilizers and insecticides, industrial waste, and thermal pollution in overheated waters. (Nuclear power plants produce more thermal pollution than conventional steam electric plants.) In New Orleans, 112 different chemicals were found in a sample of drinking water, and the rate of cancer is going up. At least 40% of the population is using water that has been used at least once before for domestic or industrial purposes, sometimes as many as five times by other people.

Some chemical substances interact with one another in water to form entirely new, often dangerous, chemicals. Chlorine can react with decomposing leaves and become chloroform. Chlorine has been accused of causing cancer, yet most of the "drinking" water in America is now chlorinated, fluoridated, and so on.

## 2.4 More Environmental Pollution

In 1970, a study showed that 200,000 children in the U.S. had overly toxic levels of lead in their

bloodstream. A more recent article stated that this number is more like 600,000. These figures don't include adults, and most people aren't even tested for lead in their bloodstream anyway. Auto exhausts and industry are putting this lead into the environment.

According to a study by the National Wildlife Federation (the country's largest nongovernmental conservation group), most of the environmental indicators of the "quality of life" show deterioration. Supposedly, 90% of all major U.S. factories now comply with pollution laws, but the report said most Americans live in areas where it is still unsafe to breathe. Land is unwisely used, soil erodes and gets poisoned, water is wasted and polluted (with over 70,000 chemicals in current commercial use, runoff can bring many to waterways), and the endangered species list has more than doubled. All these gloomy changes reflect our choice of energy consumption, and much waste and greed.

## 2.5 Nonrenewable Energy Used In the Home

With today's increased interest in good insulation, one must be extremely cautious in providing *adequate ventilation* since fumes, gases, and other toxic vapors are the byproduct of nonrenewable energy use. (This is the advantage *solar power* has over fossil fuels—it is *clean* and *safe*.) If you're using "traditional" energy sources, you must be aware that in insulating to retain heat, you may also be retaining such things as radioactive radon and its decay products or formaldehyde escaping from some types of insulation (a popular new insulation is urea formaldehyde—beware). For insulation one *can* use vermiculite, perlite, and expanded silicate—inert minerals that don't release fumes. You may be retaining formaldehyde fumes from particle board, hydrocarbons from gas stoves, and petrochemicals from paints to cleaning fluids. Soft coal fires put benzopyrene (another carcinogen) into the air. At only one part per two million, formaldehyde can cause swelling of mucous membranes. Higher levels can result in coughing, chest pains, headaches, cold- and flu-like symptoms, eye and nose irritations, bloody noses, scratchy throat, nausea, and possibly cancer. Recently, some investigations were made into complaints from people in new, well-insulated mobile homes where formaldehyde gas was detected.

Many people didn't link symptoms, which are so often associated with other "common illnesses, to anything serious so it took awhile for *any* connection to be made to formaldehyde. Often the most common building materials—concrete, brick, stone, and adobe—contain trace amounts of radium and uranium. These levels, are measurable with equipment similar to a geiger counter. As insulation to a home increases and drafts and ventilation decrease, more radon is retained at higher levels. Normally, when fresh air seeps into a house, the air is completely exchanged in one hour, but heavy insulation can reduce this air exchange to once every five hours. Some heavily-insulated homes have been measured with an annual dose exceeding permissible levels for uranium mines. The Environmental Protection Agency examined the radon issue and concluded that 10,000 lung cancers diagnosed yearly could be caused by this radioactive gas, and warned that deaths could double or triple with increased heavy insulation. Ventilation with fresh air is *necessary*.

Gas appliances, stoves, and heaters are another source of indoor air pollution. Natural gas is one of many petrochemical agents capable of creating symptoms like arthritis, depression, water retention, and abdominal distention in *even the best-ventilated homes*. (Here, one must realize that one should not inhale a toxic fume—indoors or outdoors—because toxic is toxic, so ventilation isn't really relevant here. If one does use gas though, one should of course still ventilate as much as possible.) With gas stoves, emissions from combustion are exhausted *directly* into the air. Such an oversight would never be allowed with any other burning material, because we know that the products of combustion are hazardous to inhale. The two major pollutants produced by combustion are carbon monoxide and nitrogen dioxide. Carbon monoxide displaces oxygen in our blood's hemoglobin, and can cause headaches, exhaustion and asphyxiation. Nitrogen dioxide is a byproduct of high-temperature combustion, and studies have shown that levels may be five times greater indoors than outdoors, especially in major cities. One investigation found that operating a gas oven at 350 degrees for one hour, with little ventilation, resulted in excessive levels of carbon monoxide in the house. Excessive amounts

were also found with moderate ventilation, but levels did decrease when speed of ventilating fans was increased. The health hazards of cooking with natural gas are mostly respiratory in nature, and some studies showed a statistically significant difference in lung capacity between children living in homes with gas stoves and those with electric ranges. Another study showed that twice as many residents with gas reported chronic coughing, and three times as many had impaired lung function. (Fortunately, those of us on *raw food diets* need not be burdened with these worries but not everyone is so fortunate.)

Kerosene heaters, sold by the millions the last five years, give off substantial amounts of carbon monoxide, nitrogen dioxide, carbon dioxide, and sulfur dioxide. These emissions are said to be especially dangerous to pregnant women and their fetuses, babies, and persons with respiratory problems, anemia, angina pectoris, or a heart condition. Any unvented heaters are obviously sending combustion byproducts right into the room just like a gas stove. (Some heaters also present fire hazards if improperly used.)

Lignite is a low-grade coal that poses several health problems. Uranium in the material above lignite deposits could cause both pollution *and* health danger when disturbed. Those operating a lignite plant are working close to known carcinogens, and emissions from the plant include sulfur oxides, which combine with moisture in the air and produce sulfurous acid, sulfuric acid, and ammonium sulfate which can corrode buildings, damage vegetation, and cause respiratory ailments. Much carbon dioxide is formed and released, and it combines with water to form acid rain. Lignite has been presented in some areas as an alternative to nuclear power, but people living near lignite plants would absorb about five to six times as many milli-rems of radiation as the "accepted maximum dosage allowed" for areas around nuclear power plants. When lignite burns, radioactive isotopes are released. Nearby water risks contamination and depletion because vast amounts of water are used at all stages from mining to burning and sludge disposal.

We can see why it will be a welcome relief to make the switch to a cleaner, safer energy source that doesn't result in so many complications and compromises! Yet the negative side-effects of all these nonrenewable energy sources pale in comparison with the problems encountered with nuclear power.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 3. Nuclear Power

## **3. Nuclear Power**

### **3.1 The Politics of Energy**

In 1981, there were 78 nuclear power plants operating or under construction, with 16 more on order. Outside the U.S., there were 182 operating reactor units with another 138 under construction.

One of the first things to remember in dealing with the politics of nuclear power is that using nuclear power to solve the energy crisis seems perfectly normal to the select few who will profit from it and perhaps not be affected by its dangers. This "privileged elite" must convince the workers who labor that a common good will come of it all, although the elite will keep control over the largest portion of the resulting wealth. It has been this way since the beginning of time. Near the top we find people at the next layer of power—the professionals. These are our educated. Intellectuals are usually glad to compromise ethics for the generous compensation given out by those at the top. (We might note that doctors fit into this category, as do many scientists, engineers, corporate executives, and so on.) There is always a "professional" ready to tell you why nuclear power is safe and desirable, just as the surgeon will insist that his surgery is safe and necessary. When "studies" show that "all is well," one might do well to note that many a drug has "passed inspection" and many pesticides have "been approved" all

because of "studies." It is suspiciously easy to find scientists who will come up with just about any result desired by commercial interests.

There were biologists in laboratories funded for 20 years at \$50 to \$90 million per year to study the biological hazards of ionizing radiation, but *little* has been said on the possibility of death (which is certainly a "biological hazard"). But because cancer can begin for a variety of reasons, it is conveniently impossible to prove that a particular cancer or death was caused by radiation. This protects private and governmental polluters, because who can *prove* they have caused even *one* cancer?

It is certain that ionizing radiation can induce cancer in humans, and it can also be mutagenic—mutation-causing. It's hard to know what damage has already been done to future generations by the continued casual dumping of pollutants into the biosphere by "advanced" nations. Would we be as willing to accept nuclear power if we had to *name* 100 or 1,000 or 100,000 people each year to be executed by a firing squad in exchange for electricity? How different is it to give the go-ahead for nuclear power, when the same odds are at stake, and victims are like guinea pigs in an experiment?

Nuclear power appeals to the privileged elites that control all societies, because it is a centralized system, not a do-it-yourself technology like solar power—it allows them better financial control. Power is being centralized in other areas such as the auto industry, food growing/distributing functions, and so on. The energy source that best meets the need of the elite is that which guarantees *dependence* on a central source. (You'd probably see that *centralized* solar electric systems would be the first strongly promoted types of solar energy if the energy companies become involved.)

Although nuclear power is being pushed with a fervor, it is becoming outrageously expensive and many power plants are plagued with cost overruns, because the costs of the nuclear industry are rapidly escalating.

There is another, more subtle side to the financial coin with regards to the politics of energy known as "economic blackmail." People are taking whatever jobs are available because of their basic survival instinct. So, if a scientist does speak out, he may say something like "a solution for *managing* radioactive poisons will be found" instead of "radioactive poisons are hazardous to your health" (or "run for the hills!"). In fact, some have even gone so far as to say "don't worry if you get cancer—they're working on finding a 'cure' now!" Not very reassuring.

Use of nuclear power violates our most basic law, not to kill, because it implies premeditated random murder, committed by all the nuclear power plants. (In 1978, *Honicker vs. Hendrie*, a lawsuit challenging the "right" of the Nuclear Regulatory Commission to commit premeditated random murder by licensing nuclear power plants, was filed.) We will discuss how nuclear power plants cause deaths and genetic damage in the population later.

Long ago the government teamed up with industry to perpetuate a fraud about the safety of nuclear power—one source likened this fraud to "making Watergate seem like a kindergarten picnic."

Whatever happened to our inalienable constitutional rights to *life*, liberty, and the pursuit of happiness? Nuclear power will commit crimes against innocent victims, now and in the future. We seem to have forgotten that these future people will be more *highly-evolved* human beings. It is quite unlikely that they would choose to be poisoned if they had the chance to decide for *themselves*!

We are becoming involuntary human subjects, being experimented on daily by chemical compounds in the atmosphere. Remember that in the mid-50s, the toxicity of low-dose radiation was "uncertain," so bombs were tested in our own country. Now people with cancer that lived near test sites and were told they were "safe" are suing the government. We are becoming more and more aware of the dangers of radiation. The crime goes from "experiment" to murder, and if this permission for random murder is *granted*, people risk loss of freedom, justice, and their lives.

It is ironic that when antinuclear activists are arrested at demonstrations, some people just see them as "protesters," when here they are trying to wake up a slumbering public, and save the lives of this

generation and of generations not yet born—definitely humanitarian motives.

Up to 1969, the Atomic Energy Commission (AEC) and nuclear industries promoted the idea that radiation would do no harm to humans below a certain level. Since it is now known that there is *no* safe dose, the so-called "safe" standards for public exposure could have caused 32,000 extra cancer deaths per year (and that's assuming the public wasn't exposed to *more* than the "safe" limit). Chances are the exposure was, and is, higher. The genetic consequences after several generations could be between 100,000 and 1,000,000 extra deaths a year. The AEC and nuclear industry tried to ridicule and deny these statistics, but after a two-year study, a committee of the National Academy of Sciences *agreed* that there was no safe dose of radiation, though their estimate of the number of deaths was lower. Nevertheless, their estimates did admit to many thousands of deaths. (The official recognized statistic of the nuclear power industry is 0-3 possible cancers a year.)

When pressured further, the AEC and nuclear industry, instead of *lowering* the allowed radiation dose, then said that they "don't intend to *give* anyone the dose permitted by regulations anyway. "That's not very helpful when we can see from the history of pollution of any sort that polluters always pollute as much, or *more*, than is legal. When an industry doesn't want to *lower* a poison's legal limit, it is because it plans to give *at least* the presently permitted dose. Doses that exceed the "permitted" level because of some unforeseeable accident *will not count* because they fall into the category of "unplanned" or "abnormal" circumstances. So, whatever dose we get will be "O.K." as long as it's unplanned!

Often the nuclear power promoters will remind us that we're exposed to "natural" radiation from the earth. Perhaps so, but we can't very well move from the plant. That source of radiation is bad enough without that imposed by the nuclear power industry. They also say that there won't be more radiation than say, our X rays might give us; here, beware, for X rays are harmful since there's no safe dose of radiation.

We can already see how complex nuclear power is, but this is just scraping the surface. Let's see what else happens before, during and after nuclear power production.

### **3.2 The Dangers of Nuclear Power Problems BEFORE We Get to the Plant**

When uranium is mined, two highly carcinogenic and radioactive substances are released: radium and radon. Radium, an alpha-emitter with a half life of 1,600 years, is a decay product of uranium which is found in uranium ore. Its particles of dust from uranium mines are swallowed, the radium is absorbed by the intestine and can cause cancer. Radon, a gas, can cause lung cancer if inhaled. Before the dangers of radon were known, 20% of all uranium miners in the United States died of lung cancer and a similar percentage was found among German and Canadian uranium miners.

After the ore is mined, it's ground, crushed, and chemically treated to extract the purified element. The waste ore, called tailings, is discarded outside the mill and left lying on the ground in huge mounds. To fuel a *single* power plant for a year can create a half a *billion* pounds of tailings. These tailings contain thorium (half-life of 76,000 years) and radium. If the radium is exposed to the air, it will give off radon gas for as long as 800,000 years. This radon gas is killing people *now* and can do so for at least the next billion years.

Until recently, hundreds of acres of tailings lay on the ground in Grand Junction, Colorado. In the mid-60s, tailings were used around town for cheap landfill and concrete mix, and this went into schools, hospitals, private homes, roads, an airport, and a shopping mall. In 1970, a local doctor noticed an increase of cleft palate, cleft lip, and other congenital defects among newborn babies in the area. Further investigation showed that parents of these children lived in houses built with tailings, and when tested, many of these buildings showed very high radiation levels. Soon after this, some people at the University of Colorado got funds from the former Environmental Protection Agency to study the correlation between low-level radiation and a rise in birth defects—a year later funds were cut off and they were told the government had to cut back on many programs for "budgetary reasons."

Next, uranium ore must be "enriched" so that its Uranium-235 content makes up 3% of its bulk, since only 0.7% of the uranium found in its natural state is of the U-235 variety. This process is extremely expensive and uses vast amounts of energy. It leaves radioactive tailings similar to those produced in milling the ore. In the United States, the federal government has to subsidize the enrichment process because it costs so much.

After enrichment, uranium ore is processed into small pellets. A typical 1,000-megawatt reactor has bundles of fuel rods that use 100 tons of uranium. (Workers exposed in making these pellets are susceptible to dangers of gamma radiation emitted from the enriched fuel.) The enriched uranium is now ready to undergo fission, during which hundreds of radioactive isotopes (all carcinogenic and mutagenic) with half-lives ranging from several seconds to 24,400 years are released. Even though symptoms haven't appeared, the doses already received by workers will result in thousands of cancer victims, and this random murder of workers is politely referred to as "health effects" by government regulatory agencies. Fifteen years of records from one of the two hospitals in Durango, Colorado, site of one of the nation's huge exposed radioactive mill tailings piles (a 1.5 million ton pile), show a rate of lung cancer four times the national average. Earlier in 1979, more than 30 radioactive sites were discovered in Denver and elsewhere in Colorado—remnants of the radium industry that flourished at the turn of the century. There are over 4,000 such radioactive sites in this country.

Workers at mines are exposed to higher levels of radioactivity, radon, and toxic materials than the public, and there are even infractions of the official "safe" dosages. Many workers are poorly informed on the dangers of the materials they are working with. Worker turnover is high and no follow-up is done on workers. Some long-range effects of exposure may not show up until years later.

After the uranium is mined, it must be transported to its final destinations. Our nation's highways and railroads are being crossed daily with radioactive materials and workers who handle these shipments are often exposed to radiation. Between 1974 and 1978, there were 328 transport accidents involving radioactive cargo—118 serious enough to release radiation into the environment. (This amounts to about three accidents every two weeks involving shipment of radioactive materials.) Nine out of ten occurred on public highways. (Even planes carrying nuclear weapons have crashed—there are over 30 such accidents on official record, but one source says this may be a fourth of the real number.) Civil defense and fire personnel are ill-equipped to handle nuclear emergencies.

Another problem with nuclear power is the choice of some of the power plant locations. There are quite a few nuclear reactors in geologically unsound areas. The South Texas nuclear plant is being built over the convergence of three earthquake fault lines and is built to withstand 90-mph winds in an area where hurricane winds have been known to greatly exceed that. The Diablo Canyon (California) power plant is three miles from an offshore earthquake fault, and other California plants have been built that are dangerously close to fault systems. Within a 200-mile radius of New Madrid, Missouri (the region hit by powerful quakes in 1811), nine nuclear power plants are situated. In New York state, the Indian Point power station is located within a mile of the Ramapo fault system, and this plant is only about 25 miles north of New York! The industry will say that power plants are designed to withstand earthquakes but in 1979 the Nuclear Regulatory Commission closed five eastern power plants because an error in the computer model used by the engineering company understated the stresses that the piping in the coolant systems of the reactors might have to withstand in the event of an earthquake. (We will discuss meltdowns, which can result with failure of the cooling systems, later.) About a month later, an earthquake struck Bath, Maine, with tremors being felt in a 200-mile radius, which includes three nuclear power plants.

Another problem with nuclear power is that the fuels used can be used to make bombs and are therefore vulnerable to theft, smuggling, and terrorist activity. Approximately two *tons* of weapons-grade enriched uranium and plutonium have already been stolen from nuclear facilities in the United States. These thefts, whether by nations, terrorist groups, or criminal elements will become a standard feature of a nuclear world.

### 3.3 Problems At the Power Plant

Once inside the plant, we can become concerned with the possibility of sabotage of the power plant, i.e., terrorist threats, or blackmail. Then come engineering defects and errors, which have been discovered; the problem of "human error" in the nuclear industry is a big one because the stakes are so high. Next, we have "routine emissions" and leaks such as: a mechanical failure that caused a plant to "burp" radioactive xenon gas into the atmosphere, or radioactive steam that spewed into the air for 27 minutes at another power plant. Hundreds of these "nonserious" accidents are on record over the years, and the space of this lesson does not permit coverage of all the mistakes. Suffice it to say there is a wealth of documented scare stories available.

Perhaps the best known failure was at Three Mile Island, when a series of accidents led to a buildup of pressure in the reactor and the release of radioactive steam into the atmosphere. The atomic core was difficult to cool, radiation leaked, and a hydrogen gas bubble inside the reactor could have become explosive.

Estimates were made that childhood cancers could increase up to 60% in the five years following this accident within a 200-mile radius of the plant. If the worst had happened at Three Mile Island, at least 200 and perhaps up to 23,000 outside a 50-mile radius would have died of cancer.

The biggest danger in nuclear power is the possibility of a meltdown. Whether caused by a defect in design or construction, human error, or sabotage, it could release a reactor's deadly radioactive contents into the atmosphere, killing thousands of people and contaminating an area the size of Pennsylvania. Over the course of the next generation, genetic abnormalities and thyroid cancer would strike untold numbers of additional people.

A meltdown can occur if the coolant water at a reactor's core drops below the level of the fuel rods, which would become so hot that they would melt and then the whole mass of molten uranium would burn through the "container" (the concrete base of the plant) and 1/4 mile into the earth, triggering a tremendous explosion that would blow the containment vessel apart, releasing the radioactive elements into the atmosphere. After the blast thousands die immediately. More would die within two to three weeks of acute radiation illness. Food, water, and air would be so grossly contaminated that in five years there would be widespread leukemia, followed 15-40 years later by an upsurge in cancers. The genetic deformities that might appear in future generations are inconceivable.

The potential enormity of such a meltdown cannot be exaggerated. The Union of Concerned Scientists conducted a two-year study that projected 15,000 people could die of radiation-induced cancer from minor reactor accidents by the year 2000. In the same period, there's a 1% chance that a major nuclear accident will occur, killing nearly 100,000 people. There have already been some close calls.

We still haven't mentioned the "routine" exposure to radiation of nuclear power plant workers themselves. As with uranium miners, they are often not informed specifically of the dangers of radiation, only told in *general* terms that it can be dangerous. Workers wear badges that monitor the level of exposure to radiation, but this device registers only gamma radiation and disregards alpha and beta emissions, which can be swallowed or inhaled. Workers are permitted to receive 30 times as much radiation as the limit set for the general public. The nuclear industry keeps records of no more than five years after an employee leaves the job. This is obviously ineffective in pinpointing slower developing cancers or in spotting cancer in the *offspring* of victims. Unskilled or migrant laborers are often hired for high wages in areas of intense radiation. After they receive their six-month allowable dose at one facility (sometimes in only *one day*) they may be hired on at another power plant without ever being questioned about their previous radiation exposure. (When a pipe broke at the Indian Point plant and it was rendered inoperable for six months, 1,300 certified welders—almost every certified welder in the New York area—were needed to repair the damage. This is because within a few minutes, each worker would receive the dose of radiation "allowable" in a six-month period.)

Last year, statistics on 68 operating plants showed that their work forces were exposed to 35% more

radiation in 1980 than in 1979 even though there was only one new plant. The doses these workers get can provoke genetic injury; with intermarriage with nonworkers, some genetic degradation of the population-at-large can result.

Studies have also shown increased cancer in areas around nuclear power plants. A nuclear power plant must release radiation into the environment in order to do its job. Low-level radiation, the alpha particles get carried away on dust or pollen by wind or water.

Every *independent* study in this country in the last 20 years (i.e., studies not conducted by the nuclear power industry) has shown that current standards of radiation are too high. Workers and the public have been deceived concerning "permissible" or "tolerable" doses of radiation. There will be injuries in proportion to the *accumulated* dose of radiation, down to the lowest doses, although radiation effects may not show up for as long as 30 years. (Remember, however, if genetic damage occurs, it is *immediate*.) Still, the nuclear power industry continues to claim that "no one's been harmed by radiation."

Radiation is insidious because it cannot be detected by the senses. We are not biologically equipped to feel its powers, or see, hear, touch, or smell it. Radiation harms us by ionizing—that is, altering the electrical charge of the atoms and molecules comprising our body cells. Of all creatures on earth, human beings are one of the most susceptible to the carcinogenic effects of radiation. There is also one flower that is very sensitive to small amounts of radiation, called the *Tradescantia* or spiderwort. Down to 250 to 300 millirems of radiation can change the genetic character of this plant so that it changes color—the stamen changes color—so they have planted them around nuclear power plants in Japan.

Within every cell there is thought to be a regulatory gene that controls the cell's rate of division. If our bodies are irradiated or we inhale a particle of radioactive matter into our lungs, this radiation can chemically damage a regulatory cell. It may continue to function normally, but one day, five to forty years later, instead of dividing to produce two new cells, it goes berserk and manufactures billions of identically-damaged cells. This type of growth is called cancer. Cancer cells can break from the main mass of the growth, or tumor, and enter the blood or lymph vessels, travel to other organs, and divide again uncontrollably to form new tumors. These cells are more aggressive than normal body cells. This is why there is no safe dosage of radiation—it takes only one radioactive atom, one cell, and one gene to initiate a cancer or mutation cycle.

In considering all these facts on radiation, we should remember one important fact, that all the nuclear industries are relatively *young*. Nuclear power has only been in commercial production in the United States for 25 years, and arms production for 35. Since the latency period of cancer is five to forty years and genetic mutations may not manifest themselves for *generations*, we can see that we have barely begun to experience the effects radiation can have upon us. (Madame Curie, who is known for her work with uranium, died later, not having known in time the dangers of the substance she worked with.)

The moment a plant begins operation, injury to humans, is guaranteed. Nuclides are released during so-called "normal" operations. Because the "regulatory" processes do not want to protect the public and licenses continue to be granted, it is clear that we cannot count on protection against victimization through the regulatory process. Even the Environmental Protection Agency said in 1975 that nuclear power will kill hundreds of people yearly even if everything goes perfectly. (This, again, is an underestimation of victims.) The Nuclear Regulatory Commission did admit in 1978 what others had already said, that there was no safe dose of ionizing radiation, and no "threshold."

In the meantime, we are injured in the form of mental anguish. People have already undergone a certain amount of "psychic numbing" by the shadow of potential nuclear war hanging over their heads, in which continual stress has caused them to try to "blank out" the fears. Most humans don't want electricity at the cost of death or injury to themselves or their fellow people.

Because uranium resources could be depleted at the turn of the century, the nuclear industry wants *breeder reactors* to ensure a future for nuclear power. These reactors are expensive, dangerous, and

would require production and shipping of plutonium—a poisonous, carcinogenic material used in hydrogen bombs. The breeders would use up the wastes of the first generation of nuclear reactors and "breed" their own future fuel supplies by creating even more plutonium over time. Whether fueled by plutonium or thorium U-233, these substances will be produced and handled by the *thousands of tons*. These two substances are in the class of alpha-emitters, providing the same radiation as has claimed the lives of uranium miners by lung cancer. Plutonium is so toxic that current occupational limits allow a worker to inhale no more than 0.2 of a *millionth* of a gram over his lifetime (one must, of course, be suspicious of *any* "safe" dose).

Plutonium and uranium are the stuff from which atomic bombs are fabricated, and as we mentioned before, several tons can't be accounted for by the processors already.

Errors plague the production of breeders just as with the regular light water reactors—in the extreme, a breeder reactor can suffer a runaway nuclear reaction and conceivably blow itself apart. ("It could make Three Mile Island look like a tea party," said Thomas Cochran of the Natural Resources Defense Council.)

One-half pound of plutonium trapped in human lungs could cause billions of lung cancers. Yet there are waste sites of plutonium with leaking rusty barrels, and there have been plutonium spills, and it has been tracked around by workers, accidentally found on the ground and elsewhere in plants handling plutonium, and so forth. At one point, planes were carrying plutonium oxide into Kennedy airport until these flights were stopped, after some calculations figured that a crash causing plutonium dispersal could have killed the 8,000,000 residents of New York City at the time! Plutonium in the earth, under its mantle, doesn't pose a threat—it's the airborne plutonium that creates the inhalation hazard.

Let's stop a moment and see what *responsibility* the nuclear industry has taken to ensure our safety. The Price-Anderson Act was passed in the 1950s to *absolve* America's power companies of major responsibility in the event of a nuclear disaster. Without such a bill, the nuclear industry would have never gotten off the ground. (If insurance companies were willing to cover the risk, the premium required to ensure a nuclear power plant yearly could be roughly equivalent to the entire yearly costs of plant operation and maintenance.)

In cases of extreme nuclear accidents, we might also do well to question how quickly and effectively evacuations would take place. How would a city like New York be evacuated within hours?

If we have managed to make it through the production and power plant operation phases, we come to the final problem posed by the use of nuclear power: nuclear *waste*.

### **3.4 Problems After the Plant—Nuclear Waste**

It may be noted that much ado is made about waste disposal, sometimes to divert peoples' attention from the fact that even without the waste, the reactors are killing people now. It's easier to promise people safety and "99.9% containment," and then catch them up in the emotions of the waste dumping issue than to admit this fact. This is not to say, of course, that waste disposal isn't also crucial. The entire cycle of nuclear power is serious.

What exactly is the cause for concern with nuclear waste? The General Accounting Office of Congress has said that by the end of the century there could be one-*billion* cubic feet of nuclear waste in the United States—enough to cover a four-lane highway coast to coast a foot deep.

The operation of nuclear reactors generates astronomical quantities of radioactive garbage of several types, the amount of radioactivity generated being in direct proportion to the amount of electricity produced. In one year a 1,000-megawatt nuclear power plant generates fission products (like Strontium-90 and Cesium-137) in a quantity equal to what is produced by the explosion of 23 megatons of nuclear fission bombs—or more than 1,000 bombs of the Hiroshima size! (Remember, the industry wants 300 or 400 such plants in the U.S.A. alone by the year 2000.) This means that every year we would generate the

Strontium-90 and Cesium-137 garbage equivalent to a *full-scale nuclear war*, year after year until fuel runs out. If breeders are developed, we could have 1,000 to 2,000 plants, because they solve their own fuel shortage problem.

This is one of the few facts *not* disputed by the experts, how much waste would be produced—because waste is waste and its amount is determined by the law of physics. However, it cannot be destroyed—it must be *stored*. It carries the risk of cancer and genetic damage and must therefore be isolated. If released into the environment, it will contaminate land and water. Do we have a moral right to unload these poisons on future generations when it is obvious we *ourselves* do not know what to do with them?

Even after 1,000 years the waste will still remain dangerous isotopes. Plutonium takes about a quarter-of-a-million years, or more, to decay to relatively "safe" levels (and of course this "safe" is doubtful when agreement can't even be reached on what *is* "safe").

Remember that the Bering Strait was dry land 12,000 years ago. So if we're talking about plutonium and 250,000 years, we're dealing with a time period during which volcanos, earthquakes, changes in the continental plates a themselves, meteors, or who knows what else can shape or reshape our physical world. We're talking about *hundreds* of generations of humans into the future. We cannot even conceive of all the possible changes in their environment or evolution, and this is our legacy to them?

No one can honestly say that all that waste can be safely contained for such lengths of time. Who will be keeping watch all those years? Even languages change over time. What manmade storage containers can last all that time? There have already been numerous leaks at waste storage facilities and toxic waste dumps.

No matter how much waste is produced, it is the incredible *toxicity* of the waste that concerns us. Strontium-90 takes 300-600 years to decay to a relatively "safe" level. If ingested, it can lodge permanently in the bones, replacing calcium. Cesium-137 lasts about the same time, and seeks out the reproductive system. (Remember, the half-life is not the *length* of time which a radioactive material is dangerous—it may be dangerous for five to twenty half-lives.) Iodine-129 has a half-life of 17 million years. This concentrates easily in the food chain and in the thyroid gland. Some fission products are gases, generally even harder to contain than other forms of radioactive materials. Remember that the reactor vessel construction materials are also irradiated for the operating life of the reactor. As a result, a reactor can't be approached without special shielding for 1 1/2 million years, *much longer than the lifetime of any manmade structure!*

Who wants to store nuclear waste in their back yard? There are constant battles by citizens for their rights. There have already been numerous scandals, such as a company in Florida illegally dumping hazardous radioactive waste into an open dumpster, and, in another state, putting it illegally into a public dump. Soil and ditches have been found to be contaminated, and the U.S. has been dumping wastes off-shore around the country.

Leaking barrels in the Pacific Ocean have been photographed with giant mutant sponges clinging to their exteriors. A Texas waste facility located outside of Galveston was found to have barrels leaking deadly plutonium, and they had thousands of barrels over the legal 2,000-barrel limit.

We still can't even be sure the waste is being 100% contained on the *way* to these storage sites, and must hope that no transportation accidents occur. Assuming it arrives at the dump, we can ask ourselves how radioactive garbage buried in plastic sacks or rustable barrels in shallow trenches is *contained* or *permanently isolated* from the environment and people. Much waste is now buried that way, although as time goes on, awareness has increased on the importance of good containers (although we don't know if anything for sure resists *all* the ravages of time). In 1978, the Department of Energy asked the public for help in *finding* its buried radioactive wastes—since many records were misplaced or destroyed over the years, the DOE asked that anyone who knew where such work was once done contact them! (The sites were used for nuclear work from the 1940s through the 1960s.)

Some proposals for disposal of nuclear waste have included lowering it into deep geologic repositories

or salt domes, into ice, under the sea, and so on—all of these are subject to possible geologic disturbances. Some scientists have suggested sending it to space (with the hopes that a departing rocket filled with waste does not return to earth by mistake). There have even been some people, devoid of any conscience whatsoever, who have advocated shipping our toxic wastes "abroad," where laws aren't yet as strict, and people might not be as aware of the dangers. (Definitely shaky foreign policy!) The nuclear power industry is plagued with moral problems from beginning to end. (It is interesting to note, by the way, that the American Medical Association, of all people, stoutly *defends* nuclear power. Perhaps they're anxiously awaiting all those radiated customers, who will be begging them for "cures.")

In the face of all this insanity, what does the nuclear power industry do when confronted with delicate issues? Like a good magician, it first attempts to divert attention from what's really happening. If its propaganda and tricks fail to work, however, it simply lies. The history of fraud and deceit in the nuclear power industry is long and full of "silenced concerns" and rigged or suppressed studies.

Usually whenever leaks are *independently* measured, for example, higher contamination is found than in the "official" measurements. It seems the fox is "guarding the chicken coop."

There have been cases where conscientious workers trying to bring violations to attention or inspectors at power plants have been harassed. (Inspectors in Texas reported to the Nuclear Regulatory Commission that they had been threatened by construction workers.)

So, we must involve ourselves now in ridding the world of nuclear power *and* nuclear weapons. It is a matter of survival of the planet. A thirty-minute nuclear exchange could erase all life on earth forever. Helen Caldicott has said "*we are talking about the most important issue facing the human race.*"

According to the Stockholm International Peace Research Institute, the world spent *\$1 million a minute* in 1980 on armaments and other military spending. If this money were spent on solving our energy problems, the world would be saved.

A Hygienic way of life and peace go hand-in-hand. Now let's return to *positive* energy, back to solar power, a ray of hope for mankind.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 4. Solar Systems

## 4. Solar Systems

### 4.1 Active and Passive Systems

An active solar system uses collectors to absorb the sun's heat and needs mechanical components to transfer the heat to a storage system and to circulate it to supply buildings with hot water and space heating. The mechanical parts can be pumps, fans, or other controls.

A passive solar system for heating or cooling doesn't require mechanical devices because the structure itself serves as a collector and storage medium. It relies on design features such as proper building and room orientation towards the sun, large south-facing windows, and insulating shutters and overhangs for summer shading to maximize solar gain in winter and minimize it in summer. Passive solar is best suited for new construction and space heating and cooling.

A solar greenhouse is one of the best passive heating systems for a house. Having numerous south-facing windows helps to heat a house too. Using passive solar heating combined with a solar electric system, and backed up by an active system, is a healthful alternative to using nonrenewable energy sources that create pollution.

## 4.2 Solar Water Heat

A passive solar water heater in one of its simplest forms consists of a tank painted black, mounted on a reflective surface and sealed into an airtight box that has a glazed front that lets the sun's rays in to be absorbed into the black tank (black is the most heat-absorbent of all colors).

A recycled hot water tank can be painted black and used as a collector, resulting in an extremely lowcost solar water heater. The tank is stripped of its outer covering and surrounded by flexible plastic sheeting. The tank is then mounted on 3/4" plywood covered with shiny metal sheets that reflect as much sun onto the tank as possible.

A typical flat-plate solar collector for heating water is made up of the following parts: the *glazing* is usually something like double strength window glass. The *water tubes* used to be made of copper; now usually aluminium or steel are used for economic reasons. The *flat plate* may be any metal (copper, aluminium, steel) that has good thermal conductivity and is reasonable in cost. The metal plate must be coated with a solar radiation-absorbing paint or plating. Flat black paint, properly applied to prevent peeling and cracking, will do a good job for ordinary domestic solar water heaters. The *insulation* may be any low-conductivity material available (usually something like glass wool) that can withstand temperatures up to 200°F. The *casing* holds the solar collector together and, together with the glazing, makes it water- and dust-proof. A simple wooden box, adequately painted and fitted with a hard-board base, will do. When water flows through the collector, it is heated, starting the solar cycle to work in your house.

One of the most widely-used passive designs for water heating is the thermosyphon hot water heater, which combines a flat-plate solar collector and an insulated water storage tank mounted high enough above the collector so that the cold water will go downward (heat rises, cold settles), where it will be heated by the collector and rise into the storage tank. This slow but continuous circulation continues as long as sun shines on the collector. In a good sunny location with no shadows, a 4' x 8' collector will give 40 to 50 gallons of hot water a day.

## 4.3 Solar Heating Systems

A simple and inexpensive air heater can be made with a cover glass (plastic film may also be used), a corrugated plate of sheet steel or aluminium painted black, a space through which the air can flow, a layer of insulation and a Masonite or plywood backing to keep the assembly waterproof. The air can be made to flow by a fan or blower, or, if the system is properly designed, it will rise due to convection (the "chimney effect") because the heated air is lighter than the cold air outside.

Air heaters are less expensive than water heaters used to heat air (not the same as the solar hot water heaters just discussed), because there is no need to worry about freezing, and any leakage which occurs will not cause the kind of damage water can create. The pumps used may be larger, more expensive and more power-consuming than those used with some solar water heating systems, though. Also, the ducts used to carry the air are larger and more costly than the pipes used with water systems. Each type has its advantages and disadvantages.

The simplest of all solar air heaters uses a heavy south-facing concrete wall painted a dark color and covered with a sheet of glass. An air space runs between the concrete and glass, and the chimney effect causes the heated air to rise. Openings at the top and bottom of the wall let cold air enter the air space and warm air to reenter the room. The air then circulates around the room. Small electric baseboard heaters can be used for heat during long periods of bad weather.

Solar space heating may be accomplished in many ways, but one must first estimate how much heat the structure will need during adverse winter conditions and at night. The solar heater must be able to provide not only heat during the sunny days but also have additional capacity for heat *storage*.

The best, method presently available for storing heat ,or cold in large amounts is large *water tanks* filled,

or almost filled, with water. We can store about three times as much warmth as cold, since we cannot use such a large temperature range with cold without running into the complication of freezing the water. The mechanics of storing heat in water are simple and water is available almost everywhere.

Heat can also be stored by means of *rock beds*. These can't freeze or leak, but their capacity is limited. However, they can be safely used under a building since not much can happen to them once they're put in place.

In considering all these options for solar systems, we must remember that the space of a lesson does not permit in-depth construction details—there are hundreds of books on solar technology of all sorts, and one must refer to other sources in order to learn the specifics. There have been many, many experiments made with various building materials, designs, and theories, and there are always several methods available for arriving at the same effect, whether this be heating, cooling, or whatever. An individual must determine what best meets his needs as to what's best for his climate, living structure and finances.

#### **4.4 Solar Cooling Systems**

There is no way to use the heat of the sun *directly* to produce cooling, however, we can use the heat to produce hot water or steam, and with that we can refrigerate, using the process known as *absorption refrigeration*. This was first discovered in 1824, then, about 100 years later, this principle was used for household refrigerators.

Cooling can be achieved with the aid of a humidifier and by controlling the heat radiation of the thermal mass. The thermal mass itself can be used for cooling during the summer by opening the windows and exposing it to the cool evening void. The stored heat is then radiated back to the depths of space. One way to cool a building which is tight and well-insulated is to close it up during the day. This is done with massive adobe houses. Insulated shutters, thermal curtains, or window quilts can help to keep the heat out and the coolness in.

An example of solar cooling is the "Sytherm Systems" developed by Harold Hay. These systems have large water containers on the roof that are cooled at night and keep the building cool during the day. During the winter days, they collect warmth and radiate it into the dwellings at night.

Shade roofs are roofs with extremely large overhangs and will cool a building; they are especially good in the tropics. Placement of windows to allow breezes through a structure is also helpful in cooling a building. Perhaps the very best way to keep a building cool is to build it underground in the layer of the earth that is always naturally cool in the summer.

#### **4.5 Solar Electricity**

About a century ago, a Frenchman, Becquerel, found that sunlight could produce minute amounts of electricity when it entered a very special kind of "wet cell" battery. Later, other workers found that sunlight could change the resistance of certain metals and that very small amounts of electricity would be generated when sunlight illuminated discs of selenium or certain types of copper oxide. These devices were useful as light meters but didn't produce enough power to do anything more than move a pointer on a meter or activate a very sensitive relay. In 1954, a new treatment for ultra-pure silicon was discovered which gave it the property of generating electricity from sunlight with a conversion efficiency of 6%. This was 10 times better than any previous efficiency for the direct conversion of sunlight into electricity, and the invention was immediately applied to a small transistorized radio transmitter and receiver.

In 1957, the space program found a unique application for the silicon solar battery. NASA put silicon cells on its first permanent satellite, and they worked so well that all but one of the satellites orbited since that time have been powered by increasingly complex arrays of silicon solar cells. Communication satellites use tens of thousands of these cells. Each cell alone contributes a small amount of power, but

silicon cell technology has advanced so rapidly that tens of thousands of individual cells can be connected together, rapidly and reliably. Today the communications satellite has become the standard means of intercontinental communication for voice, television, and even computer language.

The cost is still a bit high for installation of great panels of solar cells on every rooftop, but great strides are being made, and the cost has already been reduced from \$1,000 per watt to \$20 per watt with more reductions on the way. Ways of producing less expensive silicon cells are being intensely studied. Some specialists say the cost will come down to \$2 per watt within another decade.

Solar cells come in a wide variety of sizes. There are larger units for supplying large amounts of power, and small photovoltaic devices to supply operating power for devices such as electronic watches, calculators, and flashlights. These small solar devices are called microgenerators, and are actually made up of several extremely small solar cells connected in series.

A solar electric system has no moving parts and usually requires little, if any, maintenance. The two main considerations in the design of any solar electric power system are, first how much sunlight is available at the proposed site and how it varies with the seasons of the year (this tells us the size of the solar electric generator needed to supply any given amount of power), and the second consideration is the characteristics of the load including the average current requirement and the duty cycle (this tells us how much storage battery capacity we will need to keep the system operating when sunlight isn't available).

Solar cells can be used in radio and television, in agriculture (for irrigation, pumping water, charging storage batteries at remote locations, etc.), at construction sites where electricity isn't yet available, in remote areas, for work or recreation, and so on.

Solar arrays should face due south, but "trackers" have been developed, whereby the solar panels are mounted so that they can move, so as to remain pointed in the correct direction at all times for maximum sunlight. A small sensor on the array provides electrical signals that tell the control system which way to turn the array to get the most sun.

## **4.6 Solar Water Distillers**

A solar water distiller consists of a water-tight compartment painted black to absorb the solar radiation which enters through the glass roof of the still. Water which is brackish or impure flows through the box in a four- to six-inch deep channel, where the intense solar heat in the box forces the water to evaporate and to condense on the inner side of the roof where it is drained off to a holding tank. The end result is pure drinking water.

The ocean rescue still, developed in 1940 by Dr. Maria Telkes, can be used to make drinking water from ocean water.

Dr. M. Kobayashi of Tokyo developed a solar still that could extract water from virtually any kind of soil, and tested it at the top of Mt. Fuji where the soil is volcanic ash and in the arid deserts of Pakistan, and he has never failed to produce water that is pure and potable.

## **4.7 Solar Food Dryers**

Solar energy has always been used to dry crops of fruits and vegetables. Essentially this was done by exposing the food to the sun's rays and hoping it wouldn't rain. A more "sophisticated" technology has evolved to use the sun's thermal power and minimize contamination from dust and airborne debris, insects and their larvae, and animal or human interference. The drying area must be covered with a transparent material. A drying "hot box" is constructed and insulated (glass wool is preferred since it can survive any temperature and does not support insect, life). Ventilation holes at the top and bottom allow air to enter and carry away the moisture. An access door makes loading and unloading easier. The interior of the cabinet should be painted black and the exteriors of the side and rear panels painted with

aluminium paint. Drying trays can be made with galvanized wire mesh. Where electricity is available, a small fan may be used to draw air through the dryer, but it is not necessary.

The dryer should be glazed, preferably with two layers of glass, fitted in with adequate room for thermal expansion. Ventilation is essential so that moisture can escape and can be provided by screened air holes in the bottom, sides, and back of the cabinet. Such a dryer can keep produce dry during rain storms, so the glazed top should be watertight. The ventilation is also needed to prevent overheating, since a hot box of this type can readily attain temperatures above 200° F.

## 4.8 Solar Cookers

The first solar cooker was probably the one built in Bombay in 1880, and several other ingenious ovens have originated in India, as well as in other areas of the world. We won't go into detail since the Hygienic way of life doesn't advocate cooking food, but the student must at least be aware that the technology is available—even if we don't cook, we all know people who do. Solar cooking is cleaner than gas cooking, which sends its toxic combustion products into the room.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 5. A Solar Home

## 5. A Solar Home

### 5.1 Solarizing Your Present Home

The first step in solarizing your present home is to do an energy "audit"—to determine where the major heat losses occur and where the greatest energy efficiency gains can be made.

Every situation will vary, but one generally good strategy is to add a sunroom or a greenhouse onto the south side of the house. If this isn't possible, at least more *windows* can be added on the south side. If you do have a porch on the south side, or one that at least has a south wall, consider converting it into a greenhouse or sunroom. A south-facing window can be converted into a solar window box greenhouse. We must always make the *most* out of what sun we get.

There are a number of other basic steps that can be taken to conserve energy, thus working with passive solar principles to improve what you already have. Some of these are:

1. Lower thermostat or turn down heater.
2. Turn water heater thermostat down to 120 degrees, and insulate it.
3. Weatherstrip doors and windows.
4. Caulk and seal openings.
5. Add storm windows.
6. Add awnings.
7. Add attic insulation; insulate walls.
8. Convert from gas or electric to wood heat; replace inefficient heaters with more efficient ones.
9. Add fans, vents, and ceiling fans.
10. Insulate pipes and ducts.
11. Add a solar water heater.
12. Add thermal heat storage or thermal mass (one example is a hot tub).
13. Add wood solar hot water heater.
14. Add entry room to act as an air buffer so that massive energy isn't exchanged each time a door is opened (small adjoining room).

15. Add backup active solar systems for air and hot water heating.

16. Add insulated shutters and drapes.

Emphasis should be made again about the importance of providing *adequate ventilation*. We have already discussed the harmful fumes and byproducts of combustion that are present in rooms heated by most conventional methods and fumes that result from unhealthy building materials. Insulation must not become a threat to health. Ideally we could all use clean solar heat, but even then, we would want to remember that fresh air is essential to quality of life. In any case, it's better to add a blanket and sleep with windows cracked—I remember visiting in Switzerland in the mountains a few years ago, and at night we just climbed under the thick down covers—the bedrooms upstairs weren't even heated at all.

We should be conscious of the air quality in our living spaces at all times, waking and sleeping.

## 5.2 Building a Solar Home

The art of solar building design perhaps began when the cave men carved their dwellings into the south face of a hill in order to benefit most from the warm rays of the sun.

The use of south-facing windows to increase heat gain into a building became popular in the 30s and 40s in this country. In the summer, when the sun is higher in the sky than in winter, carefully designed overhangs shade the south windows and keep the building from overheating. Double-glazed windows or those insulated at night reduce the heat loss more.

The use of a greenhouse as a heat trap is an extension of the solar window design. On dark, cloudy days and at night, the greenhouse can be sealed off from the rest of the house to prevent heat loss. The greenhouse serves as a thermal mass to reradiate stored solar heat at night.

Water provides an excellent thermal mass, and has the highest heat capacity per pound of ordinary material. The storage tank is usually insulated to reduce conductive heat losses.

The seasonal angle of the sun changes in a regular, predictable cycle. When designing overhangs and collector angles, you need to know your latitude and the maximum high and low angles of the sun. The sun changes about 46 degrees from the summer to the winter solstice, higher in summer and lower in the sky in winter.

The *insolation* (or *incident solar radiation*) is the amount of energy that reaches the surface at a given location. Insolation tables are available for various latitudes.

Another factor to be considered in choosing a solar site is the amount of shading available. This can be in the form of overhangs or natural vegetation. A combination of shading, cooling, and ventilation elements must be considered as well as the solar factors. Evergreen trees planted to the north of a building help block the cold winter north winds, rain, and snow. Deciduous trees (those that lose their leaves in winter), such as fruit trees, are suitable for planting on the south, east, and west sides. In the fall and winter when the trees are bare, the sun's rays penetrate to the building and in the spring and summer, the hot sun is blocked because the trees are full of leaves, flowers, and fruit. A simple idea thus becomes delicious and rewarding. Vines and climbers can also be planted to shade east, west, and south facades, as well as lattices or trellises covered with growth.

Walls should be as well insulated as possible on the outside and include thermal mass on the inside for heat retention. Thermal mass can consist of 55-gallon drums (water-filled) painted black for maximum absorption, or large rocks. Rocks can be used in the foundation and walls. (If using painted barrels, the nonsolar-collecting sides can be painted any colors.)

Inside walls that receive sunlight can be faced with brick or stone. There should be an insulator like gravel under the floor. Clay tile floors store heat well. They come in a rainbow of colors and designs, making some beautiful mosaics possible, that are both functional *and* aesthetic.

We receive our life nourishment from the sun, so it is only natural that we harness its energy and put it to

good use.

### **5.3 The Solar Greenhouse**

The primary reason for building a greenhouse is, of course, food production. Growing your own food saves money, and it is always ready to be picked—fresh, ripe, and organic, grown without the need for any farm machinery.

As mentioned, the greenhouse may be built on the south side of the building where it will receive full sun. It can be constructed quite simply with concrete blocks for the foundation, and other massive building materials such as ceramic brick, stone, adobe, poured concrete, or cinder blocks can be used for thermal mass. These massive walls are insulated on the outside surface.

For the glazing or clear film that is attached to the frame there are many choices of material: glass, roll plastic, sheet plastic, corrugated clear plastic, etc. Doors and vents must be tight-fitting and weatherstripped, and all surfaces should fit tightly together.

At night, the windows should be blocked with movable insulating forms or covered with shutters or curtains. This will keep the heat level constant at night.

Heated air in the greenhouse rises and flows into a high opening to the home, and a low opening in the shared wall lets cool air from the house enter the greenhouse for heating. The plants in the greenhouse convert carbon dioxide into oxygen-rich air for the house occupants.

When you build a greenhouse, you will be creating a special space, a microcosm, a living place that will grow and truly add life to your home.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 6. Solar Energy And You

### **6. Solar Energy And You**

Now that you know why it is so important to make the change to renewable energy sources, hopefully you'll try to incorporate some of these changes into your lives. Anything you can do to get other persons in your community involved in promoting the use of solar power and other renewable energy sources will be a step toward saving our planet.

There are solar industries springing up all over the place that you and other interested persons can contact for advice and support.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 7. The Future And Politics Of Solar Energy

### **7. The Future And Politics Of Solar Energy**

If there is one organized body capable of the political leverage needed to give solar energy a boost, it is the American union movement. They will be able to see the job potential of solar energy. However, the job-creating powers of solar energy could hold it back in *corporate* circles because industrialists want to keep a certain measure of control over people when there is adequate *unemployment* to hold down wages. That is, the more people out of work, the more competition there is for what jobs are available,

and the easier to keep wages down and hold back unions (of course, no one will admit to this outright). Remember, the nuclear power industry has \$100 billion dollars on the line.

In this country the top 19% of families owns about 76% of all the privately-held wealth, with the bottom 25% having no assets at all (Dr. L. C. Thurow, M.I.T. Department of Economics, 1979). The concentration of power and wealth is such that the top 5% of the American population owns more assets than the bottom 81% combined. Goods produced, no matter what their function, are looked at in terms of selling them at a profit. Purchasers are locked into a system of dependence with built-in obsolescence. Products that become a *necessity* in life and that can't be made by the purchasers themselves are considered best. Centralized energy fits into this category, and decentralized solar energy gets only lip service from our rulers. The people themselves are surely intelligent enough to see that solar energy works in their best interest.

A newsclip from June 1981, stated that "in a sharp reduction of the federal government's role in solar energy, the Reagan administration has ordered the dismissal of 370 of the 959 employees at the four-year-old Solar Energy Research Institute at Golden, Colorado, and has fired its director." In addition, the institute's budget was to be cut to \$50 million for the next year, which was a 50% reduction. This would reduce spending for outside research. The Reagan administration's "logic" was that most development work should be carried out by private industry—it increased the budget for nuclear power, however. An internal Department of Energy report concluded that American taxpayers have quietly subsidized the private U.S. nuclear industry with almost \$40 *billion* over the past 30 years. In reality, nuclear-generated electricity is actually costing Americans two times what the atomic industry claims. So, is it alright for us to subsidize nuclear power, but different when solar power is concerned? The report says that between 1950 and 1979, billions of dollars in federal subsidies went for such things as designing early reactors, getting low-cost fuel to reactors and guaranteeing loans to power plants.

The Energy Research and Development Administration (formerly the Atomic Energy Commission) says "solar energy falling on about 3% of land, if utilized at about 10% efficiency, could meet the total projected U.S. energy requirements for the year 2000."

The big hurdle in promoting solar energy is getting the public enlightened. Changes must really be made on a *worldwide* basis in order to be effective, because the biosphere is like one big aquarium—we have seen how pollution affects *everyone*. We who are already enlightened about pure diets based on living food, and using alternative, renewable energy sources, should reach out to others and share the knowledge.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 8. Other Renewable Energy Sources

## **8. Other Renewable Energy Sources**

### **8.1 Water Power**

We've all seen destruction caused by floods, erosion, and the energy of water in the sea waves, and swift rivers and streams. Water power also has a great capacity for useful work. Water power is essentially a form of solar energy, because the sun begins the hydrologic cycle by evaporating water from lakes and oceans and then heating the air. The hot air then rises over the water, carrying moisture with it to the land. The cycle continues when the water falls as precipitation onto the land, then it starts over again.

Water is relatively easy to control and produces a high efficiency, because from 80% to 90% of water energy can usually be converted to work, compared with 25-45% efficiency for solar, chemical, and

thermal energy systems. For this reason many rivers have been dammed so that waterwheels and water turbines could capture the energy of water.

Individuals and communities can harness this energy to produce power in small hydroplants. The dam increases the reliability and power available from the stream, and is a means for regulating the water flow and depth. People should be aware that a dam changes the local ecosystem, though, and should only do so conscientiously.

Water turbines can produce either direct current (D.C.) or alternating current (A.C.) electricity. The power available will not always supply the total amount desired, so it is useful to think of an integrated power systems approach from the beginning, and combine this with another renewable power source.

## 8.2 Wind Power

Wind is another form of energy created by, the sun—the heating of our atmosphere during the day and its absence cooling the night sky—like the earth is *breathing*. Wind is the reaction of our atmosphere to the incoming energy from the sun—heat causes low-pressure areas and the lack of heat results in high-pressure areas, causing the wind.

The wind is probably the oldest and most constant energy source, probably one of the first sources harnessed by man, and now it's being rediscovered as "new."

Wind energy is not as constant and predictable as the sun and water, but there are also solutions to this problem. Usually a *storage* system is installed that is designed to have the energy available when it is needed. The selection of the site for wind power is very important—for example, it shouldn't be placed near trees that are growing taller, etc. Other factors should be considered on a basis of *frequency* and *intensity*: rain, freezing temperatures, icing, sleet, hail, sandstorms, or lightning.

Windmills have been known for centuries. Even Persia had a primitive horizontal windmill in the tenth century that was used to grind corn. Mills were commonly used in China for irrigation. Modern wind generators not only use the wind for mechanical energy, but also convert the energy into electricity. Wind water pumpers are also available. Most generators consist of the tower, devices to regulate the generator or voltage, the propeller and hub system, the tail vane, a storage system to store power during windless days, and an inverter that converts the stored D.C. into regulated A.C. if it is required. There is often an optional backup system (such as a gas or diesel generator) to provide power through extremely long calm periods. Even better, of course, would be a solar backup system.

## 8.3 Biofuels

Biofuels are renewable energy sources from living things. Fossil fuels are also of biological origin, but they are *nonrenewable*. All biofuels are derived from plants, which capture the sun's energy, convert it to chemical energy by photosynthesis, and in the process of being eaten or decayed, they pass this energy onto the rest of the living world. In this sense, all forms of life, and their byproducts and wastes are storehouses of solar energy.

Every day, over 200 times more energy from the sun falls on our planet than is used by the U.S. in a *year*. About half this energy is reflected back into space, and what does penetrate the atmosphere charges all our energy systems.

All plant matter is called *biomass*. Microbes, plants, trees, animals, vegetable oils, animal fats, manure garbage, and fossil fuels are all forms of biomass energy that can be produced, cultivated, or converted in different ways for our needs. All we need to do is use it. Each year the U.S. produces over 870 million dry tons, of discarded organic matter.

*Agriculture* is the means by which solar energy becomes our food energy, and organic farming techniques and a realization that planting fruit trees is a *priority* in attaining higher quality of life for

humans are the goals we should be pursuing. Please refer to the lessons on organic gardening and tree crop agriculture for more information.

When organic material decays it yields useful byproducts, depending on the conditions under which decay takes place—it can be aerobic (with oxygen) or anaerobic (without oxygen). Any kind of organic matter can be broken down either way, the end products of each will be different. If we imitate the natural anaerobic process and put manure and vegetable matter into insulated, air-tight containers called *digesters*, biogas or methane can be produced.

Another source of energy is *alcohol* in its pure form, which can be used for heating, cooking, lighting, and motor fuel. It is high energy and clean burning. There are two types of alcohol: ethyl alcohol (ethanol or grain alcohol) and methyl alcohol (methanol or wood alcohol). Ethanol can be produced from carbohydrates (starches, sugars, cellulose) found in various farm products such as sugar beets, sugar cane, molasses, fruits, starch crops, grains, etc. Methanol can be produced from wood, sawdust, farm wastes, and urban refuse.

Wood is a renewable energy source that should be used with a conscientious replanting plan, and can be used to supplement other renewable energy systems. (A word of caution: even though wood fires are considered "natural" or "romantic," they put carcinogenic agents into the air. In fact, efficient, slow-burning stoves pose a bigger hazard than roaring flames, since they produce more polycyclic organic compounds (POMs, linked to lung cancer).

We need to learn how to integrate the heat from solar energy, the mechanical power from wind and water energy, and the chemical energy from biofuels, in order to get as much continuous energy as possible from the diverse energy sources.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > 9. Questions & Answers

## 9. Questions & Answers

**A lot of people are talking about underground homes nowadays. What's the story on this?**

An "underground house" above ground can be had with a sod roof—the earth covering acts as a moisture barrier and insulates the roof. Actually, nowadays people are discovering that underground houses are very comfortable. In hot and cold climates, weather isn't as extreme underground, and the homes aren't dark, damp, or dismal either, which might be our first impression when thinking about living below the ground. Many homes are built with a regular south wall with windows, and the rest under the ground. In either case, skylights can provide lighting. Less heating or cooling needs to be done in an underground home, so energy is conserved, and underground buildings are quiet and blend nicely with their environment, leaving nature virtually untouched.

There is a subdesertic region of Turkey, Cappadocia, where people have been living in underground towns and cities since the years B.C. in settlements, some of which extend eight or ten stories below ground. They are hewn out of the soft stone common to the area. The climate there is comfortable despite harsh variations of heat and cold on the surface. There are even some "luxury" caves in France's Loire Valley where some caverns were furnished and carpeted and sold to wealthy city dwellers who appreciate the coolness in summer and natural winter warmth.

Underground homes don't need to be painted, roofs don't need to be replaced, pipes don't

freeze, and they have a low-cost construction.

### **What is the effect of radiation in the gene pool?**

For people still in their reproductive years, whether male or female, injury can occur either to the sperm-generating cells in the testes or the ovum-generating cells in the ovary, and injury to the genes there can cause hereditary changes or disease or death in generations for many generations beyond the irradiated individuals.

### **What about the effect of radiation on a developing fetus?**

Radiation injures the genetic material that is guiding the cells in a developing fetus to form the various organs and tissues. Evidence indicates that the developing fetus is more sensitive to ionizing radiation in terms of the effects caused than children are, and children in turn are more sensitive than adults. (In fact, the fetus is even more sensitive to radiation in the *first* trimester of pregnancy than in the third.)

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > Article #1: Truths About X Rays by Virginia Vetrano

### **Article #1: Truths About X Rays by Virginia Vetrano**

Television radiation is an addition to background radiation, fallout, luminous dial watches, radiation from medical and dental X rays, fluoroscopy, and radiation from fluorescent lights, under which most workers have to work. These sources must be added, not compared, because it is the way it works in the living organism. All radiation is cumulative, that is, it is additive, one dose is added to another, and so even if one would appear unharmed by X rays, the cell never seems to recover completely. The least amount of radiation absorbed in living tissue produces damage.

It has been known for a number of years that X rays produce cataracts. The lens of the eye is extremely sensitive to radiation and is irreversibly damaged by ionizing rays.

The cell is capable of preventing most drugs from entering and combining with it, thereby killing it. But the cell has no defense against the onslaught of X rays. At high speed they penetrate the cell like bullets and damage enzymes and enzyme systems, disrupt proteins, genes, fats, and other large molecules, impair some metabolic processes and completely block others. Irreparable damage is done so quickly that defense is impossible. There remains only cellular confusion with feeble attempts at repair.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > Article #2: No Permissible Radiation Level by Virginia Vetrano

### **Article #2: No Permissible Radiation Level by Virginia Vetrano**

At the Atom Bomb Hospital in Hiroshima, survivors of the August 6, 1945, holocaust are still dying at the rate of four to six a month. Even this figure does not represent the total death rate, for there are other hospitals, and not everyone patronizes hospitals in the first place. The paper from which I received the

above figures says: "After years of study, world scientists are still unable to agree just how lethal the latent after-effects of exposure to an atomic bomb can be." The scientists don't wish to admit that every one of the victims will die ultimately, from the latent effects of exposure to radiation. Instead of an instant death these survivors will suffer long years of miserable sickness until finally, after a continuous struggle to repair damaged tissue, the organism will succumb to the deteriorating forces.

It is well-known that all radiation, however small it may be, shortens one's life. Hence, all radiation is lethal. Watch for equivocal and ambiguous scientific cant and you will be amazed at their unequivocal dishonesty.

All talk of protection against atomic radiation, of bomb-proof shelters, etc., is based on wishful thinking. Eventually one will have to come out of the shelter to eat, drink and breathe, and consequently be exposed to the excessive radiation still in the air, food, and water. Hence, one is thus subjected to the process of a slow and painful death. There is but one possible protection and this is the immediate cessation of all nuclear explosions. Dr. Shelton says of this, "As our world is a lunatic asylum controlled by the worst elements of our population, it is doubtful that this will be done." However, we must still try.

But we have to be educated into understanding the double talk of the hired scientists before we can realize that damage is being done from all these nuclear bomb tests, which eventually, may lead to another nuclear holocaust. The tests themselves are contaminating the earth and causing many lethal illnesses. The hired scientists cover up the facts by saying that there will not be any "statistically significant" deaths from these tests. To these scientists we are looked upon as *so many guinea pigs*, so if 1,000,000 guinea pigs should die in a population of say, 180,000,000, that is statistically insignificant. Do you feel statistically insignificant?

To continue bomb testing, the Atomic Energy Commission (AEC) had to rationalize their actions. It is their attitude that, so long as we can't observe the persons being harmed with our own eyes, then they can continue testing and permit the fallout level to rise just that much and the masses won't rebel.

The "permissible" level of radioactivity to be absorbed by the population as a whole is based on the ideas discussed above. Many well-informed persons have stated that the true facts are *not* disclosed to the general public.

Reassuring statements regarding fallout hazards are always preferred by the majority, hence they close their ears to anyone telling the truth about these matters and label them "alarmists." To the statement that fallout is definitely doing damage to the genetic pool as well as to somatic tissue, they retort exactly what has been brainwashed into them: "That the radiation from fallout is not more than what we have, all through the years, been accustomed to from natural background radiation." These people are fooled by such statements. They are not thinking for themselves, or they would realize that fallout is, in addition to background radiation, augmenting the dosage which we habitually receive as the radioactive fallout increases. A book which contains many selected reviews by AEC scientists reads: "As more and more experience with X rays and gamma rays has accumulated, however, the concept of 'tolerance dose' has changed somewhat to the thought that there is no such thing as a literally harmless dose of radiation—that any amount, however small, does some damage."

Moreover, many experiments involving radiation have been made on rats, and it has been proved that man is *more susceptible* to radiation than the rat.

Scientists know now that the least possible amount of radiation does cause various diseases, but this does not make them stop the arm's race. Why? Obviously, since the United States is vulnerable to an economic collapse as a result of a sharp decline in arms production, so tests and weapons production will continue as a means of saving our tottering capitalism.

An important thing which we must not overlook when evaluating the "permissible" dose of radiation is that it disregards completely the hereditary damage done to our genetic pool.

### **Article #3: To Mutate or Not to Mutate by Virginia Vetrano**

The result of the Manhattan Project, an experiment to determine the effects of radiation, are very terrifying. The Manhattan Project was top secret but some scientists were permitted to view the experimental animals at various stages because it was the project that developed the first atom bomb dropped on Hiroshima.

Groups of mice were exposed to gamma rays from the experimental piles, each succeeding group receiving double the dose of radiation of its predecessor, until a point was reached where the mice were being obviously burned. The mice were kept and the developments recorded over the next several months. All except the first three groups were dead or showed signs of lethal damage at the end of a few weeks, leaving no progeny. After being watched for a month or two the "undamaged" mice were set aside for other experiments—that is, they were treated as new stock and all seemed to go well until the next generation.

Then a startling discovery was made. Many abnormalities and "mutation" showed up. A higher and higher percentage of the mice exhibited degenerative changes and deformity each generation. Although, in almost all cases, the deviation from normal was accompanied by sterility, this was not always so. Then some of the slightly deformed mice produced larger and better looking mice than usual.

All of these mice, large and small, degenerate and deformed, were allowed to breed and in the fifteenth generation, all had warped and distorted limbs and bodies, and what was even more noticeable, queer behavior and unreliable temperaments. Stillbirths were increasing and greater numbers of the survivors were sterile and suffered from nonhealing sores or cancers. From the twenty-first to the twenty-fifth generations all had become cancerous imbeciles, unable to feed themselves. Handfed, a few survived to produce a twenty-ninth generation, but these mice were paralyzed and brain cells were growing on the outside of the skulls.

All of this happened to mice that were by all appearance and by all tests completely undamaged by the radiation. Is this evidence that mutations, like somatic damages, can develop latently as I suggested in the first part of the article? But this was not all, many of the offspring of these mice were born albinos and many were born blind, than after the seventh generation not only were they born blind, but many were born without eyes at all and many did not grow any bones, apparently because the bonegrowing genes had been omitted, and their skulls and teeth did not grow. Beginning with the twentieth generation the brain protruded unprotected and exposed to the open air. There were many monstrous developments, such as young born growing together, twins were born with only parts of their bodies separated. Many of that generation were born with what the investigators call the "death gene," which means that their progeny were completely sterile, which is, perhaps, the best solution to a condition so abnormal.

According to the Public Health Service Report, man is more susceptible than the mouse and logically an experiment made on mice would be magnified in man.

If human "mutations" develop at the same rate as those observed in the mice, we must wait up to 250 years, to know that we have come through the present spread of radiation over the earth, while, to develop the worst effects from present day exposure we must wait 400 to 600 years.

The gonads are integral parts of the body and are fed by the same bloodstream that feeds all other parts of the body. Experiments with radioactive isotopes prove conclusively that radioactive substances are carried by the bloodstream to all parts of the body. It is certain that radioactive materials, such as strontium 90, are carried to the gonads where they reach the hereditary units carried in these glands. What effect does this have on the chromosomes and genes? Is it as destructive to the germinal material as to the bones and other tissues? Will its presence, even in minute amounts, result in the production of mutations? If so, what kind of mutations may we expect?

Radiation escaping from industrial plants so constitutes a menace, not only to workers in these plants, but to the populations living within the contaminated areas. George Truman, vice-chairman of the Chemical Worker's Union, said in a speech before the conference on Industrial Health, in Manchester, England, in 1955, that men at the atomic works were sterilized by the radiation to which they were subjected. The same thing has been found to result to the men working at Oak Ridge in this country. It is obvious that scientists, militarists and manufacturers, who plan to make use of atomic power in industry, are playing with a dangerous fire that may ultimately extinguish the whole human race, even without the occurrence of an atomic war. The plain fact is that nobody knows how to bypass the unspeakable biological debasement which always follows any widespread increase in nuclear radiation.

Due to the fact that certain tissues tend to concentrate particular chemical elements, sometimes to tens of thousands of times that present in the surroundings, even though only traces of radioactive substance may be present in the water from an atomic power station, plants growing in the water or air may absorb and store the substance until a really high concentration is built up. Animals eating these plants will receive and suffer from radiation. The Japanese found, to their horror, that it takes a surprisingly short time for fish to eat slightly contaminated smaller forms to become themselves highly radioactive.

Most all the inhabitants of the earth are receiving minute, but *cumulative* doses of radioactivity and all future testing of atomic hydrogen and cobalt bombs will increase the danger to human, animal, and plant existence.

When in April of 1958 Dr. Linus Pauling called attention to the radioactive menace of carbon 14, which results from nuclear explosions, his statements were hooted at the subsidized scientists of the Atomic Energy Commission, who said that his statements were exaggerated and they accused him of irresponsibility. He had said, among other things, that the radiocarbon from thirty megatons of fission "will ultimately be responsible for the birth of 230,000 defective children and also 430,000 embryonic and neonatal deaths."

The scientists of the AEC have since eaten their words. A document titled, "The Biological Hazard to Man of Carbon 14 From Nuclear Weapons," has sustained Pauling's estimates. Dr. Ralph E. Lapp, of the commission, says that Dr. I. Leipunsky, also of the AEC, concludes that "bomb carbon 14 as of 1960 may ultimately involve 100,000 cases of gross physical and mental defects, 380,000 cases of stillbirths and childhood deaths and 900,000 cases of embryonic and neonatal deaths. Dr. Pauling's previous estimate was based on thirty megatons, which were about half the megatons exploded up the summer of 1958. His estimates are quite close to those of the AEC. Lapp adds: "Absolute numbers, such as those cited for carbon 14 genetic damage are impressive, especially when they apply to the 266 future generations covered by the persistence of carbon 14's long life (average life of 8,000 years)".

I would substitute the word *frightening* for the word impressive in this last statement. The fact is that today, nobody—physician, physicist, biologist, or geneticist, knows the long-term, ultimate effects of radiation. The study of these effects is only in its infancy and there remains much yet to be learned. Indeed, there is reason to think that there is much already known that has not been made public.

It is noteworthy that from the outset of the study of radioactive damages, there has been a repeated downward revision of the maximum permissible dose. Looking back, it is obvious that our scientists have constantly underestimated the hazard. The permissible dose of 1931 was reduced by half in 1936 and then to less than half again in 1950. By 1957 the figure had been reduced to less than a third of the 1950 dosage. This is a total reduction to one-fifteenth of the 1930 dosage. It is now generally thought that there is no threshold dosage, as I have mentioned before. Commenting upon this steady-lowering of the permitted maximum dose, Dr. L. S. Taylor, of the U.S. Bureau of Standards, said: "It will be extremely difficult to lower the standards further and still permit the effective use of radiation in medicine, industry and research."

A luminous dial wrist watch worn twenty-four hours a day would give the central body including the sex organs a dose of about 40 mr/year. Airplane pilots also receive a considerable dosage per year from luminous instrument panels. It seems that every modern invention is fraught with danger, and the only

intelligent thing to do is to scrap the so-called "modern conveniences" (the harmful ones) if we wish to preserve the human race in some intelligible form.

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) >

#### **Article #4: A New Pathway to Extinction by Virginia Vetrano**

The only way to stop the threat of an atomic war is to ban the use of all nuclear weapons and cease manufacturing fission products by the use of atomic power plants. Power plants are contributing heavily to the pollution of our streams, rivers, seas, and our atmosphere. If this rate of pollution continues, soon there will be no food, no water, or air which is safe to eat, drink, and breathe respectively. We are destroying our planet and working for the extinction of mankind. We must stop all nuclear explosions and all atomic power plants. There is no need to be cowards and let ourselves be pushed around from now to eternity, which won't be far off if this testing of nuclear weapons is not stopped and atomic power plants abolished.

With increased bomb testing, we have nothing to look forward to but showers of invisible radioactive dust pouring down upon us and penetrating our bodies by means of our air, food, and water for the next five to seven years or more. The most ominous threat, however, is to our children. They are the ones who will reap most of the harvest of this madness called "preparedness for peace," and the younger the child the more sensitive and more easily damaged are his cells from radiation.

Dr. Linus Pauling most forcibly says, "The only safe amount of strontium 90 in the bones of children is zero." Unfortunately atom and hydrogen bombs never yield this safe amount. He further emphasizes that if testing of atomic bombs continues, about 100,000 children of the next generation in the United States will die. He also stated, and this was before the French tests in the Sahara, that "these bomb tests will also cause the birth of 200,000 seriously defective children in the next generation of human beings, children with serious mental deficiency or serious physical defects."

Can we afford to "relax and enjoy life" when the very essence of life is being destroyed? The pool of human germ plasm is being greatly damaged, our mental capacities are diminishing, our physical capacities deteriorating and yet we do nothing. A national revolt is no longer adequate; what we need is a world revolt. Billions of yet unborn children will come into this world with diminished mental capacities and serious physical defects *because we, the thinking portion of the population, have not made ourselves heard*. It is we who are to blame for this gross crime committed against the future human race. In the history of the United States, no unwanted thing continued to exist when the whole population stood together and rebelled. Unfortunately, rebellion and singularity seems to have been knocked out of all Americans.

We must unite to fight every profession using X rays for diagnosis and therapy, we must fight the Atomic Energy Commission and every other nation which desires to enter in the atomic race. Every source of damage to our children and future children must be abolished lest we perish from this earth. We must expect much strong opposition from all these sources because not only are their bread and butter in jeopardy but also their diamonds, fur coats, and Cadillacs.

Furthermore, this class of people won't stop their damaging practices unless they are forced to do so, as is evidenced by the cumulated facts before us. Despite the fact that scientists have predicted the strontium 90 content in Japan would be beyond the AEC safety limit by 1962, and that in 1959 stillborn babies of Southern Japan were being found with the Sr 90 content already exceeding the so-called "safe limit," nations continue to clamor for more testing of atomic and hydrogen bombs. Other evidence that force is necessary to stop these damaging influences is the fact that the x-raying of pregnant women has

been continued well into the present time, although for years it has been known that exposing a fetus or an embryo, even momentarily, to X rays could cause cancer in early childhood.

Even authorities, such as Schubert and Lapp are disturbed over what they call "our irradiated children." They say "thousands of infants and children in the United States are needlessly exposed to more radiation in one year than would be allowed atomic energy workers in a lifetime." They were speaking of medical and dental sources of X rays, which is another thing the AEC overlooks when planning on contaminating the air with more fallout; the fact that our population as a whole is already over irradiated from medical and dental uses of X rays only more aggravates the hurt. Our responsibility is to protect our children from these unnecessary and inimical sources of radiation. Fortunately, it is still within our power to refuse medical and dental X rays, although we are still helpless under the blanket of fallout blasted into the air by our "mad scientists."

Rapidly dividing cells, as seen in embryos, infants, and young children, are more sensitive to all kinds of radiation, i.e., they are more easily damaged. The younger the child, the more likely will he suffer from delayed effects such as cancer and leukemia. A person of advanced age, receiving a dose of radiation, will probably die before cancer has a chance to develop, but if an American boy, with an average life span of 66 years, or a girl with an average life span of 72 years, has been irradiated in the embryonic state or in early infancy, there is more than ample time for him or her to develop cancer or leukemia in early life.

The fact that the young are more sensitive to radiation and that they have many more years to live is reason enough to exclude all sources of radiation from them, but there is another very important reason which we should not overlook. These children will grow up to reproduce their kind and if no more effort on the part of hospitals, physicians, and radiologists is made to shield the germinal elements of these children than has been made in the past, *the human race will be mutated out of existence*. Through surveys made by prominent men, it has been shown over and over again that physicians fail to protect the gonads while x-raying and that even in the best and well-equipped hospitals no effort is made to protect the gonads of children while treating them. The many thousands of articles written to warn physicians of the dangers engendered by failing to protect the gonads of the young are written to no avail as the advice seems not to be heeded. It is still up to the people themselves to stop the practice of irradiating the young altogether.

During the early embryonic stages, from the moment of fertilization to approximately the end of the third month, human cells are most sensitive to radiation. Investigations have shown that even small doses of radiation during this period may lead to malformations and sterility. Just as there are certain stages in cell division (mitosis), in which the cell is more sensitive to radiation, there are also certain stages in embryonic development when organs and organ-systems have an augmented sensitivity to radiation.

*Reprinted from Dr. Shelton 's Hygienic Review, July, 1960*

[Home](#) > [Lesson 53 - Solar Energy And Your Health](#) > Article #5: Solar Energy Will Revolutionize Your Life

### **Article #5: Solar Energy Will Revolutionize Your Life**

How would you like to see your *total direct* energy bill drop from say \$1,500 per year to a mere \$50 to \$75? And your *indirect energy bill*, as represented in the products you buy, drop yet another \$ 1,000 or so?

Fantasy?

Absolutely not! The technology is here now, today!

There is a gremlin in the works, however. But we're betting this dark shadow will not be around long. There's too much in favor of this getting into foreign hands, etc.

An inventor and electronics specialist, Stanford R. Ovshinsky of Troy, Michigan, has made the most startling energy breakthrough in all history! In fact it is so revolutionary that all other forms of energy utilization are immediately obsolete! And therein is the rub.

Mr. Ovshinsky developed what he called "ovonic materials" for applications in the computer industry. Imagine how stunned the scientific world was to learn that not only were the materials "dirt cheap" but that they transformed solar energy directly into electricity at a cost of about 1/25 of the cost of such conventional sources as coal, water power, etc., presently our cheapest sources for power.

Can you imagine paying a service station say \$5 for a battery power back charge for your car and driving from 500 to 700 miles before having to change packs or, if you have the time, of recharging the battery pack from your own home-owned generator made of ovonic materials? Or of having your own power generator made of ovonic materials right on the roof of the your car?

Can you imagine meeting all your home power needs with a few solar panels located on your roof or wherever you place them such that they capture the sun?

Can you imagine the great grid power system that mars our land with endless lines disappearing?

Can you imagine yourself being free of outside energy needs altogether? Of being an island unto yourself in meeting your energy needs just as you presently meet your needs for air?

The revolution will be so sweeping anything you visualize will probably be far short of the mark.

But the rub? What is that little gremlin we spoke of?

Mr. Ovshinsky went heavily into debt. Help came in the form of monies from two industrial giants who, to all appearances, want to keep ovonic materials AWAY from consumers.

The easy path Mr. Ovshinsky took to free himself of burdens was to sell part interest in his solar devices to, *and get this*, United Nuclear Corporation and Exxon Corporation.

United may well find rescue in the new technology. But Exxon? Do you for a moment think they have anything to gain? Do you think they will let their multibillion dollar investment in oil and coal go down the drain? Do you think they will permit their annual multibillion dollar income to plummet to near nothing by marketing a solar device that practically kicks them out of the energy marketplace?

Much remains to be seen in this case. We're confident that overriding factors even larger than United and Exxon will bring ovonic materials or even better materials to the consumer and relatively soon.

Mr. Ovshinsky must be hailed as having made the most humanitarian invention of this century. And we must push with all our mights as interested parties to see that this invention sees widespread application as soon as technically possible.

## Lesson 54 - Weather And Human Well-Being

- [1. Introduction](#)
- [2. The Body's Natural Protective Systems](#)
- [3. Bioelectronic Factors In Nutrition](#)
- [4. Questions & Answers](#)
- [Article #1: The Weather In Your Health By Mike Benton](#)

### 1. Introduction

At first glance, a discussion of that universal subject—the weather—might seem out of place in a Life Science/Hygiene course in human nutrition. But, since nutrition is a unified or total body process, any influence that can disrupt this complicated and marvelous process anywhere along the great chain of nutritive systems would seem to justify its study in relation to human health and nutrition. And, while many sincere investigators (past and present) have delved deeply into nature's secrets of human nutrition, as yet we cannot see but can only infer by deductive reasoning the mysteries of the inner metabolic processes going on in the living cells of the body. We can deduce that certain things are going on, but we cannot be sure all these deductions are infallibly correct.

#### 1.1 Twentieth-Century Technology—A Two-Edged Sword

Meanwhile, the mounting evidence seems worthy of note and concern that the human race—the 20th-century human race—has caused "unnatural" weather conditions (such as worldwide air pollution, nuclear blasts, burning of fossil fuels, etc.), which can then become a cause of "unnatural" stimulation or shock to living bodies, on the same order that drug poisons create an unnatural stimulation (shock reaction, etc.) to living bodies. Of course, the effect of the weather will be different on different people, depending on the condition of their bodies. The heat of a noon-day sun (shining through visible and invisible layers of air pollution) will have a different effect on a sober person from the effect it will have on a drunkard (including a food drunkard).

One of Life Science/Hygiene's most vital concerns is the mounting evidence that the two-edged sword of modern technology may be creating a technological world which, instead of enhancing life on this planet, could be making it unbearable (and unlivable!).

One area, however, that 20th-century technology would seem to deserve credit for opening some dramatically revealing new studies is in the area of this planet's weather, and how recent findings would seem to lead to the conclusion that air, electricity, ions, weird winds, sunspots, etc., have a greater effect on human health, nutrition, moods, etc., than was thought in the past. Those Life Scientists seeking new challenges should find this area of study fascinating.

#### 1.2 Our Fabulous Body Intelligence

This new field of scientific investigation of how weather affects living things has been given the name of "biometeorology." The findings so far show that when the weather changes, the body wisdom quickly makes changes in the body—adjusts our marvelous internal body systems to keep the vital functions at the constant level necessary for life. All the body's functions give evidence of marvelous intelligence, prevision, and provision, and nowhere is this better exemplified than in the living body's master

thermostat called the "hypothalamus." Working faster than the most advanced modern computer, this temperature control system of the brain adjusts the body to external changes of cold or heat with lightning speed. It, and other body control systems, make possible the seasonal acclimation process of living bodies. This entire process of adjusting and switching the entire metabolism of living bodies from one season to another, or to sudden shocking changes in the weather during a mid-season, should show even the most hardened skeptic that the wisdom that created the living body and maintains it is (and always will be) greater than the conscious mind of man can conceive. Our duty, according to Hygiene/Life Science philosophy, is to learn all we can about it and how it works, but to never lose our awe and respect for it.

But these natural responses of the inner body wisdom to sustained or changing weather conditions can be hammered, and interfered with by a myriad of external and internal factors and conditions. One analogy of the living body would be to liken it to a fine electric motor that someone drops a wrench in. The wrench stops the motor though the electric power that ran the motor is still here ready to do its job of starting the motor when the wrench is removed. We can, for purposes of analogy only liken the marvelous, intelligent life force that "builds" and runs the human body to the electric force of the motor. And, we can liken such things as the weather, wrong diet, drugs, etc., as the wrenches that thwart the body wisdom in its work. Life Scientists should include the weather, and its influence on living bodies, in their studies on nutrition.

We constantly hear people say that they "can't take the weather as well as they used to when they were younger." But, the cause is not their age in years, per se, but the accumulated wrongs done to their bodies over a period of years. Many of these wrongs are self-inflicted, but not all. There is very little we can do to change the weather, and evidence is mounting that certain weather conditions can have deleterious effects on the living body, causing such maladies as migraine headaches, depression, heart irregularities, metabolic disruptions, and a host of other ills. The body, and its governing wisdom, though astounding in its capabilities and sensitive adjustments, cannot dominate the external environment (like it reigns over the internal environment), except to a very limited extent. Even the culmination of some of this century's most vaunted technology, such as NASA's space shuttle, must pay obeisance to the weather, as happened recently with the voyage of Space Shuttle Columbia, when it was forced to stay in earth orbit an extra day due to very strong cross-winds at the prime landing site.

### **1.3 Natural Weather and Manmade Weather Affect Health and Nutrition**

Theoretically it seems possible (even probable) that the present "arms race," with its continued nuclear explosions (one by Russia in the sixty-megaton range!), may have already upset nature's delicate balance at the electronic level. And, some of these weird winds, and strange weather patterns all over the planet, in these hectic, closing years of the twentieth century, may be nature's way of trying to restore the atomic and electronic balance! If either of the so-called "super-powers" have done any investigation into whether or not their continued insane atomic blasts have disrupted nature at the atomic and electronic level, they are keeping their findings well hidden. And, of course, in addition to this new manmade atmospheric pollution and disruption, nature has to contend with natural pollution—such as the recent catastrophic volcano eruption in the Yucatan peninsula of Mexico. Incalculable tons of molten ash and other volcanic debris were exploded into the upper atmosphere changing the immediate weather picture around the world, according to meteorologists!

And, as far as humans on this planet are concerned, our natural atmosphere is our most vital natural resource, for we must breathe it all the days and nights of our lives. And, the electromagnetic condition of the atmosphere has been shown (by recent biometeorology research) to exert probable and significant effects on life on this planet! As this century draws to a close, evidence is mounting that man has (over the years) with sometimes good intentions, but with seldom any thought of future consequences, probably interfered in the natural environment so much that the natural electronic balance may have been vastly disrupted to the detriment of life on this planet. Nuclear explosions are the latest and greatest

madness in tampering with the natural balance of our environment. Technologically-advanced "civilization" does not necessarily mean a culturally-advanced one!

We can, to a limited extent, help the body's adjustment to external environmental conditions (sudden weather changes, etc.), with artificial "microclimates" of our 20th-century technology. But, as in the use of anything artificial, this again proves to be a two-edged sword. The best and most astounding piece of "machinery" human beings can have is their own bodies. And these marvelous systems of living equipment have their natural rhythms, their natural systems of adjustment, etc., to maintain certain standard levels of function within the body. These can be interfered with by artificial climates, etc. However, in some conditions of impaired health and disrupted nutritional (metabolic) functions, the temporary use of artificial climates has proven to have a temporary helpful influence. But, our bodies were designed by an incredible, invisible power and wisdom to respond naturally to weather conditions. These natural responses can be thwarted and weakened by artificial (technological) conditions.

[Home](#) > [Lesson 54 - Weather And Human Well-Being](#) > 2. The Body's Natural Protective Systems

## **2. The Body's Natural Protective Systems**

Clearly, in the living body, the body "chemistry" changes when there are changes in the weather. Technology can thwart the body's efforts at correct changes. But, modern technology is not the only thing that interferes with the body's natural functioning and responses to changed conditions in order to maintain internal temperature and other vital functions at a constant level. As Hygienists know, "toxemia" can play havoc with the body's internal economy; prolonged mental or physical stress can disrupt the body's internal adjustive mechanisms, and present a constant interference with the body's natural functions; and, of course, one of the worst causes of complete and deadly disruption of natural body functions is drugs.

### **2.1 Drugs Thwart and Impede Internal Vital Functions**

Both the so-called "primary" and "side effects" of many drugs can critically interfere with the body's natural functions. For instance, tranquilizers, prescribed to "relieve" stress during prolonged heat waves, have actually killed people due to their "side effects" of blocking the body's natural system of cooling itself by sweating! And, it has long been known that the drug, nicotine, can constrict circulation in the extremities. The western world's love affair with coffee makes millions of addicts to caffeine, another drug that can cause the constriction of blood vessels, causing a rise in blood pressure and giving a deceptive feeling that the body is naturally warmer. Other drugs, such as amphetamines, marijuana, and King Alcohol, can play havoc with the body's natural temperature-regulating systems.

The body's incredible sensitivity to changes in atmospheric pressure, and its remarkable internal adjustments to stabilize its functions in relation to external changes, can be fatally interfered with by drugs. According to scientific studies, the side effects of certain drugs prescribed for heart patients, for instance, can prove fatal to some patients taken under conditions such as the sudden dropping of atmospheric pressure preceding a storm, or in the lowered air pressure of the mountains.

### **2.2 More Influences on the Body**

And, who knows how many highway accidents, job-related accidents, marital break-ups, etc., are caused by the changing weather's effect on "weather-sensitive" people, who develop circulatory problems, fatigue, inability to concentrate, moodiness, depression, instant anger, migraine headaches, etc. The

nervous system of the marvelous living body is so sensitive to external influences (such as infrasound influences) that it can "feel" certain sounds that winds make which are of too low a vibration to affect the human ear.

Every year, in certain parts of this planet, weird winds spring up that in folklore have been called "witch's winds," because in their wake there seems to be a rise in accidents, illnesses, crimes, etc. Both weather-sensitive humans and animals seem to "sense" the coming of these winds. Now a scientific explanation has been given this folk wisdom of the ages. Scientists researching this phenomena now call this the "ion influence." They claim that in weather changes, it is these ions or electrically-charged molecules of air, to which people are really sensitive. They theorize that a natural balance of positive to negative ions of five to four increases strikingly as these "witch's storms" approach. The conclusions of these bio-meteorology researchers is that this upsetting of the ion balance causes immediate and drastic changes in the body-regulating systems of weather-sensitive people who are truly living barometers. One widely-noted effect is the overproduction of adrenalin, which as a secondary effect causes adrenal exhaustion symptoms such as extreme fatigue, nervous tension, moodiness, depression, etc.

Ion research at the University of California, Berkeley, has discovered that negative ions reduce normal blood levels of serotonin, a hormone that "carries messages" (according to brain specialists) within the brain processes. These findings concluded that positive ions, on the other hand, increase serotonin levels. This increase in serotonin caused by an increase of positive ions is declared to be the cause of illnesses related to "witch's winds," according to ion researchers. The theory is that wind friction caused by moving air masses, layers of wind, etc., creating friction with existing, relatively motionless surrounding air, tends to cause massive electrical disturbances by "knocking off" negative ions and increasing the overdose of the number of positive ions. Ion researchers now conclude that an overdose of positive ions affects the body processes, metabolism, temperature regulating, etc., of all living creatures on this planet.

### **2.3 How Can We Control How the Weather Affects Us?**

If these current findings about weather-related illnesses caused by an upsetting of the body's internal systems hold true after much future investigation, then an equal, if not more important, area of investigation would be to see if we can discover how the body itself best copes with these outward, adverse changes and influences. Life Science already has a key understanding in that the healthy, normally-functioning body can more quickly adjust to and overcome enormous external adverse influences. But, the body's energies and intelligence not only have to be expended in adjusting to massive external influences, like the weather, but it also has to use its precious life energies neutralizing and expelling drugs that are deadly to the body's internal processes; plus the processing and expelling of wrong foods, bad combinations, etc. But, the primary law of physiology of the body is "self-preservation" by the great wisdom within. Life Science/Hygiene teach that a living body not burdened with toxemia, and correctly nourished, can withstand external environmental changes, like the weather, with a remarkable resilience, and that weather influences on such a healthy body are more temporary with less lasting disruption of body economy.

We've all heard the saying, "Everybody talks about the weather, but nobody does anything about it?" But we all can do something about it by correct living in such a way that we help the body to help itself, in its readjustments and responses to the disruption of its internal equilibrium by such conditions as sudden weather changes, etc., and not in such a way that we are constantly throwing deadly "wrenches" in the body's incredibly complex works. Or, to put it another way, study and listen to your own body, for its wisdom and marvelous workings are the best indicator, maintainer, and adjuster of total body health (physical and mental) whether in weather changes or whatever, and not some external authority, drug prescription, injection, etc.

Thus, the constantly increasing discoveries of how the weather can be a disrupting factor in health, nutrition, etc., show dramatically, again, the great value of the Hygiene/Life Science way of life, as the

best way of helping the body cope with these disruptions. One of the basic pillars of the Hygiene/Life Science way of life is correct nutrition. We have already mentioned the deadly effects of many prescription drugs on the body's ability to adjust to weather changes. But few of the contemporary works on nutrition equate all the harmful additives in food as being drugs also, and just as poisonous as prescription drugs to the living economy.

Many things popularly thought to be foods are really poisons. For instance, sugar and salt are not foods, but poisons. The enormous amounts of salt and sugar consumed by Westerners produce untold ill health, misery, and death. Salt buildup in the body causes increased loss of potassium, and this depletion of potassium can lead to heat prostration, headache, lassitude, sleeplessness, localized pain, inability to concentrate, etc. Much evidence is available to show that its cumulative effect over a period of years is one of the culprits in kidney disease, high blood pressure, heart enlargement, etc. Refined sugar is consumed in towering amounts by our Western society and culture, and is suspected of being a major factor in heart disease, arterial diseases, teeth and bone deterioration, etc.

It is not hard to see how the complex body system, disrupted constantly by the ingestion or injection of dangerous drugs, chemical additives/etc., could be unable to cope with sudden and vast changes in the weather. On the other hand, a smooth functioning body whose cells and tissues are kept well cleansed and well nourished with the biologically-suitable diet of mankind—fruits, uncooked vegetables (especially green, leafy salads), and nuts, can withstand and adjust to weather changes to a remarkable degree.

Space is limited, so this must necessarily be a rather general survey and summary of some of the recent investigations and discoveries in this fruitful and fascinating field of biometeorology—the study of weather, climate, etc.—and its mysterious influence (in several aspects) on human health. Here is surely a fertile field for present and future investigation, for those Life Scientists/Hygienists who desire to strike out into newer fields of creative thinking, investigation, and discovery for the benefit and betterment of humankind.

[Home](#) > [Lesson 54 - Weather And Human Well-Being](#) > 3. Bioelectronic Factors In Nutrition

### **3. Bioelectronic Factors In Nutrition**

Those who probe, poke, and pry into the living body trying to force it to reveal its innermost secrets of nutrition and life, finally come to an invisible, impenetrable wall, and the message of nature seems to clearly proclaim: "Thus far shalt thou go, and no further!" All investigation seems to run out into unfathomable mystery. The living body's ultimate processes of nutrition are a nature-kept, or life-kept, secret. Nor, is it necessary that we know these ultimate nutritive processes, for nature (or the invisible life force of nature) would still have to do the ultimate processing by the same natural laws as it has done since life first began on this planet.

The one vital area where nature requires our conscious participation is that first important step along the long and winding nutritive road, of providing the body with the biologically-correct food, and of course, proper mastication of that food.

Even our 20th-century technology, remarkable as it is in some areas, cannot take a television camera into the inner recesses of the living cell and show us its ultimate nutritive processes. Thus, it has always been, and shall always probably be. We can only speculate, theorize about ultimate processes, and up until recently that seemed counterproductive since nature goes right on with her great secret work regardless of our questions about it. But, in the light of recent investigations and findings (as summarized in the first segment of this lesson, on the weather), showing that weather, climate, drugs,

etc., can seemingly have an often devastating effect on living bodies by disrupting electrical balances, etc., perhaps a renewed, more intense speculative look, or theorizing, about what may go on behind the great barrier of effects in living nutritive processes may now be more fruitful.

And, it must be admitted at the outset that this will be mostly theoretical and speculative, as, in this writer's opinion, investigations of invisible ultimate nutritive matters (no matter how sincere and dedicated) cannot at present (if ever) be considered as having absolutely-established conclusions that present final "scientific proof." But, Hygiene/Life Science ever seeks to increase the light of human understanding and betterment, and if questioning and theorizing into new fields of thinking lead to that worthy goal, then more power to it—as long, of course, as this thinking does not subvert or take us astray from the time-honored and proven basic principles of Hygiene/Life Science.

Since all material things seem to run out into invisible electronic mysteries, for purposes of this lesson let us approach the living body from that standpoint. The pioneer in "bioelectronics" was George W. Crile, who as early as 1889 began his researches into the electronic nature of the living cell, and reached the conclusion that every cell of the human body is really a tiny bipolar battery carrying two electronic charges—a negative charge on the outside, and a positive charge at the center. But Crile, and the bio-electronic researchers after him, started their investigations with a "full-blown" cell which has turned out to be a very complex thing indeed!

Crile's researches and findings were later duplicated and verified by Lakhovsky and others. They concluded that a predominance of a positive electronic charge brings total health, abundant energy, extended youthfulness, etc., while a predominance of negative charge or potential in the cells caused cellular fatigue, structural deterioration, exhaustion, and eventual death of the cells.

This might lead some to conclude that electricity, or electronic energy is life, or the life force. We are no more able to resolve the problem of the ultimate nature, essence, mystery, and miracle of life than any other Hygienist/Life Scientist, and claim no special mandate to give such final dispensation. We can only offer our own ideas held at the present (which could change in the future, in the light of newer thinking and investigation) with no implication that we think these are final and unshakeable conclusions. And, with the hope that present and future Life Scientists/Hygienists can delve further into this great mystery. There are those who will dogmatically state that the life force is you, or your subconscious mind, etc. But such statements lack absolute, demonstrable proof, and therefore are assumptions, not conclusions. Others will claim, just as dogmatically, that the life force is electricity.

It is this writer's considered opinion, however, that life, or the life power, is probably not the same as electricity, but that the life power "uses" electronic energy to "build" or form the body and put it' into a certain condition so that life can manifest more fully. There are just too many unresolved (and probably unresolvable) differences between the life force and electricity. Perhaps there are even "life fields" and "body fields" that intermingle and interpenetrate. The pioneering work of Harold Saxon Burr is highly interesting along these lines of investigation of the ultimate cause of the great barrier of effects in living processes.

And, to try to reduce the life force to the same size as the "electronic building blocks" it uses, as the reductionists try to do, is as futile as trying to describe and reduce the brick mason to the same size as the bricks he uses! Those, who in their philosophical considerations, try to reduce the life force to its tiniest "building blocks," are following a wrong theory, in this writer's opinion.

But, who can say they know, and can prove for absolute certainty, what life really is? Perhaps we will never know what the life force is, in its ultimate essence. It is a nature-kept, or life-kept secret, and one that Mother Nature seems not to want to share with us! Perhaps, for us humans, it is just as important to know that life is *not* as to know what it is!

Many Hygienists/Life Scientists of old wrote as though they considered the life force and nerve force as the same thing. I have expressed my own opinion (above) that I do not think the life force and electricity are the same. Yet, nerve force does appear to be some form of electricity or electronic energy. How do

we resolve this? Theorizing from bioelectronic research findings, and from Hygiene/Life Science philosophy, the conclusion seems inescapable that here, perhaps, we can deduce a reasonable hypothetical explanation to account for the perplexing paradoxes and contradictory aspects of nerve force and life force. They are apparently two different things! At least that is the conclusion we are drawn to, at this time, by our evaluation of current bioelectronic research. It should remain an "open-ended" subject, however, and it should be understood that we are not here claiming to present absolutely final conclusions about it! To return from this needed digression to the comparison of the life force and nerve force—nerve force is a variable factor—life force is a constant. Nerve force would appear to be the "positive aspects" of the bioelectronic energy of the nervous system, and rises and falls with certain conditions. Life force, on the other hand, is a constant and not a variable factor. It is not "used" by the body, but uses the body and nerve force as its manifesting instruments. Life force initiates intelligent action in the body, while nerve force, being apparently a form of electricity or bioelectronic energy, has no power of intelligent initiation. And the Hygiene/Life Science philosophy shows that even life, itself, must work within the confines of biological laws.

At the present state of bioelectronic research, nerve force would appear to be generated within the body, although there are those who think it also can, to some extent, be generated from without. Here, as elsewhere, the infinite power and wisdom of the life force may have designed more than one way of doing things as an emergency, self-preservative influx. Who knows? But, if our bioelectronic theorizing is to be consistently developed as a theoretical explanation of the differences between the life force and nerve force, we must postulate that for the maximum healthful functioning of the body, and full manifestation of life's powers, the life force apparently must maintain a nerve force balance of positive and negative electronic energy charges, with slightly more of the positive charge predominating.

Since all matter in the universe is built, and has an electronic basis, food must also have its electronic basis with its positive and negative electronic charges. And, it would seem logical, and consistent with our bioelectronic theorizing, to conclude that all foods either have a predominantly positive potential or a predominantly negative potential, or else a near balance of positive and negative potentials.

We do not get life from food, for food cannot give what it does not possess in the first place. Food, in the state it is taken into the body for nourishment, is dead, inert material that is acted on by the life force. Let those who claim that electricity is life explain this—food matter contains electricity (electronic factors) in its very basic makeup, but it does not contain life. A predominance of negative electronic potential in inert matter, as in dead bodies and dead foods, is still electricity or basic electronic factors. Is not a dead body still composed of electricity in the material of which it is still composed? And, yet it does not contain or manifest life. We do not get life from dead, inert material like food. What we do apparently get from food (at its ultimate breakdown by digestive processes) is electronic energy, if our electronic theorizing is to be consistent. Reducing food to its cells, the food cells themselves are further reducible to molecular and then to atomic and subatomic or electronic levels. Upon correct and complete digestion and assimilation, the electronic energy is freed from the foods. Thus, under the bioelectronic view, we see that the so-called "biochemistry" system of food science would not be correct food science, and would be of relatively minus value to the Life Scientist/Hygienist, as its conclusions are reached from the data and studies of contrived experiments, research on rats, manufactured deficiencies, and research on dead bodies, dead foods, and the dead chemical elements of these.

But, under the bioelectronic view, it is seemingly the electronic energy in the foods (according to bioelectronic research), and not the chemical elements that should form the real basis for a genuine science of living nutrition. Reasoning from the findings of the bioelectronic researchers leads to the conclusion that the chemical elements in foods are apparently the transport-carriers of the electronic energy that is seemingly the real goal of the long chain of nutritive processes in the body. When this electronic energy has been released from food cells, the chemical transporters that are left, and that are not utilizable by the body, are poison to the living body and must be speedily eliminated by the self-preservative instincts of the body wisdom. Pursuing this reasoning further, another apparent conclusion to be drawn is that fractured and fragmented food supplements are unusable by the body, and therefore

foreign to it (poison), and also must be quickly eliminated as life-threatening materials.

### **3.1 Food and Electronic Energy**

A bioelectronic food science based on the electronic energy would show whether a food had a predominance of positive or negative electronic potentials, or is almost neutrally balanced. But, this does not mean that we need to always follow some complicated chart showing the positive and negative, or neutral potentials of every food in existence. Nor does it mean we have to be always keeping the positive and negative electronic condition of the body in mind, so that we will be sure to eat foods and maintain a proper balance to keep us healthy and fully alive. As in so many other things, wise old Mother Nature has preceded us and provided the perfect balanced food to maintain maximum health. Since this is the natural, biological food for humans, and since health results from its use (other things being equal, of course), it seems a fact of observation that this food, designed by wise nature for human use, has a perfect balance of electronic potentials to maintain the living human body at its highest level. That perfect natural food of mankind is, of course, the many wonderful varieties of edible fruit, along with uncooked vegetables (especially green, leafy ones), and nuts. In the master drama of human nutrition, our prime role or duty is to see that we eat the natural diet that contains the essential nutritive factors. And, we can then put our trust in the great wisdom within to do its marvelous work of building our bodies as healthily as possible—as it has done for untold ages past, since life first manifested on this planet Earth.

### **3.2 The Body As a Bioelectronic Phenomenon**

In the first segment of this lesson, I indicated that scientific findings show that disruption of body processes by weather is done at the electronic level. But, how much greater is this electronic disruption from wrong food, and wrong food combinations? And yet, nature has seemingly made our correct biological diet such a relatively simple objective for us, and we humans seem to want to make it so complicated. Our theoretical reasoning leads us to believe that the wisdom in nature has made the natural food of mankind so perfect as to its ultimate electronic potentials needed for the body processes that no human genius in electronics, or the most sophisticated modern computer, could even begin to compare with it.

Thus, theorizing (or deducing) from the bioelectronic viewpoint, nutrition at its ultimate invisible goal after releasing or unlocking of the electronic energy, possibly consists of some magical (and there's no better word to describe it) transformation of ultimate electronic factors of foods into some higher state or condition that is closest to the essence of the life force, itself, and can best be utilized by it in that "higher" condition. Perhaps, again, this ultimate energy unlocked from food consists of some peculiar and higher form of vibration of the released electronic factors. Thus, certain radiations, at certain wavelengths, might be the invisible "building blocks" that the life force uses in building and maintaining animate bodies.

Of course, the mysterious energies locked up in the ideal foods—fruit, uncooked vegetables, and nuts, in correct combinations, cannot be available to the life force unless they are unlocked and set free by correct functioning digestive processes all the way down the Ion road of nutritive processes. And these digestive processes can be interfered with and disrupted and perverted in a myriad of ways and conditions, such as sudden weather changes, wrong food combinations, enervation and toxemia, wrong emotions, overwork, etc.

### **3.3 The Hygienic/Life Science Way**

And, while fruits, uncooked vegetables, and nuts, in correct combinations, are nature's ordained diet for mankind! it may be that with more knowledge in the future we will discover that during certain times, and under certain conditions, we should favor the combining and eating of certain fruits, vegetables, and

nuts over others, for their slightly different predominance of electronic potentials. For example, future findings might show that *specific* fruits, vegetables, and nuts, properly combined, may be better for weather-sensitive people whose ion balance has been upset by adverse weather conditions, etc. This is, of course, speculative, and awaits more research for possible verification in the future; but, as stated at the beginning of this part of the lesson, this brief speculative analysis of bio-meteorology and bioelectronics hopefully may arouse further thinking and investigation by Hygienists/Life Scientists into these relatively little investigated areas of nutrition and related subjects. For we can never reach the omnipotence and omniscience of nature, or the life force and wisdom that ever remains hidden within manifested nature; but in the constant journey, struggle and out-reaching to learn more of nature's secrets, in order that we may learn to live in compatibility with her ordained ways, we grow and expand our lives and our consciousness. And, creative outreaching is initially speculative, until more definite evidence catches up to it.

[Home](#) > [Lesson 54 - Weather And Human Well-Being](#) > 4. Questions & Answers

#### 4. Questions & Answers

**You say if one eats Hygienically and is in good health that he or she will not be adversely affected by the weather. But I'm in very good health, eat no wrong foods, and yet as soon as winter comes (I live in Michigan), I get sick for long periods of time. Could it be that my attitude toward the weather (I hate winter and being indoors) has physiological effects on me?**

Most certainly, yes. Attitude is a very important factor in human health—almost as important as diet. Observe those around you who are always negative in their thought processes—check how often they become ill despite their diets and lifestyles. This does not mean, however, that you should neglect your diet. Maintain a good, healthy diet and a good, healthy attitude.

**Every time it rains my joints ache. I've been to the doctor for this problem on several occasions and he says I don't have arthritis or anything like that. What could cause this?**

Apparently your diet and your lifestyle are not as pure as they need to be to maintain optimum health. Try adding more fresh, raw fruits, vegetables, nuts, and seeds and eliminate harmful items in your diet such as refined products, salt, condiments, alcohol, drugs, meats, etc. You'll be amazed at the difference the next time it rains.

**Whenever it is just slightly cold out and everyone around me says it's just right—such as when the temperature is about 65 or 70 degrees—I still feel cold. The same is true when it's in the upper 70s and 80s—everyone around me says it feels good and I'm too hot. Why is this so?**

Perhaps your body's temperature controlling device, the hypothalamus, is not functioning properly. This is caused by improper diet, poor environment (too much artificial cooling and heating), not enough exercise, fresh air, or sunshine. Try improving your diet and getting out in the open air and sunshine for exercise regularly.

In this lesson I have shown that the weather can and does affect one's health. I have also shown that it will have less effect on you if you abide by nature's laws—that is eat only of natural fare (raw fruits, vegetables, nuts, and seeds), drink only pure water, take exercise, fresh air, and sunshine, and apply the other essentials of life as taught previous to this lesson. This lesson pointed out that every cell of our bodies has an electronic nature—that is, a

positive and negative charge. The food we eat also has electronic energy which when released from the food's cells, nourishes our bodies. More studies need to be conducted regarding the electronic nature of foods and how they affect our well-being.

[Home](#) > [Lesson 54 - Weather And Human Well-Being](#) > Article #1: The Weather In Your Health by Mike Benton

## **Article #1: The Weather In Your Health by Mike Benton**

It was many years ago. I was a small boy visiting my great-uncle on his farm in the back country.

On a warm and sunny day in early November, he told me, "Better pick all those fall tomatoes. Probably be snow on them by tomorrow."

I thought he was joking, but I harvested all the tomatoes just the same, sweating in the garden in a pair of shorts.

The next morning I woke up and saw snow all over the fall garden. My uncle met me at breakfast. "It's my wrist," he told me. "Better than any weather vane. Always acts up before a snow or a rain."

How many times have you heard people say that they knew a storm was coming by the "way their bones felt?" How about hearing people complain that they feel "under the weather?" How about yourself? Do you drag around when it's cloudy and feel great only when the sun shines?

No doubt about it. Weather affects all of us in some way or another. Many people seem more strongly bothered by the weather than other people. Some blame the weather for that ache or pain, or their own poor health in general. But what roles does weather play in how good or healthy we feel? Is the weather responsible for the many symptoms that people feel, or is it something else?

### **Weather Sensitivity**

How weather influences living things is what the science of *biometeorology* is all about. The biometeorologist studies how the daily and seasonal changes in the weather influence animals and humans.

These "weathermen-biologists" say that while changes in the weather affect everybody, about one in three people is extremely sensitive to these changes (like my great-uncle) and that they may express one or more of over forty different symptoms associated with changing weather.

For instance, pains in the joints or other parts of the body that precede a change in weather have been known since the times of ancient Greece. Rheumatism sufferers are the most affected—sometimes up to two days ahead of the changes in the weather. Many people with fractures, dislocations, burns, and even chafed areas or corns have a sort of weather barometer "in their bones."

Other symptoms that accompany weather changes in sensitive people are migraine headaches, back pain, upset stomach, irritability, loss of appetite, severe depression, feelings of uneasiness, and so on. Some people blame all their ills on the weather.

However, it is important to remember that the weather itself does not produce weather-sensitive people. *The sensitivity people experience with changes in the weather is a function of their own physiological makeup.*

"A healthy, robust, and well-balanced person is rarely sensitive to changes in the weather," says Michel

Ganquelin, a weather researcher. Generally speaking, people who are overly sensitive to the weather tend to suffer from chronic diseases, and they react with pain to barometric changes.

A strong and healthy person can endure stress on several levels and not exhibit any signs of illness or discomfort. Weather is probably the most basic stress that all humans experience. It changes almost every day, and with these changes come new situations and stresses that we must adjust to.

## **The Weather Fronts**

Perhaps the most stressful weather condition is the passing of cold and warm fronts. William Thomson, author of *Climate and Health*, believes that people respond more to weather fronts than to any other single weather factor.

A cold front coming through means more than just a drop in temperature. It also means complex changes in the barometric pressure, wind direction, humidity, and even pollutants and radioactive fallout may be carried in. All of these changes affect our bodies, our endocrine systems, our nervous systems, and our cardiovascular systems.

The biometeorologist, Dr. De Rudder of Paris, says that the "death rate often increases while fronts are passing." For people in good health, fronts may only cause temporary feelings of discomfort. But for the person whose system is weakened, or who has undergone surgery or has high blood pressure, this feeling of discomfort can become something much more critical. Heart attacks often accompany weather front passages, and in general any disease which is aggravated by stress increases in intensity when a front goes by.

While a healthy person does not react as severely to the passing of a front as does a "weather-sensitive" person, all people experience many physiological changes that are being constantly modified by the climate and weather.

## **Weather and the Changes In Your Body**

Here are some of the findings of weather researchers and biologists about how just one weather phenomenon—weather fronts—affect *everybody*.

1. Blood clotting occurs faster just before a front passes.
2. Fibrinolysis, or the dissolving of blood clots, increases after the passage of cold fronts.
3. The amount of urine passed increases when cold fronts are passing and decreases when a warm front has passed.
4. The blood-sugar level is changed by the passage of a front, as are the levels of calcium, phosphates, sodium, and magnesium in the bloodstream.
5. The amount of blood in the body decreases and the blood sedimentation rate is lower after the passage of a cold front.
6. White blood cells increase in number when the barometer falls sharply.

### **A Case History In Weather Changes: Rheumatoid Arthritis**

In healthy people, the changes that accompany passing weather fronts are minor, almost unnoticed. In an individual with rheumatoid arthritis, however, the changes can be quite serious.

A seven-year-old girl who already had arthritis was asked when her pain was the worst. "Whenever we have a storm, my joints feel stiff and I'm sore all over. Sometimes I get stiff before the storm starts, and sometimes I feel better before it stops raining."

Weather researchers have found that in 93% of all arthritic pain, there was a major change in barometric pressure. One suggestion for this affect is that people with rheumatoid arthritis have peripheral blood vessels that are easily constricted. The passage of fronts often causes changes in these blood vessels,

causing them to constrict farther, which decreases circulation and increases pain for those with arthritis.

A fall in barometric pressure also leads to a retention of water in the body. The cells of rheumatic tissue are not as permeable as healthy cells, so they retain this fluid more. This retention of fluid leads to the pain and swelling of the afflicted body part.

The weather did not "cause" the condition; the condition already existed, and the weather simply aggravated it. Besides arthritis, there are many other illnesses of the body that can be made more intense by weather changes.

## **The Weather Thermostats In Your Body**

Obviously weather does affect all of us greatly. Depending upon how healthy we are, we can either shake off these effects or succumb to them. To understand a little more how weather affects your body and, consequently, your health, let's look at some of the inner workings of the body as they relate to weather.

There's a portion of your brain called the *hypothalamus*. It controls digestion, water retention in the body, how we sleep, and our body temperature. The front part of the hypothalamus tells us when to lose heat by making us sweat and opening up our blood capillaries to cool us off. The back part of the hypothalamus can make the capillaries contract which helps keep our body heat in.

In older and sick people, the hypothalamus does not always function properly. This is why these people seem to chill so easily in the winter or become overheated in the summer. Toxins in the bloodstream, brought about by improper diet and poor elimination, poison the hypothalamus. Dr. N. W. Walker has said that the best way to keep the hypothalamus healthy is by eating mostly raw foods. Noxious substances from improper foods can slowly destroy the hypothalamus, which is actually the body's thermostat.

Notice, too, that the hypothalamus also controls such functions as appetite and sleeping. This might help to explain why weather, which affects the hypothalamus, can also make a person lose his appetite or have trouble getting to sleep.

The *pituitary gland* at the base of the skull controls the body's metabolism in cold and hot weather. It, too, regulates the water level in our body for heating and cooling. The posterior part of the pituitary also regulates the temperature of the body as the temperature changes. It's responsible for blood temperature, the perspiration process, and opening and closing the pores of the skin during hot and cold weather. A healthy pituitary gland can help us adapt to weather changes more easily. Again the best foods for optimum functioning of the pituitary are fresh fruits and vegetables, according to Dr. Walker who has made a close study on glandular health and diet.

If we keep the pituitary and hypothalamus healthy by proper diet, we can stay atop the weather more easily. A pure bloodstream from a proper diet, along with regular exercise, can insure the well-being for these two body parts as well as the entire organism.

## **Diet and Weather**

Your diet can help you adjust to the changes in the weather if you'll remember two things: 1) When it's hot, you need more fluids for the body; 2) When it's cold, you need more fuel.

People used to automatically change their diets to meet the seasons because they ate what foods were naturally available, such as fresh fruits and vegetables in the summer and the dried fruits, nuts and greens in the fall and winter. Nowadays, with supermarket and technological junk foods, people can eat the same poor diet all year round.

During the hot months of the summer, my own diet is chiefly melons, tomatoes, and peaches. These are high-fluid foods, and they help to keep the body water-cooled. The summer fruits are also high in

potassium and sodium, which are important minerals in maintaining the body's water balance.

You do not need extra salt or any salt in the summer. . People that eat salt sweat it out during the summer because the body is trying to eliminate it. The mistake is made that since salt is leaving the body, it must be replaced, so they eat more salt and the body must work all the harder to get rid of it again. Salt serves no purpose in the human diet, and its use in the summer (or anytime) is not recommended.

When the weather is cold, you'll need more *carbohydrates* in your diet for winter fuel—not fats or proteins. A public health nutritionist in New York, Beverly Daniel, puts it this way: "In very cold weather, people need to eat a diet heavy in carbohydrates—like fruits and vegetables. Eating fat is a good way to get fat. Fats are hard to digest in summer or winter. About seven years ago, the army tested soldiers stationed in cold mountain areas. They always picked carbohydrate foods over fats and proteins for their body's fuel needs."

Dried fruits and the more-concentrated fresh fruits (like bananas and persimmons) are the best high-carbohydrate sources for winter needs.

Incidentally, a layer of fat is *not* a good idea in winter or summer. In a 1958 government test, overweight men did feel the cold less than thin people, but when the exposure to the cold was prolonged, the underweight individuals suffered less cumulative effects of cold stress than those with heavy fat layers. Without exception, the thin people also readjusted to the heat much better than those that were overweight.

So don't use winter as an excuse to pile on layers of fat— unless, like the bear, you plan to sleep and fast until spring!

## **Manmade Weather**

Another way you can better adapt to weather changes is by avoiding as much "manmade weather" as possible, such as unnecessary heating and cooling.

Humans have a definite metabolic need for fresh air to pass over their exposed skins. Especially while sleeping do we need an open circulation of fresh air.

By living in tightly-sealed, climatically controlled buildings all year-round, we lose our ability to readily adjust to weather changes. In the perfect environment for man, temperature extremes would not require artificial heating or cooling. Actually, air conditioning in the summer is a real newcomer, and with appropriate building design and dress, it could be eliminated.

Don't make yourself uncomfortable, but do take every opportunity to keep your living and work areas open to the current weather. Don't let "manmade weather" be your constant year-round environment.

## **Becoming Less Weather Sensitive**

To become less sensitive to weather changes, improve your physical health and review your emotional attitudes. Weather sensitivity can be decreased by changing your lifestyle and the way you view the world. Weather sensitivity does change throughout your life, perhaps reflecting your strength and state of health. Infants and elderly people are the most sensitive to weather changes, followed by adolescents and adults. Young children are the least sensitive of all.

Ever notice how preschool children can play outside in the hottest sun or run around without their jackets in the snow? Their young bodies still possess boundless health and vitality that allows them to rise above the weather conditions.

We can achieve that state again, too, if we follow a few simple rules:

1. Reduce your dependence on manmade weather (heating and cooling) while still maintaining a reasonable comfort zone;

2. Eat a diet in our natural food (fresh fruits and vegetables) and eat in season—juicy fruits in the summer and more concentrated carbohydrates (dried fruits, nuts, etc.) in the winter;
3. Fast or follow an optimum diet to detoxify your body so that it will become less weather-sensitive. This is especially beneficial for arthritis and those that complain of weather-related pains, aches and allergies;
4. Exercise outside in the open on a year-round basis, even if only for five or ten minutes (if weather is severe).
5. Spend more and more time outside in the open air and less time in buildings. Living in buildings removes us from our natural environment and increases our "sensitivity" to natural changes in the weather, etc. Besides paying attention to such physical details, you might also need to consider your weather sensitivity in a psychological light.

Adapting to weather changes may just reflect a difficulty in adapting to all changes in life. People who complain about the weather all the time may be "set in their ways" and be afraid or resist any kind of change—even a passing cool front!

Weather-sensitive people, according to the biometeorologist, Dr. De Rudder, are often very emotional, perspire profusely when nervous, color rapidly when annoyed, and rarely say that they feel well. Some of these people use the weather as a convenient way to blame their own negative feelings and emotions.

Then, too, weather sensitivity may also be a reflection of our general sensitivity to life itself. Highly aware people are tuned into all aspects of their environment, including the weather. Many famous artists, musicians, and writers have often discussed their oversensitivity to changes in the weather. Being aware of weather changes is one thing; having them dominate your life is another.

### **Weather You Believe It or Not...**

The weather is the great equalizer of mankind. Rich and poor, old and young—we all share the weather again.

Like any other aspect of our environment, the weather is going to affect each of us in different ways. The way your body responds to the weather is dependent on your level of health, both physical and emotional.

You've heard it said that you can't do anything about the weather but talk about it. Well, that's not true when it comes to your own health. A healthier person does adapt to weather changes better than his sickly neighbor.

So don't just talk about your health, do something about it, and you'll never feel under the weather again!

## **Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth**

- [Article #1: Joyous Childbirth, Hygienically By Ralph C. Cinque, D.C.](#)
- [Article #2: Feeding Mothers By Herbert M. Shelton](#)
- [Article #3: Prenatal Life By William L. Esser](#)

### 1. Introduction

## **1. Introduction**

Approaches to pregnancy and childbirth have changed gradually through the ages. Primitive women went through their entire pregnancies with no problems. When the time to give birth arose, she merely went about it quietly and with little or no pain. There was no interference from anyone. The whole birth process took her away from regular life activities for perhaps a couple of hours.

As people became more "civilized" (in their diets and lifestyles), they began creating means of intervention—attending the processes of pregnancy, labor, and delivery "better than nature" could. One tribe of people is reported to have hung pregnant women upside down from a tree to scare the baby out. Another tribe had someone sit on a pregnant woman's belly to force out the child. These people had no understanding of the mechanics of labor and childbirth.

Man had a wonder and fear of childbirth as he had never observed it. He believed women possessed some sort of "power." Because of this, he eventually took charge of the entire birth process (from conception to birth) by interfering in its natural progression: Practices such as drugging during labor, Caesarean sections, forceps deliveries, drugs for various "complications" of pregnancy, etc., were ushered in.

Now there are even more devices to "aid" women through labor and delivery. Devices such as sonar sound, fetal heart monitors, etc., are very commonplace in hospital deliveries. You can even find out the sex of your baby ahead of time now.

Humans seem to have lost faith in nature and most do not believe that a birth can be natural. Most of us have little or no knowledge of the factors that create a normal pregnancy and childbirth. Pregnancy is regarded as disease to be treated. Women usually give birth in hospitals for the convenience of physicians. Physicians have long since discovered that interference in childbirth is an economic plus for them.

Despite all of this, there is a growing number of women (usually educated) that no longer patronize physician/hospital births. They are choosing homebirths attended by midwives or by their husbands alone. These women have a thorough knowledge of the mechanics of their bodies throughout the birthing process and also know that diet, exercise, etc., during preconception and pregnancy have much to do with how well the birth process will go and how healthy the child will be.

## 2. Preparation For Pregnancy—Preconceptional Care

### 2. Preparation For Pregnancy—Preconceptional Care

The quality of a child's life is determined before birth—it even begins before conception. A woman's body must be healthy prior to conception to insure proper development of the new being.

The prospective mother needs to exercise regularly, think positively, breathe fresh air, take sunshine, keep clean, get adequate sleep, and, above all, improve her diet at least six months prior to conception (if it is not already good). (However, any improvement in the diet at any time during pregnancy is better than no improvement at all.) The fetus will then develop in an already clean, healthful environment.

#### 2.1 Fasting To Improve Baby's Future Environment

The best way to create an ideal fetal environment is to fast. It's sort of like cleaning your house before the arrival of a guest. A fast will enable the body to eject uneliminated toxins from tissues. Toxins may have been building up for years. Ridding the body of toxins causes better assimilation of foods and thus better nutrition. One long fast or a series of short fasts followed by a diet mostly of raw fruits with some vegetables, nuts, seeds, and sprouts will prove very helpful before and during pregnancy and lactation.

#### 2.2 Improving the Diet

The best time to improve the diet is *before* conception. An all-raw diet following a fast will be less difficult to achieve than switching directly from a conventional diet to the Hygienic diet. But for some it is easiest to *gradually* eliminate meats, grains, processed and cooked foods, etc., and to eat more and more fresh fruits and vegetables as time goes on. Which way is chosen to improve the diet is less important than the fact that the diet is improved at this crucial tie.

#### 2.3 Exercise

*"The stronger the body, the more it obeys; the weaker the body, the more it commands."*

—Rousseau

A woman's muscles need to be firm and well toned to allow for ease of delivery and less pain during the processes of pregnancy and childbirth. Starting an exercise program before conception, if not already on one, is essential. To start an exercise program during pregnancy when the body has been inactive prior to that time and the muscles are flaccid, could be dangerous.

Many women are accustomed to wearing tight-fitting clothing. Therefore their muscles haven't been used to support their internal organs as they should. Muscles, especially those of the abdomen, become flabby and weak when not used. These are the muscles to which most attention should be focused in preparing the body for pregnancy and childbirth.

Exercises such as sit ups, push ups, deep-knee bends, leg lifts, and yoga postures strengthen the abdominal, back, and leg muscles. These exercises should be as vigorous as the woman's physical condition permits. Start out slowly and gradually work out more and more and establish an exercising routine that works for you.

Many women suffer from lower back pain during pregnancy and labor. Had these women strengthened their spine and its supporting muscles prior to this time, this pain would not have occurred. These muscles will have the strength to support extra weight while pregnant if used regularly as they should be. (Note: the lower back is also a dumping site for toxins if the body is in a toxic state—exercise alone cannot alleviate back pain—a pure body is also necessary.)

## 2.4 Effects of Birth Control Pills, IUDs, and Abortions Prior to Conception

Women should not conceive immediately after stopping use of birth control pills or after the removal of an IUD because this can pose danger to the fetus. Prior abortions, which stress the woman's reproductive organs, also pose danger to future fetuses. They can cause babies to be born prematurely.

The body needs a housecleaning to prepare for the fetus. Fasting, followed by a proper diet and other life essentials will prepare the body for the incredible feat of pregnancy and birth.

[Home](#) > [Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth](#) >

### 3. Care During Pregnancy

### 3. Care During Pregnancy

Women are convinced by the media, their physicians, relatives, etc., that prenatal care means going to the doctor for regular checkups. Frequent examinations are required by physicians to check for sugar in the urine, blood count, edema, etc. These "complications" are considered by conventional standards to be normal and therefore need to be checked for. Instead of avoiding these complications by right living, these abnormalities are tested for throughout pregnancy. What women are not told is that all these tests (especially vaginal exams) are very enervating and should be avoided and, in fact, visits to physicians are not only needless but fraught with many dangers for both mother and progeny.

We are told that only an uneducated, ignorant woman would neglect visiting an obstetrician regularly during pregnancy to make sure everything is going okay. But why wouldn't everything be okay? These obstetricians are trained to treat pregnancy as a disease rather than the normal and natural condition that it is.

The medical establishment conducts many tests on pregnant women to discover trouble only after it is developed. They have no ways of guiding women to health—they deal with pathological effects, not causes. Normally, physicians utilize drugging, which adds to the harm, to "remedy" the "problems" they purport to discover with their tests.

Prenatal care, however, does not mean visiting your obstetrician at all. It means providing the healthful conditions so as to produce and maintain better health and development in the unborn child. In other words, the child is very much so "at the mercy of the mother" for all the requisites of development and growth and freedom from harmful toxins. As Dr. Shelton says, "the child's needs are best served when those of the mother are perfectly supplied."

Prenatal care includes wholesome outdoor exercise, pure air, rest and sleep, sunshine, freedom from worry or anxiety, absence of overwork, and most importantly, proper food. The unborn child is totally dependent upon the mother to provide these things prudently.

Pregnant women need not eat more food than they did prior to pregnancy as is commonly asserted. They need only eat the best of foods—raw fruits, vegetables, nuts, and seeds. These foods will provide an abundance of minerals, vitamins, and high-grade proteins for both mother and baby. Good foods are the raw materials for better eyes, better bones, better teeth, a better nervous system, a better brain, and better development all around the baby. Proper foods also improve the health and comfort of the mother and allow, for greater ease in delivery and healthier nursing.

Good food is not enough, however. A pregnant woman must secure the best conditions for efficient utilization (assimilation) of her food. She must observe food combining rules, eat only when hungry, never overeat or eat when emotionally upset or physically tired, never drink with her meals, etc.

"Well-nourished mothers (this does not mean overfed) give birth to well-nourished and, therefore, well-developed and vital children. Not merely the bones and teeth and respiratory organs are involved in the results of adequate or inadequate diets, but every tissue in the body is weakened or strengthened, as the case may be, by the mother's food. Mother's nutrition is the real prenatal influence." — Dr. Herbert M. Shelton, *Hygienic Care of Children*

### **3.1 Proper Diet**

The best diet for a pregnant woman (and, indeed, for everyone) is that which has a proper balance of carbohydrates, fats, and proteins. This can be obtained by eating a variety of mostly raw fruits with some vegetables, nuts, seeds, and sprouts. In eating this diet, the pregnant woman provides her baby with all the mineral salts, vitamins, and other food elements necessary for its proper growth and development.

The mother to be must also make sure she combines the foods according to food combining rules (no fruits with vegetables, no proteins with fruits, no starches with proteins, etc.) so she will assimilate the nutrients in these foods most efficiently and place the least burden upon her digestive facilities. Also, eating in an atmosphere of peacefulness as opposed to upset, in a well-ventilated environment, and in moderation are very important factors in proper nourishment.

Although most people will strongly advise against fasting while pregnant, it can be advantageous to both mother and baby to undertake a short fast (one to three days) during the early months of pregnancy. Many women, at this time, experience some form of nausea and discomfort and loss of appetite. This is not due to her pregnancy, but to her toxemic state. Needless to say, when there is no appetite, no food should be taken. Nature knows best and attempts to put the physiological house in order causing the pregnant woman discomfort and lack of appetite. A few days of fasting should restore comfort to the mother and enable her to eat without distress. Many people will tell the mother that harm will come to her baby and to her if she does not eat plenty of "good nourishing food" at this time, but what will she gain if she eats when she is nauseous and then ejects the food as soon as it is eaten? (See section on complications in pregnancy.)

A long fast during pregnancy, however, is not recommended. The fetus is growing and obtaining nourishment from the mother and can only go so long before deficiency will result.

Short fasts give the body a chance to adjust to the pregnant state. They allow the organs to rest and cleanse themselves to prevent abnormality of the fetus. Short fasts improve assimilation and utilization of nutrients from the food taken following the fast. Fasting also improves metabolism which makes nutrition more complete, not only in the intestinal phase, but also when it reaches the cell of the fetus.

### **3.2 Items To Avoid While Pregnant**

While it is true that eating fresh, raw fruits and vegetables will have a positive influence on the health of the offspring; it is also true that consuming unnatural and toxic substances such as drugs, coffee, alcohol, fluoride, salt, vinegar, condiments, preservatives, processed foods, etc., will have a detrimental effect. These items, and more, must be avoided if optimum health is desired, for one's child.

### **3.3 Drugs, Alcohol, and Cigarettes**

More and more young women drink alcohol and coffee, smoke cigarettes, and eat junkier foods than in the past. Along with this fact the number of unhealthy and defective babies born each year increases.

Many studies have been conducted in recent years that indicate the harmfulness of alcohol, drugs, and cigarettes on the unborn baby. It is known that even moderate consumption of alcohol—in fact, even one drink—can have an effect on the fetus. Severe birth defects have been caused by alcohol consumption in

pregnant women. Some babies are born with "fetal alcohol syndrome"—that is, they have shortened features, a pugnacious cast to their faces, and their eyes are very close together. Spontaneous abortion, smaller than normal babies, very small head size, mental retardation, complications of pregnancy (see section on this), and a broad range of other adverse effects are caused by alcohol consumption.

The placenta, which supposedly filters out harmful substances ingested by the mother, does not filter out drugs, alcohol, tobacco poisons, caffeine, spices, etc. This is why it is imperative that these substances be avoided by pregnant women (and everyone).

Smoking while pregnant causes a baby to be smaller and weaker. The smoke in the mother's bloodstream prevents oxygen from getting through to the fetus. Thirty-five percent of premature births (terms of eight months or less) are from smokers. Also, babies born with weights of less than 4.3 pounds are almost always from smoking women. Physicians, in many cases, merely warn their pregnant "patients" to cut down on cigarettes rather than to cease them completely. The same is true for alcohol.

An example of how deadly drugs can be is as follows: in the 1950s and 60s, a drug called thalidomide was marketed. It was frequently prescribed to pregnant women to help them to sleep. Not only did it not help them to sleep; it also caused them to prickle, perspire, tremble, vomit, become giddy, lose feeling in their extremities, and worst of all caused their babies to be born with severe deformities. Thalidomide babies were often born with seal-like flippers for arms and legs among other deformities. Seven thousand of these defective babies were born before the drug was removed from the market.

This is just one drug, however, amongst the myriad of drugs that has been, and still is being, prescribed to pregnant women to remedy a variety of symptoms ranging from morning sickness, eclampsia, etc., to sleeplessness, nervousness, etc. All drugs are harmful to everyone who takes them but even moreso to an unborn child.

Various parts of the fetus' body are formed at different times during pregnancy. For example, the nervous system forms 15-25 days after conception; the limbs 24-36 days after conception; the heart 28-45 days after conception; the fingers and toes 36-42 days after conception; and the ears and nose at 29-45 days. A drug taken at any one of these stages of development can cause defects of varying degrees to the body part that is developing. "Medicines," tranquilizers, X rays, insecticide sprays, exposure to smog, etc., are all very harmful to the fetus and should be avoided as much as possible.

A recent test conducted on 3,528 drugged (anesthetics, pain relievers, tranquilizers, muscle relaxants, etc.) pregnant women proved that children born of these women were slightly to severely mentally retarded. They lagged in language and learning skills. Their perception and memory were below normal and their judgments were faulty.

Physicians, in spite of the results of this test, say that the FDA is stringent in its protection of pregnant women. They claim there is not one nonprescription drug that has adverse effects on the fetus. (What about aspirin?) It is also claimed that obstetricians will not prescribe drugs that are harmful to baby. Yet they prescribe all of the drugs that have proven harmful in the above-mentioned test, oftentimes just to "keep a woman happy" without warning them of the possible "side effects" of the drugs. Remember: all drugs are very harmful to the unborn child. Drugs never produce health—only untoward effects.

### **3.4 Coffee and Other Caffeinated Beverages**

A study conducted by the FDA has found that caffeine causes birth defects. This drug is found in coffee, teas, soft drinks (mostly colas), chocolates, and in numerous over-the-counter drugs. Most of these items are routinely consumed during pregnancy.

### **3.5 Fluoride and Salt**

Physicians tell many pregnant women that the fluoride put into our drinking water will prevent future dental caries in their offspring. They're told to drink much of it while they're pregnant for this reason.

However, these same physicians admit that if these women drink too much of it, it will cause mottling of the child's teeth. But how much is too much? I'll tell you—any amount. Pregnant women should drink only distilled water and that only if they are thirsty. Fluoride is poisonous and cannot be helpful to anyone. We cannot be poisoned into health.

Salt is poisonous, but especially for pregnant women and their fetuses. Edema is attributed to a high salt intake. This problem is very common in pregnant women in this country as the salt intake is incredible—salt is in almost every processed or prepared "food." But if only fresh, raw fruits and vegetables are eaten, there will be no problem with ingesting salt that is harmful to both mother and child.

### **3.6 Processed Foods**

Pregnant women are advised to drink pasteurized milk to insure they get enough calcium for their babies bones and teeth formation. Pasteurization (boiling) is, however, just another form of processing that destroys food elements. Therefore, a woman drinking pasteurized milk thinking she is getting adequate calcium and vitamin D from it is being deceived and is depriving her child of much needed nutrients. Adults do not have the digestive faculties to get calcium from milk for it is bound in the indigestible protein complement, casein. If the milk is pasteurized, it becomes unusable due to heat derangement.

Many pregnant women are also told by their obstetricians that they should give in to their cravings—pamper themselves. They eat such abominations as cakes, pies, ice cream, pickles, candy, canned fruits and vegetables, etc., all jumbled together in a haphazard way which causes both mother and baby to be undernourished. Being filled up on these harmful foods which contain preservatives, additives, food colorings, salt, sugar, white flour, etc., a woman is no longer hungry for those foods she should be eating for adequate nourishment. Processed sugars and refined white flour and rice rob the body of calcium and other nutrients that are so greatly needed during this crucial time. The body must surrender its previous supplies of minerals and nutrients to metabolize these denuded products.

In tampering with the foods nature intended for us, man has succeeded in destroying the natural balance of his diet. But these food indiscretions are not the only causal factors in the lack of health that is so prevalent in our modern times. Such factors as foul air, polluted waters, lack of exposure to the sun, lack of exercise, lack of sleep and rest, living a fast-paced life, taking drugs and stimulants, overworking, domestic inharmonies, economic strife, etc., are also contributors to much disease common today—including the birth of many unhealthy and inferior children.

### **3.7 Overeating and Weight Gain**

Despite the fact that most women have increased appetites during pregnancy, food intake should not be increased. The greatest weight gain during gestation should be about 20 pounds. The pregnancy itself (fetus, placenta, amniotic fluid, enlargement of the uterus and breasts) weighs only about 15 pounds. Anything in excess of this is merely fat which will be difficult to remove later. This extra weight can harm both mother and the baby. It causes an increased risk and a more difficult delivery. In fact, a group of midwives in Austin, Texas, will not take on clients that are overweight for this reason. They're left for the obstetricians to handle in a hospital setting and labelled as high risk.

During gestation, a woman must exercise willpower and common sense when eating. Keep meals simple and never eat between meals. Keeping meals simple means to have not more than a few items of food at once, eating them plain—no additions such as salt, condiments, oils, margarine, butter, etc., and mostly raw.

When pregnant, all of the internal organs are "squeezed" by the growing fetus inside. For this reason, it is even more imperative not to overeat or eat foods difficult to digest or eat too often as this can cause constipation. Constipation plagues many pregnant women who, instead of complying with the aforementioned, rules, take laxatives (X-lax, herbal teas, etc.), eat bran, or give themselves enemas. These are all taxing to the system and should be shunned.

Part of the reason that a woman on a conventional diet eats so much more when she is pregnant is because this diet is deficient in most elements essential to the normal growth of the fetus. She eats more in an effort to meet the body's demands. This is unwise. It is best to eat of Hygienic fare in moderate amounts for a healthy fetus (and mother).

Other troubles overeating and wrong eating cause are morning sickness, indigestion, hemorrhoids, swollen ankles, varicose veins, overdistension of the abdomen, a fat baby, and a difficult delivery. Restricting the diet, rather than overfeeding prevents postnatal hemorrhage so common in overweight women, who have a very toxic condition.

### **3.8 Exercise and Work, Stress**

It is very important for a pregnant woman to get regular and systematic exercise. This is to insure muscle tone, elasticity, and stamina for the marvelous upcoming event (childbirth). However, it is unwise to undertake a strenuous exercise program such as horse-back riding, tennis, motorcycling, etc., while pregnant unless it was indulged before pregnancy. If a woman was, however, not much of an exerciser prior to pregnancy and wants to obtain optimum health for herself and her unborn baby, it is still possible for her to incorporate exercise into her daily life. These exercises should be taken up gradually. Exercises that are not very strenuous such as walking in the open air and sunshine or swimming are recommended.

There are a wide variety of books on the market that are very good for pointing out specific exercises for pregnant women. These may include prenatal yoga or other stretching formats that strengthen the area of the body that will be put to use during labor—the abdomen and back. Exercises that helped me when I was pregnant are leg lifts (tightened abdomen and back muscles), deep-knee bends, and kagels.

Whatever exercises a woman in gestation chooses to undertake are okay so long as she remembers to do them regularly rather than sporadically. If she exercises only occasionally, she will more likely end up with sore muscles rather than benefits. Some women claim that their ritualistic schedule of exercise achieved painless childbirth for them.

Without exercise, abdominal muscles (and all muscles) will be lax (atrophied) and will be unable to support the womb and its appendages. A very common cause of aborted pregnancies is the debility of the mother. It takes strength to carry a child and to bring it into this world and proper nourishment alone will not provide it.

Exercise improves circulation and thus there will be a greater supply of nourishment to the fetus. This, in turn, will produce a more well-developed child. It will also provide the mother with stamina during labor.

If a woman is working during pregnancy (employed), it's fine to work right up until the last day before birth if in reasonably good health and if she wants to. However, sit-down jobs can contribute to backaches (toxins settle in the lower back when sitting a lot). Sit-down jobs also prevent a woman from getting the proper exercise, fresh air and sunshine she needs to be healthy. If a woman has a sit-down job however, she should try to get up and move about regularly and to get outside whenever possible and walk in the open air.

Avoid jobs that require overwork (overtime, few breaks, etc.) as a pregnant woman needs much rest and relaxation also. A job that is very stressful should also be avoided. Stress affects your mental state which can injure the child to the extent that it impairs nutrition and thus causes a supply of faulty nutriment to reach the fetus.

### **3.9 Rest and Relaxation, Sleep**

Rushing about doing this and that is not necessary and can be harmful, especially while pregnant. Taking the time to rest when fatigued or to relax regularly instead of pushing oneself is very necessary. The

human body assimilates nutriment' better when in a rested and relaxed state as opposed to a nervous, rushing state which produces indigestion and other problems.

In our modern world, many people truly do not know how to relax. We need to learn how. During pregnancy is a good time to learn as during labor is too late. Regular practicing of relaxation techniques while pregnant will prevent tenseness during labor which is a major cause of pain and tearing of the perineum.

A definite figure as to how much sleep a pregnant woman needs is as fallacious as is a set amount of vitamins and minerals that are necessary. Each individual's needs are different. If a pregnant woman eats well, rests and relaxes regularly, exercises, and has little or no stress in her life, she will need less sleep than one who eats wrong foods, overeats, has a stressful job, is nervous, etc. The amount of sleep a woman needs while pregnant is generally no more than she needed prior to pregnancy. However, she may tire more easily in the last months of pregnancy as there is a greater strain on her body. A mid-afternoon nap is very helpful.

### **3.10 Supplements and Deficiency Diseases**

Most obstetricians recommend that pregnant women should take calcium and iron tablets and other supplements to assure proper growth and formation of bones and teeth and to prevent anemia in the mother. They also say that women have an increased vitamin need now that there are two instead of one and therefore should supplement the diet. This is a fallacy. First of all, if the woman is eating adequately of proper foods she will not need any "extra." Secondly, humans are not able to utilize inorganic minerals. Taking unnatural supplements can only cause extra strain on the mother for she will have to eliminate these toxic substances.

Milk is often used as a supplement during pregnancy. Women are told to drink preposterous amounts of milk to get their calcium. They are scared into drinking it by doctors who tell them quite correctly that calcium will be taken from their bones and teeth if not in adequate amounts in their diets. This is true, but she will not obtain proper calcium from milk. As mentioned earlier, most milk is pasteurized and therefore deranged.

Also, humans lack the enzymes, lactase and rennin, to properly digest and utilize milk even if it is raw milk, and the calcium in cow's milk has been known to absorb the finer calcium in human cells thus making it harmful rather than helpful. (See Lesson 33 for details on the harmfulness of milk consumption.)

Calcium tablets are also taken in abundance by pregnant women. These are harmful rather than helpful. They produce acidity and actually rob the body of calcium. They thus help to produce osteoporosis and osteomalacia.

A deficiency of calcium in the pregnant woman's body causes her child's bones and teeth to be malformed and weak. The child may later have dental caries, crooked teeth, etc., throughout life as a result. However, a deficiency of calcium is not due only to a lack of calcium in the diet but to poor assimilation and utilization. This may be caused by overeating, eating of wrong combinations of foods, etc., that impairs digestion and absorption from the intestinal tract. It may also be due to the faulty action of the body in general (general poor health) and the various organs in particular that handle this particular element. Also, adequate sunshine is necessary to assist in calcium metabolism. It is not how much calcium that is contained in the foods one eats, but how much is absorbed and retained that counts.

For those who do want to make sure the foods they eat contain calcium, here are some foods that have large amounts of it: fruits, cabbage, lettuce, green leaves, nuts (almonds), figs, asparagus, kohlrabi, etc. Also, Dr. Shelton in his book, *Hygienic Care of Children*, says that orange juice (fresh-squeezed) helps the body to retain calcium and phosphorus and to assimilate nitrogen (protein).

The fetus stores a calcium supply in its tissues. It can draw upon this supply at a later time. During the

first months of pregnancy is when it is most crucial for a pregnant woman to obtain and retain adequate calcium for her and her baby's health.

Another mineral that most people tend to be fanatic about while pregnant is iron. A lack of iron causes anemia. Anemia is a deficiency disease with symptoms of lack of red blood cells, a pale complexion, nervousness, night sweats, and susceptibility to disease. It is not infrequent that pregnant women become anemic. This is because of improper nourishment and the inability of their bodies to use nutriment.

A lack of proper food or the inability to assimilate food leads to a gradual decline of the body's power to produce red blood cells. This is caused by imperfect nutrition—a lack of food iron or impairment of the digestive processes.

A short fast (one to three days) helps to rejuvenate the blood and the body's ability to assimilate more so than to merely eat more iron-rich foods. Daily sun baths, exercise, and fresh air also help. Doctors recommend iron pills and eating lots of liver. Needless to say, these will not help but can only harm for they are inorganic and poisonous.

During a fast, red cells continue to drop and then new red cells with regular edges form (in the case of anemia). If wary of undertaking a fast at such a time, a pregnant woman should consult a professional Hygienist or someone else familiar with fasting.

Red cell count is tested by medics with a test called the hematocrit. When I was pregnant with my second son, I submitted to this test out of curiosity. My hematocrit was much higher than the other women that were tested at this clinic. My diet was mostly raw fruits with some vegetables and grains.

When I told the doctor this, he recommended I start taking iron tablets. He completely ignored the test results. These other women were doing everything he recommended (eating lots of iron-rich foods—organ meats, legumes, beets, etc., and taking iron tablets), and they were diagnosed as slightly anemic. You think that would've told him something!

If you eat a proper diet, you will have no problem meeting iron needs. There is no need to dwell on iron needs, or on any one nutrient. All of our needs are met by an adequate diet as mentioned earlier and all other essentials of life.

### **3.11 The Placenta**

Mother's placenta does not magically extract only those good and necessary nutrients that mother gives. It also absorbs harmful substances. Most things mother takes in through the lungs, digestive tract, and skin show up in cells and tissues of the growing baby. These toxins irritate the newly-forming cells.

These toxins may just pass through the baby, or they may cause injury such as a birth mark or a major organ failure or some other injury. Drugs, environmental hazards, food additives, etc., interfere with organ development and can cause so-called congenital anomalies or birth defects.

In 27% or more births, defects occur and are continuously increasing as more and more chemicals enter our environment. Everything from drugs to additives in foods, sweeteners, aerosol sprays, car exhaust, pesticides, household cleaners, etc., are as harmful to the unborn child as they are to everyone.

Don't take risks even though so and so didn't take care of herself and still had a normal baby. However, it doesn't help to be afraid of or fanatical about the possible hazards in our environment as the baby can pick up on your fears. It is best to avoid as many hazards as you possibly can and don't worry as you can't control all of them. For example, don't use harmful pesticides or cleaning fluids in your home. Get plenty of fresh air in your home—open the windows. (It's best to live out in the country away from the pollution.) Try to avoid driving in heavy traffic. Eat organic fruits and vegetables when available. Don't eat *any* processed foods. These are just a few of the things a pregnant woman can do to avoid harmful substances from passing through her to the placenta and getting to her unborn child.

### **3.12 Sexual Relations While Pregnant**

"A farmer who would not permit a stallion to worry his pregnant mares, will not hesitate to make regular sexual demands upon his pregnant wife. In this he is encouraged by his medical adviser, although it is the universal rule throughout nature that pregnant females will not receive the male. There are reasons to believe that coition during pregnancy is responsible for the coating of vernix caseosa (white, greasy substance on baby's skin) found on so many infants at birth and that frequent coition during pregnancy also adds to the pains of childbirth." — Dr. Shelton, *Hygienic Care of Children*

In modern times, most people do indeed indulge in sex while the wife is pregnant. Most people feel there is no harm in this except during the last month when the baby is almost ready to enter our world. According to Dr. William Esser, a normal woman will discourage sexual union when pregnant because her instinct is against it. He also says that the entire animal kingdom frowns upon sex during gestation, and the pregnant female will defend herself against such a travesty.

Sex during pregnancy can cause the woman's procreation organs to become congested with blood. This is dangerous to the fetus as it can cause abortion. Oftentimes the initial signs of abortion are present after sex, but because the mother is of strong constitution, she will continue to carry the baby. Other problems caused by the uterus being congested with blood are that of an apathetic child or a congenital idiot being born.

### **3.13 Preparing for Childbirth—Classes**

Nowadays childbirth preparation classes are very common. They may be conducted by a group of midwives or by hospitals or clinics. These classes may teach natural and/or unnatural methods of childbirth.

One thing most of these classes have in common though is that they give parents-to-be some knowledge of the physiology of pregnancy and childbirth. Stages of fetal growth are displayed. Parents are given an understanding of what is and will be occurring within a woman's body and how to deal with these changes.

Many classes (those given by hospitals and clinics that are medically oriented) teach parents which drugs will be available to them when the woman is in labor. They teach students what to expect when entering the hospital.

Taking childbirth preparation classes can be very advantageous choice for many parents to be. However, they are unnecessary. Reading the many excellent books and magazines (especially those with illustrations) that are available in libraries and bookstores as well as talking to other parents you know who have undergone homebirths is adequate for many. Knowledge of the mechanics of pregnancy and childbirth is definitely a necessity for those (and everyone) who plans a homebirth. I've found classes conducted by unorthodox (not medically oriented) midwives to be very helpful. I met other couples who planned to have midwife-assisted homebirths and we provided moral support for each other.

### **3.14 "Complications" of Pregnancy**

This section should really be called "Abnormalities of Pregnancy" as there are no complications if care is taken to produce health. However, I will call them complications as a large percentage of women do experience some of them.

"The unborn child is a parasite feeding upon the substance of the mother. If the mother's substance is physiologically, chemically, and magnetically correct according to nature's plan, the process of gestation is a comfortable and physiologically ideal experience. If there is in

the pregnant woman a chemical imbalance—in other words, if the woman is toxemic—there comes sooner or later a physiological protest accompanied by an attempt toward correction of this abnormal state. Hence the reaction, the nausea and vomiting." — George S. Weger, M.D., "The Nausea and Vomiting of Pregnancy," *Dr. Shelton 's Hygienic Review*

There are many things that can go wrong during gestation if a woman is not in optimum health. Morning sickness, heartburn, constipation, vomiting, digestive difficulties, edema, eclampsia, varicose veins, breast pain, back pain, toxemia, etc., are some of the common complications. But pregnancy, being a normal physiological process, should not be accompanied by any discomfort or abnormal state.

It seems that most women when pregnant suffer from morning sickness of varying degrees (because of the many transgressions from the ideal lifestyle). For some, it is intense and lasts all day. They may vomit to the point of not keeping any food down. This is caused by a reaction to toxic saturation from eating wrong foods. It can be corrected by a short fast. Most physicians, however, prescribe drugs and other manipulations which are harmful to both mother and baby. They specialize in relieving symptoms and treating effects.

Some women who have milder cases of morning sickness (gastric uneasiness) experience slight nausea and lack appetite. These may feel relieved after eating a heavy, cooked meal while feeling nausea after eating fruit or nothing at all. These women then blame the fruit for their nausea. This is obviously not so. The heavy, cooked foods deaden or stop eliminations and fruits or fasting allow the body to start housecleaning, which frequently has unpleasant symptoms.

The reason a pregnant woman feels nauseous in the morning is because she's been fasting since the night before. This fast has allowed her body to recuperate vitality and to eliminate toxins.

"There is a rebellion in the stomach; it rejects food. The liver speeds up its excretory function. Much bile is regurgitated into the stomach and is vomited. There may even develop a psychic revulsion to food, so determined is the organism to have its way and to clean house. If we can once understand that nature is trying to provide a clean house in which to evolve the new life, we can understand the need to cooperate in the work and not to throw monkey wrenches into the vital machinery." — Dr. Shelton, *Fasting Can Save Your Life*

Another common "complication" of pregnancy is toxemia. Toxemia is marked by a rise in blood pressure, undue weight gain with puffiness, headaches, and visual disturbances. Albumin (a water-soluble protein) is present in the urine. Toxemia in pregnant women results in malnutrition and poisoning of the fetus leading to difficulties later in the child's life if allowed to go on. Again, a fast will remove toxemia.

Many pregnant women experience eclampsia which is a form of toxemia. It usually occurs in women who gain over thirty pounds in weight during gestation. It has been observed in a study by Dr. Dieckman in the *American Journal of Obstetrics and Gynecology* that eclampsia is much more prevalent among people who eat high-protein, high-fat diets. Dr. Dieckman noted that during the second world war in Germany there was a decreased occurrence of eclampsia because of a reduction of consumption of meat and other such "luxury" foods as butter, refined products etc. He also found that eclampsia is very uncommon in the tropics where a low-protein, high-carbohydrate diet is eaten.

Other studies have indicated that women who are overweight before becoming pregnant will most likely have a prolonged labor, possible caesarean sections, other maternal complications, premature birth of their child, and toxemia. A Hygienic diet does not cause this.

Still another study found that women who abstain from refined flours, beans, peas, grains, milk, butter, and cheese and eat only fruits and vegetables will have babies born softer and smaller than other women. This is good because labor will be less complicated—it is normal for babies' bones to consolidate after birth rather than before to ease labor and delivery. The small and soft baby will soon grow in strength after birth.

Another factor that most women consider to be a "complication" in pregnancy is if they are over the age of 30. This just is not so. If the woman has been taking care of herself prior to pregnancy, during pregnancy, and continues to do so, there will be no problems.

Another abnormality common in pregnancy is edema—retention of fluids in the tissues, in the case of pregnant women usually around the ankles. This fluid is used to hold the toxins present in the woman's bloodstream in suspension so they will do the least harm. This edema is a part of the protective functions of the organism of the pregnant women to keep the embryo from suffering with fluid retention and metabolic disturbances.

There is only one reason for any types of complications when pregnant, and that is that the "ills of pregnancy, as well as those of the nonpregnant state are each and every one, of toxic origin: and the reaction, the crisis, is nature's way of calling our attention to the matter so that we may help her and thus help ourselves." (Dr. George S. Weger, "Nausea and Vomiting of Pregnancy," *Dr. Shelton's Hygienic Review*.)

### **3.15 Other Information Pertinent to Prenatal Care**

One factor a pregnant woman should keep in mind is to dress comfortably and attractively in cotton clothes that are loose—not tight. Don't wear tight clothes such as garters, girdles, tight stockings, pants, etc. Wear flat shoes as high heeled shoes will put a strain on your back. They are also dangerous as you can fall easily or get them caught on things, etc.

Women, when pregnant, should take time to take walks out in the open air and sunshine so as to provide two of the essentials for themselves and their unborn babies. This also provides a time when the mother-to-be can find solitude and think about the new being inside of her and what he or she will be like.

It is wise to avoid any lengthy traveling while pregnant. This is generally when a woman feels like "bedding down" and being stable anyway—a time to feel a sense of security in her life. Traveling by car for long distances does not allow her to stretch and use her body as it should be. Also, bumpy roads cause a great deal of discomfort to her at this time. Traveling by airplane is to be advised against especially in the later months of pregnancy. The extreme pressure and speed while flying can cause, among other things, labor to be brought on prematurely.

[Home](#) > [Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth](#) >  
4. Conclusion

## **4. Conclusion**

There is much more that could be said about prenatal care, labor, and childbirth. I could go on for many more pages about all the complications of labor and delivery that are possible if a woman does not take care of herself during pregnancy.

Even if a woman has taken proper care of herself during pregnancy, it is still not over. She has to be very cautious who she selects to help at the birth. She needs to decide whether to have a homebirth or a hospital birth. She needs to have confidence in herself, faith that all will go well, and courage to accomplish the feat of birth instead of fear.

For example, if a woman gives birth in a hospital she is at the hands of the medical personnel there—she has, in a sense, given the responsibility of her child's birth to them. Much unnecessary medical intervention such as shaving of pubic hair, giving enemas prior to delivery, giving episiotomies, strapping the woman down during labor, drugging, forceps deliveries, Caesarean sections, etc., may

occur in hospitals—and those oftentimes for the convenience of the hospital staffs. All of these actions are enervating and harmful at a time when a woman needs to be at her best.

Providing the mother is in good health (normal), she will enjoy the actual childbirth experience and always remember it as a positive, enlightening experience. Giving birth in one's own home encourages this as the mother is surrounded by loving friends rather than by strangers. The baby will therefore enter a warm, loving world instead of the cold, antiseptic world of a hospital. No bright lights, masked strangers, spans on the buttocks, chemicals in the eyes, premature cutting of the umbilical cords, etc., will occur in the home. The father can share the first days of the baby's life with him/her and the mother. The mother will be with the child and be able to nurse the baby when he/she is hungry rather than by the clock. The mother will have more opportunity to sleep and relax after the birth as there are no rigid schedules as in the hospital. Also, there will be no displaced siblings as they will share the baby's first days also.

So you see, not only does the mother need to take care of her health, she needs to make the correct decisions regarding the coming event. She needs to be aware of the importance of proper preparation to prevent undue stress at the last minutes.

[Home](#) > [Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth](#) > 5. Questions & Answers

## 5. Questions & Answers

**I am 30 pounds overweight, and I've recently started on the Hygienic diet. Although I'm gradually losing weight, it is a very slow process and I'm eager to become pregnant?**

Excess in weight is usually toxin-laden fat that causes undue risks to both mother and unborn child. If you do get pregnant while overweight, try short fasts occasionally during the early months of pregnancy. Stick to Hygienic fare with lots of fresh fruit, and some green vegetables with very few nuts, seeds or avocados.

Of course, it is best to undertake a long fast (two weeks or more) before becoming pregnant and to realiment on juicy fruits and vegetables with very few that are high in fat and sugar content. If that is not possible for whatever reason, the next best thing is to eat moderately of only fruits and vegetables of low-fat, low-sugar content excluding nuts, seeds, avocados, and dried fruits, etc., until down to the desired weight. Your body will then be ready for the fetus.

**I'm two months pregnant, and I've just found out about the Hygienic diet and am trying to stick to it. I've been a vegetarian for many years but am experiencing a mild case of morning sickness. What can I do to rid myself of this nausea?**

Take a fast of three to five days—take nothing but distilled water and rest in bed as much as possible. Short fasts will do no harm to the fetus, they will merely help to eliminate toxins more quickly. You will no longer suffer morning sickness. After the fast, take raw fruits, vegetables, nuts, seeds, and sprouts, all properly combined to assure the best nourishment for you and your baby.

**I'm pregnant and I live in an apartment in the city on a street with very much traffic. I don't open the windows often as I get strong odors of auto exhaust fumes from the street below. Is there anything I can do to improve my situation without moving which is not possible at this time?**

Naturally, it would be best to live in a purer environment, but since that is not possible try purchasing house plants which will provide a rich source of oxygen in your home. Grow an indoor garden. Get a negative ion generator to help purify the air. Also, try to get out and exercise in the open air in the country or in nearby parks often.

**I'm six months pregnant and just found out about the Hygienic diet. Is it okay for me to start on this diet from a conventional diet at this crucial lime?**

It would not be good to all of a sudden just change your diet so drastically. You'd be sending so many toxins through your bloodstream at once that some of them could pass through the placenta and harm the baby. It is good to gradually eliminate harmful items in the diet, from the most harmful to the last harmful. Start with prescription and nonprescription drugs. Then stop eating red meats, then white meats, then fish, then dairy products, etc. Try to stay with each regimen for at least a week before eliminating another few items. This way you will be improving your baby's chances to be healthy even though you got a late start.

[Home](#) > [Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth](#) > Article #1: Joyous Childbirth, Hygienically by Ralph C. Cinque, D.C.

**Article #1: Joyous Childbirth, Hygienically by Ralph C. Cinque, D.C.**

The process of giving birth is a normal, natural and largely spontaneous activity that shares many similarities with the process of defecating. I make this rather crude comparison not to be needlessly distasteful, but rather to emphasize the point that giving birth is as physiologically ordinary as having a bowel movement. Granted, it is inherently more demanding, more prolonged and more intense, but under normal conditions it is just as certain in its outcome. It calls upon many of the same muscles that are required to defecate. It occasions sensations that are very much like the urge to defecate.

If this is true, why has childbirth become such a traumatic, painful and debilitating event that commonly incurs injury to both mother and infant? Why is it that modern childbirth usually requires some kind of surgical intervention? By this I refer not only to outright surgeries, but also to the various manipulations and forcing measures that are so often employed in so-called "natural childbirths." It is vitally important to realize that under normal conditions, childbirth requires absolutely no intervention whatsoever. "Catching the baby" should be all the attendant has to do. Performing manual rotations, either internally or externally, manipulating the shoulders, guiding the head, stretching the perineum and other related procedures are in no way a normal part of the birth process. If we consider that humans in the remote past, living in a state of nature, had no understanding of the mechanics or the intricacies of birth and were therefore unable to constructively intervene during labor, we must conclude that Nature intended birth to be an entirely spontaneous process. This is certainly true of animals in the wild, who give birth unassisted. No doubt it was also true for women.

An entirely normal and natural childbirth occurs so rarely in this country that it is actually an oddity. By medical standards, anything less than a Caesarean section or a forceps delivery is considered a "natural" birth. No matter how much pain the woman suffers, no matter how prolonged the labor, no matter how much damage is done to the birth canal, whether or not the infant is battered, whether or not difficulty is encountered in obtaining the placenta and no matter how much meddling is necessary in order to accomplish the birth, as long as a major operation is avoided, the birth is considered "natural."

I attended a childbirth class once where a woman who had recently given birth at home was relating her experience. It seemed that she had succeeded at having a "natural" childbirth, even though she was in

labor for over two days, even though tremendous fundal pressure was finally required in order to expel the infant (this entails pushing downward on the uterus through the abdomen to force the baby through the birth canal), even though she was given injections of pitocin (to stimulate uterine contractions), and despite the fact that extensive tearing occurred. Yet, she did avoid being admitted to the hospital, and therefore felt that she had indeed accomplished a natural childbirth. Her last comment was that, "it was a wonderful experience and I would encourage any woman to have a natural childbirth at home." Quite frankly, it all sounded less than wonderful to me and I didn't see how she could expect the other women to eagerly look forward to such a trying experience.

Natural childbirth and home deliveries are very popular today, and the demand for competent home birth attendants is greater than the supply. "Prepared childbirth" classes are being taught in the homes, schools and even in the hospitals. Thorough preparation, we are told, lessens the risk of complications in labor and delivery. We of the Hygienic School have no argument with this statement, but we insist that the most important aspect of this preparation should be achieving a high level of health. More important than learning the mechanisms of birth, more important than practicing breathing routines, and more important than securing sterile sheets and towels, is the attainment of superb health. If a woman begins labor in poor physical condition, the process of giving birth is apt to be an agonizing and grueling ordeal despite adequate preparation, in the usual sense of the word. In contrast, a woman who knows nothing about birth, but who arrives at term in splendid form and exemplary condition, is likely to have an easy and joyous experience in childbirth.

In saying that health is the most important prerequisite for success in childbirth, we imply that truly adequate preparation must begin well in advance of pregnancy. To stop smoking and drinking (alcohol), to cease eating refined foods, to avoid salt, to shun all drugs, to secure sufficient rest and sleep—these will prove to be highly beneficial to the woman who has conceived. But, why wait until conception to stop injuring yourself and to begin to thoroughly supply your body with its needs? Why not acquire high level health before becoming pregnant and thereby provide your unborn child with a perfect internal environment from the moment of its conception? Waiting until pregnancy begins is often too late to achieve one's desired health goals. The body does not suddenly become well nourished, suddenly become cleansed or suddenly become physically conditioned. These are physiological processes that take time. Furthermore, pregnancy often limits the full application of Hygienic measures. A pregnant woman cannot fast, except for short periods. Although I know of several women who have fasted for as long as two weeks at the beginning of pregnancy, with good results, I would not advise such fasting in the vast majority of cases. Pregnancy also limits a woman's prerogative to lose weight and physically condition herself. Building health is something that should be avidly pursued years before conception.

Poor health and poor conditioning cause most of the problems that occur during pregnancy. Pre-eclampsia and eclampsia (toxemia of pregnancy) are the direct result of unhygienic practices during pregnancy. This condition, characterized by some degree of edema (swelling), high blood pressure and albuminuria (protein in the urine) is caused by the consumption of large amounts of protein, particularly animal protein, the use of salt and the ingestion of drugs. I would state unequivocally that it is entirely avoidable in virtually all cases if a Hygienic regime is followed.

Malpositions of the fetus, which can impede or suspend the birth process, can also be related to the overall maternal condition. The fetus may assume a transverse lie (which is impossible to deliver naturally) because the tone of the uterine walls is not adequate to force the head downward. Ordinarily, the uterine muscle supplies enough resistance to allow gravity to draw down the heaviest portion of the fetus, which, of course, is the head. However, when the muscle tone of the uterus is weak, the organ may "give" abnormally, resulting in a transverse position of the fetus. Such incidents are often regarded as "accidents" when they are really a matter of cause and effect.

Dystocia, or prolonged labor, is often the result of cephalopelvic disproportion, wherein the fetus is literally too big to readily negotiate the birth canal. Most often this results from excessive weight gain during pregnancy which produces an overly large infant and an overly fat mother. Hygienists have long emphasized that a small, light infant represents the biological norm for humans at birth, as it does for

other animals. A birth weight within the six-pound range is ideal. Yet, today, it is not uncommon to encounter births in which the weight of the newborn is 8, 9 or even 10 pounds. Such oversized, fat-encumbered infants are not healthy. They often injured in the birth process. The tendency toward flabbiness and bloatedness will in some cases persist indefinitely.

Excessive weight gain during pregnancy is the result of overeating. Too much food is generally recommended at natural childbirth classes, particularly in regard to high-protein foods. A pregnant woman actually requires only slightly more food than she would require under ordinary circumstances. If we assume that a woman gains approximately 20 pounds over the course of a normal gestational period of 280 days, this would amount to a weight gain of slightly more than one ounce per day, on the average. How much additional food does it require to gain an ounce a day? Quite obviously, not very much.

There is no reason to overemphasize proteins in the diet of a pregnant woman. The protein density of the fetus is actually less than that of the mother. Assuming that she is eating a diet of whole natural foods, largely or wholly uncooked, she will easily obtain the additional protein she needs by increasing her overall food consumption proportionately. Too much protein places a great stress upon the liver and kidneys. Since a pregnant woman already has the burden of eliminating the fetal waste products in addition to her own, it is foolish to add to this burden by overeating on proteins.

William's *Obstetrics* provides the following information about maternal weight gain during pregnancy:

"During a normal pregnancy with a single fetus a weight gain of nearly 18 pounds can be accounted for on the basis of obvious pregnancy-induced physiologic changes. They include an increase of almost 11 pounds of intrauterine contents accounted for by fetus (7 1/2 pounds), placenta (a little over 1 pound), and amniotic fluid (2 pounds), in addition to a maternal contribution of 7 pounds accounted for by increase in the weights of the uterus (2 pounds), blood (3 1/2 pounds), and breasts (1 1/2 pounds). The moderate expansion of the volume of interstitial fluid in the pelvis and lower extremities directly attributable to the increased venous pressure created by the large pregnant uterus is a normal event. In the ambulatory woman it most likely adds 2-3 pounds more. There is, therefore, a physiologic basis for a maternal weight gain of about 20 pounds."

In the case of a Hygienically-conducted pregnancy with a smaller birth weight infant, these figures would be correspondingly lower. This is particularly true in regard to the amount of maternal fluid retention. Most women experience a slight to moderate degree of edema during pregnancy which has come to be accepted as normal. For a Hygienic woman whose weight is normal before pregnancy, we can assume a gain of about 18 pounds represents the physiological ideal. Yet today we find women gaining 30, 40 and more pounds during pregnancy with the blessings of their physicians. These women are fat, bloated, overly distended and often hypertensive. They experience shortness of breath, backaches, constipation, difficulty sleeping and difficulty walking. During their long and trying labors they suffer tremendously and often require intervention of one kind or another in order to facilitate birth. Malpositions of the fetus (such as occiput posterior) is common among this group. Their babies, too, are fat and bloated. It is impossible to look at these women at term without sharing their distress. A pregnant woman should look absolutely radiant, but these women look tired and disabled. It is no wonder that in modern times pregnancy has come to be regarded as a disease and childbirth as a surgical operation.

Exercise during pregnancy is another controversial issue. All childbirth instructors give their prospective mothers exercises to do, but in most cases these exercises are not vigorous enough to adequately condition the woman. Doing one or two deep-knee bends and tilting the pelvis in various ways hardly constitutes a thorough physical conditioning program. It behooves every pregnant woman to strengthen the muscles of her abdomen, back, thighs and buttocks. Squatting is an excellent exercise during pregnancy, particularly since women give birth in the squatting or semi-squatting position. Doing 50 or more deep squats with the legs spread and the feet turned out will develop the muscles of the thigh and

back while at the same time stretching the adductor muscles on the inside of the thighs. Sit-ups or partial sit-ups will develop the abdominal muscles and these can be done safely throughout pregnancy. It is best to perform this exercise with the knees raised to avoid unnecessary strain on the lower back. Leg lifts can be performed lying on the back either outside on the lawn or indoors on the carpet. This will develop the psoas muscles and the lower abdominal muscles. The adductor muscles can be strengthened by assuming the "lotus" position (feet drawn up, heels together, knees apart). Place your hands on the outside of your knees and then try to lower your knees to the floor as you exert enough resistance with your hands to make it difficult. Having your husband or "labor coach" provide resistance is also a good way of performing this exercise. A good stretching exercise can be performed by holding on to a doorknob with one hand and then swinging the opposite leg and thigh in an arc from side to side like a pendulum. Then the exercise would be repeated on the opposite side. These and other calisthenics should be performed repeatedly in order to achieve a high level of fitness. Walking on all fours (on your hands and feet, not hands and knees) is an excellent exercise that works a broad spectrum of muscle groups. Jogging, bicycling, swimming and brisk walking are outstanding "aerobic" activities and there is no reason why a pregnant woman cannot fully participate in these wholesome sports. Consider what Dr. Bradley says in *Husband Coached Childbirth* about the prospect of injuring the fetus through vigorous activity:

"Dismiss from your mind the idea that if your pregnant wife fell down skating, skiing, or whatever, that she would hurt her baby. Of course, if she doesn't know how to fall correctly she can hurt herself—just as she could when she's not pregnant. In my career I have never known a mother to have harmed a baby by an external trauma. The salt water (amniotic fluid) in which the baby is floating equalizes local pressure. This idea of falling down and thereby losing a baby is a superstition that probably began with the movie *Gone With The Wind*. Rhett Butler gave his wife a shove at the top of the stairs. She gracefully tumbled down the stairs and conveniently had a miscarriage at the foot of the stairs. Immediately thereafter doctors' offices and hospital emergency rooms were mobbed with out-of-wed-lock pregnant women who were battered black-and-blue and sore but still very much pregnant! It won't work."

Remember that exercise has a toning effect on involuntary muscles as well as voluntary muscles. A hypotonic uterus, either during or immediately after labor, is not likely to occur in a woman who is in prime athletic condition. So, get out and exercise during pregnancy and gradually acquire the strength, endurance, and flexibility that will serve you admirably during labor and delivery.

The dietary needs of a pregnant woman are not radically different from her needs under ordinary circumstances but the consequences of dietary deficiencies are more profound. An abundance of raw foods should be eaten, including fruits, vegetables, nuts, seeds and sprouts. Green leafy vegetables are particularly important. Two large salads per day should be the rule. An overly restricted diet should be avoided. A woman who has been eating the conventional mixed diet should not abruptly switch to an exclusive diet of raw fruits, nuts and vegetables during pregnancy. Although a completely raw food diet is the ideal, a woman who is unaccustomed to it might not be immediately capable of extracting and assimilating a complete array of nutrients from it.

It is unnecessary and undesirable to saturate oneself with "food supplements" during pregnancy. Large amounts of calcium, in particular, are usually foisted upon pregnant women, ignoring the fact that the skeleton of the fetus is largely cartilaginous.

In Oregon, where I attended home births with a naturopathic doctor I saw several instances of calcific deposits in the placenta. a pathological condition, in every instance, dolomite or some other calcium supplement had been administered. I have never witnessed this in cases where only food comprised the diet of the mother. It is possible that these abnormal calcifications can affect the circulation to the fetus. My advice is to add the dolomite to your garden soil and then grow green leafy vegetables. This will provide calcium in a usable form that will never cause harm.

There are certain Hygienic considerations that we may wish to note regarding the conduct of labor. For many years, elaborate and complicated breathing patterns were popular among natural childbirth circles. Chief among these was the Lamaze method. Fortunately, these methods are coming into disrepute. Remember that breathing is an automatic process and that whether you are eating, sleeping; running, or giving birth, your body is fully capable of regulating its own respiration. Hyperventilation is the most obvious danger of these forced breathing routines.

Until the cervix is fully effaced and dilated, the woman should simply try to relax. Premature pushing is likely to cause injury to the birth canal and may exert unnecessary pressure on the fetal head. Deep, slow, relaxed breathing is all that is necessary during the first stage. There is no need, however, for the woman to remain recumbent. Dr. Robert Caldeyro-Barcia of the American College of Obstetricians and Gynecologists reported recently that "the efficiency of the contractions is greater in the upright position. The greater efficiency combined with the increased force of gravity, and more advantageous drive angle between the fetal and maternal spines results in significant shortening of the first stage of labor."

Walking about between contractions during the first stage of labor has a gently stretching effect upon the uterine cervix while it also serves to ease tension on the mother-to-be.

In a Hygienically-managed pregnancy, the most likely consideration during the second stage of labor (the actual expulsion of the baby) is how to avoid a precipitous delivery. It is often necessary to discourage a woman from pushing so as to avoid causing vaginal or perineal tears. Having her lie down also helps to slow down the birth, should this be necessary.

Although it is best to avoid bright lights, it is equally unwise to try to give birth in the dark (or nearly so). A very good friend of mine practically lost his son at birth because dim lighting prevented him from immediately recognizing an asphyxiated condition. Provide enough lighting so that the birth attendant can readily observe the progress of the birth, the condition of the mother and the condition of the infant.

The Leboyer bath has become a very popular adjunct to a natural childbirth. Without objecting to this procedure, I hardly think that it is as indispensable as its proponents would lead us to believe. Why try to stimulate uterine conditions for an infant whom Nature has deemed ready to function in the outside world? It seems to me that being cuddled and carressed on mother's soft tummy is every bit as reassuring as a bath.

The experience of my dear wife Margaret would serve as a fitting example of the efficiency of Hygienic methods during pregnancy and childbirth. Margaret had a joyous pregnancy during which she engaged in vigorous physical exercise on a daily basis. The very day her labor began she went out running. She experienced no backaches, no nausea, no vomiting, no swelling and no shortness of breath. Her weight gain was 18 pounds. She gave birth naturally at home and from the first true labor contractions to the birth of the placenta, all of 3 1/2 hours elapsed.

She suffered some pain with her first stage contractions but claims that it "felt good" to push the baby out. Mark Shelton Cinque was born at 3:00 a.m. on May 12, 1974, weighing 6 pounds, 4 ounces. He was unusually bright and alert from the moment of his birth, as he has continued to be in the five years he has been with us.

[Home](#) > [Lesson 55 - Prenatal Care For Better Infant And Maternal Health And Less Painful Childbirth](#) > Article #2: Feeding Mothers by Herbert M. Shelton

## **Article #2: Feeding Mothers by Herbert M. Shelton**

It is a common adage that the pregnant mother must eat for two. Unfortunately, this adage is likely to be

interpreted to mean that she must overeat and not be interpreted to mean that she should eat foods that meet the nutritive requirements of both herself and the evolving child. The influence of the mother's diet upon her unborn child is not sufficiently appreciated by women and their advisors. The newborn baby requires but half a pint of milk daily which is chiefly water. It is unlikely that the food needs of the unborn are greater than those of the newly born. There would, thus, seem to be no need for so much extra food before birth. The great demand of the unborn for nutriment would seem to be fictional.

Of old it was said: "The fathers have eaten sour grapes and the children's teeth are set on edge." Paraphrasing this ancient statement, we may say today that the mothers have eaten white bread and the children's teeth have holes in them. Many of the defects and deformities with which children are born today are direct results of a faulty diet eaten by mothers. What are called larval deficiencies are responsible for many defects in development.

Nutritional influences upon the development of the new being are commonly thought to start at conception, but there are myriads of facts that show conclusively that they begin much before this time. It is true that soft and malformed bones are not to be blamed upon a drunk father, except insofar as he fails to supply adequate nutriment for the mother during her pregnancy; but the gleam of health in the eyes of a two-year-old does not come from the grandfather and a bar of chocolate candy. It comes from fruits, green vegetables, nuts and whole natural foods. Nutrition begins with life and does not cease until death puts an end to all the life processes.

Pregnant women are urged to take plenty of milk and eggs and are often given calcium tablets; for, despite the fact that the bones of the baby will remain soft, no matter how much excess calcium the mother takes, the embryo is supposed to need lots of calcium for other purposes. So urgent is the demand for calcium that a mother's teeth and bones will be robbed to supply the needs of the unborn baby if her diet does not contain enough of it. This fact, however, does not demand that the pregnant woman should fill up on great quantities of milk, overeat on eggs and take the nonusable calcium supplied by the drug store. It means, rather, that she should eat whole, unprocessed foods—fruits and vegetables—and cease trying to nurse herself and her baby on white bread, white sugar, white rice, canned fruits and vegetables and other foodless "foods." The cow does not drink lots of milk and eat lots of eggs to provide herself and her calf with calcium. The calcium in her milk is not derived from these sources.

When it is considered that it is pasteurized milk which pregnant and nursing mothers are advised to drink in such quantities and that this milk is taken together with white bread, denatured cereals, cakes and pies, coffee and tea, chocolate and ice cream, candy and soft drinks, flesh and eggs, white sugar, canned fruits and vegetables, all jumbled together in the most haphazard and heterogeneous combinations, and that very little wholesome food is to be taken, it does not take much imagination to grasp the fact that both mothers and unborn babies are inadequately nourished.

It is understandable that women who eat such a diet, while pregnant, overeat in an effort to meet their nutritional needs. But this overeating leads to additional troubles, such as indigestion, morning sickness, constipation, hemorrhoids, swollen ankles, varicose veins, overdistension of the abdomen, a fat baby and difficult delivery. We have been conditioned to think that a fat baby is a well-nourished baby, although we know that fat at other ages of life is not a sign of good health and is not a desirable acquisition. The young of the mighty gorilla, which attains a size considerably larger than that of the largest man, weighs three pounds at birth. Some day, when we have learned to appreciate the value of proper nutrition, we will come to realize that the human infant should weigh three to five pounds at birth. Today we are very happy if the baby weighs eight to ten pounds. A ten-pound baby may be said to be five pounds of baby and five pounds of fat. Such a baby begins life with a handicap.

Many unborn babies are so "well nourished" that they weigh eight, nine, ten and more pounds at birth. This large size results in difficulties of delivery. Often instrument deliveries are performed. Due to their large size, fat babies are often injured in being born, these injuries rendering them liable to brain and cord inflammation. These "well nourished" babies are also prone to have trouble in teething, often

throwing them into convulsion. When such babies and children are subjected to any enervating influence, such as prolonged heat of summer, they are likely to develop serious diseases.

The expectant mother, desirous of doing the most possible good to her unborn child, will avoid tobacco, alcohol, tea and coffee, and drugs as she would a rattlesnake and provide her offspring with the best possible food. Instead of the commonly-eaten processed and refined foods, canned, pickled, and spiced delicacies, she will provide herself with a more abundant supply of fresh fruits and vegetables, these largely, if not wholly, in their raw or uncooked state. These foods will provide for both the mother and the unborn baby an abundance of minerals and vitamins and of high-grade proteins. She will eat other protein foods, but eat them in moderate quantities and not stuff on them, as is the common practice. It is normal to seek a sense of repletion after eating, but this repletion should be secured by consuming more bulky foods and not be overeating on concentrated proteins, starches and sugars. Fruits and vegetables make the ideal foods with which to secure the sense of repletion.

It is quite true, as we indicated at the beginning of this article, that the pregnant mother must eat for two; but it is almost never true that she is required to increase her food intake. So nearly universal is the practice of overeating that most women eat enough for two at all times. To increase the food intake because one is pregnant may mean to take from three to five times as much food as is required. When we consider that the average gain per day of the human fetus, from conception to birth, is less than a half an ounce a day, we can readily understand that the commonly advised overeating is very unwise. There is ample evidence to show that the body makes more economical use of food during pregnancy than at other times, so that instead of increasing the food intake, it is often possible to decrease the amount of food eaten with benefit both to the mother and the unborn child. It has been observed that among animal mothers, even though they may bear more than one young at a time, there is little or no increase in food intake during pregnancy. Animal mothers may reduce their physical activities, but rarely increase their gastronomic activities.

It should come as no surprise to learn that many modern mothers have reared large families while adhering closely to the two-meals-a-day plan, for this was the almost universal practice in the past, when families were usually larger than at present. That woman who has been accustomed to eating but two meals a day will have no trouble in supporting both herself and her growing infant without the addition of a third meal.

The most important factor in the nutrition of the pregnant mother is not the quantity of food she eats, but its quality. She should not eat more food, but better food—more lettuce and celery and fewer potatoes; more apples and grapes and less flesh; more oranges and peaches and fewer eggs; more natural foods and no denatured foods. Such a diet will provide for adequate development and growth of the unborn child—for better eyes, better bones, better teeth, a better nervous system, and better tissues generally.

We cannot think wholly of the improvement that such a diet provides for the unborn child. We are justified in thinking also of the improved health and greater comfort of the pregnant woman and the grater ease of delivery. This diet also provides for a more certain, a more abundant and a more adequate milk supply when the child is born. It is a fortunate fact that the diet which is best for the unborn child is also best for the expectant mother and that the diet which best promotes the health of the one will also best promote the health of the other.

The expectant mother, desirous of maintaining high-level health during pregnancy and providing adequate nourishment for her unborn child, will not only eat a diet of natural foods, but she will eat this diet in a way to secure the best digestion and the most efficient utilization of her food. This is to say, she will observe all the rules of food combining and all the rules for eating. She will not eat if she is not hungry and she will not eat if she is physically distressed or emotionally disturbed. She will not eat if fatigued, but will rest first. She will not drink with meals nor soon thereafter. She will eat in moderation and without fear that in doing so she will injure her offspring.

### **Article #3: Prenatal Life by William L. Esser**

In considering the hygienic life of a child, we must begin at the beginning. The belief that a child is born when it separates from its mother and becomes physiologically independent is erroneous. Life begins at conception, when male and female cells unite and the marvels of creation begin anew. But we should even go back several generations if we wish to consider the influences which bear on the life of the individual.

The child is fated through its whole earthly existence to endure or enjoy, as the case may be, the conditions which the good or bad qualities of its parents have forced upon it. Smoking, drinking, sexual excess and other inordinate practices may not outwardly be seriously affecting the health of adults, but when their children become nervous, epileptic and subject to all the pathologies to which mankind has descended, they may seriously contemplate the seriousness of their weaknesses.

Though the seeds of both parents are vital in influencing the future of the child, it is the mother who after initial union must assume the delicate responsibility of making its first nine months perfect. Nature has appointed woman to the mission of motherhood and by this mission she is directly charged with the early life of the child upon which so much of future good or ill depends. The rights of children begin while they are still in fetal life. Not by any will of their own do they come into existence.

Children are what parents make them. Children in later life are often condemned and punished for things for which parents are directly responsible.

Though it should be unnecessary to mention it, there are still those who harbor superstitions in connection with influences during pregnancy. It is thought that if the mother hears beautiful music while carrying her child it will develop into a musician, or that if she reads or thinks about certain favorable subjects, the child will have favorable tendencies in the particular field desired. It is desirable that the mother be surrounded by beautiful things, lovely music, inspiring books, because these things all contribute to poise and health, but listening to the moving passages of a Wagnerian masterpiece will not develop a little Wagner any more than looking at a Ford automobile will make a budding automotive genius out of little junior. These superstitions are just as untrue as the belief that the sight of a rat will cause a brown mark on his forehead, or that baby will certainly be an idiot because mother happened to see a case of insanity sometime after conception.

Russel T. Trall, M.D., has this to say for the expectant mother: "Motherhood should be normal. But it never will be and never can be under the prevailing fashions of society. A man might as well drink intoxicating liquor and then endeavor to walk erect with face upturned to Heaven, without gibbering or staggering, as a woman expects to eat, drink, cress and dissipate in the fashionable ways and be the mother of healthy offspring.

"One of the pernicious errors abroad is that woman is the 'weaker vessel' physically; thus accounting for, if not excusing, her manifold infirmities. Fashion is justified and nature blamed. This doctrine has its origin in viewing 'woman as she really is,' and not 'woman as she should be.' The fact that woman in civilized life is, as a rule, feebler than man is taken as evidence of constitutional and natural infirmity.

"There is no truth to this notion. Physically woman is man's equal. In bodily stamina, powers of endurance, vital resources and muscular strength, under the same circumstances of habit and education, she is no sense inferior; on the contrary, if there is a difference, it is in her favor. This should be so; and there is an anatomical and a physiological reason why it is so. The woman has not only to nourish herself but others. She must construct and replenish her own structures and those of her offspring. Hence she has the greater nutritive apparatus."

A woman living a rational life free from superficialities will have a normal, painless pregnancy and

labor. The labor will be painless without the use of anesthesia and the abusive treatment of hospitalization. There are occasionally cases of badly formed pelvises which no amount of perfect living can alter, in which a certain amount of pain cannot be avoided. It is more important in these than in any that the patient live as closely to the laws of health as possible.

A pregnancy fraught with the usual discomforts, sickness and painful labor is simple to avoid. Mothers should live as close to their usual routine of duties as possible. This applies, of course, to women in the home rather than those who are working in defense plants and under other types of stress. A woman carrying a child should not be engaged in laborious occupations where she cannot rest when the inclination is there, and where she is subject to the vicious emotions of jealousy, hatred, deceit, etc. A poised, serene, self-controlled disposition should be cultivated. The atmosphere of the expectant mother should be one of quiet and refinement, one of happiness and love, and the husband should assist his wife in supplying that medium.

The unborn baby must have as perfect a home as possible. Its food supply which it receives from its mother's bloodstream should be clean and laden with rich nutriment for perfect growth. Hence the mother must take great pains to eat only the best food, in the best combinations and in the amounts best suited to her needs. Though it may sound like repetitious record, it is nevertheless important to stress the importance of not "eating for two" since the habit seems to be just as prevalent as always. A fat baby is diseased and because of its size will cause an uncomfortable pregnancy and a painful labor. Under normal circumstances a child's weight should be no more than six pounds at birth.

The child in the womb should have freedom of movement and for this purpose, the mother should allow her body all the freedom from dress that convention allows. She should dress comfortably and wear no tight garments of any kind. Her shoes should be low-heeled, or better still, have no heels at all. Whenever possible barefooted walking is good.

Sun-baths should be a regular part of the prospective mother's program. The sun creates vital changes in the body for the child and mother, improving the tone and vigor of the body. Women living in the north where the sun is scarce must be certain to expose themselves at every opportunity to insure at least a minimum amount. It is because of the need of sunshine that Dr. Herbert M. Shelton in *Care of Children* urged that babies be born in the spring. He writes as follows, "Babies born in the late fall or early winter, and who live through the winter, nearly all develop rickets to a greater or lesser degree. Fewer cases of rickets are seen in children who have the advantage of sunshine and sun-kissed food during their first months of life. That sunshine is absolutely essential to the normal assimilation and utilization of calcium (lime) and perhaps also of iron and other elements, is certain. This is true of plants, animals and man. If your child is born in the early spring or the closing of winter, it need never have rickets and will also have reasonable assurance against scrofula, tuberculosis, anemia and other diseases."

Exercise should be regular. Dancing, calisthenics, golf, hiking, tennis, swimming, if the water is not too cold, can and should be indulged in with care until the end of the pregnancy.

It should hardly be necessary to state that smoking, the use of alcoholics, coffee, cola drinks, and other suicidal habits must be outlawed. If a woman cannot make these sacrifices for her baby and for her own improvement, she certainly does not deserve the right and honour of having a child. These vicious habits make the mother a neurotic and the poor child nervous and irritable. There, can be no compromise.

Sexual abuse is a common and dangerous occurrence during pregnancy. Miscarriages are not infrequent and the abortion habit is often the result of this cause. It' is not uncommon to have expectant mothers forced into submission to this unnatural practice with threats of infidelity.

John H. Tilden, M.D. says. "The stockman, as well as the humane society, would prosecute anyone ignorant and stupid enough to allow the males of any breed of animals to tease and excite sexually the pregnant females; but this health destroying practice is permitted without protest among human animals."

The very least the husband can do is to cooperate with the mother of his child in this matter and other

conditions pertaining to her's and the baby's health. He must consider that she is making much greater sacrifice in the deal than he, and that a little self control and a less stimulating mode of eating and living will reduce his rapacity and improve his health.

The Hygienic mother has nothing to fear. The parturition will be painless and the newborn babe blessed with the health and promise every proud parent wishes it to possess. Home or a hygienic institution are the best places for the birth to take place. Likewise, a midwife, if obtainable, is the safest practitioner to have present at the time. The hospital and its brutal methods of hastening the parturition with drugs, anesthesia, forceps, and Caesarian section (the latter being routine procedure in some establishments) should be avoided with rightful dread. Here, everything is anti-natural. The birth of a child is treated as though it were the removal of a cancer instead of a perfectly normal, completely physiological, function.

The hospital mother is rarely capable of performing the most important function for her child after it is born; namely, that of lactation, of nursing it at her breast, because of the destructive medical procedure. If she can, the milk has invariably been made unfit for the same reason and rarely lasts beyond the fourth or fifth week. To the hygienic mother, these are all nightmares and disappointments she will never experience.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > 1. History Of Infant Feeding

### **1. History Of Infant Feeding**

Until recently, women never considered not nursing their babies. It was the only means available to them at the time—the only way they knew how to feed their babies. In fact, not only did they breast-feed their babies but they did so until the child was at least two or three years of age.

Shelton points out in an article, "The Story of Infant Nursing," that most civilizations of people nursed their babies and for long periods of time. He included the Egyptians, the American Indians, the Mesopotamians, the Greeks, the Romans, and the Orientals in his documentation of this fact. In these cultures, a wet nurse (a woman with breast milk who nurses your baby for you) was utilized only by rich women who thought they were "above" nursing their own babies.

When babies were first artificially fed, it was on bread and water. Then came the use of cow's milk. The invention of the bottle naturally followed. The first bottle consisted of a cow's horn with a couple of pieces of leather sewn to the narrow end which had a hole in it. The baby sucked the milk through the holes between the stitches of the leather. Next came the invention of artificial formula milks and all sorts of canned baby foods—and needless to say, the deterioration of health.

Nursing, and in fact nursing for long periods, continued in this country until the beginning of this century. After this, the decline in breast-feeding was very rapid in America. This is largely due to the medical profession advising mothers that bottle-feeding is better (cleaner) for the baby and will allow them more freedom. This decline was also due to the rising dairy industry followed by the manufacture of artificial formula milks which were pushed for a profit.

By the 1920s, a women's rights movement began and breasts went out of style. Women were moving into a men's world and took jobs outside of the home. They were no longer able to stay home and nurse their babies.

Besides women being forced into the work world, doctors—and other "experts" were urging mothers not to breast-feed and if they do breast-feed, they should wean early. These "experts" claimed that if mothers nursed their babies too long, their child will become too attached to them, become emotionally retarded, or that it will ruin their marital relationships, etc.

With the 20th century came so-called scientific child rearing—rearing the child on a schedule rather than on instinct or common sense. Up until a generation ago, children mostly stayed home with their mothers until kindergarten or first grade. Each year it seems the age of children being cared for by those other than parents gets lowered. Now even infants are raised in day care centers. Much of this is due to the economic situation—our exploitive industrial society—forcing women to work and away from their children.

In the 1960s and 1970s the trend, however, came back toward breast-feeding. Women began questioning the "experts" and feeling there must be a better way. Now there are many books available on the subjects of natural birthing and breast-feeding. There are also organizations such as the La Leche League willing to help and urging women to go back to nature's way of nourishing their young.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > 2. Importance Of Breast Feeding

## 2. Importance Of Breast Feeding

"Breast milk as the baby draws it directly from the maternal fountain without the interference of a middle man, is drawn from the living cells that produce it for the specific purpose of nourishing the baby. It is taken directly into the baby's stomach at the temperature at which it leaves the breast, without oxidation or contamination. Its ingredients and physical characteristics are especially adapted not only to the needs of the digestive organs of the human infant but also to the nutritive requirements of the infant. It is even designed to educate the digestive organs of the infant." — Dr. Herbert M. Shelton, "The Story of Infant Nursing," *Hygienic Review*

The only perfect food for an infant is its own mother's breast milk. Of course, under certain circumstances, it is not possible for the mother to breast-feed (this will be covered later in this lesson). However, most women can breast-feed their young and should if they want to have the healthiest baby possible.

"Nature has made provision for the infant to be nursed. She has equipped women with milk-producing glands and the normal woman is possessed of instincts that lead her to nurse her baby. At the same time, the baby itself is equipped with instincts that cause it to seek for the maternal breast and to extract its food from this source." — Dr. Herbert M. Shelton, "Baby's First Years," *Hygienic Review*

There are many advantages to breast-feeding your young which I will go into in the next section of this lesson. There are also some myths surrounding the advantages of breast-feeding. One of these is the idea of immunity. Most books or articles on the subject of breast-feeding state that breast milk produces an immunity in the suckling infant to certain diseases. From previous lessons touching on the subject of immunity you are probably aware that we can be made immune to nothing. If we indulge in the causes of disease, we suffer disease. The same holds true for infants. Breast-feeding builds stronger, healthier babies that—providing the mother is in good health and the infant isn't being fed any unwholesome foods in addition to breast milk and exposed to unwholesome environmental influences—will be free of disease.

Another claim by the aforementioned books and articles is that breast-feeding prevents breast cancer. Again, if the causes of cancer aren't indulged, cancer will not occur.

Perhaps the fact that most women who breast-feed their babies are much more health conscious than those who bottle-feed is an explanation for the lower rate of breast cancer among these women.

In spite of these myths, however, there are many advantages to be had by breast-feeding your young.

## **2.1 Advantages of Breast-Feeding**

Several years ago, a study was conducted by Dr. Randolph Paine of the University of Iowa's department of family practice. He tested 40 breast-fed babies and 66 bottle-fed babies for a period of six months from birth. He found that breast-fed babies visited a physician an average of 1.6 times due to illness. The bottle-fed babies visited 2.8 times during this period. This is nearly twice as often.

Other studies have shown that breast-fed babies have six times the chance of living through their first year as bottle-fed babies. Ninety percent of all infantile deaths occur in bottle-fed babies.

Breast-fed babies are vigorous and healthy and are less likely to develop diseases—especially, the so-called contagious diseases, breast-fed babies will be less likely to have bowel troubles and gastrointestinal impairments.

Breast milk is always ready—it requires no fixing and is always there. It does not contain dirt or contamination and doesn't need preparation or measuring. It is always fresh and cannot deteriorate.

Breast-feeding is cheaper than, bottle-feeding (it costs you nothing) and gives you more time to be with baby because you spend less time preparing, sterilizing, warming, cooking, and cleaning up after bottles.

Breast milk is formula perfect for baby's digestive system. It is readily assimilated and easy to digest, allowing baby more energy for better growth of brain and body.

A baby has an inexhaustible need to be loved. Breastfeeding shows him he is loved. It gives him a secure feeling of being snuggled closely to you when nursing. Breastfeeding provides closeness and warmth—a close contact that bonds a mother with her child.

Baby's sucking after birth helps the uterus of the mother to contract to its normal size quickly. This prevents excessive bleeding after delivery.

Babies that are breast-fed are less likely to be constipated or have skin disorders and respiratory ailments. They will not have any of the so-called "allergies" common among bottle-fed babies. They're also free of gastroenteritis, blood poisoning, and will have fewer dental problems later in life.

If a woman is breast-feeding solely, that is, not feeding her baby anything but breast milk, her ovulation will be postponed for as much as two years. This means that if she does indulge in sex while lactating, she will not get pregnant as soon. Thus, natural child spacing and no artificial means of birth control is necessary.

Another advantage of breast-feeding babies is that their stools will not smell foul. They smell sweet and are loose and yellowish in color rather than hard, dark-colored, and foul smelling as in bottle-fed babies. This is because breast milk is easily digested and it doesn't putrefy in the baby's body.

In spite of the many advantages of breast-feeding, it does not guarantee good mothering. There is much more to good mothering aside from providing the best food.

Also there is much to know about breast-feeding such as when to feed, how often to feed, under what conditions to feed, how much to feed, etc. This will be covered later in this lesson.

## **2.2 Bottle-feeding**

Bottle-feeding became popular with the belief that it was cleaner, somehow better than breast milk. It was also considered advantageous for the woman on the go—she didn't have to be with baby all the time in order for him to be fed. Someone else could give him the bottle as well as she. It allowed her to go to

work.

However, as far as I can see, there are no advantages to bottle-feeding. Even if a woman has to work there are ways to breast-feed her baby. She can hand express her milk before work in the morning or the night before and freeze it. It will be there for the caretaker to put out at room temperature ahead of time and be ready for baby when baby is hungry.

There are many, many disadvantages to bottle-feeding though. One is it can lead to obesity. The artificial carbohydrates in formula milks are habit forming and increase consumption of artificial sweets later in life. Artificial formulas contain much salt which can lead to dehydration in infants and toxicity. There are high levels of lead in formula milk that has been stored in tin cans.

Bottle-feeding is a very unnatural approach to handling an infant's nutritional needs. It comes complete with schedules, bottles (which can easily become contaminated), complicated preparation, a waste of precious energy, a waste of time, etc. A mother has to be concerned with which formula to use, how to prepare it, how much to use, how often to feed, whether or not to hold the baby, etc. And at best, all the manufacturers can claim is that their formula is "most like mother's milk."

Bottle-fed babies are more likely to develop disease. So-called "allergic" reactions to the milk such as eczema are common. Many nutritional ailments are caused by bottle milks as mother's milk cannot be duplicated. No one even knows all the components of breast milk, and, therefore, formula milks are likely to be deficient in one or more necessary element. One formula milk was found deficient in vitamin B-6 after it was discovered that this vitamin is contained in breast milk.

Bottle milks are difficult for baby to digest. Therefore, much energy is spent in breaking these down to a usable form and less energy is directed toward baby's growth and development.

Bottle-fed babies who are fed cow's milk often have intestinal and gastric disturbances. This is because cow's milk is not suitable for the baby's digestive system. Cow's milk contains more fat, more calcium and much less tryptophan (an amino acid) and lecithin than mother's milk. Tryptophan and lecithin are used in building brains and nerves. Calcium is employed in building bones. This is why cow's milk has the components it has—a cow's bone structure grows rapidly, and its brains and nervous system are not highly or delicately organized. On the other hand, a baby is relatively small of bone and have a large, highly-organized brain with a perfection of senses and bodily control. Babies fed on cow's milk primarily have softer brains and are less likely to be as intelligent as breast-led babies. The excess of fat and cream in cow's milk also produces digestive disturbances in baby.

Cow's milk contributes to hardening of the arteries and high blood pressure later in life. It also can cause low-blood calcium in the newborn, an overload in the infant's kidneys from having to expel the excess proteins, diarrhea, respiratory infections, etc. Tonsillar and adenoid troubles are also common with babies fed cow's milk.

However, under certain, abnormal conditions, it becomes necessary for a mother to include cow's or other animals' milk in the diet of her baby. These will be included later.

Another problem with bottle milk is that it does not change with the hormonal and nutritional needs of the growing baby. The makers of baby formulas cannot duplicate the changes in composition or volume that takes place continuously in mother's milk as her baby grows.

Yes, mother's milk cannot be imitated in the laboratory. Nature had it perfect to begin with, and there is no perfect or near perfect substitute.

### **2.3 Common Worries and Apprehensions About Breast-feeding**

Some women feel that because their breasts are small they will be unable to nurse their babies. They feel that somehow larger breasts are able to produce more milk. This is, most definitely, not true.

Other women feel that nursing will spoil the shape of their breasts. This is also not so if the woman is

taking good care of herself—eating right and exercising. Even if this were so—which is more important, the shape of your breasts or your baby's health?

A belief that an inability to nurse exists because your mother or grandmother were unable to is also unfounded. No diseases or disfunctions are hereditary. Your equipment is entirely independent of your mother's.

A fear that your milk won't be rich enough is also unfounded. Studies conducted have shown that even the milk of unhealthy, emaciated mothers is better than artificial formulas.

What if I can't produce enough milk? If this happens, just nurse your baby more. The more often a baby nurses, the more milk is produced. Also, eat plenty of juicy fruits to produce good milk.

There's no way your baby can be "allergic" or sensitive to your milk. If you've eaten spicy foods, processed foods, etc., it will go through the milk and the baby will most certainly react negatively. This is why it is important for mother to eat right and avoid toxic substances. (See Don'ts While Breast-feeding.)

You may wonder if your baby is getting enough milk. If your baby is growing, energetic, sleeping well, and displaying other signs of health, don't worry. Nurse about ten minutes on each breast during each feeding if the baby wants to nurse that long and baby should be receiving enough milk. Also, overfeeding is much more of a problem than underfeeding.

If you have older children that have been breast-fed and especially if they still remember it, you have to be very careful in your handling of the situation. Older children need to be told ahead of time (before birth) that they are going to have a new sibling and that he or she will breastfeed just as they did. Older children tend to be jealous when they see you snuggling a baby to your breast. Show them as much love as you can to allay this.

Some special problems exist for the woman who has had a premature baby or a caesarean section. A premature baby may be in an incubator for as much as several months being fed on special hospital formulas. If you wish to breast-feed when you get your baby back, you still can. You need to hand express your milk while the baby is in an incubator to ensure your milk supply will keep flowing. When you do receive your baby, he will need even more closeness and nourishment than a term baby.

He may nurse very feebly at first and require much coaxing and patience on your part to get him nursing.

A woman who has a caesarean section has received an anesthetic and is not in as good shape as if she had delivered vaginally. She should wait until all the anesthetic is out of her system to breast-feed as this will get into the milk supply. It will take more patience and persistence to get the milk out as the natural cues of a vaginal birth are not present. She will have plenty of good rich milk, however, if she eats right and relaxes.

Another apprehension of mothers is that they should stop breast-feeding if their babies get sick. The chances of breast-fed babies getting sick are not that great, however, to cause worry. If they do get sick, they will probably not have the appetite they had when well. Just hand express the milk meanwhile to keep the supply flowing.

If you get sick, you can still nurse your baby. Your baby is already used to you and your biological makeup. He or she will not get sick by nursing from you.

If you feel you are too nervous to nurse, take some courses in relaxation or meditation techniques prior to birth. This will help you to relax when nursing for it is true that if you are tense, your milk supply can be held back.

If you have inverted nipples, you have a special problem—not one that is impossible though. I have seen mothers with this problem breast-feed normally. Pull the nipples out regularly before the birth to get them used to this. They need to be out in order for baby to latch on. Also leaving them exposed to air

and sunlight fifteen to thirty minutes several times a day helps to bring them out.

Many women may feel sensitive to cultural attitudes toward breast-feeding—families discouraging you to breastfeed as they feel it's "too animal" or sensual. Some may find it disturbing and feel it's an interference in the marital relationship. In this case, try to explain to your husband beforehand why it is important to breast-feed the baby and perhaps coax him into reading books on the subject. It is important not to have people around you who are opposed to your breast-feeding while you are doing so. The baby may pick up on these feelings. Try not to let other peoples' attitudes make you tense while nursing or dissuade you from doing so. Be strong!

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > 3. The Mechanics Of Breastfeeding

### **3. The Mechanics Of Breastfeeding**

Breast-feeding an infant is a supply and demand function. The more (and longer) a baby nurses, the more milk is produced. This causes the milk supply to keep up with the growing and developmental needs of an infant.

As explained in the definition of let-down reflex, there is front milk and hind milk. The front milk gets sucked out by the baby which causes a hormone to be released into the mother's body and lets the hind milk down. The hind milk is richer than the front milk and there is more of it. Sometimes when the hind milk lets down it drips out and may spray outward from mothers' breasts. Oftentimes the mere sound of the baby crying, the sight of him, or the thought of him, can cause this let-down reflex.

Sometimes the milk gushes out too fast for the baby to swallow and he may choke a little on it. He usually turns, his head to one side to catch a breath of air. He then gets squirted in the face. Keep a spare diaper or other cloth handy to absorb this extra milk. You may need to burp the baby after swallowing too much milk to prevent upsetting his stomach.

Nursing for just a few minutes on each breast will fail to let down the hind milk in most cases. The baby needs this richer, higher-quality milk in order to ensure his nutritional requirements. Make sure you nurse for at least five to ten minutes on each breast to obtain hind milk.

After a few weeks a new mother will get used to the feeling of the let-down reflex. She will recognize the tingling sensation in her breasts and the full feeling.

More milk will let down when a woman relaxes. If she is tense and upset, only the front milk will come out and baby will be dissatisfied. It is best to wait until calm to nurse.

Colostrum has long been thought of as useless—as a waste product—and yet it comes into a woman's breasts before birth and remains there for a few days following birth. Surely nature made no mistake in putting it there. Colostrum contains half the carbohydrates and fats of regular milk and a newborn has difficulty digesting these. Colostrum is specially adapted to meet the immediate needs of the newborn.

Many women have trouble with their breasts engorging with this fluid (colostrum) after birth. Her breasts may become swollen and sore. To alleviate this get the baby to nurse to express the colostrum. Once the nursing cycle is established this problem will disappear.

Another thing to consider with breast-feeding, especially if for the first time, is prenatal nipple care. Prior to birth "toughen up" the nipples so they won't get tender or sore from baby's sucking. Do not use soap on them as this causes them to dry and crack. To open milk ducts hand express colostrum by cupping breast in hand with one finger above nipple and the other below and then squeeze. Also

exposing the breasts to air and sunlight will toughen them.

### 3.1 Mother's Diet

"It is not possible to produce quantitatively and qualitatively adequate milk on a diet of white bread, embalmed meat, pasteurized milk, pies, cakes, mashed potatoes, etc. Eating large quantities of these rich foods is useless. These only impair digestion and destroy the mother's appetite. The one class of foods that greatly increases milk production in animals, and there are reasons for believing they will do so in women, are green foods. An abundance of these should be eaten." — Dr. Herbert M. Shelton, *Hygienic Care of Children*

A mother who eats of fruits and vegetables in their raw natural state will have no trouble producing adequate quantities of rich, healthy milk for her infant. The dairy products, herbal teas, excess drinking of water, etc., that are frequently recommended to increase production of milk in women are not only unnecessary but can be harmful.

Drinking excesses of cow's milk on the part of the mother rather than providing much calcium actually drains the calcium resources of the body. Excesses of fluid consumption cause extra strain on the kidneys to excrete them. Also herbs are irritants and not recommended.

Green vegetables have a high-calcium content and therefore should be consumed abundantly. Fruits are a rich source of a multitude of vitamins and minerals to produce the finest milk in mother.

A diet high in protein can result in excess protein in the milk and could be detrimental to the baby. Nervousness or lack of exercise can also result in too much protein in milk.

The same advice as in the last lesson on prenatal care also holds true while breast-feeding. Eat only when hungry, never overeat (to fullness or beyond), eat only when relaxed and in a positive state of mind, properly combine foods so they will digest most efficiently, exercise regularly, get plenty of rest and sleep, breathe fresh air, and get lots of sunshine.

The difference that diet makes to the breast milk is incredible. Breast milk does not remain the same no matter what you eat. It changes quite rapidly according to what you eat or otherwise ingest.

Remember, breast-feeding is easy if you eat well, live an easy, relaxed life without stress, and your family and friends have a good, supportive attitude toward breastfeeding.

### 3.2 Don'ts While Breast-Feeding

1. Do not keep long work hours, get too little sleep, get in frequent arguments, or surround yourself by critical family and friends. This affects the quality and quantity of breast milk.
2. Eating lots of contrived sweets (things sweetened with sugar, corn syrup, honey, etc.) and soft drinks. will reduce baby's appetite and cause diarrhea.
3. Hot and spicy foods result in diaper rash and indigestion in the baby.
4. Drugs, alcohol, and medicines pass through into breast milk and are harmful to baby—and you.
5. Brussel sprouts and cabbage have been known to create indigestion in babies when consumed by mother.
6. Smoking affects the taste and quality of the breast milk.
7. Eating chocolate severely cuts down on calcium level in breast milk.
8. A too-tight bra (or any bra for that matter) can cause a plugged milk duct. Symptoms of this are redness near nipple, and a core lump in breast caused by inadequate emptying of milk ducts. If this happens, let baby nurse a lot on that breast to express milk Also soak the dried secretions on outside of nipple with warm water. Keep breast empty and rest as much as possible.
9. Do not fast while lactating. A fast quickly reduces the quantity of milk and impairs its quality. The milk becomes poorer in water, protein, sugar, and mineral salts. The fat content, however,

remain the same.

10. Grief, worry, anger, fear, excitement, etc., greatly diminish the secretion of milk or alter the composition of it.
11. It has been shown that sexual intercourse while lactating often induces premature menstruation, ruins the quality of milk, and induces termination of the nursing period. During orgasm, the quantity of phosphorus is reduced and this could retard brain development in the baby. Loss of lecithin is also caused by sexual indulgence. Lecithin produces brain growth. After sexual intercourse putrefying seminal fluids may be absorbed through the vaginal wall into the lymphatic system of the mother thus ruining the milk.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > 4. Methods Of Breast-Feeding

#### **4. Methods Of Breast-Feeding**

While nursing the baby it is best to sit up—not slouched—in a comfortable chair or cross-legged on the floor. Aim the breast downward as milk flows best downhill. To eliminate slouching bring the baby up to the breast rather than the breast down to baby.

Put the breast into the baby's mouth with as much of the areola in the baby's mouth as possible. This helps the baby latch on better and get the milk out more easily and at the same time you won't get sore nipples. Merely putting the nipple in the baby's mouth will cause him to chew on the nipple with his gums in an effort to get milk out. Aim the nipple upward in baby's mouth holding breast, up with hand with thumb on top. When baby is first born, it is more difficult for him to hold onto the breast and he needs your help.

Be sure to press the breast down just a little bit away from the baby's nose so that he can breathe. The fullness of your breasts could smother him.

If baby still acts hungry after you've emptied both breasts (usually about ten minutes on each side), he may merely want your company. A good baby carrier can help so you can resume your other duties. This provides the motion and closeness that the baby was used to in the womb.

Don't try to pull baby off of breast when still sucking. This will be painful. Release the suction by gently pressing in your breast on both sides of baby's mouth.

When baby falls asleep in your arms while you nurse him, don't just lay him down by himself. Lay down with him for awhile with your nipple still in his mouth. Then remove nipple and continue lying down with him. Then get up very slowly so as not to disturb him. The baby suddenly misses the presence and warmth of mother if not done gently and slowly and may awaken.

Babies like to be snuggled firmly and closely to mother while breast-feeding. This makes them feel secure and loved.

A baby's natural reflex is to suckle the nipple if its mouth is brought close to it. Bring baby's legs close to you angling baby so he can breathe. If baby still has trouble getting the nipple, hand express some milk first and let him taste it to create an impulse in him to begin nursing.

When baby cries, it doesn't always mean that he is hungry. Sometimes merely turning him from one side to another will stop him from crying. Other times he may want cuddling or motion. Don't always assume he is hungry and immediately push the breast in his mouth. This could create a problem later in life where he seeks food for security.

## 4.1 How Often to Breast-Feed—Overfeeding, Normal Feeding

Babies need only be breast-fed three times a day for the first day or two following birth. A normal, healthy baby may only awaken that number of times during a twenty-four-hour period. A baby should never be disturbed from his sleep to nurse.

By about the fifth day after birth to the second week baby should feed at about four-hour intervals during the day. A good schedule is at six a.m., 10 a.m., 2 p.m., and 6 p.m. Never feed baby at night. Nighttime is a time for sleep, not for the burden of digestion and elimination. It may be difficult at first to not nurse at night as baby might awaken, but once you get a routine established baby will follow it.

Shelton recommends merely turning your baby from one side to the other if he cries. If this does not work, perhaps walking baby will help.

Most mothers, especially new mothers, have a tendency to overfeed. They seem to think that whenever baby cries, he is hungry. In fact, some women dislike their baby's crying so much that they get into the habit of pushing the breast into baby's mouth every time he cries. This can be detrimental to baby. Overfeeding, such as this, inhibits function and retards growth and development.

Shelton recommends that following the second week after birth baby be cut back to three feedings a day. Of course, with this amount of feedings your baby will not be the fat little butterball that is considered so healthy in this society. But he will be much healthier and will develop and mature more quickly. He will develop good eating habits later in life as a result. In fact, most bad eating habits begin during infancy.

How long should baby nurse during each feeding? That depends entirely upon the flow of milk from the breast. Sometimes the baby will be thoroughly satisfied after only five minutes on each breast—sometimes it may take ten to fifteen minutes. Watch baby to see if he seems satisfied.

Besides creating fat, slowly-developed babies with bad eating habits, overfeeding causes baby to suffer from indigestion, gas, intestinal colic, diarrhea or constipation, stuffy noses, skin rashes. Overfeeding causes a frequency of urination and bowel action so that the mother is constantly changing diapers. Even at night when baby (and mother) should be sleeping, he is busy emptying his bladder and bowels.

Another common problem among infants is hiccoughs. Hiccoughs are the evidence of undigested residue. Their purpose is to eject the overload.

Most babies have regular hiccoughs and mother usually just stuffs more in—either water or sugar or both. Hiccoughs are also a result of overfeeding.

Other common complaints are drooling and spitting up so that baby can be seen wearing a bib as regularly as he would a diaper. Teething can be a painful ordeal if baby is overfed. A baby who is fed only what he needs and when he needs it does not have this problem.

Most doctors will say that baby should gain about a half a pound of weight per week for the first several months. This is an incredible amount and it is only fat that will eventually have to be lost as fat is merely toxins.

Most midwives or alternative doctors will recommend nursing your baby upon demand. But this also is not good advice as baby does not always know what amount is best for him. He needs to be trained in good eating habits— they don't necessarily come naturally. Shelton says, "In all nature there is not another, example among mammalian species where the female permits her young to feed upon demand., All of them exercise control over the nursing of their offspring...."

Oftentimes the cries of pain a baby, lets out because of intestinal distress from overfeeding are mistaken for cries of hunger and baby is fed more. The breast becomes like a pacifier and baby equates it with security. Most of these overfed babies will sleep off these feedings like a drunk sleeps off his binge. Their lives become a round of eating, vomiting, sleeping. Most people consider this a normal infant's life though.

After all the abuse an infant receives in infancy by overfeeding, his digestive organs may never function normally. He may have dyspepsia later in life and will be more susceptible to disease.

The three-feedings-a-day plan, although it may seem cruel to some of you, is definitely adequate. Many Hygienists have proven this with their own children. Their children grow faster and develop better.

They sleep better at night and give their parents less anxiety and require less attention as they're rarely complaining or sick.

The newborn possesses the power and ability to digest and assimilate, easily and continuously, only the amount of food necessary to produce normal growth. And you'll know that when you see it.

## **4.2 How Long To Breast-Feed**

The normal nursing period of mammals, and that includes humans, is directly related to the time it takes for their young to develop. Mammals that grow rapidly and mature early have short nursing periods. Likewise, mammals that grow slowly, such as humans, have long nursing periods.

Shelton has divided the periods of feeding in a person's life into three parts. The first one is the infant period. During this period, the only food necessary to sustain normal life is breast milk. This period lasts until the infant has a mouth full of teeth—not just one or two teeth.

The next period is the transition period (discussed in next section on feeding) where baby is fed both breast milk and solid foods. This period begins when baby has the anatomical and physiological equipment (full mouth of teeth and adequate digestive juices) to digest solid foods and it ends with weaning from the breast.

The third and final period is the adult feeding period. This begins with weaning and continues until the end of life.

Most books and articles on the subjects of how long to breast-feed recommend feeding solids by the time a baby is three to six months old. They say as soon as baby begins getting teeth he is ready to handle solid food. This is obviously not so—how can anyone chew with only one or two teeth? So mother mashes, chews, and blends baby's food so that he may swallow it. But why? Breast milk is already in a form that baby can handle. When baby is ready for solids, he will have the tools to handle them.

Many doctors or books will advise mothers not to rely solely on nursing for her baby's nourishment once the baby reaches nine months to a year of age. They say mother's milk is no longer nutritionally sufficient to baby's needs and they need to supplement it. But why would nature do such a thing?—make baby's food insufficient before he is ready to deal with other foods. If mother is healthy, her milk is healthy.

The human infant is helpless much longer than any other animal. Therefore, there should be a longer nursing period. By about the age of three most children are ready to wean but some may wean earlier and others later.

By about the age of two a child has most of his teeth and has digestive enzymes to break down foods properly. By now mother's milk has insufficient amounts of iron and other nutrients as milk has already done its duty. This is a good time to include fruits and nonstarchy vegetables into the child's diet. However, this does not mean abruptly ending breast-feeding. Combine the two for as long as seems right for both you and your infant.

I realize that nursing babies for long periods such as three years, as a rule, is not an acceptable act in this culture. Many people will frown upon you and make snide remarks about it being sexual as the child is so old. Don't let this disapproval cause you to prematurely wean your child. Avoid situations and people that make you feel uncomfortable about nursing your toddler. Just remember you're raising your child as nature intended—in the best way possible.

## **5. Feeding Solid Foods**

Now that your child has most of his teeth, he is ready to start eating the same foods you eat. That is, if you are eating a diet of fresh fruits and vegetables in their raw state.

The best first food for children is fruits. Sweet juicy oranges, dates, figs, raisins, persimmons, well-ripened bananas, etc., are excellent first foods. Show your child how to eat them. Teach them to chew their foods properly and give them only when the child is truly hungry.

Feed them fresh fruits in the summer and dried fruits in the winter. Avoid nuts as these cannot be fully chewed by a small child and they have more protein than a small child needs or can handle. Never give them starches, contrived sugars, or pasteurized milks or other dairy products. Keep their foods simple. Don't combine too many foods at one meal and don't add things such as honey or spices to "jazz up" their food. Their taste has not yet been perverted and foods, especially fruits, will be delicious to children in their natural state.

Starchy foods such as potatoes, yams, rice, cereals, etc.. cannot be digested by the young child. They lack the salivary enzyme ptyalin, to break clown starches und they cause them much difficulty when eaten. Also, it is difficult for a small child to chew starchy foods properly and totally ensalivate them before swallowing.

Some children will indicate a desire to take foods by the time they're a year old. I have seen infants grab for foods right out of their parents' mouths. My son "scarfed down" watermelon by the time he was only six months old. He did not seem to have any problems handling it as it didn't require much chewing. Swishing it between his gums made it liquidy enough to swallow. Freshly-squeezed fruit juices such as orange or grape juice are good for babies this young also. They may be substituted for one of baby's regular breast milk feedings.

Most children are not particularly fond of vegetables. It is different with each child. Of course, starchy vegetables such as carrots should be held off for the first few years. Some children love greens and sprouts and others will only eat the nonsweet fruits such as bell peppers, tomatoes, or cucumbers that most people consider vegetables. Experiment and see which vegetables your child will eat.

In order for your child to best assimilate the foods he eats, make sure he gets plenty of exercise, fresh air, and sunshine. Keep the home environment free of stress, arguments, and other negativities as this also affects the digestive processes. Give him lots of love.

## **6. Feeding Under Abnormal Conditions**

Naturally, it is always best to feed the baby with mother's own breast milk but if mother is unhealthy or for some reason no milk is being secreted from her breasts, it is necessary to feed the baby in other ways. Most Hygienists would recommend serving infants under these conditions goat's or cow's milk in its raw, unpasteurized state. Doctors and others will tell you not to feed baby raw milk as it contains bacteria that could cause baby to contract an infection or other health problem. This is not so. Pasteurizing, homogenizing, preserving, and then enriching milk is what creates the problems of intestinal and gastric disturbance when milk is consumed.

As mentioned under the bottle-feeding section of this lesson, animal milks are an imperfect substitute for mother's milk. However, they are better than no milk. In Shelton's article, "Baby's First Years," he states, "I have seen babies who could not handle cow's milk very well who did fine on goat's milk. I have seen other babies who could not handle goat's milk well thrive on cow's milk. And I have seen other babies that did not handle either cow's or goat's milk well who did well on soybean milk. As a rule, babies do not grow as well on soybean milk or other artificial milk as they do upon animal milks." Dr. Shelton recommends feeding them a spoonful of milk at a time and observe how they react. If favorably, gradually add more. If not, try another milk in the same fashion. Remember also never to combine milks with other foods. When milk is mixed with foods, it causes dyspepsia and constipation.

Give the baby orange juice and grape juice at separate feedings in addition to the milk. Make sure they are freshly squeezed to ensure that baby is getting all of their nutrients.

Try making nut milks by blanching almonds, adding distilled water to them (one part almonds to four parts distilled water), and then blending them until no chunks of nut remain. Strain through a clean cheesecloth to remove particles and give to baby on a spoon. Watch his reactions.

Since cow's or goat's milk are specifically designed for the needs of these animals, they are naturally deficient in nutrients necessary to the growth of a human infant. This is why it is imperative that fruit and vegetable juices are included in baby's diet. These provide the minerals, vitamins, and fruit sugars that are lacking in animal milks.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > 7. Questions & Answers

## 7. Questions & Answers

### **How can a new mother tell if colostrum has come into her breasts yet?**

There really is no need to tell except for your own security in knowing it's there. Your baby is getting it if he is sucking. But if you must be reassured that your breasts are secreting colostrum roll your nipple around with your fingers and pinch it gently. The yellowish fluid should come out.

### **I have known many women whose hair has fallen out when nursing their babies. What causes this?**

I cannot give you a specific cause but as with all ailments and diseases a lack of health due to lifestyle and diet are causative. I would recommend cutting down on cooked, processed, refined, salted, or sugared foods and including more fresh, ripe, raw fruits and vegetables in the diet without sauces and dressings. Get plenty of exercise, fresh air, and sunshine to make sure you're assimilating the foods. Make sure you eat a variety of fruits and vegetables to get a plethora of vitamins and minerals.

### **I've noticed since the baby's born that my sex drive has diminished greatly. Is this normal?**

Yes, it is normal and natural. Nature worked out a plan so that everything would be perfect. Not only are you getting all of your touching needs fulfilled by your relationship with your baby, but your baby will be healthier without your vital fluids being drained from you. As for your husband's needs—well that's something you will have to work out together. Compassion and understanding are necessary in this case.

**I know it's best for my baby to be breastfed, but I'm feeling very inhibited and concerned that the baby's sucking at my breasts will sexually stimulate me. Do other women experience these feelings and if so what do they do about them?**

Many women have inhibitions such as these and it is mostly because our society sells breasts as play things for men rather than what they truly are—for feeding of infants. When the baby is born, your natural instinct to nurse will come and your breasts will no longer feel like sexual objects. Your baby's needs will transcend sexual needs or desires.

**What if I am six months pregnant and my first child who is two-and-a-half years old is still nursing? Will my unborn child be deprived of nutrients?**

If you are making sure that your diet is well-balanced—that is, it contains a wide variety of raw fruits and vegetables, with nuts included, then chances are it will do no physical harm to the baby. You also need much more rest than normal and light exercise, fresh air, and sunshine. However, the older child may become very jealous when the new baby comes if you suddenly wean him. You need to cut down gradually on your child's intake of breast milk and substitute other foods and juices so that by the time the baby comes he will be adjusted to not receiving as much milk as often. You also need to explain to him in as simple terms as possible that a new baby is coming and will be nursing often. You can nurse them both for awhile as long as the older child is not nursing very often—perhaps once a day or so.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > Article #1: Simplicity of Infant Feeding by William L. Esser

### **Article #1: Simplicity of Infant Feeding by William L. Esser**

Infants are submitted to a shocking array of foodstuffs and formulary in an effort to find just the right thing to make them fatter and supposedly healthier. Apprehensive parents and physicians are wont to rush from one "formula" to another, from one baby food to another, from one "lacto" something or other to another, in the desperate hope that they will find the magic panacea that will quiet the wailing babe and make it grow with rosy cheek and gurgling happiness.

The amount of money spent on expensive patented and prepared "baby foods" is vast. Nothing is too good for baby (or is nothing too "bad" for baby?) What a roundabout and torturous way to have a healthy baby. The farmer's wife will travel long miles to the big city to see her child specialist and to buy her baby's formula in the drug and grocery stores while she has all the essentials within and around her for a healthy child.

We have frequently mentioned the importance of the pregnant woman's eating and living correctly to ensure normal birth and the ability to have rich, nourishing milk for her infant. We have also stressed the wisdom of having the baby at home at the hands of a midwife or an intelligent understanding doctor versed in the Hygienic method of delivery who avoids the use of drugs anesthetics, etc., not conducive to the health of mother and child and deleterious to the function of lactation.

It is pitiful to see well-built comparatively fit mothers unable to nurse their children, feeding them unwholesome, devitalized, demineralized substances deceitfully called foods. The female of each species of animal is best suited by nature to supply its young with the most perfect food for its normal and vigorous growth. No other animal can supply an equally good substitute. The young of the human

animal have not as yet evolved to such a doubtfully happy position that they can thrive as well on substitutes whether they be of cows, goats, donkeys, or some unappetizing vegetable stewed to death in the snow white kitchen of a pickle factory or a chemist's scientific laboratory.

Dr. H. M. Shelton, in *The Hygienic Care of Children* quotes an eminent woman specialist as saying: "The finest and most important duty of motherhood is the breastfeeding of her baby. Next to the right of every child to be well born comes the right to his best food, his own mother's breast milk. Mother's milk is the perfect infant food; it cannot be imitated; and anyone who advises a mother differently is guilty of a serious crime against a helpless baby. When a baby is denied his mother's milk and put upon a bottle, he loses half his chance to be kept alive and nine-tenths of his chances to grow up into a normal healthy man or woman."

A mother who deprives her baby of this most vital link to a joyously vibrant life is to be pitied and shamed for her selfishness or ignorance. Nursing should be carried on for two years or more, not three weeks. Three weeks is the extent to which most hospital mothers can nurse their children. Then the milk dwindles away. They should fear hospitalization if they wish to nurse their baby and avoid disease, plus the pains of sleepless nights and worry.

Mothers should nurse their babies, but should prepare for it throughout pregnancy. An adequate diet of fruits, nuts, and vegetables properly balanced and combined will supply the needs of her own body as well as for the making of good nutritious milk.

If a nursing baby does not have a slow, gradual increase in growth and general aptitude, it is an indication that the mother's and child's health is being undermined because of an inadequate diet. The proper nourishment must immediately be introduced to the mother, otherwise the baby will have to be removed from the breast.

There are "students" of various health movements and reforms, who, having brushed against the skirts of Hygienic philosophy, seem to be of the impression that they have thereby become lay authorities on health and its laws. Frequently children and friends are made to suffer from nutritional deficiencies because of their half information. Mother's milk is the finest, the most perfect food for children—if—mother is in good health. If she is in very poor health, baby should be removed from the breast.

The baby may and should have supplemental feedings of undiluted orange or grapefruit juice within several weeks after its birth. Given two ounces at first the amount should gradually be increased over the following months until it may be given from six to eight ounces by the time it is eight months old. Oranges selected should be ripe and sweet. Sugar or other things should never be added to any fruit juices.

No more should be given regardless of generous feedings incited by baby's smiles or cries. Young puppies are constantly seeking out the mother to suckle, but the female dog only permits them to eat when instinct allows, otherwise they must exercise firm control throughout the infancy and youth of her children, else they will easily develop the glutton habit.

Baby should be permitted to empty both breasts at each feeding. It should require only ten minutes to accomplish this. Complete emptying ensures full meals at each feeding. If the mother's milk is unfit for her baby, the next best food adapted to the young digestion is goat's milk taken from a group of healthy animals. Three-, four-, or five-ounce feedings for the baby will be enough. At the sixth month, the quantity may be gradually increased six to eight ounces by the ninth month. When goat's milk is not to be had, clean cow's milk may be used. Milk should be diluted with equal parts of distilled water until the sixth month. Thereafter, one part water to two parts milk.

The controversy over raw or pasteurized milk goes on and on between the phantoms of the laboratory and the naturalists, but the facts remain the same. Recently a test was conducted in New York on a group of babies. One group was subjected to pasteurized human milk and the other to raw cow's milk. The ones given the raw cow's milk were superior in growth and I.Q.s to those who were given pasteurized human milk. Had the human milk been raw and from healthy mothers the result would have been the

reverse.

Pasteurization is a process which submits the milk to a temperature of from 130° Fahrenheit to 160° Fahrenheit for a period of from ten to thirty minutes reputedly to destroy all harmful organisms. In destroying the organisms, it also destroys the vitamins and nutritive qualities of the milk.

After the first few months other fresh fruit juices such as grapes, figs, berries, etc., may be given in the same amounts as the orange and grapefruit juices.

Milk or fruit juices should be prepared immediately previous to feeding and not for the whole day's schedule. Food quickly loses nutritional value when prepared in advance. Room temperature is best for all foods given to the baby. Fruits should be left out of the refrigerator for a time previous to the feeding. Milk in the bottle should be immersed in a utensil filled with warm water to remove the chill, not poured into a pan and heated over a flame.

Nipples and bottles should be well cleaned after use but the superstition-inspired measures of sterilization are unnecessary.

So often repeated that mentioning should be unnecessary, we wish to stress the importance of not feeding the baby at night and of not awakening it at any time for a feeding. This will cause restlessness, rob the baby of sleep, and promote gluttony.

How adults love to watch baby's reaction when they offer it a foreign food! The digestions of most children suffer one outrage after another as fond papa, uncles, aunt and friends offer the helpless little life anything from drumsticks to pickles, cigarettes to coffee, and beer to salted peanuts. No doubt it is "cute" to watch the little one's face distort into amusing expressions but in addition to being "cute" it is also stupid, poisonous, and criminal,. Infant's arid children do not crave or desire these things. Adults seem to believe that the little innocents are born with the depraved habits which are theirs. Their bodies are still clean, pure, and undefiled. They are potentially strong, vigorous, and noble. Why offer them candies and ice cream? Why give them spoonful of the food from your own plate? Why coax them into eating rubbish that will destroy the beautiful handiwork of nature? If a man purchased a thoroughbred dog, horse, or livestock he would be most cautious about every ounce of food given to the animal and would sue the man that fed him otherwise. He would no more think of offering the creature beer to drink or spaghetti to eat than he would to feed him a dose of poison. Yet his own child, which should be far more precious to him, he treats as badly as a little boy does a grasshopper or fly as he plucks out wings and pushes needles through the squirming body.

Infants should not be fed if they do not take the feedings willingly and eagerly, they are sated or indisposed and the meal should be omitted. If a fever is evident, nothing but water should be given for a day or two. Every time a baby cries it is not hungry. Look for other causes.

Infant feeding is simple and must be kept so, otherwise the usual diseases of children will be developed. Forget the cereals, the drugstore pictures of fat, adenoidal babies, the strained vegetables, and feed the newborn babe the natural, wholesome, effortless, simple way which nature outlined far back in the dim recesses of time. It is a famous and proven recipe!

[Home](#) > [Lesson 56 - Normal Feeding Of Infants; Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > Article #2: Indigestion in Babies by Dr. Herbert M. Shelton

## **Article #2: Indigestion in Babies by Dr. Herbert M. Shelton**

I receive frequent letters from anxious mothers asking what causes indigestion in their infants (under two years) and what they can do about it. Indigestion in children under two seems to be very common.

Let us try to answer the first question: what causes it? Nerve energy is functioning power and anything that lowers nerve energy and brings on enervation will cause indigestion. Excessive play, overexcitement, overindulgence, overeating, eating between meals, eating when tired, or when excited, starch eating before the end of the second year, being tired from outings, neglect of the afternoon nap, being overheated, or chilled, drugging and anything that will use up nerve energy excessively may result from too much juice being fed the baby. Some mothers seem to want to drown their babies in juice.

The first symptoms of indigestion are "nervousness," irritability, bad breath, bloated bowels, coated tongue, cold feet, constipation, colic, hives, sleeplessness, grinding of the teeth in sleep, drooling. Babies are always irritable and cry easily when they have indigestion. There will be undigested curds in the stools and often foul stools.

Teething does not cause indigestion, but indigestion may result in difficulties in teething. There can be no doubt that teething, which is normally a painless and unnoticed process, can be very painful in sickly babies. The gums may become inflamed and painful, the baby will cry and fret and its digestion will be upset still more, but the basic cause of the indigestion, which is the forerunner of painful teething is enervation.

What can be done about indigestion? Remove the cause. How? Stop the overfeeding. Cease overexciting the baby. Discontinue feeding it between meals and at night. Cease feeding starch and other foods which it is not physiologically equipped to handle. Give it less juice. Stop over-bathing it. Dress it more warmly or less warmly, as required. Do not permit it to overplay. Give due attention to its afternoon sleep. Give up the drugging.

Mothers want to know what they should do immediately, when the baby has indigestion. The care required is simple. Put the baby to bed with something warm at its feet. Let it rest and keep quiet until it is normal. Often within twenty-four hours the baby will be able to eat. If baby wakes up smiling, in good humor and with a sweet breath, it is ready to be fed. But, if it wakes up crying and irritable, with pungent breath and white lines (lines of stomach irritation) around the mouth and nose, complaining of discomfort, the fast should be prolonged for another twenty-four hours. Indeed this program should be continued until the baby is normal, even if it takes several days. Mothers are usually in a hurry to feed and by feeding prematurely, they prolong the indigestion. Give the body an opportunity to get rid of the surplus food, toxemia, and to restore functioning power.

When baby is ready to resume feeding, the food should be a little fruit juice—orange juice, fresh tomato juice, or other fresh fruit juice in season (I have used watermelon juice, canteloupe juice, papaya juice, peach juice, apricot juice, plum juice, pear juice, apple juice, etc.) which may be given every three hours. If the baby goes through this first day of feeding comfortably and rests well through the night, the next day regular feeding may be resumed, giving but about one-third what had been previously given. In one or two days, if the baby continues to do well, the amount may be increased to half the amount the baby had been in the habit of eating. After another day or two a full diet may be resumed. By a full diet, I do not mean the diet conventionally fed to babies, nor do I mean a return to the prior overfeeding and feeding between meals.

Until the baby is two years old it needs and should have no other food but milk and fruit juices. The best food in the world for the baby is its own mother's milk. There is no adequate substitute for mother's milk. Baby is physiologically unequipped to chew and digest starches before the age of two years and starch foods should not be given before that age. Indeed, baby is not equipped to chew solid foods until it has a mouth full of teeth and, normally, a full set of deciduous teeth is developed at 24 months.

Mothers and others who care for children, whether under or over two years of age, should be able to recognize the symptoms that precede, accompany, and follow indigestion, constipation, gas, distention of the bowels, excessive urination, a gradual growing state of dissatisfaction, white curds in the stools of milk-feeding babies, hard stools, etc. It should be known that white curds in the stools indicate that the baby is getting more milk than it can digest. It is being overfed. Mothers should not wait until the child is pronouncedly sick before doing something about this. Cut down the milk one-half and continue this

feeding program until the bowels are moving regularly and the stools show a normal consistency.

When the baby is obviously taking in adequate amounts of milk and there are still curds in the stools, it means indigestion. The indigestion must be remedied before more milk is given. Unfortunately, our love of feeding and fondness for "butter balls" causes us to want to overstuff babies at all times. If a baby is not gaining weight or if it is losing weight, we tend to become frantic and fly to extremes.

During the hot months, constipation often fluctuates with diarrhea. The diarrhea is the means of expelling the accumulation in the bowels. Some children will have both vomiting and diarrhea. The care in these cases should be the same as that previously described. Put the baby to bed, stop all food, and keep him/her warm. No food is to be given until all indications of diarrhea are gone. If there is pain in the abdomen, hot application to the abdomen may be used for relief.

I do not advise water for infants during the first year of life. So long as their diet is all fluid—milk and fruit juices—there can be little or no need for water. But, when the child is going without food, all the water it desires may be given.

[Home](#) > [Lesson 56 - Normal Feeding Of Infants: Feeding Babies Under Abnormal Conditions Until Weaning Age](#) > Article #3: The Long Nursing Period by Dr. Herbert M. Shelton

### **Article #3: The Long Nursing Period by Dr. Herbert M. Shelton**

Recently a woman called the Health School from a distant city to make arrangements to come here for a fast. She stated that she was nursing her four-year-old son. Although, historically, the long nursing period has dominated human infant feeding until very recent times, such a long nursing period is at present considered an oddity. Under the able tutelage of physicians, pediatricians, the dairy industry and the manufacturers of canned baby foods, mothers of today tend to regard nursing their infants as an activity that belongs to lower stages of culture. They do not think of actively nursing their babies as a biological function, but as a mere cultural activity.

In the Renaissance, French upper-class women refused to breast-feed their babies. Not having cows as substitutes for mothers, they secured wet nurses, commonly young farm women, to nurse their offspring. This is not the first historical instance in which women have found it beneath their dignity to nurse their babies. A leading Chicago pediatrician recently stated in a radio interview that in some parts of Africa, in which the people have been recently introduced to civilization, malnutrition in infants and children is on the increase due to a change in the infant-feeding pattern. As these countries become more civilized, he stated, mothers identify themselves with their more affluent counterparts and are turning away from breastfeeding.

Contrast this attitude and practice with that of the ancient Egyptians, among whom it was the custom to nurse their babies three or more years. Among these ancient peoples, declared by some students of the subject to have been the healthiest people that history records, even the goddesses nursed their young, as revealed by the fact that Isis nursed the baby Horus. Statues of the infant Horus drinking her milk and gazing up admiringly into her eyes may be the original Madonna and Child. Among a people whose goddesses do not find it beneath their dignity to nurse their offspring, those mothers who refused to do so must have been quite rare.

In *The Hygienic Care of Children*, I stressed the principle that the nursing period bears a definite relation to the time required for the young mammal to attain maturity. Animals that grow rapidly and mature early, as a rule, have short nursing periods; animals that grow slowly and mature later, as a rule, have longer nursing periods. There are exceptions to this rule, found largely among carnivorous animals. It is

a significant fact that the young of carnivorous animals are more poorly developed at birth than the young of vegetarian animals, are likely to be born blind, and pass through a period of helplessness.

The female walrus suckles her young for two years, or until their tusks are long enough to dig for clams. This is an example of how young mammals are nursed until their anatomical equipment is sufficiently developed to enable them to eat other foods. Baby gar seals are weaned during the third week after birth, as the cows again take to the sea. They must now feed themselves. For the next two weeks they do not eat, but rely upon their accumulated food stores. Becoming hungry, they take to the sea and learn to find food.

The elephant matures at 14 years, but is ready for mating at 11 or 12 years. The usual range of life of the elephant is about 50 to 60 years. The young elephant sheds its milk tusks five or six months after birth, but continues to suckle for another two years. The young stay with the mother three to four years, perhaps sucking most of this time. Indeed, up to the age of five, the trunk is of little use to the young elephant; but at this age the youngster begins to gather grass and ceases to depend upon its mother's milk.

Man grows slowest and is longest in maturing of all the animals. We should naturally expect to see the normal human nursing period to be a rather lengthy one. And, indeed, it has been lengthy throughout recorded history until within the lifetime of many now living. Sixty years ago it was not unusual for mothers to nurse their babies for two, three, and four years.

An old book, *A Description of Pitcairn's Island and Its Inhabitants*, tells us that the women of Otaheite sometimes do not wean their babies for three to four years. The Dyak women, chopping wood and tending fires, while their husbands are out hunting, are still perfectly capable of nursing their offspring, whom they suckle until they are two to three years old. Aztec children were weaned in the third year.

The Spanish explorer, Cabeza de Vaca, who spent a few years among the now extinct Karankawa Indians who inhabited the coast, offshore islands and a narrow strip of mainland South Texas, from the west side of Galveston to Corpus Christi, tells us that they nursed their children until they were 12 years old, because, as they explained, it was frequently necessary to go without food for several days and the children had to be suckled for a long time. These food gatherers, living in a land where food was not abundant and wandering from campsite to campsite as the food supplies of one region were exhausted, seem to have often been short of food.

This may be accepted as an example of the manner in which the nursing practices of mankind have been determined by the exigencies of life. Where food has been plentiful and its character such that very young children could eat it, the children have been nursed for shorter periods; where food was scarce, often lacking entirely, and coarse, hence unsuited to the very young, the nursing period has been prolonged. Fortunately for these children, primitive women have been able to provide milk for their young. They have not called upon milk animals to substitute for them.

It may be reasoned that because in modern life food is abundant, of great variety, and our means of preparing it far beyond anything the primitive mother ever dreamed of, we are justified in reducing the nursing time of our infants to a bare minimum or in omitting nursing altogether. But inasmuch as no substitute for mother's milk has been found that equals it in meeting the needs of the human young, it seems that there is an irreducible minimum of time during which all babies should be nursed. Nursing is not only a nutritional must, it also possesses psychological value for which no adequate substitute has been found.

The foregoing fact was early recognized by Hygienists. Dr. Thomas Low Nichols gave expression to it when he said: "The best food for an infant is the milk of a healthy mother. The mother's love strengthens her babe, and their lives mingle in the act of nursing. A mother gives much more nourishment than her milk. She gives of her nervous power, her vital force, her heart and mind and soul." That there is any transfer of nerve energy or of vital force from mother to baby is extremely doubtful, but that the mother gives of her heart, mind, and soul, in that she gives the baby her love, comfort, a feeling of security and

a feeling of belonging is now coming to be recognized by orthodox psychology.

During uncounted ages, antedating nursing bottles and nipples, the first sustenance the newborn baby received came from its mother's breasts. This is still the best source of nutriment for the human infant. There is another and, I think, fundamental question I should ask in this connection, namely: what are the results of breaking the normal sequences that have been established in nature? Pregnancy and birth are normally followed by a prolonged nursing period. When a woman fails to nurse her offspring, this normal sequence is interrupted. There must inevitably be unwanted consequences of this break into the normal order. A study of such consequences, if it were possible under present circumstances, might reveal some connection between woman's failure to nurse her babies and the increasing prevalence of breast cancer. It might also reveal a connection between this break in normal order and woman's nervous troubles.

Many women complain that they are unable to nurse their children. In most cases, it seems to me, this is merely a camouflage for her refusal to do so. I believe that most women can nurse their babies for prolonged periods if they really desire to do so. Life is hard in *primitive* societies and food is often scarce, but these mothers succeed in nursing their babies and children for a few years. Life has always been hard among the masses of mankind, yet peasant women, doing hard work in the fields, have throughout history nursed their babies for two, three, and four years. In many instances they have nursed their own baby and that of another woman.

When a woman's own mammary glands refuse to secrete food for her offspring, it is high time we stop and ask a few serious questions. Why are women so defective that they cannot secrete the essential food of their young? What has happened to them that the race could not survive except for the assistance of the cow or goat? If tomorrow all the milk cows of the land were killed or were to cease producing milk, hundreds of thousands of babies would suffer for lack of food. Many of them, no doubt, would perish. This is a precarious position for any species of animal life to find itself in. Is it possible to restore the human breast to full functioning power? If not, must the human race be forever be the unweaned parasite of the cow?

## Lesson 57 - Weaning The Infant; Feeding Children

- [1. Introduction](#)
- [2. Weaning](#)
- [3. Feeding Children](#)
- [4. Conclusion](#)
- [5. Questions & Answers](#)
- [Article #1: Feeding Your Child From Two to Three Years By Paula Duvall](#)

### 1. Introduction

Throughout history and in most cultures women never thought to stop nursing their babies until they are *both* emotionally and physiologically ready. It was natural (and still is) for a child to be nursed at least two or three years—until all their teeth have developed.

Until the advent of modern technology (bottles, blenders, baby food grinders, etc.) babies before about the age of two or so were fed only mother's milk. No other food was necessary nor was it available. Baby was unable to chew foods without teeth and mother had not the tools to make the food pureed.

In recent years doctors have advised mothers to feed solid foods to their babies younger and younger. They have told these mothers that their milk is inadequate and babies will have nutritional deficiencies if they don't stop nursing immediately and start feeding abominations as pureed meats and vegetables (cooked); cooked, enriched cereals; cooked, pureed fruits; etc. Mothers followed this advice and ended up with insecure, overweight, dyspeptic, and sickly babies.

But now, amongst more educated women, the trend is going back toward the natural way of raising our children. Women nurse their children for longer periods and wait until the physiological signs (teeth) and emotional signs (willingness to give up the breast) occur before totally weaning their babies.

In the last lesson I covered feeding baby as well as nursing before actual weaning. Now I will discuss totally weaning the baby from the breast, how to do it, why to do it, as well as feeding a child once it is totally weaned.

### 2. Weaning

In his book, *Hygienic Care of Children*, Dr. Herbert M. Shelton said, "Weaning should be gradual, as we see it in nature, beginning at the age of two and lasting at least until the third birthday." If weaning is abrupt, it is no longer natural as no other creatures who suckle their young would suddenly cut them off. Babies need time to adjust to new foods as well as to emotionally adjust to not having the close physical contact with their mothers any longer. Also, women's breasts would become swollen and sore if they abruptly stopped nursing—they would become filled with the milk that was meant for their babies. Another problem with sudden weaning is that the natural child-spacing effect breast-feeding creates

would be halted.

In the book *The Womanly Art of Breast-Feeding* by the La Leche League, the philosophy of weaning is to let the baby do it—let him nurse until he wants to stop. A mother should be sensitive to the specific needs of her baby and not follow the rigid guidelines of any book. Just as some babies get their first tooth at only five months old and others not until they're well over a year old, some are ready to wean at younger ages than others.

## 2.1 Should Baby Be Weaned?

This is a question asked by Dr. Shelton in his book, *Hygienic Care of Children*. He discusses the various reasons women have for weaning their children. He claims that most of the reasons are invalid and that babies need not be weaned at all until they are ready to. In other words, when the baby is six or nine months old or even a year old, he or she is most likely not ready to be weaned and should not be if superior growth and development is desired.

## 2.2 When to Wean

Naturally there is no specific date to wean your child. As I mentioned earlier, each individual child has its own needs and each grows and matures at different rates. You need not decide in advance when to wean. For example, most mothers when asked how long they plan to nurse their babies have an exact age in mind. Usually this date ends up passing and the baby is still nursing. The mother then wonders where she went wrong. I had planned to nurse my two sons for only two years and each one went months past that date. In fact, they would have nursed much longer if I had let them. Planning a time when baby and you will be ready is incorrect and may lead to disappointment or abrupt weaning. Let nature judge when the time is right.

But how will I know how to read nature's signs? When the time comes, your baby will let you know. This may be quite a bit later than you anticipated so you may wonder if there will ever be signs to know when to wean. But if you're patient, they will come. He/she will show an interest in food and this interest will gradually increase with his/her needs.

There is in our western culture an unacceptance of children nursing for two or three or perhaps four years. If you're out in public and your toddler expresses an interest in nursing and you nurse him, people may show disapproval in their facial expressions and comments. Ignore them if possible. Your breast-feeding relationship with your child is based upon your mutual needs and the opinions of others are not as important as you and your child's welfare.

In other cultures where lengthy breast-feeding is acceptable and weaning is done in a relaxed way children grow up to be gentle and agreeable and more well-adjusted. People may suggest that your baby will be too dependent if you nurse him too long but just the opposite appears to be so. La Leche League has shown that "little ones who have been allowed to grow out of nursing gradually and at their own pace, without anxiety or prematurity on the part of the mother, are happier, *more* independent little people."

Dr. C. E. Page in his book *How to Feed the Baby* explained that if a breast-feeding mother had fed her baby properly of breast milk, there would be little problem with weaning. He says, "They are virtually weaned already; for not being excessively, or too frequently, fed, the appetite will be sufficiently healthy to accept needed food whenever, and however presented."

In choosing the proper time to wean Dr. Page also says: "There are good grounds for preferring the cooler months of the year for weaning from the breast, and in general I would recommend an observance of this rule, though I do not hesitate to say this is less vitally important under the system herein recommended ..." Dr. Page did not give any specific reasons for this, however.

Many people in this country still recommend early weaning from the breast. In the book, *The Complete*

*Book of Breast-Feeding*, it is said, "At six months of age, the baby in a modern industrialized society can meet his nutritional needs through cow's milk and a wide variety of solid foods. ... After nine months, a nursing mother usually produces less milk and her let-down reflex takes longer to operate. ... at about nine months of age, when a baby can crawl around after food, has several teeth to chew it with and has the intestinal maturity to handle a diversity of foodstuffs." This is not good advice.

First of all, most babies (and adults) cannot properly handle cow's milk because they lack the enzymes to digest it properly and it is naturally for calves—not people. Second of all, nursing mothers naturally produce more milk as their babies needs increase. I, for one, produced just as much milk for my babies well past their second birthdays. Nursing is a supply-and-demand mechanism and, if you nurse regularly, and eat right of course, there will be, plenty of milk for your baby. It's when you start feeding your baby more and more solid foods that your milk production slows down.

Another falsity of this statement is that babies do not "crawl around after food." It is true that they put many things in their mouths but not necessarily for nourishment. This is their way of exploring various objects they come into contact with.

Having several teeth does not allow the baby to chew things very well either. Most of their food would have to be pureed in order for them not to choke on it. This, in itself, is unnatural. (Certain foods, however, do not require much chewing, such as watermelon which when the seeds are removed baby can merely squash with his/her gums and swallow.) Babies at nine months of age do not have the "intestinal maturity to handle a diversity of foodstuffs." Why do you think so many babies have "allergies" to so many fine foods at this time? They are not ready for them, that's why.

Basically, good advice as to when to stop nursing your baby completely is when he/she has all teeth and seems to enjoy the foods (preferably fruits) given. If the foods he/she eats, digest without causing the baby any discomfort, then baby is ready and nursing can be replaced with foods—gradually of course.

## **2.3 Why to Wean**

The foremost reason to wean is because baby is ready for solid foods. He indicates an interest in foods and exhibits an ability to handle them. Gradually the child comes to ignore mother's milk.

As mentioned earlier, some women feel the need to wean because of social pressures. A child may be weaned from the breast prematurely and still have the need to suck. Therefore a bottle may be given. But is it any worse for a toddler to be nursing at the breast than it is for him to be running around with a bottle hanging out of his mouth?

If baby is going through emotional adjustments, such as a major move of the family, divorce of his/her parents, etc., it is best not to wean. He/she needs time to adjust to one new situation before being confronted with another.

Other reasons to wean are justified. For instance, if the mother has an acute or chronic disease that may impair the quality of her milk, it is best to feed whole, natural foods than to continue nursing.

If you should become pregnant again, immediate weaning is unnecessary. This is usually advised because it is too much of a drain on the mother to nourish two others besides herself. But, if mother is eating whole, natural foods and taking care of her other basic needs, she should have no difficulty in nursing well into the pregnancy. You can begin weaning early in the pregnancy so that by the time the second baby is born the first one will be completely weaned from the breast.

To sum up this section: baby needs to be weaned from the breast because he/she needs outside sources to obtain nutritional needs. The child needs to make gradual adaptations to these physiological changes. The only other reasons to wean are abnormal as mentioned above.

## 2.4 Methods of Weaning

Again, do not abruptly wean. Gradually wean baby from the breast. But how, you say?

Eliminate one breast-feeding at a time and replace with a serving of fruits—fresh, ripe, and raw and in a form that baby can properly handle. For example: say baby normally has four breast-feedings a day—one in the early morning upon arising, one in late morning, one in mid-afternoon, and one in the evening. Eliminate the late morning nursing and serve him/her some sliced bananas, a piece of deseeded watermelon, or some other fresh fruit in season. Stick to this schedule for at least a week or two.

Then eliminate the mid-afternoon feeding and replace it with a solid food. Stick with this schedule for a long enough period for baby to adjust to it. Remember not to introduce too many different foods to baby too quickly. Variety is not necessary. If he/she is truly hungry, the mono-meal of the same fruit each day will be relished and he/she will have time to adjust to the new food before another is tried.

It is important to remember not to refuse the breast during these early replacement feedings. Just don't offer it. Baby may fuss and refuse the foods offered. Try skipping this feeding—no food or breast milk.

If this seems too traumatic for baby, perhaps he/she is not ready to give up this breast-feeding. Try again at a later date.

A hint in deciding which feeding to eliminate first is to watch your baby and see which one is least interesting to him/her. Eliminate this one first. Continue, gradually, in this manner until he/she is completely weaned.

Be flexible in your weaning. If it seems to upset baby too much, wait a while. Also remember never be abrupt about it. This can cause psychological problems in your baby and also discomfort for you from milk pressure in your breasts.

La Leche League adds: "You will find that if you devote your attention to your baby-child not only when he is nursing but in other ways as well, his demand to be nursed lessens. ... Even an eighteen-month-old enjoys being read to or just talked to, not in an absent-minded, distracted way while you are preoccupied with other things, but with your whole attention centered on him." This is good advice. Distraction works with many things as well as weaning in raising your children.

[Home](#) > [Lesson 57 - Weaning The Infant; Feeding Children](#) > 3. Feeding Children

## 3. Feeding Children

This period of feeding children after breast-feeding is one of the biggest changes in infancy. It is the mother's responsibility to see to it that the child is properly nourished and develops good eating habits. Before this time, it was easy—all mother had to do was put her baby to the breast. Now she has to provide the proper foods at the right times so that baby can make best use of them and be healthy.

### 3.1 When Is Baby Ready to Eat Solid Foods?

As mentioned in the earlier parts of this lesson, when baby has all the physiological tools necessary to chew and digest foods properly, he is ready for food. He is also ready when he shows an interest in foods and a disinterest in breast milk. Baby, when gradually introduced to new foods, will eventually be completely off breast milk and have a regular diet just like the rest of the family.

Many books on the subject of infant feeding will tell you how to feed your infant solid foods and what foods to feed them and in what form, "infants," however, do not need anything other than breast milk.

When baby is ready, there will be no need to spoon-feed him/her. This is clumsy and messy because baby is not really ready for it. In fact, most of the conglomerations or purees, cereals, etc., end up spit out by the baby because his/her senses have rejected them.

In *The Complete Book of Breast-Feeding* it is said that "an easy way to provide a balanced diet is to take advantage of the many strained baby foods on your grocer's shelves. These are prepared under strict Hygienic conditions and are extremely convenient to use." This is pernicious advice.

First of all, I wonder if the author visited the factories at which these "foods" are prepared to prove they are prepared under "hygienic conditions." Secondly, these foods are generally unfit for the human diet. As well they are cooked with sugar, salt, and preservatives added to enhance flavor that was taken away by the cooking process. If baby has to be fed his food on a spoon by his mother, then he is not ready for solid foods. When he is ready, he will be able to hold a food in his hands and chew it. These foods are often called finger foods. Give your child a piece of banana or some other raw fruit and see if he can handle it or if he merely plays with it or throws it on the floor. This will determine readiness.

If baby is prematurely introduced to solid foods, overfeeding can be the result. He is only used to sucking. The mechanical motions of chewing food are much different and require a period of adjustment or changeover.

Food "allergies" are not so much the result of the food not being right for that particular baby's constitution as they are the result of introducing foods too early. Baby is not allergic to the food but instead does not have the digestive enzymes to sufficiently break down the foods being given. Therefore, he/she naturally rejects it. Wait—do not force food on your baby when you think he/she is ready. He/she will let you know.

### **3.2 Baby's First Food**

What should baby's first food be? Experiment. Some babies love bananas, some watermelon, some peaches, etc. Try one fruit at a time but never more than one at a time. Once you find a fruit your baby enjoys, stick with it for a long enough period for your baby to get used to it. Also give only small amounts at first.

Never be in a hurry to try new foods. If he sees you eat something and seems interested, let him try it (provided it is wholesome). Fruits are naturally the best first food for baby as humans are natural frugivores. The baby is already used to the sweetness of mother's milk and will accept fruits before vegetables. In fact, it is a rare child indeed that even enjoys vegetables. Their taste for vegetables has to be "cultivated."

You need not worry about deficiencies if your child won't eat vegetables at first. Once he is used to a wide variety of fruits, serve him these, one at a time, and he will get a variety of nutrients.

You can add vegetables later. Many children like carrot juice as it is sweet—try this. But not too soon, as carrots are starchy vegetables and children before the age of about two do not have the physiological tools necessary to digest starches. Starch merely ferments inside them and causes indigestion and discomfort. Stick to foods that are easy for him/her to digest—namely fruits.

As the child gets older, about five or so, you can add nuts and seeds. Before this it is difficult for baby to properly masticate nuts and, therefore, they're difficult to digest. Wait on these. The article in this lesson, "Feeding Your Child From Two to Three Years," is very helpful in suggesting particular menus.

### **3.3 Developing Good Eating Habits**

Good eating habits are the most important aspect of diet. If a child learns these when young, they will carry over into adulthood. Good eating habits begin with breastfeeding which is totally up to the mother. She needs to breast-feed him only when he is hungry and only in the proper amounts necessary to

sustain him. A fat baby is a sign that poor eating habits are already being established.

Many parents try very hard to feed their children right at home but have a difficult time getting others to accept their rules of feeding their children. For example: some mothers might send their children to their grandparents' house for the weekend and grandma feels they're being deprived by not being allowed to have candy. She gives them candy, cookies, cakes, etc., to supply this "deprivation" and gets them hooked on these. She is not respecting her daughter's or son's wishes to raise a healthy, well-developed child. Perhaps it would be best to allow your children to be with their grandparents only when you are there. Of course, it is impossible to protect your children from all the evils ("foods") that are about (and screaming out at them through the media) in this society, but if you teach them good habits and why they need to eat right and if they respect you, they will follow your rules. (See Lesson Fifty-nine on "Teaching Your Children About Healthful Living.")

There are some rules to follow to assure your child is getting good nourishment:

1. Never add salt, sugar, honey, etc., to any of their foods.
2. Only feed natural, uncooked, unprocessed foods to your child.
3. Teach them not to drink with their meals. On a proper diet they will not want to anyway.
4. Teach them how to properly combine their meals for best digestion if more than a single food is served.
5. Feed only three meals a day, and don't allow them to eat between meals.
6. Show them how to chew their food well.
7. Have only natural foods in the house so they will not be tempted by others.
8. Keep meals simple—don't combine too many things at once.
9. Do not stuff your child—feed only moderate amounts of food.  
A child usually refuses natural foods when he/she has had enough.
10. Provide a calm, relaxing environment for him/her to eat meals in.
11. Teach him/her to sit and relax while eating.
12. And most importantly, show a good example. If you're eating all sorts of wrong foods, it will be very difficult to teach your child otherwise. That is cruelly hypocritical!

Dr. Tilden has said, "Fit children to the food and never attempt to fit the food to the children." This means that a child must learn good eating habits by your example and words. If a child does not like a certain food, do not force him/her to eat it. There are plenty of good foods available and missing one particular item of food in his/her diet will certainly not create any sort of deficiency. Never force your child to eat anything.

[Home](#) > [Lesson 57 - Weaning The Infant; Feeding Children](#) > 4. Conclusion

## 4. Conclusion

Now you know that weaning your child from the breast should be a positive and gradual experience for you and your baby. He or she will be more well-adjusted and more likely to learn good eating habits. The best time to wean is when your child is ready. He/she will let you know when that time comes—you merely have to be observant. A full mouth of teeth is a good indication that whole foods are needed and that by now your milk supply is probably lessening. Experiment with fresh fruits and keep them simple—monotrophic. Follow the rules for good eating habits and you should have a happy, healthy child.

## 5. Questions & Answers

**My child is already two years of age and does not seem interested in food at all. He is very thin and his front teeth are brown and pitted and all he wants is breast milk. I feel he has a deficiency of some sort because of his teeth but he won't eat. What can I do?**

Try improving your diet. Watch what you eat. Eat fewer empty foods and more whole, fresh fruits, vegetables, nuts, and seeds—all raw. Try to remain relaxed and poised as much as possible as stress can deteriorate the quality of your milk.

It is unusual for a child of your son's age to not be interested in food, but believe me, he will eventually be and when he is, you may not be able to turn off his appetite. Don't worry. Nature has it all worked out. Just do your part.

**My child is 18 months old and I no longer enjoy nursing him. I feel like I should continue to do so but I don't want to. Would it be right to wean him so young?**

It is better to wean him at this time than to nurse him out of guilt. He can pick up on your feelings and this could affect him psychologically. It is best to nurse him longer, however, in your case to gradually—and gently—wean him would be acceptable and perhaps the best thing to do. Use the methods for weaning that I've described in this lesson and you should have no problems.

**My child is one year old and I've recently introduced her to solid foods. I started with bananas and she loves these. She seems to have no difficulty digesting bananas but her stools are very sticky and harder than before. Does this mean she's not digesting the bananas thoroughly?**

No. Her body needs time to totally adjust to the eating of foods. All she ever had is mother's milk and bananas are new to her—anything that's new requires time to adjust to. Her stools are naturally going to be of a different consistency than when taking only breast milk. Her stools will probably never look like that again. However, they will be less sticky and softer when her body has accommodated to eating foods not as liquid as milk.

**I have a six-year-old son who just won't stick to only natural foods. He's influenced by the other kids at his school and they all eat what's advertised on T.V. What can I do?**

The best you can do is to provide him with the best of foods at home and show him a good example by keeping good eating habits yourself. Try to expose him to other children that are being raised Hygienically and don't allow him to watch so much (if any) commercial television. Give him positive reasons why he should eat good nourishing foods.

### **Article #1: Feeding Your Child From Two to Three Years by Paula Duvall**

When your baby is two years old, you can start feeding it whole fresh fruits and vegetables, in addition to breast milk. This transition period can be a difficult time, and I would like to share with you my

experiences that I have had with our two children.

First, let's review some very important rules to follow that are covered in Dr. Shelton's book, *The Hygienic Care of Children*. It is important for you to understand that you cannot decide what food you would like your children to have; you must feed them foods that agree with them and keep them healthy. Some important basic rules, including food combining rules which are covered in Dr. Shelton's book, are worth repeating:

1. Feed the child natural, that is uncooked, unprocessed, unsterilized, unadulterated, undrugged foods.
2. Do not stuff the child. Feed it three moderate meals a day.
3. Feed simple meals. Do not feed foods that are mixed in such a way as to cause fermentation.
4. Do not feed between meals, nor at night.
5. If the child is upset, or feels bad, or is excited or tired, or overheated or chilled, or in pain or distress, or is sick, don't feed it; if there is fever, give no food.
6. Do not feed the child cooked fruit.

And here are the food combining rules:

1. Do not feed acid fruits and starch foods together.
2. Do not feed acids with proteins.
3. Do not feed sweet fruits and acid (sour) fruits together.
4. Do not feed sugars or starches with protein foods.
5. Do not feed sweet foods with starch foods.
6. Feed only one protein at a time.
7. Feed fresh milk alone.
8. Feed plenty of green vegetables with both starches and proteins.
9. Do not feed butter, oil or other fats with protein foods.

Both my children were nursed; one until the age of two, and the other for only one year. Therefore, neither child was on breast milk during the transition feeding period at two to three years old.

The schedule that your child is on around the age of two, if fed Hygienically is milk, juice, milk, juice, milk. To start the transition to adult foods, the first juice feeding in the morning can be dropped, and the child can be given fresh, whole fruits combined well. At first, I gave my children only one kind of fruit. Now I give them only two kinds of fruit at one meal.

You may have started your child on this morning fruit feeding earlier than at two years of age. The fruits that my children digested well before two years of age were blueberries, any kind of melon, papaya, pears, oranges, grapefruit, mangoes, fresh figs, apricots, and plums. They also digested well any other berry fruit, like strawberries, raspberries, and any other wild berry. Here in Ogden Dunes, Indiana, we have a lot of wild berries growing, and our family has a fun outing looking for these and picking them. We always go berry picking around ten in the morning, so the children can eat their meal right from the bush or tree. You can't expect to take children berry picking without them eating the delicious fruit!

Fruits that my children did not digest at first were apples, bananas, cherries, grapes, and the sweet dried fruits. Both children had problems digesting bananas and apples in their early years. I did not feed them cherries because of the pit, and I did not feed them grapes because of the seeds. (The "peel" around grapes is not chewed well enough by a toddler and usually comes out whole in their stools.) Even if the grapes were seedless, for some reason the children did not digest them well in their early years. Now, of course, my five-year-old Jacquie digests all of these fruits very well. But I still stay away from the concentrated sweet dried fruits, such as raisins, dates, dried figs, and prunes. If there is fresh fruit at the market, which is usually true most of the year, I buy it in preference to the dried fruit.

The best way to tell whether your child is digesting a food is to check its stools. If chunks of the food are coming out, then you know the child is not digesting that particular food, or is not chewing it well.

When your child is between the ages of one and two, I feel you can try it on the pulpy fruits. If the child does not do well with them, then put it back on the juice. When I first introduced fruit to my children, I introduced one fruit at a time. I found it was better if I gave them two oranges rather than two kinds of fruit at the same time. Papaya is quite a rich fruit, and one half of one is enough for any child. The overfeeding of fruit will cause digestive problems of protein foods. I also discovered that if I overfed my children fruit, they would break out in skin eruptions. I fed the fruit to my children between 10 a.m. and 11:00 a.m. It always depended on their waking hour. My son, Donny, awakes at 7:30 or 8:00 a.m. so I do not feed him the fruit meal until 11:00 a.m.

Now that Donny is over two, I give him a more substantial lunch at 11:00 or 11:30 a.m. and totally skip the noon milk feeding. When a more complete lunch is given the milk is not needed and, if fed after such a large lunch, can cause health problems. Here are some suggested larger lunch meals:

two oranges (small)	pears
kale	peaches
celery	celery
avocado	swiss chard
2 fresh figs	blueberries (1 good-sized bowl)
celery	celery
romaine lettuce	bibb lettuce
apricots	
mangoes	papayas
celery	celery
red-leaf lettuce	brocccli leaves and stems

At 1:30 or 2:00 p.m. both children nap. My five-year-old daughter is the only among her friends, who still takes a nap. I have seen the other children in the afternoon, and they are tired too. But they cannot lie down and rest peacefully because of poor diet consisting of meats, starches, and sugared products. And those poor moms have a long day with their children, with no time to rest themselves. My children and I rest every day—the children nap for two hours. And it is a wonderful break in the day for me. These other mothers must be exhausted tending their children all day. I talked to one mother whose son is only three years old. He gets up at 6:00 a.m., does not nap, and goes to bed at 8:00 in the evening. Of course, when the child gets fussy, he is fed, and this makes it impossible for him to even rest because his digestive system is constantly overworking. By the way, this child has already had some serious health problems—such as constant cold and bronchial pneumonia last year.

When my children awake around 4 o'clock, I feed them a vegetable dinner. When you make the transition diet, use only raw foods. My children did better on raw foods. They eat less, chew better, and it lasts longer. They seem to overeat on the cooked foods and swallow without masticating properly. Cooked broccoli will slide down a lot easier than when it's raw. Also, the child may develop digestive

problems from overeating cooked food. I found that cooked food came out undigested more often than the raw food.

It is good to try nuts. Pine nuts are very easily digested. They are the softest nut I have found, and the children do very well with them. Raw cashews were difficult for my children to digest. My children also do well with pecans and walnuts. Almonds are quite hard and not as easy for them to chew. Of course, my five-year-old now can digest almonds. Here are some suggested vegetable meals:

cucumber	cucumber
celery	celery
tomato	tomato
string beans	green pepper
red pepper	kale
nuts	avocado
cucumber	cucumber
celery	celery
carrot	green pepper
kale	romaine lettuce
coconut	baked squash
cucumber	
celery	
red pepper	
cauliflower	

A nice starch meal can be given in the evening, as you can see, with baked squash. We use yams, Irish potatoes, and squash.

If you find that the child is starting to get sick, put it back on the juice schedule or a fast until it's back to normal. If the child gets sick from overeating or from experimenting with the diet, then of course you will have to fast it. Short fasts should be sufficient for any child who has been reared Hygienically.

The dividends are high when you bring up your children this way. They are healthy, happy, alert,

beautiful to look at, and certainly your home life is less stressful because your children are not fussy and constantly crying. Do not cheat from this diet. You and your child will pay the price. Stick to the schedule. You can do anything you want around a well-organized schedule.

## Lesson 58 - Fasting Children During Disease

- [1. Introduction](#)
- [2. Childhood Illness And Fasting](#)
- [3. The Mechanics Of Fasting](#)
- [4. Questions & Answers](#)
- [Article #1: Sick So Young, But Well At Last!](#)
- [Article #2: The Hardest Thing to Do Is "Nothing" By Dr. V. V. Vetrano](#)

### 1. Introduction

"He won't eat a thing, and I always fix him his favorite foods." The mother looked anxious as she told the Hygienic practitioner about her young son's refusal to eat

"And what does your child like?" the Hygienic doctor asked the woman

"Oh, you know, the usual things like ice cream, chocolate chip cookies, and lots of peanut butter sandwiches. He won't touch a fresh piece of fruit or any vegetables. I'd do anything to get him to eat. I always have his special food favorites around, but he just doesn't have any appetite for good foods. What should I do? I don't want him to starve."

"Leave your son with me and my wife for one week. When you return for him, you will not believe he is the same boy."

Reluctantly the woman left her young son with the Hygienist for six days. When she returned for him on the seventh day, the doctor showed her the boy happily eating a large raw vegetable salad with keen appreciation

"What did you do? How did you get him to eat like that?" the mother asked.

"Well, when he refused to eat the foods we provided him, we let him go without. After three days of not eating, he discovered that an apple or banana tastes pretty good."

"You mean you let my son go without food for three days?" The woman looked shocked. "That's cruel. That's child abuse."

"No madam," the Hygienic doctor replied. "Stuffing your child with junk foods and fretting over him constantly is child abuse. We just let nature take its course, and I might add, your son seems all the better for it."

Fasting a child or withholding food from an infant does seem like a cruel practice to some people. After all, the primary responsibility of parents is to provide sufficient food for their offspring. Not feeding a child seems like a drastic neglect of parental duty. A careful abstention from food for a limited period of time, however, may not only be beneficial but absolutely necessary for a youngster's health and well-being.

There are many questions and misconceptions about children and fasting. The purpose of this lesson is to answer these questions and remove the fears that surround the fasting of children.

## 1.1 Why Children May Need to Fast

Children usually need to fast for the same reasons that adults do. A fast is sometimes needed to give the body a total physiological rest so that it may rebuilt its health quickly. A controlled withdrawal of food for a reasonable period of time can allow the body to revitalize itself and to carry out the healing processes.

It is true that children are in a stage of rapid growth and physical development. During such a time, the demands by the body for high-quality food are great and must be met. But this does not mean that food must be always present or that overfeeding should be practiced.

Fasting is a time-honored method for improving the health of any person, regardless of age. Simply because a child has very definite needs for sustained and optimum nutrition does not mean that a fast for a reasonable length of time cannot be employed. Indeed, many times the child's body is better able to assimilate and utilize the food given following a fast than it was before the fast.

So, why should a child fast? For basically the same reasons that an adult may wish to fast: to achieve and maintain superior health and development by allowing the body a period of complete physiological rest (which includes a "rest" from the digestion and assimilation of foods).

## 1.2 When Should Children Fast?

According to Dr. Herbert M. Shelton, the world's foremost authority on fasting, children should not receive food when:

1. They are upset or feel bad.
2. They are excited or tired.
3. They are overheated or chilled.
4. They are in pain or distress.
5. They are sick or have a fever.

In other words, if a child is uncomfortable or disturbed in body or mind, then a meal should be postponed or skipped. Usually the simple missing of a single meal will often be enough to correct any temporary problem or passing illness of a child. This could hardly be called fasting, yet missing a meal can give the child's sensitive and vital body a chance to reestablish its normal balance and well-being.

Unfortunately, many parents become worried, nervous, and distraught if their child refuses to eat a meal. The idea of actually forcing their child to forego a meal seems almost unthinkable. Yet if there are signs of physical discomfort or disease, then abstaining from food for at least one meal is only sensible.

Missing more than one meal or going without food for over a day is the beginning of a fast. A fasting period of a day or more is advisable for most children during the time of illness and disease. In fact, most periods of childhood fasting coincide with the periods of childhood disease and illness.

An illness or sickness is proper enough reason for a child to fast, and the results from such fasting are nothing short of spectacular in rectifying physiological problems. In his book *The Hygienic Care of Children*, Dr. Shelton devotes many pages to the discussion of various diseases and illnesses suffered by children. This is the proper way to discuss the fasting of children, as it is during sickness that a fast should be employed.

## 2. Childhood Illness And Fasting

"Wise parents," wrote Dr. John H. Tilden (an early Hygienist), "will never feed their sick children. Be not afraid to let them fast. For, every day that they fast lessens their illness and their danger. Feeding adds to their suffering and danger and prolongs their illness."

Dr. Shelton also echoed these sentiments when he said: "Whenever animals, both young and old, become sick they instinctively refrain from eating. Warmth, quiet, and fasting, with a little water, are all they want. Infants, too, when sick require only warmth, quiet, and fasting, plus some water."

### 2.1 Specific Illnesses and Fasting for Children

Hygienic literature, and especially those books by Dr. Shelton, contains much practical advice about the care of children during illness. During almost any disease or illness of a child or infant, the basic requirements are the same: rest, fresh air, pure water when needed, warmth, and quiet. Fasting plays an important role in the child's recovery from sickness.

What follows in this section is a list of some of the common childhood illnesses and the suggested course of action by the parent in caring for the sick child.

### 2.2 Anemia

Anemia is a lack of red blood cells. "The value of a fast in all forms of anemia is beyond doubt. Children that have been allowed to develop anemia should be given a short fast—three to five days; older children longer—or a few days on orange juice and fed properly thereafter."

### 2.3 Rickets

Rickets are bone changes brought about by impaired nutrition. "Fasting has a beneficial effect in cases of rickets. Fasting properly done promotes growth. After a fast, an increase of body mass is accomplished which may have required years of normal growth."

### 2.4 Colds

A cold is a process of vicarious elimination. "For the 'common cold,' the child should be put to bed, all food stopped, except perhaps some orange juice (if there is no fever), and kept warm. That is all there is to the treatment of any so-called acute disease—rest, fasting, warmth. No cold can last long when the child is cared for in this manner."

### 2.5 Colic

Colic is digestive impairment of an infant. "The remedy for colic is: stop all feeding until comfort has returned."

### 2.6 Fever

Fever indicates poisoning; usually through decomposition in the intestines. "Fever will last until the poisons have been eliminated and the decomposing food voided. When such cases are fasted and not fed, the troubles end. Feeding and drugging are the elements of danger. When animals, *young or old*, become sick, they refrain from all eating."

## **2.7 Vomiting**

In infants, vomiting is usually the first sign of acute disease. "Vomiting is a means of emptying the stomach before beginning housecleaning of the body. No food should be given the sick child."

## **2.8 Measles**

Measles begin with a "head cold" and are accompanied by fever and malaise. "No food should be allowed until 24 hours after all acute symptoms are gone. Feeding should begin with fresh fruit juice, and then followed by fresh fruit the next day."

## **2.9 Whooping Cough**

Whooping cough is a paroxysm of coughing. "Unless such a case is fasted, the coughing becomes more severe. The child should be given as much fresh air as possible and as much water as thirst calls for, but no food of any kind should be given until complete relaxation is secured (usually within three or four days). After full relaxation occurs, fruit juices may be given for two or three days, after which fresh fruit may be given. If the coughs tend to increase after meals, stop the feeding at once."

## **2.10 Mumps**

Mumps are an inflammation of the salivary glands, especially the parotids. "Rest in bed with warmth until the temperature is normal and the swelling has gone. No food and no drugs should be given. If the child refuses to fast, orange or grapefruit juice may be used. After the swelling is gone, fruit may be fed three times a day for the first three days. After that, a gradual return to a normal and healthy diet may be done."

## **2.11 Diphtheria**

Diphtheria is an inflamed and feverish throat condition. "Food must not be given until the throat is healed. Then fruit juices may be given for two days and then a gradual return to the normal diet. It is the fat, soft, 'well-fed' children who generally develop this sort of disease. I have never known a case of diphtheria in strict vegetarians on a low-protein diet."

## **2.12 Typhoid Fever**

Typhoid fever is an acute disease involving mostly the small intestine. "When such patients are fasted, the stools and urine are pure by the time convalescence begins."

## **2.13 Tonsillitis**

Tonsillitis is an inflammation of the mucous membrane. "In acute cases, all food should be withheld until the symptoms are gone. After this, a fruit diet should be given for three to five days. If the case is chronic, then a fast or orange or grapefruit diet may be employed until the throat is clean and breathing is easy."

### **3. The Mechanics Of Fasting**

#### **3.1 How Long Should Children Fast?**

The most common question about children and fasting is: how long should the child fast?

A specific number of days cannot be given for all cases. Generally, a fast is conducted until all the symptoms of an acute illness subside. Chronic problems are sometimes handled by a series of fasts of varying lengths.

Most Hygienic practitioners, however, generally agree that children should not fast as long as adults may. That is, lengthy and extended fasts for children should be properly planned, supervised, and wisely considered. Short-term fasts for children, however, may be safely undertaken by knowledgeable parents.

To be more precise, Dr. Shelton tells us that he has seen very few cases of children or infants requiring an extended fast. "Fortunately," Dr. Shelton writes, "few infants require more than two to three days of fasting." In general, when nature cuts off the appetite of a child, he or she should be permitted to fast until there is a demand for food.

Dr. Shelton tells us that "infants may be fasted for days without harm, although they seldom have to fast as long as an adult." Infants and children, according to several Hygienists, recover more rapidly while fasting than do adults and so do not require to fast as long.

As a general guideline, Dr. Shelton and other Hygienic practitioners, seem to suggest that fasts for children be for periods of one to five days, with the time limits of two or three days being the most common length mentioned.

Once again, there can be no exact length for a fast in all cases. However, there is general agreement that since a child is usually less toxic and more vital than an adult, short-term fasts of one to three days are usually sufficient for most acute problems. Of course there may be circumstances and conditions that require a child to be fasted for longer than a three- or four-day period. Parents who are considering fasting their children for longer than a five-day period should probably consult a professional Hygienic practitioner.

Long-term fasts for children must be approached with caution. Not because fasting itself is dangerous, but because misinformed family, friends, or authorities may try to prevent such actions. In these cases, the support of a professional Hygienist can help the parent through any difficult times.

If you have no access to a practicing Hygienist, you may still fast your child without worry for short-term periods of one to three days. The exact length for a fast by a child or infant cannot be specified and depends upon the illness and the vitality of the youngster.

#### **3.2 How to Fast Children**

The needs of a child when fasting are basically the same as an adult's: warmth, quiet, rest, fresh air, and pure water. Fasting for short periods of time may be supervised by the child's parent. If a serious illness is present or if a fast must be conducted for more than several days, then the advice of an experienced Hygienist should be sought.

#### **3.3 Beginning the Fast**

No elaborate preparations are needed before a child is fasted. In cases of acute conditions where the symptoms of disease appear quickly, a fast may be begun immediately. In fact, as soon as there is a sign of serious illness in a child, the fast should start.

There is no need to give an enema to a child before the fast starts. If time and conditions permit, the child may be placed on an all-fruit diet for a day or so before the fast begins.

### **3.4 During the Fast**

The child should be kept warm, comfortable, and quiet. He should not be permitted to play or exercise vigorously while fasting. It is more important that the child be allowed to rest totally while not eating. This allows the body's energy to be directed toward cleansing and detoxification instead of being expended in play or excitement.

Whenever the child is thirsty, distilled water at room temperature should be given. Do not force the child to drink excessively, but be sure that plenty of water is available for the child to drink. If the child is an infant, it may be given as much water from a bottle as it desires.

Fruit juices, such as orange or grapefruit juice, may be used if it is desired not to fast the child completely, or if the child refuses to drink only water. Drinking juices, however, is not a good idea since pure water is really all that is required by the fasting child. Dr. Shelton and other Hygienic practitioners, however, have used fruit juices when "fasting" children.

Particularly when no fever is present or no crisis is evident, fruit juices may be given to the child. Juice drinking or the eating of only fruits, however, do not constitute a true fast. For some cases, however, a diet of fruit juices or fruit only may be used with great benefits when fasting is impractical or not desired.

Placing the child on a strict diet of fresh fruits and freshly-squeezed juices can be done for an extended period of time and does not require the supervision of an experienced Hygienist. The benefits of this diet are enormous.

### **3.5 What to Expect During the Fast**

During the fast, the child's urine may become dark. He may experience brief periods of diarrhea or constipation. The breath will probably smell foul and the tongue may become heavily coated. None of these signs are cause for worry, but indicate that the fast is progressing normally—that detoxification is being effected.

Once the fast begins, there is no need to worry about constipation or bowel movements. If none occur during the fast, do not worry because the child's regularity will return when the fast is broken.

Show no worry or concern with the fasting child. Do not let other adults' remarks about the "safety" of the fast, or demonstration of fears about the child's health affect you in any way. It is best to fast your child in private and without discussion, especially in front of the child. If fasting is treated as a normal part of living and if the parents also practice fasting as a regular part of a healthy lifestyle, then the child is more likely to view his own fast as a positive experience.

### **3.6 Breaking the Fast**

The fast should be broken after all the acute signs of illness are gone, or the child experiences true hunger, or after a reasonable period (two to four days for an unsupervised fast). Hunger may be present during the first day of the fast. This is not a sign that the fast should be broken early, however: If the child expresses a strong desire to eat after the first day or two of the fast, that is a better indication that true hunger has returned and the fast should be ended.

Breaking the fast should be done carefully. Either a piece of fresh fruit or a small glass of fresh fruit juice may be given as the first food after the fast. Have the child sip the juice very slowly. If fruit is used, let the youngster have a single bite at a time and have him chew each bite very well.

A few/hours later, more juice or fruit may be given. Do not be in a hurry to introduce heavy foods back into the diet. As long as the child is happy and satisfied eating fruit alone, then allow him to continue with this diet. Gradually, fresh salads, nuts, and seeds may be introduced.

If the child is an infant or is still nursing, then the fast should be broken with mother's milk.

### **3.7 After the Fast**

Following a fast, the child should be placed on the optimum Life Science diet. This consists primarily of fresh; raw fruits with raw vegetables, nuts, and seeds eaten in appropriate combinations. Of course if the child is very young, then mother's milk, fruit juices, blended fruits, and so on are appropriate.

Do not be in a hurry to overfeed or stuff the child with high-calorie foods in order to replace the lost weight. By no means should the child's natural appetite and hunger not be satisfied, but food should not be pushed onto the unwilling youngster.

After a fast is an ideal time to improve the youngster's diet. The fast provides an easy transition into better eating habits and food selection. The first days after a fast will find the child keenly appreciating the simple and natural foods in their uncooked state. This is an excellent time to include more and more fresh fruits and vegetables into the child's diet, and eliminate any substandard foods that may have been eaten prior to the fast.

### **3.8 Handling the Fears About Fasting Children**

The greatest obstacle to fasting children will not be from the child but from overly-concerned parents and relatives. In some people's minds, fasting is the same as starvation and they worry needlessly about the child's safety during a fast.

A good education about the absolute safety of fasting children is necessary so that these fears can be eliminated.

When asked about the possible complications and difficulties that might result from fasting children, Dr. Shelton replied: "Complications result almost wholly from feeding and drugging. They almost never develop in cases that are not fed and not drugged. I have fasted numerous children and babies and it is my observation that they bear fasting well."

Still, there is often the worry that fasting will cause the child to lose too much weight or it will be harmful to growth. In fact, the most common fear is that if food is withheld from an infant or child, it will lose weight and never regain its full growth potential. Such fears are groundless.

Dr. Shelton tells us that "it has been fully demonstrated that repeated short fasts of one to three days in growing animals produce better growth and strength. Children are not harmed by fasting, but only by starvation." And, I might add, children are harmed by eating when food should be foregone.

Fasting, properly done, can stimulate growth. Professor Morgulis, a researcher on fasting and animals, states that as soon as any animal, including man, loses weight through fasting, it then begins to gain at a spectacular rate once proper nourishment is again provided. "There is a rapid gain in weight," writes Professor Morgulis, "which is a manifestation of a vigorous growth process in animals after a fast.

There is prolific cell multiplication. Frequently, there is an increase in body mass that normally requires years of growth."

Dr. Shelton also remarks that he has seen periods of increased growth in children following a fast. It is not underfeeding or fasting that is to be feared, but rather overfeeding the child with improper foods.

Any weight loss experienced by the child on a fast will be quickly reversed once a diet of optimum foods is given after the fast is broken. The parents should simply make sure that the child has all the wholesome foods he wants or desires. His appetite will be hearty after a fast, and normal growth patterns

will be rapidly reestablished.

Perhaps the best reassurance a parent can have when fasting a child is to read about the thousands of youngsters who have been fasted by Hygienic practitioners. Dr. Herbert M. Shelton's book, *The Hygienic Care of Children*, provides many examples of the success obtained through fasting children. Parents may also contact other Hygienists who have fasted their children for their advice.

Unless the parents have a sympathetic listener, it would be best not to talk about the fasting of their children. Some people including medical doctors, have a mistrust of fasting and may actually take steps to prevent parents from fasting their children. These people often fill the parents with fear and guilt about fasting their offspring. In some cases, legal action has been taken against parents who were only trying to insure their children's health and well-being through fasting.

To avoid such complications, the wise parents will fast their child in private and without consulting various "authorities." Again, it is suggested that such parents try to contact other Hygienists for their support during the first fast for a child. Regardless, a short-term fast of one to three days can never do any harm and may be safely undertaken by any knowledgeable parent.

### **3.9 The Benefits of Fasting for Children**

Children can quickly benefit from a fast, and it is encouraging to see the many positive results that occur so dramatically after a fast. Youngsters have vital and relatively clean bodies that respond well to a fast.

All the body's functions are normalized during a fast. Indigestion, constipation, headaches, colds, fevers, diarrhea, and a host of other childhood complaints often disappear quickly during a fast. The body can discharge its eliminative tasks much speedier during a fast.

Fasting also allows a child's weight to normalize. Overweight children will lose excessive pounds during a fast while underweight youngsters often quickly add pounds after a fast.

Fasting is an excellent way to introduce the child to a new diet, such as the optimum Life Science diet. In fact, many children can make dietary changes much easier than adults, and very often, they are easier to fast and, complain less.

Children, if old enough, should be carefully taught the benefits of fasting. They should be told or shown how animals fast naturally in the wild, and that fasting is a normal life process. Teaching your child how to fast properly is as important as teaching him to eat properly. Some parents find it easier to fast along with their children, and this is an excellent idea if conditions allow. Any fear of fasting that the child might have is quickly alleviated if the mother or father fasts as well.

Fasting is a time-tested method of insuring superior health for people of all ages, it should be employed by both young and old alike, and the fasting of children should be regarded as a safe and natural method of insuring superior health and vitality.

[Home](#) > [Lesson 58 - Fasting Children During Disease](#) > 4. Questions & Answers

## **4. Questions & Answers**

**My child doesn't understand fasting. He thinks he is being punished when I put him on a fast. Help!**

If the child is old enough (around four years or so), he or she can understand what fasting is all about if you explain it in a general way. If you have any animals or pets, by all means

make it a point to assure your child how these creatures fast naturally during time of discomfort. If you can, you or your spouse should practice fasting in front of the child before he is put on a fast. Tell the child that when you are sick, your body and stomach must rest, so no food is eaten.

If the child is very young or is an infant, then you have little choice but to let the child fast and listen to his complaints. Actually, many children after the first day of the fast adapt very readily to not eating—more so than adults.

It may seem cruel to you to deny a crying child his food, but if you are intent on furnishing him with superior health, then you will have to make this sacrifice.

The easiest way to handle this problem for a child past two or three is to let him see that fasting is a natural thing to do, and is not a punishment or something to be afraid of. Our culture promotes eating and overfeeding. You must show your child the other side of the coin, and develop good health habits at an early age.

The parent should set the example for the child and abstain from food too. In this way the child will be a participant rather than an outcast.

**I want to fast our child, but my wife says no. None of our other relatives are sympathetic either. What should do?**

In these cases, a compromise is necessary. Placing the child on diluted fruit juices or fresh fruit only will certainly allow the body to its work more efficiently than a conventional diet. While not as effective as a fast, such a modified diet is often quite effective in the healing process.

Meanwhile, try to cooperate with your spouse. You yourself should fast to remove any fears about the process. Provide your relatives with information about fasting, such as this lesson, and seek out other parents who have had experience in fasting their children. Often a spoken word from another person who has fasted his or her children successfully will do much to allay your spouse's fears.

**I have trouble knowing when to break my child's fast. She always says she is hungry, so that's not a good indication. How can I tell?**

One rule is to never feed during a fever. If hunger is present at that time, it is usually a sign that liquids are needed—specifically, distilled water. You can generally ignore complaints about being hungry for the entire first day. If the child is very young, it is possible that true hunger could return as soon as the second or third day of the fast. If no major symptoms appear and the child indicates hunger by this time, then break the fast with fruit juices or fresh raw fruit. Continue feeding at this level for as long as possible. As long as the tongue is coated and the breath strong, the child will not evince true physiological hunger.

## **Article #1: Sick So Young, But Well At Last!**

### **The Juliet Groll Story by Paulette Groll**

Juliet was born December 7, 1979. She came into this world drug free (but within her first year of life this would drastically change), a beautiful, 7 lbs. 1 oz., full-term baby girl. We were thrilled! After nine years of marriage we finally had our baby girl.

Three days after her birth we were told we would have to leave Juliet in the hospital nursery because of a high bilirubin count. Reluctantly, but obediently, we agreed. Mother and daughter were separated long enough so it took days to reestablish breast-feeding.

After this episode I believed we were off to a great healthy beginning. This was until Juliet's "well-baby" checkups came along. Each one was more disturbing than before. "Her weight is still down." "She's so far off the (weight) graph she isn't even in the running." For months her legs did not rotate properly in the hip sockets. (This later corrected itself.) Her skin was pale and looked transparent. She was losing some gross motor movement. At six months the test for cystic fibrosis was just around the corner. Fortunately, this never happened. Our temporary "solution" to our daughter's weight problem was the magical "formula." Yes, her weight increased, but at the same time, another more serious problem was on the horizon.

Juliet had an ear infection. The usual treatment was given—antibiotics. We thought nothing of it at the time. But what was to follow brought much thought and change into our lives.

From this first ear infection our journey down the long road of one ear infection after another began. Constant probing, ear "floodings," lab tests, hearing tests, along with ear drops and more antibiotics. A few months later came the ear "specialist" with more "specialized" equipment which terrorized our little girl. On one visit it took her mother, two nurses and the doctor to hold her still so the doctor could get a better look. As Juliet worsened, the medical visits out of town increased. A week without antibiotics and she had a roaring infection. Constant pain, illness, and exhausting examinations filled Juliet's life. For months we dumped antibiotic after antibiotic into her precious body. We ran the antibiotic gamut, then repeated them over and over.

At this point I was just learning about Natural Hygiene. Having followed the diet, along with weekly 24-hour fasts for eight months, we were considering (very cautiously) Natural Hygiene for Juliet. A Christian counselor friend had introduced me to Natural Hygiene. After years of therapy for depression, counseling, along with the principles of Hygienic living, brought me tremendous freedom and health. So, when he suggested trying mashed banana instead of formula, we decided to give it a try. This was the beginning of Juliet's introduction to the world of Natural Hygiene.

Now we found ourselves torn between the world of medicine and Natural Hygiene. A natural diet of raw fruits and vegetables, with nut butters was being topped off with antibiotics for dessert! We were told this long road of ear infections hopefully would come to an end—after surgery. Self-dissolving plastic tubes were to be placed through both eardrums. I asked to read the medical textbooks about this procedure but was put off. By this time Juliet's ears were bad and her hearing was minimal. We had no encouragement to resist. So, out of ignorance and desperation we allowed our 13-month-old to be hospitalized in January of 1981, and surgery was performed.

The surgeon told me, "We really like to feel justified in doing surgery on such a small child. In her case it was justified. The liquid behind her eardrums was like glue. If this doesn't work, there's nothing more we can do."

We really were hopeful. We wanted an end to all this misery for our daughter. And we thought that end had come until another ear infection came along. Then another. We were on the same journey down that

same long road again! Juliet was on "antibiotic row" until she developed a reaction to a common drug. Her body was covered in red blotches from her toes to her chin. She was given adrenalin. When still another antibiotic was prescribed, I declined. My only thought, "There just has to be another way."

## **Out With the Old, In With the New**

My Christian counselor friend had recently told me about a place in Hollister, California, the California Health Sanctuary. He was going there to fast under the supervision of a Hygienic practitioner. I had been interested in going for myself. By now, my thoughts were on Juliet's immediate need. Could a one-year-old be fasted? We had many questions and concerns. With a feeling of nowhere else to turn, my husband and I made an appointment with the Hygienic practitioner at the California Health Sanctuary. Everything he said about the body's being able to heal itself, and that fasting provided the best environment to do so, made perfect sense. He explained that healing is a normal body process which goes on all the time in relation to the amount of energy available. During a fast, the body can save all the energy usually used in eating and other activities and use it to cleanse, repair, and restore itself. Juliet's body needed repair and restoration for sure. So, a week later, April 27, 1981, we arrived at the California Health Sanctuary to embark on a totally new experience.

I knew this would be a unique experience and began keeping a journal the first day. Mother and daughter would stay at the Sanctuary, while father and son returned home. We did not know how long this separation would be.

Juliet walked and played outside all afternoon. The Sanctuary is beautiful and perfect for a toddler to explore. We began getting to know the staff and other fasters. All around us was a spirit of love and sensitive caring. Juliet was given a bottle of distilled water. She always had her bottle close by whether for thirst or comfort. She quickly entered her fasting experience by vomiting a little on the second day. Her breath smelled of anesthesia, so did her body and diapers. As the fast progressed, her nose and ears drained and she had upper respiratory congestion. All this was her body's way of eliminating the poisons within.

While fasting, Juliet enjoyed being outside in her crib or going for long walks in her stroller. She would look up and give me her special smile as if to say, "I understand I'm getting well." It was a special time for both of us. We were totally together. I held her much and slept with her cuddled in my arms.

On day eleven of her fast I knew Juliet was on the road to recovery. Her symptoms were slowly lessening. Still, I was anxious. How much longer would she fast?

The most difficult part of Juliet's fast was not the fast itself, but others' reactions to us, as parents, fasting our child. Some of our dear friends (who knew us and trusted us) thought we had lost our minds. Many could not understand our new approach to health, and a few would not even respect our right to choose what we thought best for Juliet. But none had walked in our shoes. None of these people had been forced to seek a health alternative as we had been. How could they understand?

Yes, there were days I was tired and ready to go home, but the strength always came. God used all those at the Sanctuary in a beautiful way to give Juliet and me all that we needed to go on and see that her body was restored to health. My husband's support was invaluable. He didn't have the benefit of seeing firsthand Juliet's body healing itself. He had to rely on my secondhand information. Also, he did not have the fellowship of the Sanctuary people, those who already knew the healing that was and would continue to be taking place in our daughter. We were trusting the principles of Natural Hygiene through faith, not experience.

## **A Good Sign Appears!**

Day twelve the drainage from Juliet's ears became "runny." This was a good sign! When it became like water and then stopped altogether the fast would be nearing a close. Day thirteen Juliet's ears drained

liquid but she was congested. This would have to clear before she was ready to break her fast. Day fifteen the director gave his first and only prediction as to approximately when Juliet would be ready to break her fast—two or three more days! I was excited until the next day when Juliet showed a lot of mucus, ear drainage, and congestion. As the fast came to a close (day eighteen) her breath was sweet, her body and diapers had no odor, her chest was clear with no drainage from her nose or ears. Her ears were healthy for the first time in nearly a year! Her eyes were bright; her face alert. Day nineteen came and Juliet was breaking her fast. She really ENJOYED her first fluid ounces of diluted, fresh-squeezed orange juice. It was a JOY for me to give it to her.

We stayed on at the Sanctuary while Juliet was gradually placed on a diet of raw fruits, vegetables, and nut butters in proper combinations and in modest amounts. Now, seventeen months old, she was also given bottles with freshly-prepared juices (apple, green leafy vegetables, and orange).

It was time to bring our daughter home. This was just the beginning of health for Juliet. She is twenty-six months old now and doing fine.

Try Natural Hygiene for yourself and your children. It's a great way to live!

[Home](#) > [Lesson 58 - Fasting Children During Disease](#) > Article #2: The Hardest Thing to Do Is "Nothing" by Dr. V. V. Vetrano

## **Article #2: The Hardest Thing to Do Is "Nothing" by Dr. V. V. Vetrano**

"Poor baby, she's so sick. And look at her, she can barely lift her head!"

"Yes, it is true, she *is* sick and has a high fever. But don't worry, she's fasting and the fever won't last too long."

The first day went by without the in-laws saying too much, so I felt relieved. My husband thought I knew what I was doing and he didn't bother me too much about how I fed our baby. So I didn't have too much concern that he would stop me from fasting her.

The second day went by. All the family came to visit the baby. They were a little concerned. But when the third and fourth days had passed and the baby still had a fever, I really had to calm their fears. It was an unheard of thing, to fast a two-year-old baby. Everybody knows when babies have fever they need penicillin to knock it out. To refuse to see a medical doctor when a baby is ill is a crime, they say, and to fast a baby is even worse. ... it is sheer craziness. I'm surprised the family put up with my ways as well as they did. Perhaps I acted like I knew what I was doing or my faith in Natural Hygiene was so strong that it calmed their fears for a while, but on the fifth day of the child's fast even my husband panicked. He stormed out of the house saying, "If she isn't better by tomorrow, I'm taking her to a doctor."

I was just as concerned for my baby as they were, but to let my concern or lack of faith show would have been the end of her Hygienic care. I waited it out patiently, knowing that nature heals. I took her temperature daily, kept her warm, permitted her to rest quietly, and prevented people from smoking in the room, or from waking her up to see if she was alive. I kept the place quiet so she could sleep and do nothing else.

It's hard to buck the whole world, but it is even harder to sit back and wait for the day when a fever will drop. Every day you watch, listen, and hope. Infants that are fasting and who have fever are very quiet. They sleep a lot and this is also disquieting when you are a neophyte Hygienist and not a doctor. All sorts of fears enter your head.

"Is she okay?" you keep wondering. "Is she breathing?" "Is she still alive?" You are scared to death. You want to shake the child, or awaken it, or do just anything to reassure yourself that everything is fine. But I didn't do anything rash. I had to have patience and wait upon nature to complete her wonderful healing process. I was very worried, but I had faith in the living organism. Finally, her fever broke about mid-day on the fifth day of her fast, and there were sighs of relief all around. Her father was no longer tense and worried. The baby's great aunt was no longer hovering over her, wringing her hands. In fact, we all relaxed. That was the only time the baby was sick in her life. Thank goodness! I had weathered the storm. But I know how hard it is to sit and wait, and do absolutely nothing intelligently.

I am pleased I held out. I waited patiently for nature to heal my little baby. But others don't. Just recently, the parents of a six-month-old baby became frightened by their baby's symptoms. They called me, but instead of doing what I suggested they took the baby to the physician. They didn't want to fast the baby. This is when the trouble started. He insisted on all sorts of harmful and painful tests for the baby, including X rays. It takes so long to establish a diagnosis that, had the baby been cared for Hygienically, it would have been well long before the medical diagnosis was complete.

Finally, the physician began the treatment. They went to the physician simply to get a diagnosis. They couldn't forget about diagnosis and just fast the baby. They had to have a label. They were under the impression that if they just got a diagnosis and knew exactly what was wrong with the baby they wouldn't be so fearful. They just couldn't wait and rely on the natural healing powers of the body for their infant's recovery. They forgot all about the treatment that comes after the diagnosis. When they balked at the treatment, the physician became suspicious. He then insisted on the parents carrying out his orders. He even brought the authorities on the case, and the baby was held in the hospital against the parent's wishes. They were forced to submit to treatment of the baby. When they finally got the baby back home, they had to put up with the child abuse bureau visiting them twice a week to see that they were carrying out the physician's instructions regarding the care and feeding of the infant, and they were forced to begin feeding the child meat and cereals against their wishes. It took the infant six months to recover from the medical abuse called "diagnosis and treatments." All this trouble came about because the parents: had no faith in the living body to heal itself, and because of their inability to sit back and do absolutely nothing. "Doing nothing" intelligently is the hardest of all things to do.

Just the other night I was jolted out of my sleep by a ringing phone. It was a lady with a three-year-old baby. Deep concern, bordering on real fear, was in her voice. "I'm worried," she said, "my baby is so listless. There's no life in him at all and he has a fever of 104.5°F. I fasted him seven days and the fever went down. But he was very weak so I didn't wait the 24 hours necessary after the fever subsided. Now his fever has come back, and I'm really worried. I fed him only two ounces of orange juice three times, but his fever returned. He's so weak, and he's still sick." Her voice cracked, and she was crying.

I began asking her questions to try to discover how the child got sick and what the problem was. The baby had hidden himself on a back porch and had gotten into a dried dog food when the parents were visiting friends. When he was found, he was happily stuffing himself on the dried dog food, and had probably been doing so for about 15 or 20 minutes.

He developed a fever, a cough after that, and so the child was fasted. The parents were naturally very concerned and when the fever didn't come down in about three days, they became even more concerned. Many things went through their minds. Would the child survive? He had done this once before, but he had been discovered quickly enough to stop him before he had eaten very much. Under the stress of fear, and impatience, for the fever was still high, the baby was weak and getting weaker, and there was no sign of improvement, the parents decided that since the baby had not had a bowel movement, it would be best to give the child an enema. They reasoned that the dog food was an irritant and still in the colon, causing the temperature to remain high. "We must get rid of the irritant." So an enema was given. The child, however, was still even more listless and it did not bring the fever down.

The parents couldn't wait until the body rectified all the wrongs.

As the child had not vomited we know that the dog food was at least digested enough to pass from the

stomach to the small intestine. By the time it reached the colon, most of it had been digested. The preservatives, other poisonous chemicals, and decomposition products were absorbed from the small intestine. The time to have done something was when the child had first eaten the dog food. Vomiting could have been induced when the food was still in the child's stomach. But perhaps they did not realize just how much the child had eaten and the child was not yet sick. But, to give an enema after the food had already passed the absorbing area was useless and wasted the child's nerve energy. Had the material in the colon been a great enough irritant to cause fever, the body would have forced it out by a diarrhea.

The parent's reasoning was obfuscated because of the weakness and listlessness of the child. The tendency is to do something to make the child appear lively again. Parents forget that when nerve energy is being expended in one direction, it is withdrawn from another. It is normal when the body is fighting off poisons that all its energies, both nervous and physical, are directed to the area of the body that needs it most. The physical weakness comes because the blood and nerve supply has been withdrawn from the skeletal muscles of the body and directed inward to help rid the body of the poisonous substances. It is natural to be listless and weak under these conditions. However, seeing a listless child is frightening and there is that strong urge to do something, just anything, to see a manifestation of life to do nothing, I repeat, to do nothing, intelligently, at these times takes great courage and faith in the human organism.

Fevers may last for more than three days, when there is a need for it. Fasting, of course, is the quickest means to help the body rid itself of irritants that are occasioning the fever, but it sometimes takes more than three days. We must not panic if the fever does not subside more quickly. Children presently are developing fevers that last longer than in former decades. I have cared for several children recently and have noticed that the fevers seem never to quit. The children of this generation are not as strong as those of the previous generation, for many reasons. We will have to expect more acute illness and less robust children until we clean up the environment and straighten out our method of growing and processing foods. The race is slowly but surely committing suicide.

Meanwhile, we must work in more harmony with nature than ever before. We must not needlessly cause the expenditure of any vital energy of any sick person, child or, adult. We must learn to conserve energy as we have never before conserved it, simply because there is less vitality and less functioning capacity than ever before.

If child or adult develops a fever, fasting is the best means for permitting the body to rid itself of the cause. The fever will never go as high when fasting as it does when feeding. "But," you ask, "what about brain damage if the fever should go up to 106°F?" Remember, first of all, that cells can function only at optimum temperatures. The minute the temperature goes up too high, the cells automatically cease functioning and the temperature spontaneously drops. Cellular metabolism contributes greatly to the rise in temperature, and when it is so hot that the cells can no longer function, metabolism slows down and automatically the temperature drops. Actually, it is the suppression of a fever by drugs and other measures causing retention of the poison, or the bacteria or whatever is the occasion for the fever, that damages the brain, never the fever per se. The fever is the necessary biological process to help the phagocytic cells eat up the bacteria or destroy and render nontoxic, the poisonous substance that may have been ingested. The drugs themselves are poisonous and only add to the load that the body has to eliminate. The drugs, plus the bacteria, and bacterial toxins and other poisons in the system are what damages the brain, not the fever which is only the body's best and speediest means of ridding itself of noxious agents.

No matter how hard it may be to sit and wait until the body heals itself, it is still the wisest thing to do.

### 1. Introduction

The boy was at his father's funeral. He sat quiet, staring ahead, his eyes unfocused. No one at the funeral felt sorry for the orphaned boy. The boy himself felt no sorrow, no remorse, no guilt. But perhaps he should have. Because he was the cause of the funeral. He had shot his father in the chest with a shotgun that he carried in his truck.

Perhaps there should have been sorrow for the father, murdered by his own son. But there wasn't. It was town gossip that the father had started his sons on illegal drugs at the age of twelve. "They'll get drugs sooner or later," the father had said, "might as well come from me instead of some stranger."

The man had been a long-distance truck driver. He saw his sons rarely, and he shared the pills, the stimulants, and the depressants he took while driving with his teenage sons. One day the father and son were both "on pills" and a fight started. It ended with the father in a pool of blood, the son standing dazed over him, and the sheriff rushing to the scene.

This story is true, and it happened in a community of less than a hundred people. Drugs, vices, and a destructive lifestyle are no longer problems just for disadvantaged children and youth. Our children and teenagers everywhere are being poisoned, devitalized, and sickened by the unhealthy lifestyles being taught to them by schools, parents, and friends.

The current state of our children's physical, moral, and emotional health has never been lower. If we are to have a society worth living in, then we must launch a full-scale effort to educate every child about the virtues of healthful living and Hygienic practices. Healthful living is the only salvation for damaged youth and children, and we must learn how to teach them the most basic necessity of life: how to grow and prosper in health and happiness.

#### 1.1 What Is a Healthy Child?

Few people have seen a healthy child. You may have seen children that are not currently sick, cranky, or irritable. You may have a child that is usually a source of great pleasure for you. But unless the child has been thoroughly taught and raised according to the principles of healthful living and Hygiene, then it is doubtful that he or she is truly or completely healthy.

In fact, there are few totally healthy people, adults or children, in today's world. Dr. Herbert M. Shelton is the world's foremost teacher of healthful living for both children and adults. He has raised children, grandchildren, and great-grandchildren according to the teachings of Natural Hygiene and Life Science. His book, *The Hygienic Care of Children*, is still the standard work on healthy child rearing. He has this

to say about what constitutes the healthy child:

"There are certain leading characteristics of a normal, healthy, well-nourished child which every parent should become familiar with. Here are the following evidences of health in a child:

1. Mental alertness, brightness.
2. Cheerfulness and a contented disposition.
3. Bright, sparkling, wide-open eyes.
4. A good appetite.
5. Absence of vomiting and regurgitation of food.
6. Normal bowel movements.
7. Very little crying.
8. A steady gain of healthy weight, not fat.
9. Firm elastic flesh with springy muscles.
10. Perfect, sound, continuous sleep all night.
11. Constant growth in health and intelligence.
12. Symmetrical development of muscular tissue.
13. A clear skin complexion.
14. No evidences of pain and discomfort.
15. Freedom from *all* sickness, disease, illness.

A healthy child is a happy child. A healthy son or daughter respects parents and returns the love given. For a child, health is much more than simply freedom from common childhood illnesses. Radiant health in a child indicates vitality, cheer, cooperation, and a pleasant disposition.

Health is the natural gift of childhood. Unfortunately, this gift is often taken from the child by misinformed parents and educators who do not understand the basics of healthful living. A child must be taught how to live in a healthy manner—not because health is an unnatural state that must be learned, but because the child is led astray, miseducated, and seduced by the perversions, shortcomings, and misunderstandings of the modern world.

You who have the knowledge of healthful living must share it with the children of the world—whether they be in your family or in your community. You must become a teacher of healthful living practices to those who are young and look for your guidance. You must teach your children how to live a life that will always be full of health, well-being, and cheer. This lesson teaches you how to instruct the children in your life about the enormous benefits to be obtained from a life of healthy habits and practices.

[Home](#) > [Children And Healthful Living](#) > 2. Teaching The Basics

## 2. Teaching The Basics

Fortunately, knowing *what* to teach a child is relatively easy. The requirements for health are always the same—whether the person is an infant or great-great grandparent. The eternal and ever-present needs of life, health, and activity are: sunlight, pure water, fresh air, natural food, poise, rest, sleep, exercise, cleanliness, cheer, hope, poise, and freedom from devitalizing habits.

These are the basics of healthful living, and the proper subjects to teach the developing child. Let's look at each of these requirements for health in more detail and see how they may be effectively explained, taught, and demonstrated to a child.

## **2.1 Sunshine, Fresh Air, and Exercise**

Fortunately, three of the vital requirements for healthful living—sunshine, fresh air, and exercise—are easy to teach children. Every child, from the newborn to the teenager, should receive copious amounts of fresh air and sunshine, coupled with outdoor exercise.

Children have a natural desire for exercise. They call it "play" and they run, jump, tumble, and climb without any encouragement. Instead of scolding children for "wasting" their time in play, they should be encouraged to play or exercise outdoors and almost year-round.

If the child is withdrawn or spends all of his time reading or watching television, the parent should take the child outside for play or walks or day-trips. It is important that the child be taught at an early age that playing outside in the sun and open air is as essential to growing up as is sitting passively in a school classroom.

In fact, most children spend six hours a day sitting behind a classroom desk. While this may be excellent training for desk-bound adults, it is a poor substitute for childhood. If your child is in a conventional school, then make sure that playtime is scheduled after school and before supper.

As long as the child receives encouragement and support from you in natural outside play, then additional teaching about sunshine, air, and exercise is not needed. The child should be taught the value of fresh air in the home, and should have the windows open as much as possible.

## **2.2 Pure Food and Water**

The hardest area of healthful living to teach to children is that of a pure diet. Actually, there would be no difficulty at all in teaching a child about a good diet if it were not for television, public schools, misinformed parents, or ignorant relatives.

A child will eat the same diet as his parents without question if he is not exposed to the negative influences of junk food advertising and peer junk food eating. It is indeed hard to explain to a child why the sugary cereals he sees advertised during his favorite T.V. shows are actually poisonous substitutes for real food. It is difficult to tell a child that the foods his grandparents or aunts or uncles or cousins or friends are eating will make him sick.

When a child is old enough to begin questioning why he cannot eat the same poor foods most of the people in this country eat, then it is time to begin a program of education about proper diet.

Most children cannot understand that if you eat an ice cream cone that you will eventually feel bad and suffer for it. A child's concept of the "future" is poorly formed. A child lives mostly in the present. Not eating a particular food because it may have future harmful effects is a concept many children will have difficulty understanding. In other words, understanding diet and health as a "cause-effect" relationship will be a new concept for a child (and for many adults as well!).

In this case, it is usually best to wait for the "effect" in order to explain the "cause." If your child indulges in junk ' food or other poor food choices, then simply wait until he becomes sick and then very pointedly explain that the reason he is now feeling sick is because of the foods he ate yesterday or last week or last month or whenever.

Every chance you have, use "sickness" as the stick to keep the child on a good diet. Any time someone is sick at his school or in the family, try to show how a poor diet and other unhealthy practices led to the sickness. On the other hand, use happiness as the "carrot" for keeping the child on a good diet.

After a wholesome meal of foods, emphasize how good you feel and how happy you are that you ate such delicious foods. You don't need to overact, but make sure that you are very vocal about how eating good food makes you, the parent, feel good.

After awhile, the child will begin to imitate you. He will express delight at wholesome meals (if you do

the same) and will eventually associate illness with a poor diet.

Parents may also use animals as teachers for their children about proper diet and drink. Show the child that wild animals have their natural diet. They don't buy junk food at the store, but eat things that grow out of the ground. Animals don't drink soda pop; they sip clear cool water.

If a child can be strongly taught that there is a direct relationship between what he eats and how he feels, then he will be better able to follow the optimum Life Science diet. This teaching will take some time and effort by the parent. Without sounding obsessive, the parent should try to get the child to understand that any illnesses or discomfort the child may feel is linked with the foods eaten. After all, even a child can understand what it means to feel "good" or feel "bad."

### **2.3 Rest and Relaxation**

Teaching children the need for rest and relaxation is usually not too hard. Children will play hard and sleep well during their early years. Adults, however, often have a hard time relaxing and resting because of the stress and demands made upon them.

Children too can suffer from stress. School problems, fights with playmates and friends, trying to live up to the parents' expectations—these are all sources of stress for a child and such stress can make a child irritable and unable to relax.

The parent can best help the child by removing all unnecessary stressful situations from the child's life. Parents with unreasonable expectations can cause their child to suffer as much as the ulcer-ridden businessman.

A good way for the parent to teach the child the value of rest and relaxation is to practice these virtues himself. If the parents make a regular habit of having a rest and relaxation time or activity each day, then the child will see that resting and relaxing are as normal to a healthy life as is work and productivity. Many parents are anxious that their children do not grow up lazy or nonproductive. Sometimes this concern makes the parents push the children to succeed in school, sports, or social activities.

For your child's health, adopt a less anxious attitude and encourage the child to develop habits of regular rest and relaxation during the day.

### **2.4 Fasting and Drugs**

Two essential health-promoting practices that children should be taught are fasting and the avoidance of all drugs. In many cases, prescription and over-the-counter drugs are used in childhood illnesses. Without exception, the child's health would improve by employing fasting as one of the methods to overcome disease. Drugs, vaccinations, remedies, herbal treatments, and other so-called cures and preventatives should be exposed as false and dangerous modalities. They interfere with the body's efforts to restore normalcy.

Fortunately, you don't need to do much educating to get a child to avoid pills, bitter medicines, and painful injections. Given a choice, any intelligent person—child or adult—would not swallow the foul drugs or be shot full of "medicine." Our instincts usually try to protect us, but our intellects override our gut feelings. Unfortunately, most people don't realize that they do have a choice or an alternative way of dealing with illness.

The purpose of educating a child in this area is to disillusion him or her about "medicines." If the child never sees his parent swallowing aspirins, antacid tablets, or any other drug, then there is no role model for the child to imitate. If these drugs are never brought into the home or used by other family members, then the child will not enter into the remedy mentality. A child instinctively rejects drugs, pills, and nonfood substances.

The parent should not tell a child that if he "takes his medicine" that he will feel better. Most people use

drugs and medicines because they have an expectation of relief and cure. If the child is never given this expectation nor is taught that an aspirin can remove a headache, for example, then there will be no attraction for the drug. The child usually comes to be an image of parental beliefs and practices.

This approach toward prescription and over-the-counter drugs also applies to illegal drugs. Many adolescents and adults use illegal or "recreational" drugs because they have been raised in a culture that praises and promotes drug use. If the child has been taught, for example, that a particular drug can relieve indigestion and pain, then he will be equally likely to believe that another drug like cocaine, for example, can relieve emotional pain or mental distress.

The most valuable lesson a parent can teach the child is that all drugs, regardless of origin, have absolutely no beneficial powers on the body at all.

Fasting is the healthful approach to dealing with problems that people use drugs for. If you will set the example by fasting when you feel "out of sorts," then the child will accept such activity as normal.

If you have a pet or any animals nearby, take the opportunity to show the child how an animal will refuse food when it feels sick. Whenever your child is sick, he or she normally loses the appetite. During this time, you can explain to the child that his body doesn't want to have food because it is too busy trying to get him well again. Show no concern at all about the child's lack of appetite. Force no food on the child, and demonstrate no worry.

If the child sees that you are relaxed and unconcerned about his lack of appetite while sick, then he will be more likely to want to continue the fast on his own accord. Most difficulties about teaching fasting to children come from anxious relatives and neighbors who can sabotage your efforts. In this case, it is always best to make no mention that you are fasting your child during sickness. Otherwise, if the child hears any adults arguing over fasting, then it may make him feel uncertain.

If your child is fasting, then you should fast as well if at all possible. If fasting is a normal family affair, then the child will have no fears about short fasts. When the child's body has detoxified and an appetite returns, then do not make the mistake of denying the child food when he is truly hungry. Otherwise, he may see fasting as a form of punishment, like being sent to bed without supper.

Among these lines, it is *never* a good idea to either reward *or* punish a child with giving or withholding food. Such use of food as a reward or punishment can cause serious problems in the development of the child and foster destructive eating patterns in his later years.

For example, one young man had been force-fed strawberries as a punishment for not cleaning his plate. This action resulted in the man never wanting to eat another strawberry or almost any fruit at all during his adult years. On the other hand, some adults give or promise their children "treats" or candy or desserts as a reward for some behavior. This is dangerous because the child then associates eating certain types of foods (usually a junk food) with parental approval. Many adult "ice cream addicts" got their start at the hands of well-meaning but misinformed grandparents. Ice-cream eating thus becomes an emotional substitute for approval and security, and a destructive eating pattern is set in motion in early childhood.

There are many other areas of healthful living that you will want to teach your child. Emotional poise, freedom from devitalizing habits, industriousness, happiness, and other qualities may be demonstrated by the parent throughout the day. The young child is like a sponge; he is ready to receive and remember whatever teachings you have to offer, so make sure that you are giving him the best example possible to follow in his life.

### **3. The Tools For Teaching**

Although some hints were given about how to teach a child the basics of healthful living, additional mention about the ways you can use to instruct young people should be helpful. Many of the ways used to teach children are counterproductive. For example, if you punish and scold a child every time that he or she does not live up to your teachings, then the child may become increasingly rebellious and never learn the methods for a happy and long life. You are a partner in the child's preparation for life, not his taskmaster.

*How* we teach a child is as important as what we teach him or her. There are four general, effective, and harmless ways that you can use to teach children about healthful living.

#### **3.1 Teaching by Example**

"Don't do as I do; do as I say," is a remark often used by parents when instructing their children. The truth, however, is this: if a parent wants the child to act positively and develop lifelong healthful habits, then the parent must be a strong example of this as well.

*Children learn by imitation.* Reasoning and logic are not yet fully developed in a young child. They learn to do things by imitating those around them. If you want your child to have healthy habits, then you must demonstrate these habits in your own life so that the child can imitate them.

You cannot tell your child to behave in a certain manner if you will not following your own strictures. The health and well-being of a child is intimately and irrevocably linked to the health practices of the parents. Your children will only turn out as "good" as you yourself are good. You should not expect more from your children than you yourself are willing to do.

You must be an unquestionable, strong, unfailing, and dedicated exponent of healthful living practices if you want your child to adopt the same. You cannot give your children health; you must show them how to live it.

Here is what Dr. Shelton has to say about the parent as example: "Children pattern themselves after their parents as naturally and spontaneously as they eat or sleep. This is the reason that the right kind of home influences are so important. The child does what he sees his parents do and says what his parents say. See that you are a real parent and a good example for your child, and not merely an occupant at the same house with him."

#### **3.2 Teaching by Association**

Children learn not only from their parents, but from other adults and children as well. Whenever possible, you should have your child in the company of similar health-minded people.

If a child is shown that other people besides those in his immediate family also practice healthful habits, then he will be more likely to imitate these positive actions. Finding similar-minded people, however, may be difficult for those that live in rural areas or small towns.

Your best bet is to try to visit other families that have expressed health interests similar to your own. This can be done by contacting other Life Science students who live in your area, or by getting in touch with several of the Hygienic communities or networks that exist throughout the country.

Some families who are intently serious about their well-being often find it advantageous to live in a community situation with other Hygienic families. If nothing else, it is always beneficial to live within the same locale as one or two other Hygienic families so that information can be exchanged and support given during the child-rearing years.

If these suggestions are impractical, then at least try to take a health-minded or Hygienic vacation or trip where your child may meet other children that come from similar backgrounds.

However you approach the problem, it is vital that the child does not feel totally isolated from other people. Any type of social activity, gathering, or family events where health-minded people get together is an excellent opportunity for your child to see others practicing what you have been teaching.

Community and companionship is one of integral requirements for a healthy and productive life. You must not insulate your child from the world, but instead find some type of social situation that will promote the healthy habits that you are trying to instill.

A man may be judged by the company he keeps, but a child's character and habits are molded by the company he is exposed to. Try to choose your friends and associates carefully so that any teachings you may give to the child are also reinforced by those around him.

### **3.3 Teaching by Instruction**

As your child grows older, he or she may be taught the precepts of healthful living through the conventional methods of books, stories, and field trips. Although there are very few Hygienic materials written for children, there are now other children's books that teach healthful living habits.

For example, there are now several books published on vegetarianism for children of all ages, as well as for preteens and early adolescents. There are storybooks that reinforce such teachings as kindness, consideration, fair play, and other positive values. By carefully selecting your child's reading, you can expose him or her to some character-building ideas.

Movies and television can also be used to instruct. Much care and caution should be exercised because most commercially-produced movies and T.V. shows are simply reflections of a culture obsessed with material goods, stimulation, fast foods, money, and exploitation. There are some good children's programs and instructional video tapes, however. Be alert for any of these in educating your child about healthful living.

Perhaps the easiest and most inexpensive way to teach by instruction is a carefully planned field trip. If you want a child to reject meat eating overnight, take them on a tour of an animal stockyard or slaughterhouse. Show them how poorly the animals are treated, and emphasize that if you don't eat animals, such things would not occur. All children can understand and deeply sympathize with cruelty to animals. This is an extreme example, and should be used with caution so as not to shock or traumatize the child.

More positive and enjoyable field trips can be made to parks and wilderness areas. Use the opportunity to show the child how animals live in the wild, and how they take care of all their needs naturally. Encourage the child to identify with such natural living, and to enjoy the outdoors.

Another excellent field trip can be made to orchards and home gardens. Many gardens and orchards in the summer offer outsiders a chance to pick their own fresh produce. Taking your child to a fruit orchard where he can pick his own lunch from a tree will greatly excite him and educate him about man's natural food.

Children love adventures and trips, and they needn't be expensive or far away. By using your imagination, you can take your child to see various sights that will deeply affect and shape his mind toward healthful living habits.

Give the child beneficial, direct experiences in healthful living, and these will make a far greater impression than simply words and advice.

### **3.4 Your Child As Teacher**

You've heard it said that the best way to master a subject is to teach it. So it is with kids and healthful

living. After your child has learned some of the facts about healthful living habits, you should encourage him or her to share these truths with a younger brother or sister or with their friends.

You don't want to make your child into an obnoxious brat who continually badgers people about their unhealthful habits, but you can let your child share his new knowledge with those around him.

If the child has a younger sibling, then give the older child the responsibility for teaching the younger one about healthful habits. Encourage your child to explain to his friends, and, playmates why he doesn't eat meat or take, shots. If this can be done in a nonargumentative way, then the child will feel as if he is sharing privileged knowledge and will be eager to learn more from you.

Do be careful, though. One beautiful Hygienic girl of nine had soon convinced her entire class at school to become vegetarians and no longer eat their friends, the animals. The meat-eating parents of the other children were enraged and threatened by the young girl's behavior, and soon forbade their children to play with her. Your child can learn by teaching, but let such experiences come naturally from the child's desires instead of from your urgings.

[Home](#) > [Children And Healthful Living](#) > 4. Overcoming Obstacles In Teaching The Child

## **4. Overcoming Obstacles In Teaching The Child**

Teaching a child about healthful living would be easy if it were not for various obstacles that society, friends, and families sometimes present. Your efforts at educating your child can be undermined and undone by misinformed teachers, spouses, and playmates of the child.

If you want to make your teachings "stick," you need to know how to handle the most common obstacles that will arise during the education of your child in the ways of healthful living.

### **4.1 Public Schools and Indoctrination**

The public education system can often undo in a matter of weeks what you have spent years teaching your child. One mother who practices Natural Hygiene and follows the teachings of Life Science enrolled her son in kindergarten. She stressed to the teacher that the child was raised as a vegetarian, and she wanted her son to eat the lunch she packed for him each day instead of the usual school lunch.

All went well for a few weeks, or so the mother thought. One day she came to school unexpectedly early to take her son on a trip. She arrived at lunchtime, and saw her vegetarian child with a hot dog. The nervous teacher explained that she didn't want the boy to feel different from his classmates, so she gave him what the other kids were eating. The young boy did not know that a hot dog came from a cow or that he was eating an animal. He thought he was getting an acceptable meal, like his friends.

The trouble with most public schools is that they perpetuate the same mistakes, false beliefs, and lies that you have tried to dispel in your child. Public education is not intentionally evil or destructive—it's simply ignorant, and exposing your child to that type of ignorance can destroy years of careful teaching and explaining.

Dr. Shelton wrote that what now passes for education is "a miserable distortion of what it should be. The most vital facts of life are concealed and distorted. Each generation is thus forced to repeat the mistakes of the past, because it is left in ignorance of the vital forces and facts of life. When are we going to really begin educating our children?"

If you must place your child in public school, then you must also institute a home education program to combat some of the lies and half-truths that they will be taught. A child may grow very confused when

he is told one thing by his teacher and another thing by his parents. In such cases, it is best to explain to the child how different people think in different ways. Then you must guide your child toward developing his own way of thinking and reasoning.

In fact, your best defense against the indoctrination of public education is to teach your child at a very early age *to reason for himself*.

Dr. Shelton writes: "Always give the child a reason why he shouldn't pursue a line of conduct. If he is too young to understand the reason, tell him that he will be able to understand the reason later. Your child should be told why one way of living is superior to another way. Children should be allowed to use their own brains. The highest aim of education, whether it is at home or in the school, should be to help the child to attain rational self-control and righteous self-determination."

## 4.2 Trouble at Home

Sometimes your greatest obstacle to teaching your child about healthful living practices may come from a spouse, grandparent, or other relative. For some reason or the other, one member of the family may feel negative or antagonistic to the teachings of Life Science or Natural Hygiene. Perhaps your wife or husband or mother or father is not in sympathy with your own healthy lifestyle. Such a split can make it difficult for the child to learn correct habits.

A classic example is the case of the father who was very much against the vaccination of his child before being admitted to a public school. The mother, however, could not understand why her husband was so upset. After all, she had been vaccinated, with no apparent harm, so she could not support her husband in this decision.

The child was caught in the middle. His father told him that all shots were harmful and needless; his mother told him that the doctor would have to give him a shot before he could go to school. No matter what happened after that, the child would lose respect for one or the other parent.

If your spouse or a close family relative is absolutely dead set against your new healthful living practices and teachings, then you will have to reach some sort of arrangement. Parents who argue and fight continually do as much emotional harm to the child as any unhealthful habit.

The parents and relatives of the child must *agree among themselves* as to the approach to take in teaching the child. It is far better for both parents to strongly support some type of compromise approach than for them to be at odds. If a child sees the parents are not in agreement, then he may use one or the other to get his own way.

In this case, it is best that the parent who strongly advocates a healthful lifestyle to be a shining example to the child. By presenting a positive, happy, and enthusiastic example of health to the child, the parent will have a greater effect than the negative influences of the other spouse.

## 4.3 Trouble at Play

Another obstacle to teaching the child about healthful living may be playmates and friends of the child. Children who were not raised Hygienically may expose your child to negative habits. Realize that such exposure is inevitable, sooner or later, and that you must devise a way of dealing with these influences.

A child does not like to feel "different" or be called "strange" by his friends and playmates. He doesn't want to feel out of the ordinary or be an object for ridicule. The child should not be isolated from other children simply because they have negative or unhealthful habits. It is necessary for the child to learn at an early age that certain actions bring about certain results.

For example, any time that one of your child's friends or playmates is sick, ask your child why he thought that his friend was sick. Then show him how he rarely becomes sick because of the habits he has formed. Don't make your child feel superior to his playmates; simply show him how negative actions

and habits on their part produce negative results. In other words, try to help him learn from the mistakes of his friends.

Instead of having your child change his positive behavior to match the negative habits of his playmates, see if he can influence his friends to become healthier and happier. One way of doing this is to invite your child's friends over to share a meal with your family. If your child can share his health-building habits with his friends, then it becomes fun or like a game of discovery.

One excellent way to avoid strange feelings between your child and his playmates is to arrange a "Hygienic" style party for your child's friends. Serve them natural treats, and plan wholesome group activities for them. You may win a few converts, and you'll certainly be helping the other children in a small way.

[Home](#) > [Children And Healthful Living](#) > 5. The Rewards Of Teaching Your Child

## 5. The Rewards Of Teaching Your Child

You will be continually well-rewarded for your efforts in teaching your child. A child who has learned the ways of healthful living will be cheerful, free from disease or distress, and a source of enjoyment to the parent.

Dr. Russell T. Trall, a pioneer in the Natural Hygiene movement, wrote this about the outcome of teaching your children how to live healthfully:

"In youth, children are the dependencies of their parents, and subject to their government which may either be wise or foolish. When they enter the world, they will go forth either as useful members of society or constant annoyances and curses. Their eventual actions and character were predetermined long before their assuming personal responsibility. They are the products of their parents' teachings, and show the result of the care or lack thereof that was bestowed upon them from the time of conception to the day that they step into the world."

Finally, the words of Dr. Herbert M. Shelton should serve as inspiration for those of us who must teach the young how to live in this world: "We can build a nation of super-Venuses and Apollos, with minds as well-developed as their bodies and with splendid morals and lovely characters. As parents, your greatest charge is to acquire and make use of the available knowledge in teaching children how to live a healthy, happy, and long life."

[Home](#) > [Children And Healthful Living](#) > 6. Questions & Answers

## 6. Questions & Answers

**What should you do when you discover your child going against the teachings you gave him? My youngest son who is twelve has been chewing tobacco with his friends.**

The best reaction is to be unemotional and logical when you talk to your child about such a problem. By the age of ten or so, you can start treating your child as an adult. You tell him that he alone will have to take full responsibility for his actions, and that if he suffers or becomes sick because of his habits, then it is his fault. Many people, both adults and

children, indulge in destructive habits because they do not understand the eventual outcome, or they believe that the evil they do may be undone by medicines, doctors, or other treatments. If your child fully understands that he alone is responsible for his health and happiness or sickness and misery, then he may act more responsibly

All children experiment with "bad" habits that they may pick up from their peers. If you do not overreact (which is what the child is sometimes seeking), then the habit may be dropped. Incidentally, children often do just the opposite that is told them in order to get some sort of attention. Show no outward concern and worry, but make sure that you increase the amount of love and attention you give a child that is indulging in bad habits. This positive reinforcement, instead of a negative and emotional outburst, will impress the child and lead him back to the healthful habits that you have taught.

**I became interested in health after my children were in school. It's hard to get them to change to my new life.**

Why should you expect your children to make a change that took you twenty years longer to do? The people who first realize the truth about health may be the blindest when it comes to accepting the shortcomings of others

The approach to take when this occurs is to make all of your new healthful habits part of your old lifestyle. Children distrust and fear radical changes in their parents, and it may confuse or repel them. They may react so negatively to these changes in a parent that they will overindulge in destructive habits, as a way of asserting their own independence from the parent

The best way to handle this is to try to get the entire family involved in your new healthful lifestyle. Let them discover the advantages of healthful living along with you, instead of you presenting it to them. Involve them with your new lifestyle, diet, and exercise program. Let them help plan the meals, exercise along with you, and just be generally a part of an exciting new adventure in health

At this stage, it is important to emphasize the positive sides of this lifestyle, and not dwell upon the old negative habits. For example, instead of telling your children that there will be no more candy in the house, tell them that you will be getting delicious dried fruit, dates, raisins, and nuts for them as a snack. In other words, always make the child believe that healthful habits mean more fun, more life, and more things to do. Don't make health a "negative" experience by telling the child he can't eat that or he mustn't do this or he shouldn't act this or that way

Children react strongly to positive, new changes. If you present your new lifestyle as a way of having more fun instead of denying old pleasures, then the children will follow you gladly.

**The only problem I've had in teaching my child is that he doesn't want to be different from his playmates. He can't understand why he can't have a "Kool-Aid" sales stand or eat candy bars, and he doesn't like the kids making fun of his lunches.**

You will have to be more creative. You can make your child "candy" from various dried fruits, or suggest that he sell fresh fruit juices instead of junk beverages with the kids. Invite his friends over to lunch some day and go all out for a great Hygienic meal

Don't let your child become isolated because of his healthful habits. Encourage him to play

with his friends, regardless of their differences, and make sure you give him enough support when he needs it. Also, try to anticipate any situations that may make your child feel uncomfortable, and do your best to smooth the way

Every child, at some time or the other, will be teased for being different in some way. If you remain supportive and demonstrate unreserved love for the child, then such situations will not be harmful.

[Home](#) > [Children And Healthful Living](#) > Article #1: Does Your Child Have Eating Problems? by Joyce M. Kling

## **Article #1: Does Your Child Have Eating Problems? by Joyce M. Kling**

Overeating, undereating, eating poor foods, playing with food and fussing during mealtimes—does your child display any of these problems. If so, the first step is to find what causes them.

### **Finding Causes**

Perhaps you have too many mealtime rules such as don't talk, sit still, eat everything on your plate, don't make a mess, etc. All these rules may make your child uncomfortable and cause him to fidget when he should be relaxed.

Do you condemn him for his eating habits? This may make him insecure and the problem may grow rather than dissipate.

If your child is angry at you for something and knows that certain eating patterns are likely to "get" you, he may just try them. If your child feels unloved, either because of jealousy of a sibling or because you've been less attentive than he feels you ought to be, he may undereat, overeat, or fuss to get your attention.

If you're fanatical about his diet, you may be causing him to desire exactly those foods that you don't want him to have. Idling a child that a certain thing is "bad" may make him more curious about it, especially since he sees so many other children eating it.

### **Finding a Solution**

First, create a pleasant and relaxing atmosphere for your child's meals. Make sure that the chair he sits in enables him to reach the table and is comfortable. The area he eats in should be well-lit so he can see his food. Eliminate such distractions as TV, radio, frequent dinner guests, etc.

Don't make a big deal out of mealtime. It shouldn't be considered a special time of the day but an ordinary routine. "Special" times often mean that the child is supposed to behave extra good and may cause him to do the opposite.

Instead of condemning your child for his habits, try to understand his actions and explain to him why it's best to relax while eating, eat certain foods that are nutritious or to eat certain amounts for best health. Praise him when he behaves rather than punishing him when he doesn't.

Never force your child to eat if not hungry. It's best to let him skip a meal if he's not feeling well or is tired.

Liquids are best not served with meals. They dilute the digestive fluids in the stomach and also give a child a "toy" to play with. Children often pour their beverage into their foods.

Make sure there's variety in your meals. If you serve the same things day after day, he may get bored and not eat.

If you want your child to eat nutritious foods, teach him about them because he won't get this information from other sources. The influence of T.V. junk food commercials on children is amazing. T.V. commercials proclaim, "Aren't you hungry for...?" and then flash a big juicy hamburger across the T.V. screen thus enticing young viewers. Try to balance out the input he gets from peers, the media, etc., regarding foods and eating habits by setting a good example.

One mother who is raising her child on raw fruits and vegetables once let him eat his share of junk foods. He got very sick and she explained to him that that's what happens when you eat wrong things. He no longer desires what the other kids eat.

However, it's not always that easy. My son is always desiring junk foods and when he tried a hot dog, he didn't immediately get sick despite the fact that I had told him he would. He then thought I was lying to him. In this case, I still try to provide him with a nutritious diet and eliminate his exposure to junk foods as much as possible. He'll probably get some "bad" foods at times but it won't be as bad as most children who get it all the time.

### **Get Your Child Involved**

Get your child involved with the selection and purchase of foods, their preparation, as well as the after-meal cleanup, and he'll take a greater interest and may eat better. Ask him what he wants for dinner and you may be surprised how reasonable his choices can be. Then let him help to prepare the meal in as simple a way as possible. He'll show great enthusiasm and want to get involved more often.

My five-year-old son enjoys making his own "smoothies" and feels very independent when doing so. He usually sits still and eats it to completion afterwards.

### **Results of Good Eating Habits**

Knowing that you don't have to "live with" your child's eating problems should be a relief to you. The effort you take to modify your child's behavior creates harmonious meals that digest fully. You'll all enjoy your meals more.

- [Article #1: The Natural Food of Man By Emmett Densmore, M.D.](#)

The Hygienic lifestyle and the basic Hygienic philosophy lends itself easily to a self-sufficient lifestyle. As we have stated before, man is a frugivore, as are the other primates. A brief study of these primates will give us a clearer picture of man's dietetic nature.

### 1. Similarities Among The Primates

In 1680, Edward Tyson was the first to use comparative anatomy extensively and demonstrated the similarities between the orangutan and man. His best known work was published in 1699 which compared the anatomy of a Pygmie with that of a monkey, an ape, and a man. Tyson was himself surprised at how closely the orangutan resembled man.

In 1758, Carl Linnaceus recognized the close relationship between humans, monkeys, and apes. He was the one who officially devised the group name or order, primates, to encompass them all and to denote their high ranking in the organization of the animal kingdom. At the time it was generally held that species were fixed. The arrangement of the animal kingdom was seen as a precise hierarchy of increasingly complex forms, each created independently of ones to either side of it—beginning with the humblest creature and culminating with the primary of man. Linnaceus's work did not threaten this theory. He believed that all animals had been created by the hand of God and that man had been set apart from them in a special way.

By the end of the 18th and well into the 19th century, two distinct lines of approach had appeared. There were still those who saw all forms of life as having been created by the hand of God, and there was a now hardening core of evolutionists who thought in terms of gradual processes of complexity. The conclusion that man was in effect a highly-developed ape was a bombshell to Victorian Britain and to the world at large. It was in direct contradiction to the Biblical doctrine that man was made in God's image.

The debate on man's origins continues to rage, though among scientists rather than theologians. A mass of fossil remains have been found to justify Darwin. The evidence does not suggest, and never has, that we evolved from any ape that we know today. It suggests that both we and these apes had a common ancestor which developed along different paths, going their different evolutionary ways, something like 20 million years ago, during the Miocene Period.

So far as the anthropoids are concerned, it is apparent that they began as arboreal creatures, living on the fruits that trees yield especially for consumption. Wild fruits constitute nearly the whole diet of the orangutan and the chimpanzee. The gorilla, whose weight brought him along with man, to the ground, has expanded his menu to include wild cherry, berries, and bamboo shoots, and some roots.

A key factor to the behavior of the orangutans is the distribution and seasonal ripening of the fruits of the forests. Orangs show a strong liking for such fruits as figs, lichees, plum, mangosteen, durian, and rambutan, all lone trees scattered somewhat thinly through the forest. To survive, they must know exactly where these delicacies are located, and when they will be available. When they find one of them ready for eating, they will immediately strip it bare and then set off for the remaining trees of the same species growing within their range. This mono diet of fruits proves most conducive to the health of the orangutan and the perpetuation of their species.

The full-grown gorilla male may weigh as much as 600 pounds. Yet despite their great size and fierce aspect, gorillas have remarkably peaceful dispositions and lead generally tranquil lives. Found only in tropical forests and mountains of central Africa, they feed on the fruits and the vegetation that they find there.

Charles Darwin predicted more than 100 years ago that Homo Sapiens would be found to have evolved in Africa. It is now accepted that he was right. Fossil bones and stone artifacts found over the last decade in Tanzania, Kenya, and Ethiopia have extended human history back over five million years. It now seems certain that our prehuman ancestors shared their African homeland with creatures—the Australopithecines—to whom they were closely related, but yet who vanished into evolutionary oblivion.

Analysis of the protein molecules of blood among living primates suggests, on the basis that the more similar they are from different animals, the more closely related those animals are. A significant result of these blood tests was that in the chimpanzee and man some 99% of proteins are identical, confirmation of their closeness to man.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 2. Man's Fruit And Vegetable Culture

## **2. Man's Fruit And Vegetable Culture**

Like the apes, humans have always been gatherers of fruits. The tropical fruits we know today are the result of cultivation. Similarly, the fruits of the temperate zone—the apple, lemon, orange, pear, fig, apricot, plum, filbert, walnut, etc.—could only have reached their present position through their improvement by man over many millennia. Most of these food plants are of Asiatic origin: they are the products of an age-old fruit culture.

The more important annuals appeared first in association with man and the simultaneous appearance on the historical record indicates a greater age of agriculture than the archaeologists and anthropologists have allowed. This is a logical conclusion because, as cultivated species, fruits and nuts could only have been developed from time to time under the artificial conditions imposed by humankind. If they should be abandoned to nature, they would disappear. The wild fruits eaten by anthropoid creatures were the prime factor in human development and not a product of that development.

According to Henry Bailey Stevens (*The Recovery of Culture*, New York: Harper & Brothers Publishers, 1953), it was after the second glaciation that human tools made their appearance. It appears that there are two main types of tools which were used during that early period. They are the hand axes that originated in the South and the flakes that were used as spears and harpoons in the North.

The hand ax is particularly well fitted for dealing with trees and wood, digging up roots, and cultivating the ground. Also, from this point of view, it seems rather obvious that the hand ax must have originated in a southern, tropical, or subtropical country, where forest and tuberous plants abound. The presence of stone tools at this time suggests that man was actually planting seeds.-The great body of mankind living in the warmer portions of the earth need have been no more concerned with hunting and fishing than were the apes. Their main interest lay in obtaining food from plants, and they became horticulturists.

When the ice age came and most men went south, scattering tribes were caught in the peninsulas or between mountain ranges and the ocean. These tribes had to face living in a world where green life either vanished or became very meager. If they were to survive, they had to readjust themselves drastically. They came to eat great quantities of shellfish. They learned the use of fire and they became beasts of prey. It was they who developed the spear and the harpoon and became accustomed to eating meat.

As the ice receded and plant food became again abundant, the capacity of the middle lands increased and the growers of crops moved into a region accustomed to the hunting economy. Thus the ultimate population of these lands was exposed in the Stone age to two distinct types of culture—one of the handax culture of the South, the other, the spear culture of the North.

The evidence appears overwhelming that the intimate relationship between anthropoids and fruit trees did not end a million years ago when man descended to a terrestrial existence. Rather, the association continued in the southern lands and was the actual impetus in our whole cultural development. It was when man found that he could affect his food supply through the selection and planting of seeds and cuttings and the improvement of soil conditions, that he started the great upward spiral that set him above the apes. Culture developed when we evolved from the simpler primate into the complex human.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 3. Food Self-Sufficiency

### **3. Food Self-Sufficiency**

Like our food-gathering predecessors, we can also be self-sufficient in obtaining our daily food. (Editor's note: Of course, this is not possible now for most people but, most people can be largely or wholly food self-sufficient as many people in this country and the world over are.)We do not have to rely on supermarkets for tasteless, overfertilized, and oversprayed fruits and vegetables. Since all of the food that we require is easily cultivated, and since we do not have to rely on animal products, we can easily grow our own foods.

Even the city dweller can grow fruits and vegetables in containers and be able to at least significantly contribute to their food needs. Many cities now have started community gardens where you can rent a plot for the season and grow all of your own vegetables. In the warmer sections of the country, this can be a year-round project. There will never be any need to purchase any supermarket produce. Even in the cold regions, the use of cloches, cold frames, and hotbeds can greatly extend the growing season. With a root cellar to preserve many of the vegetables and fruits, you can be self-sufficient even in the North. Lets take a look at some of those aids to food self-sufficiency.

#### **3.1 Cloche**

A chloche is a glass or plastic tunnel not more than 24 inches wide and of any length. It is designed to cover crops that are in the field or garden and thus offer them protection from extremes in temperature.

Thus, with a cloche, you can get a jump on the season and set out plants weeks earlier than you normally

could. You will be harvesting fresh lettuce before most people think of putting the plants in the ground and other more tender crops such as tomatoes can be gotten off to super early starts with earlier harvests.

At the end of the season, plants can once again be protected by these handy devices and you will be still harvesting weeks after the first frost.

### **3.2 Cold Frames and Hotbeds**

Using cold frames and hotbeds will bring us one step closer to food self-sufficiency. One main advantage of these devices is that you can start your own vegetable plants and not rely on the few select varieties that are offered by the local nurseries. You can select those particular varieties that do especially well in your particular growing area and suit your needs and tastes. You will also be assured that your seedlings are not given chemical fertilizers and pesticides that result in weaker and less desirable plants.

Cold frames and hotbeds are of similar construction. They both have a wooden frame with glass windows on top that allows sunshine to reach the plants. These windows can be opened and closed to regulate temperature and for ventilation.

What is the difference between a hotbed and a cold frame? A cold frame has the same construction as a hotbed, except that there is no extra heat introduced into the cold frame. In a cold frame you can propagate such cold-loving plants as cabbage, broccoli, and cauliflower. Or you can use cold frames to acclimate to outdoor temperatures plants that have been started in hotbeds. Start heat-loving plants—peppers, tomatoes, eggplants, and others—in a hotbed.

There are two types of hotbeds. One is heated by a great deal of fermenting straw or fresh manure, which has been placed in a pit 2 1/2 feet deep. Another type is made by arranging electric heating cables five inches below the surface of the topsoil seedbed. The coils produce a steady heat day and night while the fermenting straw method is only effective for a few weeks.

### **3.3 Greenhouses**

There are several advantages that all-year gardening greenhouses afford. Summer and fall crop yields can be stretched one season longer, often through the otherwise deadly winter season. Gardeners also use their greenhouses to gain a head start on springtime planting.

Another important plus to greenhouse gardening comes with the opportunity to control the growing environment. Frosts, blizzards, rainstorms, and other weather threats can be virtually ignored behind the protection of greenhouse windows and walls.

Further, there is a health-promoting aspect of home gardening. Tending fresh fruits, vegetables, and ornamental flowers throughout the year is considered by many doctors to be of value to help overcome daily stress and work tension.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 4. Fruit

## **4. Fruit**

Basic to the Hygienic diet is fruit. This ideal food can be easily grown by a Hygienist and bring him one step closer to food self-sufficiency. There are many things that you can grow on a long-term and short-term basis. First of all, to get a quick crop of fruit during your first year, melons and tomatoes are the answer. They are easy to grow and will produce in virtually any part of the country. For those living in

the northern sections, look for varieties with short maturity dates. In the warmer sections of the country, the season can extend over a long period of time.

For the second season, you can additionally enjoy many varieties of berries. They will begin to bear the second year after they are planted and will produce in abundance every year thereafter.

Grapes are also a fairly fast crop to mature and an excellent addition to the Hygienic diet. Some fruit trees are suited to every part of the country and the possibilities are broad. If space is a limiting factor, try the dwarf varieties. They will begin to bear fruit early and the quality of fruit will be excellent.

## **4.1 The Orchard**

It is natural for man to desire to plant and live in an orchard as his ancestors did. Given a choice, almost anyone would choose to surround himself with trees and follow our primal instincts. Here, we are surrounded with our basic food of fruit and nuts and a serene environment that will produce mental and physical health. The orchard provides the most natural and healthful habitat for man.

The Hygienist lives symbiotically with other creatures in his orchard and lets these creatures maintain harmony within the orchard. Thus, predatory insects keep pests down to reasonable numbers, as do birds. Since the homesteader does not see the orchard with dollar signs in front of his eyes, he accepts a few mishapen fruits and shares some of his bounty with the insects and birds. There is plenty to go around. Some of the culls can always be made into juice or put on the compost pile to enrich the soil. The beautiful blossoms in the springtime are not only an esthetic delight but benefit both man and bees. Bees collect pollen to manufacture their honey and at the same time pollinate the blossoms assuring perfect and bountiful fruit for man.

## **4.2 Dwarf Fruit Trees**

Dwarf fruit trees, usually from six to ten feet tall, are easier to plant, fertilize, mulch, and harvest than are standard-sized fruit trees. They usually begin fruiting far sooner, often by their second year and sometimes the same year they are planted. Standard trees usually take five years to begin bearing and sometimes as long as ten.

A mature dwarf apple or pear can produce two or three bushels of quality fruit per season. Semidwarf varieties, growing from 12 to 15 feet tall, are also available. These produce more than twice as much fruit per season in a quarter of the space necessary for the standard tree. The fruit from dwarf trees is equal in size and quality to that of the standards, and is often larger and of better quality because of the individual care the growers lavish on their type trees.

Dwarf trees allow the homesteader with a small plot of land to have a variety of fruits in a succession of harvests. For example, the 40 by 40-foot space usually deemed necessary for the standard 25-foot apple tree could accommodate 16 dwarfs, each of which requires a 10 x 10-foot space.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 5. Nuts And Seeds

## **5. Nuts And Seeds**

The third most important item in the Hygienic diet is nuts and seeds. Although it takes several years for nut trees to reach maturity, it is well worth the wait. Just about all parts of the country can grow hickory nuts, English and black walnuts, pecans, or filberts. A couple of these trees in your back yard will satisfy all desire for nut protein for your family for the entire year.

While you are waiting for your nut trees to mature, you might want to try growing sunflower seeds. These plants are very quick to mature and will yield an abundance of nutritious seeds. Pumpkin seeds are another item that you might want to consider. There are now hullless varieties that you should consider planting in your garden.

## 5.1 Sunflowers

Growing sunflowers is an enjoyable experience. When plants are young, their heads will turn to face the sun each morning. Sunflowers grow very well with mild, organic fertilizers, and they have few insect pests, so spraying is unnecessary. They will grow on just about any soil although they may need some kind of support. A gently looping of two or three stalks together will help the plants withstand damaging winds. In a small garden, sunflowers should be planted in the back or along the perimeter of the property.

Sunflowers can be harvested as soon as the backs of the seed heads are brown and dry. At this time, the inner rows are ripe, but need drying. To harvest, cut off the heads with about a foot of the stalk attached. The stalks are tied together, and the heads hung in a airy room to dry. When thoroughly dry, remove the seeds by rubbing the heads lightly. If stored in airtight containers, their food content and vitamins will remain in good condition for a long time.

While sunflowers come in dwarf, semidwarf and tall varieties, the best kinds for the average gardener or homesteader are the common garden sunflower (*H. annuus*) and the giant sunflower (*H. giganteus*), also called the Indian potato. The common garden sunflower sometimes reaches heights of 10 to 12 feet, with blossoms one foot or more in diameter. The plants are widely cultivated in the United States, the Soviet Union, India, South America, Canada, and Egypt. It is the state flower of Kansas.

The giant sunflower is a strong-growing perennial that climbs to 12 feet or more and bears a huge flower packed with big seeds suited for harvesting and eating. Most popular and widely grown of the giant varieties is the Mammoth Russian, which matures in about 80 days. Besides being the largest and tallest of all sunflowers, it bears big, striped seeds that are thin-shelled, meaty, and rich in both flavor and food value. The plants' towering, husky stalks make excellent screens or field backgrounds. When grown, close together, their broad leaves block the sun from weeds.

Sunflower seeds are concentrated source of protein, calcium, phosphorus, iron, vitamin A, nitrogen, thiamin, riboflavin, niacin, and vitamin E.

## 5.2 Pumpkin Seeds

Pumpkins, a member of the squash family, will flourish in every part of the United States where enough moisture is available. They prefer a reasonably rich soil and sandy loam is ideal. A well-drained bed containing a supply of humus and rotted manure will produce healthy plants. Regardless of the condition of the garden, greater success will be assured if you add compost to each hill.

Pumpkin seeds should not be planted until all danger of frost has passed. They need to be spaced about 10 to 12 feet apart as they need plenty of room to grow. Six seeds to a hill covered with an inch of soil will be sufficient. Thin each hill to the two best plants. Where the growing season is short, plants may be started indoors about a month before they can be planted outdoors. Outdoors, set two seedlings to each hill.

Pumpkins may be harvested when they achieve their characteristic orange color and the rind is hard. Then cut the fruit in half and scoop out the seeds. It is best to purchase the hull-less varieties that are now available. (Most seed companies carry them.) After you have removed the seeds, separate them from the stringy pulp and spread them out on screens or newspapers to dry. After thoroughly dry, place them in jars for storage.

Pumpkin seeds make an interesting addition to our diet and contain high-quality proteins, vitamins, and

minerals. You do not have to pay high prices for these nutritious seeds when you can so easily grow them yourself on your way to self-sufficiency.

As you can plainly see, all of the food components of the Natural Hygiene diet can easily be grown and propagated. This type of diet lends itself easily to a self-sufficient lifestyle.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 6. Food Preparation

## **6. Food Preparation**

Since all foods are eaten in their raw state by Hygienists, we do not have to worry about cookstoves and the gas or electricity that is unnecessary to operate them. In fact, the Hygienic diet is so easy to prepare, there is practically no preparation at all. All that is required is a quick rinse to wash the dirt off of the fruits and vegetables and that's about all.

Shelling nuts is really more fun than work. Shelling also makes you eat slower and masticate the nuts well. This ensures better digestion and assimilation.

Since little time is spent in food preparation, more time is available for enjoying the other benefits of the Hygienic lifestyle.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) >

## **7. Sunshine, Fresh Air, Exercise**

Other aspects of the Hygienic lifestyle consist of sunshine, fresh air, and exercise. These fit easily into a lifestyle of self-sufficiency. While we are gardening and planting our fruits and vegetables, we are receiving the sufficient benefits of all three life essentials. We do not have to think about doing morning calisthenics when we are getting so much natural exercise tending to everyday chores.

Country living and homesteading bring the benefits of, fresh air that is so scarce in the cities. All of these factors come naturally and easily when a Hygienic lifestyle is followed.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 8. Rest, Relaxation And Emotional Well-Being

## **8. Rest, Relaxation And Emotional Well-Being**

After working in the fresh air of your homestead, rest and relaxation will also come naturally in your tranquil environment. There is nothing like fresh air and exercise to promote sound and restful sleep and you will wake up refreshed and ready to meet all of the challenges of the day.

When you are healthy physically, you will be likewise healthy mentally and emotionally. Nothing is more restful emotionally than tending your flower bed around your house, planting the seedlings and

watching them slowly bloom during the season. It is really a satisfying feeling of accomplishment to know that you had a part in such a beautiful display of nature.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 9. Our Body Is Self-Sufficient

## **9. Our Body Is Self-Sufficient**

While striving at self-sufficiency on a homestead, our body is already an "old hand" at such matters. From the moment of birth, the body is self-healing or self-repairing, self-directing and self-regulating on a continual basis. Let's take a look at how it has been accomplishing this task.

### **9.1 Cells of Repair**

Our body has certain cells with very specialized jobs to perform. These cells work for us to maintain health and thwart any outside influence that may interfere with our well being.

### **9.2 Neutrophil**

The neutrophil is a white blood cell that is one of the most common and most important of the cells active in the healing and repair process. These cells contain large quantities of a characteristic protein that has a marked ability to dispose of decayed or spent bacteria and other debris.

During the inflammatory reaction, neutrophils migrate into the tissues where they are very active phagocytes. In this situation, neutrophils are mainly responsible for ingesting the unwanted debris that accumulates. During phagocytosis, the granules or lysosomes of the cells are discharged and many of the cells die; the aggregate of dead neutrophils forms the material known as pus. Bacteria then proliferate to feast on this pus, thus making it easier to expell.

### **9.3 Eosinophil**

Eosinophils are white blood cells that occur in the bloodstream in much smaller numbers than do neutrophils. They are also somewhat phagocytic and are found in greatly increased numbers in both blood and tissues during inflammatory conditions.

### **9.4 Basophils**

Basophils constitute only 0.5 percent of the white cells of the blood. They are said to contain histamine and a heparin-like substance. Histamine dilates capillaries and often permits fluid to move through the capillaries and into the tissues. Heparin is an anticoagulant of the blood. Apparently tissue basophils become the mast cells of the tissues. The large granules of mast cells are thought to store enzymes.

Mast cells are important in cellular mechanisms needed during injury.

### **9.5 Monocytes**

There are comparatively few monocytes in the blood-about 5 percent of the total white cell count. Monocytes are actively motile and phagocytic. It is thought that they function in contributing to the repair and reorganization of tissues.

Monocytes and macrophages are capable of engulfing old, worn out neutrophils, mast cells, and

particles of tissue in the process of cleaning up an area of inflammation after the initial stages have been passed and recovery is in progress.

## **9.6 Fibroblasts**

The function of fibroblasts in tissue repair is to lay down dense collagen fibers to form a firm, mechanically-strong replacement for dead tissue. The simplest such situation is after an incised wound has been made in the skin. There the collagen fibers are oriented transversely across the incision, restoring mechanical strength.

## **9.7 Lymphocytes**

Lymphocytes are also strongly phagocytic and carry out their duty of healing and repair by assisting the neutrophils during inflammation conditions and injury

## **The Organs of Repair**

### **9.8 Lymph Nodes**

The lymph nodes contain small lymphocytes and large dendritic macrophages. The dendrites of the macrophages carry important impulses or messages to the cell body.

The lymph stream widens very greatly as it passes through the node; therefore the rate of flow is greatly reduced. The lymph filters through a maze of passageways lined with phagocytic cells. Such cells engulf bacteria and other foreign materials from the lymph stream. Thus the body is kept in a healthy and stable condition.

### **9.9 The Spleen**

The spleen has four major functions:

1. Blood destruction - Old red blood cells are destroyed in all parts of the reticuloendothelial system, including those of the lymph nodes and spleen. (Reticuloendothelial system applies to those cells scattered throughout the body that have the power to ingest bacteria and solid particles.)
2. Cellular production - The spleen manufactures lymphocytes and monocytes.
3. Blood storage - The spleen serves as a reservoir for blood, or, more specifically, for red blood cells, as most of the plasma is returned to the circulation whereas red blood cells are enmeshed in the splenic pulp. Marked contraction of the spleen occurs during muscular exercise, thereby releasing red blood cells and increasing oxygen capacity. The spleen undergoes rhythmic variations in size in response to physiologic demands, such as exercise and hemorrhage, and thus influences the volume of circulating blood. The volume of stored blood may vary from a liter to as little as 50 ml.
4. Blood filtration - The spleen, serving as a part of the body's reticuloendothelial mechanism, filters spent cells and their debris from the blood.

### **9.10 The Liver**

Organisms are filtered from the blood by macrophages in the wall of the sinusoids (minute blood vessels), and various toxic chemicals are removed from the blood by liver cells.

The sinusoids are lined partly by flat nonphagocytic endothelial cells and partly by more rounded and irregular shaped macrophages (or Kupffer cells) that project into the lumen of the sinusoid. These cell?

are similar in structure to macrophages elsewhere and are avidly phagocytic.

The protective function of the liver is associated with its ability to detoxify products of catabolism, that might accumulate in dangerous proportions. These products are changed chemically into substances that can be excreted by the kidneys or through the intestinal tract. Macrophages present in the liver sinusoids aid in filtering foreign matter from the blood.

## **9.11 The Bone Marrow**

Bone marrow is highly important as the source of the cells of the blood and other cells in the body's system. Development of blood cells within the bones commences during the fifth month of fetal life.

Blood-forming elements appear initially in the centers of the bone marrow cavities; the blood-forming centers later expand to occupy the entire marrow space. This widely-dispersed blood cell formation continues until puberty, when the marrow in all the ends of the long bones becomes less cellular and more fatty, giving rise to yellow bone marrow, in which most of the hematopoietic tissue has been replaced by fat. In the adult, only the red bone marrow, located principally in the skull, vertebrae, ribs, sternum, and pelvis, retains hematopoietic activity. The total productive bone marrow in the adult is about 1,400 gm.

It is apparent that a most important part of the bodily repair mechanism is the production of cells—polymorphs, lymphocytes, macrophages, and plasma cells. When bodily mechanisms break down, one of the commonest causes of impairment is failure to produce these cells. The failure may be due to drugs or poisons, to gross errors in diet, to destruction of the bone marrow by neoplasm, or to irradiation of the marrow. The way that the mechanism fails depends on what group of cells is most severely affected. If the precursors of neutrophil polymorphs are affected, then there is an acute shortage of cells able to phagocytose dead or decaying bacteria. Alternatively, the megakaryocytes may be damaged. These are the precursors of the blood platelets, the cells that play a vital part in blood clotting. In their absence, the blood will not clot and the individual may bleed to death. Such abnormalities only occur in an enervated and toxic body. When you are living correctly, cells that are active in healing and repair will be present in correct numbers to maintain a state of health.

From the above study of the roles of the cells and organs of repair, you can clearly see that the body is constantly at work to maintain homeostasis or ideal operating conditions. Even under some adverse conditions (when we disobey some physiological law of nature), these forces remain active. It is only after repeated abuse that the healing forces fail because they become overwhelmed and exhausted. It is the duty of the teacher, then, to instruct his client to restore the conditions of health. The body's healing forces will then reachieve normalcy.

## **10. Inflammation**

Inflammation is a healing response. Whenever there is tissue damage as a result of injury, the damaged tissue cells produce histamines. These histamines cause changes in tiny blood vessels, which in turn release fluids into the injured area. Local blood flow increases, bringing special blood cells (whose specialty is collecting alien substances for elimination) to the area. Along with these cells comes fibrinogen, which causes clotting. The clotting results in what is called "walling off," that is, nature literally builds a partition between the infected area and the rest of your body. The partition, or wall, stops body fluids from moving outside the infected area, and these fluids build up in the area, causing the characteristic swelling of inflammation.

Before inflammation can arise, there must exist an exciting cause in the form of some obstruction or of some agent inimical to health and life. In this light, we see inflammation as a healing process.

Dr. H. Lindlahr explains that the body does not suppress the growth and multiplication of bacteria until the morbid matter on which they subsist has been decomposed and consumed, and until the

inflammatory processes have run their course through the five stages of inflammation. He says serums and antitoxins given in powerful doses at the different stages of any disease may check and suppress microbial activity and the processes of inflammation before the latter have performed their natural roles and before the morbid matter has been eliminated.

The five stages of inflammation as described by Lindlahr are as follows:

1. Incubation - During this stage, morbid matter, poisons, and other excitants of inflammation collect and concentrate in certain parts and organs of the body. When they have accumulated to such an extent as to interfere with the normal function or to endanger the health and life of the organism, the life forces begin to react as an emergency basis to the obstruction or threatening danger by means of inflammatory processes to accelerate healing.
2. Aggravation - During the period of aggravation, the phagocytes engulf toxins within the body. This is accompanied by a corresponding increase in fever and inflammation, until it reaches its climax, marked by the greatest intensity of feverish symptoms.
3. Destruction - There is disintegration of tissues due to the accumulation of exudates due to pus formation and body development of abscesses, boils, fistulas, open sores, etc., as exits for the toxic suppuration.
4. Abatement - The absorption and elimination of exudates, pus, etc., takes place during the period of abatement. It is accompanied by a gradual lowering of temperature, pulse rate, and the other symptoms of fever and inflammation.
5. Resolution or Reconstruction - When the period of abatement has run its course and the affected areas have been cleared of the morbid accumulations and obstructions, then, during the fifth stage of inflammation, the work of rebuilding the injured parts and organs begins.

It is extremely important not to interfere with any of these stages. The best action to take is to put the body to rest so that all of the energy can be utilized for healing. Lindlahr explains what may happen if healing is suppressed during any of these stages of inflammation.

### **10.1 Suppression During the First Two Stages of Inflammation**

Lindlahr says that this practice always involves the danger of causing uneliminated poisons to overwhelm vital parts and organs, thus laying the foundation for chronic destructive disease.

### **10.2 Suppressing During the Third Stage of Inflammation**

If suppression takes place during this stage, the affected areas may be left permanently in a condition of destruction and this also leaves the affected organs permanently in an abnormal condition.

### **10.3 Suppression During the Fourth and Fifth Stages of Inflammation**

If these processes of elimination and reconstruction are interfered with or interrupted before they are completed, the affected parts and organs will not have a chance to become entirely well or strong. They will remain in an abnormal, crippled condition, and their functional activity will be seriously handicapped. Rebuilding has not been completed. The body will effect a thorough and efficient repair if allowed to do its work unhampered.

Often, people regard inflammation as a "disease" entity to be suppressed, but in reality it is a healing process where nature makes massive attempts to reestablish health.

### **10.4 Healing in the Skin**

An excellent example of the healing powers of the body is seen in wound healing. When the skin is broken due to a wound, the tissue is first sealed by plasma that leaks from the severed ends of small

capillary blood vessels. It clots forming a glue-like substance that binds the sides of the wound together. This substance is proteinaceous in nature.

Small buds of cytoplasm from the capillary lining cells move into the clot where they fuse in the middle. The neutrophils and macrophages now move to the site and remove debris by phagocytosis.

Fibroblasts begin to synthesize collagen fibers that are laid down in amounts greater than normally found in the skin. This forms the scar tissue that is normally seen after healing of any cut. The epithelial cells move and divide and eventually restore the skin to normal proportions.

## **10.5 Enkephalins**

Another example of the ability of the body's own intrinsic forces to take care of every need is demonstrated in the newly-discovered enkephalins.

It was suspected that the brain and spinal cord contained narcotic receptors. These are sites on cell surfaces where a narcotic would have to bind in order to produce narcosis. It was reasoned that if the body has receptors for narcotics, then it must produce some narcotic-like substances.

On December 19, 1975, Hughes, Kosterlitz, and their coworkers discovered a new material from pig brain and reported its chemical structure. It turned out to be two substances, both peptides that were called enkephalins. It is thought that the enkephalins cause a reaction that inhibits the release of the sensory nerve's neurotransmitter when they bind themselves to the receptors. This partially blocks the impulse to the brain and as more enkaphalins are available on the portion of the end of the sensory nerve, neuro-transmitter production is blocked and still less pain is perceived. If still more enkephalins are produced, pain may be greatly eased or eliminated completely.

It is suspected that enkephalins exist to a certain extent at all times but the levels greatly increase during times of need. A signal of pain would initiate further production of this chemical.

It is theorized that enkephalins may also play a role in mental illness. A normal amount in the amygdala (a mass of gray matter in the anterior portion of the temporal lobe of the brain) may act as the body's own defense against disappointments and losses. A deficiency of enkaphalins in those brain regions that are involved in emotions may result in increased mental pain and depression.

It has been discovered that certain brain receptors still bind morphine more effectively than it binds enkaphalin. Now scientists have discovered small amounts of morphine in both human and cow's milk. Plants in the diet are likely sources for this morphine. Lettuce, for example, has been found to have measureable amounts.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 11. Freedom From Reliance Upon The Medical Community

## **11. Freedom From Reliance Upon The Medical Community**

Since the body is a self-healing and self-repairing organism, the Hygienist does not rely on physicians, psychiatrists, drug companies, or hospitals. You can be self-sufficient with the knowledge that the body will heal itself when the need arises and the latest "cures" that are offered by physicians need not be considered. Their nostrums interfere with healing.

When you are choosing a site for your homestead, you do not have to consider the availability of drugstores to supply you with any of their poisons. You know that such substances are neither needed nor desirable. Your lifestyle will be so satisfying and fulfilling that emotional well-being is ensured. No

visits to the psychiatrist will ever be required. You will truly feel free and self-sufficient.

[Home](#) > [Lesson 60 - Self-Sufficiency And Natural Hygiene](#) > 12. Questions & Answers

## 12. Questions & Answers

**If we choose to purchase our food from the supermarket, is there much of a problem regarding food contamination with pesticides, etc.?**

The environmental contamination of food is a nationwide problem. In a government survey of the 50 states, 243 food contamination sources were identified. These include only the most poisonous substances that have resulted in immediate sickness or death. The government attempts to regulate the use of these poisonous sprays so their use is not so heavy to occasion immediate death but this does not mean that they are safe in small amounts. Any amount is deadly because it will accumulate in the tissues of the person eating these sprays on their fruits and vegetables. The only way to safeguard yourself against these poisons is to grow your own or purchase organically-grown foods.

**If our supply is limited in organic produce, what can we grow to supplement our needs?**

Sprouts is probably your best bet for ease of growing in a limited space during the off season for gardening. The sprout is very high in all vitamins and minerals and is most easy to digest. The proteins are split into amino acids, fats into fatty acids, and starch into sugars. They are therefore, an excellent addition to our diet.

**While we are waiting for our nuts and seeds to ripen on our homestead, can our protein needs be met with the fruits and vegetables we grow without the concentrated proteins?**

Yes, your protein needs can be met most adequately on a diet of fruits and vegetables. Following is a list of the protein content for some fruits and vegetables: (From *Composition and Facts About Foods* by Ford Heritage.)

Grams per 100 grams edible portion

Fresh peas 6.3  
Kale leaves 6.0  
Pawpaw 5.2  
Dried apricot 5.0  
Brussels sprouts 4.9  
Collard leaves 4.8  
Dried fig 4.3  
Broccoli 3.6  
Cauliflower 2.7  
Raisin 2.5  
Savoy cabbage 2.4  
Date 2.2  
Kohlrabi 2.0  
Snapbeans 1.9  
Sapote 1.8  
Celeriac 1.8

Black raspberry 1.5  
Banana 1.2  
Fresh fig 1.2  
Casaba melon 1.2  
Red raspberry 1.2  
Chinese cabbage 1.2  
Eggplant 1.2  
Carrot 1.1  
Tomato 1.1  
Apple 1.0  
Apricot, fresh 1.0  
Orange 1.0  
Soursop 1.0  
Celery 0.9  
Cucumber 0.9  
Honey dew 0.8  
Tangerine 0.8  
Blueberry 0.7  
Sweet red pepper 1.4  
Lettuce (Romaine) 1.3  
Pear 0.7  
Japanese persimmon 0.7  
Strawberry 0.7  
Grapes 0.6  
Guava 0.6  
Nectarine 0.6  
Papaya 0.6  
Mango 0.7  
Cantaloupe 0.7  
Grapefruit 0.5  
Mamey 0.5  
Plum 0.5  
Pomegranate 0.5  
Watermelon 0.5  
Pineapple 0.4  
Apple 0.2

Our protein needs are not large—certainly much less than the Daily Recommended Allowances. A daily average of 20 to 25 grams of protein is a generous one. There are many people who can get along fine on as little as 16 grams a day. From the above list, it should be obvious that the Hygienic diet generously fulfills this need even without the addition of concentrated proteins in the form of nuts and seeds.

## **Article #1: The Natural Food of Man by Emmett Densmore, M.D.**

In studying the writings of Trall, Nichols, Shew, and other writers and Hygienic physicians, I became convinced that what is sound reasoning and good practice in the case of the illness of horses and cattle is equally wise and good in the treatment of human beings; and since in the case of the sick horse the chief remedial measure for his recovery is a restriction of his diet, so I became convinced it ought to be in the event of a human being taken ill. Moreover, since, as before remarked, animals in a state of nature are quite generally in vigorous health and strength, just so, I argued, will man become and be if the causes underlying his illness are discovered; and I became convinced that when these causes are discovered they will be seen to relate chiefly to the matter of diet.

In pursuance of this inquiry, and meditating upon the data which this theory furnishes, I noted that animals in their natural state live upon foods which are spontaneously produced by nature, while man not only does not live upon foods so produced, but is almost universally living upon artificial foods artificially produced.

The thought occurred to me that since nature has provided a natural food for all animals below man, it is not unreasonable to suppose that no exception was made in his case, and that nature has provided a food that is as natural to man as grasses to the herbivora, or flesh to the carnivora. If so, what is this natural food of man?

Scientists are in agreement that man made his advent upon the planet in a warm climate; also that primitive man was without tools and without fire. If this position be contested, it is not difficult to substantiate it. If it be allowed without challenge, the inquiry as to what must have been the natural diet of man becomes simple and easily solved. If man first lived in a warm climate, and if, like other animals, he subsisted on foods spontaneously produced by nature, these foods must have been those which grow wild in such a climate, quite probably such foods as are still spontaneously produced in such localities. The woods of the south, as is well-known, abound in sweet fruits and nuts. It is taught by botanists that wheat is an artificial product developed from some grass plant not now known.

Moreover, cereals are the product of the temperate zone, not of those regions where there is no winter; and it was therefore a necessity of man's sustenance when he was without agriculture, without tools, and without fire, and had to depend upon foods spontaneously produced by nature, that he live in a region where these foods were produced at all seasons of the year. This narrows or confines the inquiry to two articles of diet—fruits and nuts.

When this thought was fully borne into my mind, I first asked myself: how adequate is such a diet for man? It is well-known that there are three principal classes of food which are required in every healthy dietary, namely, the carbonaceous, the nitrogenous, and the phosphatic or mineral. The function of the carbonaceous food is to support the heat of the body and the vital power; the office of the nitrogenous is to support muscular growth; and that of the phosphatic is more especially to support the brain and nerve tissues. The proportionate amounts of these various foodstuffs daily required are said by physiologists to be about 22 ounces in the dry state, and of these about 20 ounces are needed of the carbonaceous, about one ounce of the nitrogenous, and less than an ounce of the phosphatic. How, I asked myself, does this natural food—fruit and nuts—answer these requirements? I saw at a glance that, according to eminent chemists and authorities on the constituent elements of these foods, they abound in the requisite elements for the adequate support of the human frame, and, moreover, that they contain these elements in about the right proportion. Furthermore I saw that I had not only hit upon foods spontaneously produced by nature, but also upon foods which need no artificial preparation, no cooking, no sweetening, seasoning, or manipulation of any kind to make them palatable and attractive. If the dishes that are set before a gourmet, those that have been prepared by the most skillful chefs, and that are the product of the most elaborate inventions and preparations, were set beside a portion of the sweet fruits and nuts as produced by nature, without addition or change, every child and most men and women would consider the fruits and nuts quite equal if not superior in gustatory excellence to the most recherche dishes.

Granting all this to be true, it does not follow that the problem has been solved. While fruits and nuts may be the natural food of man, and might have been an adequate diet for primitive tribes who had nothing to do but pluck and eat, and who had none of the severe mental strain inevitable to those in active pursuits in modern civilization, it does not follow that these foods are adequate for civilized man in his vastly changed nature and conditions. A scientist is said to be one who observes facts and classifies them, and science, then, is nothing more nor less than systematically classified facts. I saw that nothing but a scientific test could solve the problem. While it does not follow that sweet fruits and nuts are an adequate diet for man today because they undoubtedly formed the diet of primitive man, still, the fact that they contain every element needed for the support of the human frame, and the fact that these foods were undoubtedly those on which primitive man subsisted, afforded a sufficient basis for justifying an experiment to ascertain what would be the effect of such foods upon modern man. The primal aim underlying this inquiry is the effort to determine what are the causes of modern diseases, and how man may be made as healthy as the animals are in a state of nature.

Instituting a comparison between sweet fruits and nuts on the one hand, and the diet of civilization on the other, I soon detected an essential difference. I saw that while bread, cereals, and vegetables are the basis of the diet of the present day, that starch is the chief element in these foods. Scrutinizing the component parts of sweet fruits and nuts, I saw that these fruits contain very little starch, and hence perceived that I had brought to light a fact that was not unlikely to bear an important part in the solution of the problem before me. What is the effect of starch upon the system? Wherein does a diet that is without starch differ physiologically from one in which starch is the predominant element? In that the two foods involve a very different process of digestion. Sweet fruits are composed largely of glucose, with a fair proportion of nitrogen. As soon as such fruits are eaten the glucose is found ready, prepared by the hand of nature, to be absorbed and assimilated by the system. When first taken into the stomach, the nitrogenous portion of these foods is unassimilable, but when they meet and mix with the gastric juice, they are readily converted into a substance which is at once soluble and assimilable by the system. When the nuts of southern climes—almonds, Brazil nuts, and the like—are ingested, the nitrogenous elements are fixed or free oils are the chief elements of nourishment. The nitrogenous portion, like the same elements in the sweet fruits, is made soluble and assimilable by the gastric juice; the oil is carried to the intestines and meets with the pancreatic juice before it is made into an emulsion which renders it assimilable. There is a small portion of starch in most nuts, and in some fruits. While the ptyaline of the saliva will convert a small fraction of starch foods into glucose, as will hereafter be shown, only a small portion of this transformation is effected in the mouth. As soon as the starch undergoing digestion by its admixture with the saliva reaches the stomach, the acid nature of the gastric juice at once prevents any further change of the starch into glucose, and therefore, although undergoing in the stomach mechanical processes of digestion sufficient to render fruits and nuts soluble and assimilable, the starch is still undigested, and must be passed on to the intestines to undergo a second process of digestion before it is soluble and assimilable.

We are here confronted by a somewhat startling discovery. If it be granted that the sweet fruits and nuts of the south are the natural food of man, it follows that very much the larger proportion of the nourishing elements of man's natural food is digested in the main stomach. True, there is a small percentage of starch in some nuts and in some fruits, and nuts are rich in oil, and this oil and starch must be digested in the second stomach. This relatively small amount of food requiring intestinal digestion is somewhat in proportion to the relative size of the two stomachs, the main stomach in both man and the higher apes being a large organ, and the duodenum or second stomach a small one.

Granting that fruits and nuts and like foods are naturally adapted to man's digestion, this adjustment of the relative sizes of the two stomachs is quite in harmony with the food to be digested. Since man, by artificial contrivance and agriculture, has developed and employed cereals and starchy vegetables as the basis of his diet, he has reversed what appears to be the natural order. He is now living upon a diet the larger proportion of which, although remaining in the first stomach to await the digestion of the nitrogenous portions, still remains mostly undigested, and is passed on to the second stomach before

digestion takes place. That the main stomach is thus called on to perform but a relatively small part of the digestion of his food, and the second stomach, although in point of capacity a relatively insignificant organ, is called upon to perform the digestion of the larger portion of his food.

It has been urged as an objection that since the second stomach is provided with a digestive ferment that is adapted to the digestion of starch foods, this fact is to be taken as a proof that such digestion was designed in the formation of man's body. A satisfactory answer to this objection is found in the fact, as before stated, that man's natural food—granting that southern fruits and nuts constitute that regimen—has a proportion not only of oil but of starch, and hence there is a good reason why man's second stomach was provided with a digestive juice adapted to such digestion. But since in man's natural food the starch and oil constitute but a small fraction of his entire food, it is reasonable to expect that a smaller-sized apparatus would be found adapted to their digestion; and such is the fact as regards the relative capacity of the two stomachs.

It has also been urged by objectors that the thousands of years during which man has made cereals a chief portion of his diet have not unlikely modified his anatomy and physiology by evolutionary changes, and that, whatever might have been his diet and physical conformation originally, these thousands of years have developed him into a natural starch-eating animal. A conclusive refutation of this contention is the fact—more fully amplified in succeeding chapters—that the orangutan and the several species of long-armed apes, which have, apparently since time began, fed upon nuts and fruits, to the exclusion of cereals and starchy vegetables, have today the same digestive apparatus in substantially the same proportion of parts as man, after his thousands of years of cereal eating. This fact is undeniable evidence that man's organs have not undergone essential modification or change by these centuries of unnatural diet.

### 1. Introduction

During the last fifty or so years, we have witnessed a veritable explosion of magazines and other materials being offered to the public, a goodly number of these being devoted to the care of the skin.

In the earlier years the discussions and recommendations in these publications were largely aimed at the female members of the reading public, but in the last few years more and more words have been targeted for both sexes with suggested methods of skin care being accepted as scientific "truth" by many of the readers.

Why such great interest in the skin, this outer integument which holds us together and prevents the parts from scattering to the winds? It is probably because instinctively we recognize that the outer skin is the visible evidence of the condition of the inner man or woman, the mirror that reflects the health, or lack thereof, presently possessed.

Interest in the skin is nothing new, of course. Women throughout history and in all cultures have had recourse to outside agents, including herbs, chemicals, and other concoctions, all supposedly enriched with specific properties capable of enhancing personality and beauty and endowed with mysterious substances to retard the aging process.

In earlier times, when surgery was a relatively new technique on the medical scene, it was the custom in some European medical schools for budding student surgeons to demonstrate their "fitness" for the profession by draping a human skin over their shoulders and strutting around the operating theaters for all to see and admire.

Curiosity being just as much a part of scholastic life in those days as it is now, these students and other scientists, perhaps by accident and even by intent, were enabled to learn much about this very important part of the human body. They learned that the skin is not a dead bit of drapery but rather a functional part of the living body, that it housed a number of very interesting organs and parts and played host to and participated actively in a wondrous array of mind-boggling performances. Surprisingly, too, they also found that the skin itself played many roles vitally important to life itself and that it was a very complex entity, indeed.

Centuries have passed in review since the first timid advances were made to explore the intriguing

mantle of man and, of course, much still remains to be learned in this day of electronic wonders.

In this lesson we will unravel some of the mystery of the skin. We will learn how to care for it and how to feed it so that it will remain always glowing and youthful looking in all climates and throughout our entire lifetimes, always remaining a thing of beauty and service.

[Home](#) > [Lesson 61 - Nutrition And The Skin](#) > 2. Natural Hygiene Represents Nutrition For The Whole Person

## **2. Natural Hygiene Represents Nutrition For The Whole Person**

Those who adhere to the principles of Natural Hygiene are not members of a cult or of a religious group. They are not "oddballs." They are rather a people divorced from the herd because they have observed the herd and do not like the largely inherited common practices of the herd. Neither do they admire what they view as the natural results of such practices, especially those seen as direct consequences of the prevailing eating and living habits of the masses.

Natural Hygienists realize that we are presently witnessing the beginning results of the largest chemical experiment in the long history of mankind. They realize that physiology teaches us certain facts about the requirements of life and that life itself tells us that when these requirements are fully met as and when presented, superior health is as natural a result of this kind of intelligent action as the bursting forth of a wondrous oak from the seed when the environment is friendly and conducive to the life process. Life Scientists believe that, if we desire full health and not just a reasonable facsimile thereof, then we must answer our bodies' needs in every particular and at the right time, but not in excess thereof. Simply put, Natural Hygiene is the study of discipline of total human nutrition and the application of its principles in one's daily living.

### **2.1 Putting Life Into Perspective**

In these fast moving times, in this period in our history when a constantly changing kaleidoscope of newly gleaned facts and details flood the media of the world about things and chemicals purportedly guaranteed to restore youthful beauty and health to the millions, Life Science (Natural Hygiene) represents an "anchor in the wind," a beacon of truth to guide the most weary and inspire the more informed.

If anything be certain in this world it is that life is change, that tomorrow we will not be as yesterday: that we can either be less productive, less healthy than we are today or that we can take positive, physiologically- and biologically-sound steps to gain something back of what we may have perhaps carelessly tossed aside because we formerly lacked knowledge or perhaps even thought that tomorrow would always be forthcoming in spite of all of our shortcomings and errors, known and unknown. Life Scientists, however, know that, within the parameters of the possible, tomorrow, our beauty and our very presence, will depend on the correctness of what we do this day, today.

If we are correct in the doing, tomorrow, our being and our beauty, will all be there. And, perhaps, as Life Scientists, each one of us, having reaped our own reward, can impart to others some of what we have learned and will continue to learn in this course and in reading other Hygienic studies elsewhere in an on-going effort to understand the most challenging of all studies, the Science of Life.

## 2.2 The Skin as a Part of a Complex Whole

The human skin is an amazing organ. Nothing is ever static about it. It is part of the living organism. Throughout, it is a functioning live entity, except for its outermost layer. Just as life itself is evidenced by activity, by change and motion of parts, so the skin is active in the sense that changes are constantly taking place, often very subtle changes invisible to the naked eye.

In fact, even the outermost layer participates in this change because, as dead cells are scuffed or rubbed off, they are rapidly replaced and this dead layer itself becomes a part of the ever-changing, ever-dying, and ever-rebirthing which is so characteristic of living things.

## 2.3 Quick Solutions

Because the skin lives and is constantly in flux, it is certain that when errors are made in body care and feeding, abnormal changes often exhibit in the skin. Manmade substances are not the answer when abnormality of any kind exists. Only the body possesses the inherent knowledge of what should be done, how it should be accomplished, and precisely when. As humans, we know so little about humans! About how we are made and how we function. Much of what is touted as scientific knowledge consists of estimates and guesstimates, not fully-established truth. Hopefully this discussion will provide facts and enlarge on truth.

For example, it is fact that, being a living entity, the skin must receive proper nourishment throughout the whole of life and that topical applications are never a long-term solution to problems and that they can often prove destructive to health and beauty. Face lifts and injections can provide only a temporary illusion of beauty and are unable to stem the tide of the degenerative effects of nonadherence to healthful principles of life. Life, being an ongoing kaleidoscope of change, demands total nutrition and care of person, including the skin. True beauty comes only as a response to total life care.

It is estimated that every square inch of the human skin is made up of 19,500,000,000 individual cells. This is amazing, but even more amazing is that all of these cells must work together harmoniously. They are required to serve in many diverse capacities, all of which influence the functional efficiency and performance of every other cell within the total human economy. We must pause to consider and agree that man is, indeed, "fearfully and wondrously made."

Like functioning cells, every cell of which the skin is composed is in and of itself a complete entity which is prepared to cope with all kinds of emergency situations. It possesses, among others, that amazing talent, resident only within the living, of knowing exactly how to heal its own wounds; this, of course, within the realm of possibility.

While a totally self-contained unit, it is at one and the same time a contributing member of the total synergistic society of cells, not only those which comprise the skin itself, but also those which make up the body as a whole.

Thus, the skin is an integral part of the living person and one which plays a vital role within the body economy which is both supportive and functional.

Just as the cells of the skin support the internal functions, it is, in itself, supported by that which lies within. It reflects, like a mirror on the wall, the condition of the inner SELF.

When the skin is ugly, pimply, coarse, puffy; and gross looking, it is conveying a message of internal disarray, it is telling its owner that that is exactly the way the inner body also looks and if we could hold a mirror to our inner self and examine it just as carefully as both sexes do with their faces, we might observe the inner man with some distaste and even revulsion.

The skin, just like the internal organs and parts, is subject to the same rules and regulations that pertain to every other part, whether it be bone, muscle tissue, nerve tissue, or other. Food for the skin must first be eaten, then digested, absorbed, and transported via the blood and lymph to each individual skin cell

just as food which is intended for the brain cells or for those in our big toe! Skin wastes must be eliminated as regularly as other body wastes.

If the mirror on the wall reflects a sick skin, it is giving us the word that the total body is also sick. As Dr. J. H. Tilden, M.D., one of the great early Natural Hygienists, so well said, "If the outer skin is measly looking, that's the way the inner body is, too!"

The skin is a living part of man and, if we wish to have a beautiful skin which will last for a lifetime, then it must be serviced by an inner self which functions, as close to perfection as possible. There is no quick magic road to skin beauty, no single or simple solution. Skin problems, such as rashes, itching, bumps, warts, or lesions of whatever kind, are, barring accidental injury, the result of errors in eating and living habits, errors which have caused the interior organs and parts to be reduced in their efficiency of performance to the extent that they have not fully performed their duties anywhere within the body economy including the part which we examine most closely, our skin.

The danger in looking for quick solutions to multiple problems always results in dashing our hopes and worsening an already worrisome condition. Salves and ointments can only serve, at best, to drive toxins elsewhere within the system either to remain as an encumbrance to total body performance or to add to existing debris. Regardless, in time, the poisons must emerge to the surface or create some havoc within some organ or tissue, thus further accelerating systemic decline.

We well remember a time when we were in London, England, and Dr. Elizabeth developed a rather annoying rash which was quite painful at times. This was long before we were "sold" on Natural Hygiene. We were still in the "exploring" stage and even yet wedded to the more orthodox methods we had learned at the various universities where we had studied.

We therefore sought medical advice for the rash and were given a cortisone-based ointment to put on it. In a few days the rash went away but we were soon to receive a very expensive lesson because a funny thing happened shortly thereafter. We had travelled on to Barcelona, Spain, and, "suddenly" Elizabeth came down with a cold which became so deep-seated that it kept her indoors confined to bed in the hotel for almost two weeks, all the while she continued to eat "three square meals" a day. She was so weak after that, that we were unable to resume our investigative studies for almost a month. This particular lesson was not only wasteful of money but wasteful of opportunity and time.

We had not as yet learned that it makes no scientific sense to palliate symptoms of a malfunctioning skin as we did by applying "remedies," per se. The skin is a living part of a complex whole. It must be fed through over 70,000 miles of channels by blood that is replenished from a common pool and which feeds the whole of man. The skin's outward appearance and condition reflects how well the total operation is proceeding and when it is sick, the entire body likewise suffers. To solve the skin's problems, we are required to answer the multiple needs of the entire body through total nutrition.

The new molecular biological sciences are enlarging our understanding of many of man's inner mysteries. Certainly the application of our knowledge of the manner in which all cells receive their nourishment underscores the futility of applying creams, lotions, and other manmade chemicals to the skin in the mistaken notion that they will transform a sickly skin into one that glows with vibrant health. Such is not the reality of the living man or woman.

In our work with our clients we must be cognizant of the fact that in the arena of actually practicing as professional Hygienists, we will be facing the reality of life, not the mirage of commerce. We must be able to convince our clients that when the diet and lifestyle are health producing, the skin will be health revealing! And, lest we forget, our own appearance should be such as to inspire those who seek our services to achieve some higher degree of perfection in their own lives by emulating us and putting into practice what we teach.

### **3. Structure Of The Skin**

In humans the skin is well-defined. Its membranous and cellular texture covers the whole external surface of the body. It serves to surround and hold its contents together. It continues over the lips, and up the nostrils proceeding into the innermost parts of the body.

The same membrane proceeds from the lips into the mouth and lines all of that organ's cavities. It covers the tongue and glands and extends also to cover and line all the parts of the throat and windpipe.

It leads to and through all the innumerable sacs of the lungs, lining the airways of that organ, branching so extensively therein that it presents a surface equal to and perhaps even more vast than the whole of the external body visible to the eye.

The external skin thus gradually fades into the internal but both represent a continuum, a melding together of sudden changes both in composition and functions.

The skin proceeds down the esophagus and into the stomach and through the whole of the intestinal canal. It lines all the ducts and tubes which open into that organ for purposes of servicing and feeding. It also lines all the cavities and organs in the body in a continuous and amazingly intricate network of extremely small meshes through which countless numbers of infinitesimally small capillaries, as many as 180 per square inch, wind in and out providing channels for blood and lymph as they course through and about the body performing their many and diverse duties. The multitudinous numbers of nerve tendrils also wind their own way within and without the membranous meshes and so numerous are these filaments of nerves and vessels that it is impossible to puncture any part without 'harming one or the other or both in the process.

All parts of this amazing network of skin cells must be both serviced and protected so that they can continue to function efficiently as defending and enclosing entities while all the while synergistically working as a single confining unit within an incorporated living system.

Through this vast network, internal man has contact with his external world. Through it and by means of its many passages must enter everything intended to become a part of it or which is intended for elimination from, the human body. It houses and contains, confines and molds, gives structure to all organs, systems and parts resident within the body, including over 70,000 miles of channels and tubes.

And, in the whole of it, there is no cleavage or break. It acts as a barrier to physical agents, chemical poisons, and other agents such as insects, molds, bacteria, and other parasites which might have a deleterious effect on the body tissues and fluids, including the blood.

It may not be vitally important for students of Natural Hygiene to be able to name all the many intricate parts of the skin but we do believe that all of us can get a better understanding of our own bodies and how we function and why it is so very important to have as corrects nutritional regimen as possible if we do become acquainted with some of the gross details of this very important organ, the human skin.

The skin, like all of Gaul, can be separated into three rather distinct, but nevertheless intimately related, parts known as membranes.

#### **3.1 The Outer Skin**

The outer skin is that part of the skin which all of us recognize as THE SKIN, the outer covering which we can readily see and touch, the part that holds everything else together and prevents this and that from wandering off and leaving us behind! It is known by various names such as the hide, the epidermis, the cuticle, and also as the scarf skin.

This outer skin develops from the ectoderm, the name given to the outermost layer of cells in the embryo. The epithelial ectoderm separates out at about the fourth week of fetal life and from that point

on the epidermis or outer membrane starts to develop and, in the process, splits into several specialized compartments.

The outer membrane or epidermis (in our discussion we will use the term epidermis) varies in thickness in different parts of the body. Sometimes it is thick, hard, and even horny in texture as, for example, in the palms of the hand (especially in laborers and other person who do hard work using their hands); or on the soles of the feet. It is interesting to note that these particular areas are somewhat thickened even at birth as if anticipating their future roles.

The epidermis is several cells thick and is composed of two distinct layers. The external or horny layer is made up of dead cells which are constantly shed from its surface. This layer is known as the stratum corneum.

The stratum corneum consists of slabs of flat, platelike cells which have no nucleus and thus no viable function. This is why they are called "dead" cells. They are dry and scaly and are continuously being sloughed off and then replaced, this process taking from three to four weeks. The cells of which it is composed are pushed up from the living layer which lies just below.

As new cells are born they simply move forward to replace those sloughed off. This is why correction of the diet produces rather spectacular and rapid changes in the appearance of the skin. Clients who may have consulted with skin "specialists" for years are, more often than not, greatly relieved and gratified with their new look after only a few months of following a more appropriate diet. You should be able to explain why from the information contained in this lesson.

The cells in the lower level form a single continuous sheet of somewhat flattened cells. This layer is also known as the stratified epithelium. Nature has been most ingenious in building this part of the outer membrane. Between some of the cells there is a thin layer of intercellular mortar, a kind of "stick-um" which is secreted by the cells themselves, the secretion holding one cell to the other, just as mortar holds one brick to the next.

There are still other cells which have intertwining plasma membranes which reach out "like the tentacles of an octopus," locking the cells together somewhat like pieces of a jigsaw puzzle. These intertwining cells represent the true barrier to the penetration of the inner sanctum by undesirable foreign matter.

The ingenious locking-together arrangement also blocks the pell-mell exodus of body wastes so that they can be sent to more appropriate and designated channels. This unique physical arrangement serves to keep the inner body intact and also prevents it from melting away during a heavy rainstorm or from going down the drain when we take a shower! It permits the skin, as part of a total nutritional program, to be bathed while, at one and the same time, the diluting force of water cannot adversely affect body fluids.

Some Hygienists have written us in recent days with respect to the dangers they believed might be inherent in polluted city tap water relative to bathing. The above arrangement should eradicate such concern although it is always important to use the cleanest water available simply because of the presence of chemicals in solution which can adversely affect the skin. But it is well to know that the water itself will be prevented from entering the system to any appreciable extent via the pores.

The epidermis is insensitive since it possesses no nerve endings. It has no blood vessels and, since the cells have no functioning capacity, they therefore require no nutriment. Thus it is that there is no provision for any kind of transportation mechanism to this surface collection of cells. It has no need for capillaries, for arterioles, so these are nonexistent.

Afferent and efferent nerve fibers end beyond this dead layer. Since they do not penetrate into it, this is why the epidermis itself is insensitive. Constantly we observe that, in the living body, where there is no need, the body does not provide! Thus it is that the body meticulously guards its resources. The epidermis also makes up the nails and hair, about which we will hear more later.

### 3.2 The Second Layer

The second layer of the outer membrane is the living layer of cells. It is known as the *stratum malpighii* or *germinativum*, meaning germinating layer. It is also known as the dermal layer or dermis. We will content ourselves with the name dermis.

The human dermis is a beehive of activity. Its complexity and design are cause for wonder. Irwin I. Lubowe, M.D., in his book, *New Hope For Your Skin* (as reported in "The Natural Way to a Healthy Skin" by the Editors of *Prevention Magazine*, Rodale Press, Emmaus, Pennsylvania 18049, 1972) reports that every square inch of the human skin contains the following:

- 78 nerves
- 650 sweat glands
- 19 or 20 tiny blood vessels
- 78 sensory apparatuses for heat
- 13 sensory apparatuses for cold
- 1,300 nerve endings to record pain
- 19,500 sensory cells at the ends of the nerve fibers
- 160 to 165 pressure apparatuses for the sense of touch
- 95 to 100 sebaceous glands
- 65 hairs and muscles
- 19,500,000,000 individuals cells.

We also know that our skin covers an area of some 24 square feet and can weigh as much as six pounds.

The mucous membrane is a term applied to that portion of the outer skin which lines the internal cavities of the body. There are three general kinds of membranes:

1. The outer skin or epidermis, which we have just discussed.
2. The fibrous membranes which surround all the bones, the cartilages and tendons and which also line the spinal canal and the cavity of the skull.
3. The serous membranes which line the closed cavities, such as that found in the abdomen. This membrane also surrounds all of the various organs resident within the cavities.

The specific purpose of the fibrous and serous membranes is to cover and line all the parts they service, to help hold them in their assigned positions, to secrete a special fluid which moistens and lubricates parts as they are caused to move one upon the other by body movements and activity, and to absorb any fluid which may, by one means or another, find its way into their field of operation.

The passageways of the inner body are lined with mucous membranes. All the various tubes for ingress and egress are lined with mucous membranes and anything which enters or leaves the inner sanctum must perforce pass through and over these membranous surfaces.

This membrane furnishes the appropriate tubes and organs for conveyance, exhalation, elimination, and perhaps other necessary functions. It also furnishes appropriate mucilagenous substances (mucus) as and when required and for a multitude of necessary body processes such as digestion.

The student can readily see that the skin is a part of every nook and cranny within the living body. Except for the extreme outer layer of cells of the epidermis, it is a wondrously alive part of the whole, and actively concerned in some manner with just about every function that takes place within the body. This is why its nutritional upkeep is so very important to the maintenance of a high level of systemic health. As the body is nourished, so is the skin nourished and as the skin functions in health it contributes positively to the health of the whole.

## **4. Functions Of The Skin**

Because of the vital role played by the skin in the body economy, its tonus or health, should always be maintained at a high level. When we understand the many important functions performed by the various membranes of the total skin, we can appreciate the fact that the skin does serve as a mirror of the inner state of body health. Obviously, it is not our purpose to go into great detail in this regard, but we can examine some of the more important functions performed by the skin.

The skin is a complete factory of many diverse enterprises: manufacturing, distributing, storing, and reproducing a variety of materials. It has very efficient collection, storing and disposal facilities. One of its major functions is that of sensitivity.

### **4.1 As an Organ of Sensitivity**

The human skin is the organ of feeling and touch. It is our chief contact with the world outside of the body. It is highly sensitive to heat, either external or internal. When the body gets overheated, usually from some unusual exertion or from fevers, the skin simply instigates an accelerated evaporation of water from all of its millions of pores, expanding them for this process. In this way excess heat is absorbed to power the transformation of the water to an escaping gas. The body is cooled by this process. When normalcy, or systemic comfort, is once again reached, the skin relaxes and the evaporative process resumes a more normal rate.

The skin is also sensitive to cold. We are enabled to survive extremes of external temperatures ranging from well below zero to as high as 200 degrees. When overly chilled, the body simply closes off the pores so that less water or none is evaporated, thus conserving body heat.

It is vitally important for the body's internal temperature to be controlled within rather narrow limits so that all the infinite numbers of biochemical processes we call life in action can continue with maximum efficiency. It is known that even a deviation of a single degree of temperature from the norm can be evidence of an existing pathology, of abnormal conditions within the metabolic pathways and byways, especially if the deviation persists for a prolonged period.

We must remember that the skin is actually an expansion of the nervous system. It has the ability to transmit two kinds of sensory impulses, that of touch and that of temperature.

There are two distinct sensations of touch, these being distinguished as pressure and place sensations. The palm of the hand is said to have 40 or 50 such touch spots per square centimeter. All over the body there are small areas which respond to cold, others heat. When it is cold outside, the skin simply closes up, as it were, and folds us in just a little bit more to keep in our body heat. In hot weather, it opens up more. We know that the skin's multitudinous nerve endings are so sensitive that the most minute sensations are duly recorded and appropriate messages transmitted to the nerve centers where they are interpreted and appropriate responses ordered, these then being carried out in due course by the cells of the skin. This almost instantaneous transmission of sensation and the orders for action in response thereto is the reason why it is actually unnecessary to take a cold shower following a warm to hot bath. When exposed to the colder air the pores will close automatically in response to even minute variations in the air temperature.

### **4.2 Elimination**

The elimination of a certain kind and amount of toxic wastes is one of the important nutritive functions of the skin. We are constantly surrounded by an invisible vapor consisting of toxic gases and water. We

literally walk in an invisible cloud.

Hygienists recognize that the least amount of clothing to provide sufficient warmth and prevent chilling is the most Hygienically appropriate attire for the maintenance of a healthy skin and body. All clothing should be of porous weave to permit the escape of body discharges via the skin. Closely woven fibers can prevent free passage of body wastes which can then back up into the system or collect on the surface to cause skin irritations and inflammations. Even a Hygienically-correct diet will not be conducive to superior skin and body health when tight-fitting garments are constantly worn.

This fact was dramatically demonstrated in Lou's case. Lou worked out-of-doors as a landscape consultant. He came to us with a severe skin problem. His back, underarms, and abdominal area were covered with sores which oozed pus. Lou's case history and diet profile revealed that, in general, he was in good health by present standards and that he ate a better than average diet avoiding junk foods, candy, and the like.

We observed, however, that at the consultation Lou was wearing a tightly-fitting T-shirt made of synthetic fibers, probably because he wished to display a rather well-developed upper torso. Upon questioning, we learned that Lou wore this type of garment to work just about every day. As our readers probably know the searing sun of our Arizona summers can be highly debilitating and, of course, Lou spent most of his daylight hours out-of-doors, both in winter and summer. His active life necessarily caused him to sweat profusely.

We advised Lou to discard his shirts made of all synthetic fibers in favor of shirts made of more porous weaves of cotton and to buy a size larger than he normally purchased. Inside of two weeks, Lou reported that his sores were already healing. A year later he called to tell us that he had had no recurrence of his problem!

Because our eyes can't see this invisible poisonous cloud, most of us are totally unaware of the fact that every day our skin, as part of the body's total nutritional process, pours off as much as two pints and even more of water and that this water contains many irritating contaminants in solution. Exposure of the body to moving currents of air encourages the cleansing effort as does providing passageways for exodus of gaseous wastes, as is done by porous weaves.

We should wear not only more appropriate clothing, but we should also wear less clothing. If we wish to maintain a well-nourished skin, we should also bathe frequently and change all undergarments at least once a day. Females should bathe the vaginal area following urination and males the penis. While orifices are self-cleaning within, their external surfaces are not.

Simply standing or sitting before an open window or in a passageway with free air passage without clothing for thirty minutes a day will help the eliminative process. If we obstruct the free flow of effete matter from the skin in any way, we cause the sewer lines of the body to become (logged with poisons backing up into the main channels.

To understand just how poisonous this discharged matter can be, all we have to do is to remind ourselves of what happens when the skin passageways are blocked. We have all read of heard of persons who have painted their bodies to produce a dramatic cosmetic effect. Death has often resulted within a matter of a few hours, death being directly attributed to a reverse flow of body poisons which were forced back because the way out was obstructed.

Clients must be made aware of the need for cleanliness and for keeping the pores open in order to maintain this important eliminating organ as a vital functioning unit. Intelligent choice of clothing and cleanliness is a part of proper skin maintenance.

### **4.3 The Skin and the Sun**

Another important function of the skin is to harness the sun's energy and to manufacture vitamin D. The skin, with its oils in the presence of sunshine, can synthesize this vitamin in several forms which can

then be absorbed into the body where it can help to maintain calcium balance. In our view, the importance of the skin and its relation to the sun as a remedial agent in many abnormal conditions is too often completely overlooked. Elsewhere in this course you have learned much about the effect of the sun's rays on the maintenance of health. For the skin to be maintained in good health also, it must likewise receive some exposure to the sun.

Physicians in ancient times used to maintain that sunshine was the best medicine in the world. We know that the sun's rays have germicidal power and tend to keep the pathogenic bacteria which may reside on the surface of the skin within reasonable numbers. When the entire body is well nourished, the skin will reflect this health but it can suffer, of course, from too much sun exposure.

The skin has a natural barrier against overabsorption of the ultraviolet rays that produce tanning. Students of Life Science already know that this tanning process should proceed slowly. Ideally, of course, it should start in infancy and be continued throughout the entire life span. A deep brown skin is an indication of natural protection and probably a well-pigmented skin could be exposed for much longer periods than that of most people without resulting in undue discomfort or damage.

In our experience many individuals who thought they could not tan have been able to do so by setting up a planned program in which exposure time was gradually-increased. Consistent and correct exposure of the nude body to the sun's rays is a vital part of the nutrition of the skin and without it no skin can be said to be fully healthy. To paraphrase a statement by Dr. Shelton, a pale thigh is certain proof of diminished health.

#### **4.4 Other Functions**

We have already mentioned, in passing, some of the other functions of the skin but let us briefly review. The membranes secrete certain fluids required for a variety of purposes. The skin is also an absorbing organ. It aids the lungs and stomach, for example, by taking up nourishment from without the body in the form of solids, liquids or gases, oxygen being the most important. Each cell must make its own energy so that its functions may proceed as required, so that it may carry on with the multitudinous numbers of chemical, physical and, perhaps, even electrical and other processes that are part of cellular metabolism.

We all have sick skin cells and we all also have healthy cells. If most of the cells in the skin are healthy, they will be able to maintain a working balance between their functioning duties and the elimination of their fair share of the metabolic wastes of the body.

However, the more diseased cells there are in the skin, the more disturbed body equilibrium becomes (known as dynamic equilibrium or homeostasis) and as a result, the integration of bodily function is reduced or even no longer possible in severe cases. The vigor of the important eliminating processes of the skin are always dependent upon the available energy supply. Cells enervated by toxic wastes become inefficient energy producers and thus become diseased.

Another function of the skin is protection. The skin can cope reasonably well with bruises, scratches, hard blows, and friction rubbing. When the latter, for example, becomes excessive or prolonged, the skin simply mobilizes its manufacturing facilities and produces a harder and thicker surface to act as a protective barrier, this being known to us as a callous.

A callous represents just one of the many defensive adaptive measures possible to the skin when it is confronted with danger. The human skin seems to come equipped with its own reparative supplies and with its own repairmen well-trained to cope with all common emergencies. It is fantastically self-healing.

When the skin is well-nourished and healthy, wounds seldom leave a noticeable scar. We personally had a marvelous example of the skin's ability to heal itself a few years ago when Dr. Robert, then in his 78th year, fell and suffered a deep gash over and across his whole eyelid. It extended up and across the brow

line. We applied no medication, simply washing it with distilled water to remove the dirt and blood and then applying a simple device to hold the parts together. In a few days the wound had healed and, today, there is no mark of any kind to show where the deep cut had been. Sometimes, and more often than not, the body, and especially the skin, can accomplish more when we leave it strictly alone to its own devices than when we fuss with it.

Another function of the skin is its flexibility. It can be moved in just about any direction we may choose. Whenever it is subjected to any undue pressure, it just bounces back and assumes a normal position once the pressure is removed. Perhaps the most remarkable talent of all is the skin's ability to grow as we grow and, in later life, to shrink as we shrink!

[Home](#) > [Lesson 61 - Nutrition And The Skin](#) > 5. Some Common Diseases Of The Skin

## **5. Some Common Diseases Of The Skin**

The skin is prone to diseases from external and from internal causes. Exposure to physical or chemical irritants can cause inflammatory conditions to develop. Contact with vegetable poisons such as that associated with poison ivy can have adverse effects as can sunburn from over-exposure to the ultraviolet rays of the sun. However, the most common cause of skin diseases is toxicosis or autointoxication.

### **5.1 As Recorded in Ancient Works**

Even a casual study of the history of the diseases affecting the skin reveals that man has not made any progress by treating them although he has become more or less expert in the palliation of their symptoms. There is a standard joke among professionals in the field of health care to the effect that a dermatologist, or skin specialist, has the best of both worlds: "he never cures anyone but he also never has to bury anyone!" Most skin diseases are not fatal and most physicians think that these disorders were devised as a cure placed upon the world for the special benefit of their coworkers, the dermatologists.

Throughout history at various times different cultures have attributed diseases of the skin to many outside agencies. For example, several thousand years ago the Hindus thought that skin diseases were caused by worms which invaded the body and established their breeding ground under the skin. In the Bible we read about various skin afflictions but especially about leprosy which was, apparently, a rather common malady of the times. Moses himself described two forms of leprosy, one being a rather mild form the other a malignant kind.

In Europe, during the Middle Ages and even later, whole peoples were ravaged many times by fevers and by outbreaking of the skin which was called the "Plague" or "Black Death." These plagues took huge tolls among the populaces of Athens, Rome and elsewhere, especially in Egypt and Syria. The scythe of the grim reaper made no distinctions among class or culture cutting across physical, cultural and class barriers.

We can read in the Bible about ten plagues of Egypt and it is said that God smote Egypt through the hands of Moses and Aaron in order to compel the reigning Pharaoh and the Egyptian people to depart from that country.

Today, armed with more knowledge, we can look back on these times and realize that, when the early Israelites wandered over the known face of the earth, that they often lacked proper food and shelter. They were in emotional disarray, dissatisfied, disgruntled and annoyed, not only by the hardships they had to endure, but also by the actions of their friends and neighbors. They were enervated and malnourished.

Additionally, these people were often forced to embrace both customs and food which were strange to them. Their food was unsanitized for humans. Living conditions were less than ideal. Their clothing, their person and their surroundings were, in all likelihood, filthy. It is little wonder that they began to develop running sores, skin ulcers, boils, carbuncles, and even more serious skin disorders.

In more modern times the word "plague" has been restricted to the bubonic or pneumonic plagues. However, during the last century and even in this present century there have been occurrences of smallpox and similar skin disorders which were termed "plagues." In fact, Dr. Elizabeth's maternal grandmother became a "victim" of smallpox. Her story is not untypical of the times in which she lived, the middle 1800s.

Her name was Elizabeth, too. Both of her parents having succumbed to the disease, at the age of 16, Elizabeth was left alone to die, all relatives having long ago fled from the house fearing that they, too, might fall "victims" to the curse. They joined the multitudes of peoples, who, in their terror, were trying to escape from the devastating unknown.

But, the young Elizabeth was not destined to die. As she lay deserted and delirious in her room, she was silently joined by a young merchant of the community who had long admired her radiant beauty and her lithe and graceful young figure. Hour by hour and day by day he unselfishly and lovingly ministered to her needs. He was a student of hydro-therapy. He applied cooling cloths to her brow and body until the high fever subsided and the young girl regained consciousness and became aware of the loving care. John, for that was his name, gave her no medicines but fed her nourishing broths. It was not long before the young Elizabeth regained her health and strength and, of course, fell in love with her kind benefactor.

Because of her devoted care and also because of her personal penchant for cleanliness and for all things natural throughout her lifetime, grandma suffered no disfiguring scars and remained a real beauty up to her death at the age of 87. The young man who had worshipped her from afar continued to do so all of his life.

Our favorite story about grandmother Elizabeth is how, whenever she or one of the children became ill, she would have the doctor come to the house, examine the sick and leave his colored pills and instructions regarding the care and treatment to be followed. No sooner was the doctor out the front door than our little grandmother would scurry out into the kitchen, open up the old coal stove and toss the pills into the glowing fire. Then, out the back door she'd go, into the garden to gather greens of one kind or another. Then, she would brew up her "tizzy," as she called it (a broth of greens). This would be the only food taken until recovery was assured. We believe that grandma Elizabeth was one of the first Hygienists! She had no faith in pills. The best place for poisons in her opinion, was on the open fire!

In this century, of course, there have been "epidemics" of acute diseases, especially of influenza, some of which are said to have caused the death of thousands upon thousands of people, as in World War I. We don't ordinarily consider influenza as a disease of the skin but from the knowledge we have already learned of the structure of the skin, we now know that that is actually what it is, involving, as it does, the mucous and serous membranes.

Up until recently, it was the custom to quarantine any person who developed an "infectious" disease of the skin such as chickenpox, measles, smallpox, and similar acute disorders. Only physicians, ministers, priests, and other persons of stature were permitted to enter quarantined premises.

Such precautions were deemed necessary because, at that time, the medical community and most of the people believed (and unfortunately most still do) that all such conditions were caused by an "infectious" germ or other microscopic organism that entered the body and produced the annoying pustule or rash. It was the general belief then, as now, that these demons of destruction could be airborne, passed on by sneezing, by touching an infected surface or person, and then they could "invade" the unwary victim's body to commence their devastating work.

This voodooistic theory of the origin of the skin diseases still receives enthusiastic support from a large

segment of the medical community, from drug combines and gadget manufacturers, but more and more thinking scientists are abandoning it in view of new microscopic revelations which have been forthcoming since the invention of the electron microscope with its confirmation of the existence of cellular garbage and the possibility of such having an adverse effect on systemic and cellular efficiency of performance.

Those of us who are students of the science of life believe that self-generated toxins are the basic underlying cause of all diseases, including those which affect the skin. We further believe that when these toxins are normally removed, they do not accumulate unduly within the system. Then disease becomes impossible. Skin disorders are a very unlikely possibility, except as resulting from certain traumatic happenings.

## 5.2 Herpes Simplex

As mentioned at the beginning of this lesson, there are so many different kinds of skin diseases that it is virtually impossible to imagine them, to say nothing of classifying them. However, probably fever blisters might be considered the most common affliction of man, and it is especially common among children in the one-to-five age group. It is characterized by groups of small, very itchy lesions which appear on the lips. With children, but more often among adults, these lesions may occur on the nose, face, ears, genitals, or any of the mucous membranous surfaces. They are considered by medical science to be the consequence of an "attack" by a virus but, strangely enough and unexplained by medical authorities, the condition is "self-limiting," that is, it usually disappears, the lesions healing, within a week or two. In medicine, this is known as "spontaneous healing." The virus is thought to remain dormant in the tissues, becoming active in the presence of "trigger mechanisms," these being fever, physical and/or emotional stresses, overexposure to sunlight, certain foods and, perhaps, even drugs. Medically, the disorder is known as "herpes simplex."

Life Scientists know that the skin reflects the condition of the body and it is interesting in studying the process of degeneration within humans to realize that, following enervation of the nervous system, that the digestive system is the first to give way to a condition which obviously can lead to widespread malnutrition. But, we must also note that enervation and reduced energy flow are due primarily to errors in nourishing the body leading to build-up of toxic metabolites. When the liver gets so overloaded with these metabolites that it is really struggling to maintain the "status quo," then it is that the "trigger" may tip the scales with resulting diversion of excess debris to the pore exit points.

Obviously, the method of "cure" should not be massive doses of this or that, the application of topical salves or ointments, but rather to get at the source of the trouble, poor nourishment and an intoxicating lifestyle. When the individual adopts a correct way of eating and living, the fever blisters and cold sores, and other skin disorders, soon become a matter of history and no longer a matter of concern. The fact that medical science must term this self-limiting disease, herpes simplex, seems to us just a way to keep patients coming back again and again, at great financial loss to them when, in fact, the "cure" lies within themselves. Some \$200,000,000.00 a year is spent on "remedies" to "treat" simplex!

Dr. Roger J. Williams has stated that, "The skin, partly because circulation does not supply it with copious nutrition, is notoriously sensitive to nutritional lacks." He states that the tongue, lips and gums are "favorite regions where nutritionists look to detect evidence of malnutrition." Of course, Dr. Williams advocates "dosing" patients with skin disorders with high intakes of specific vitamins, but our students have already learned that such practice can prove highly detrimental in the long run.

Using the fast to detoxify the system and realign nutritional forces within the system is the most rapid, most effective and least expensive method to rectify all skin and body disorders and, let us acknowledge, also the most beneficial.

It is interesting in considering nutrition and the health of the skin to note that diseases of the mucous membranes lining the oral cavity affect 75 percent of all adults over 50 years of age. Periodontal disease

is the most common condition afflicting these people. Medical science again, as always in their quest for isolated causes, attributes such conditions to long-term reactions of the body to certain bacteria and their products. However, more recently, four researchers from the University of Washington in Seattle presented a paper at the annual meeting of the American Association for Dental Research in which they stated that "very few people become sufficiently deprived of vitamin C these days to develop scurvy, which results in severely damaged periodontal (gum) tissues, but many individuals may not consume enough fresh fruit and vegetables to maintain adequate levels of this vitamin." Life Scientists have long known that few people, and especially in America, eat as they should. In fact, only Natural Hygienists have any concept of what a physiologically correct diet encompasses, namely, eating a preponderance of fresh ripe fruit with limited amounts of leafy green vegetables, non-sweet fruits, nuts and seeds, and eating these as and when required as evidenced by true hunger and in amounts not in excess of body needs. Eating this kind of diet contributes to a smoothly grained skin, faultlessly perfect, wrinkle-free and radiantly beautiful. This kind of eating carries a guarantee, all other life practices being equally conducive to superior health: the kind of beauty that lasts for a lifetime—a much longer lifetime!

### **5.3 Diseases of the Skin as Outer Manifestations of Inner Toxicity**

The skin is always talking and revealing. It can reveal to a competent observer just how well the body is getting along, whether the pathways are clogged with litter or whether the fluids, especially the blood, flow free and clean. When the skin looks like fine pinkish porcelain, it shouts to the world that the body is radiantly alive. But, when it is dull, pale, or yellow in hue or when it has enlarged pores or an abnormally deep flush and pimpled surface, is wrinkled, or has that deadly grey look, then it tells an unhappy story.

Such a countenance reveals a pathetically encumbered inner world, the pathways and byways of which have become obstructed, saturated, the blood thick with debris; debris that is silently and stealthily burning and irritating, working to destroy the tissues of the body. It tells of metabolic avenues and cell factories filled with garbage and of millions of enzymes floundering helplessly in the face of so much toxic wastes. The cause? Systemic malnourishment—inner toxicity.

### **5.4 Some External Signs of Inner Toxicity**

1. Excessive paleness which may be indicative of:
  - Anemia
  - Dysemia (any abnormal condition of the blood)
  - Leukemia
  - Bright's Disease
  - Amyloid Degeneration (occurs characteristically as pathologic extracellular deposits beneath the layer of flat cells of capillaries and arterioles. These deposits interfere with normal function and can lead to very serious disorders including infarction of the heart and even cancer.)
2. Paleness combined with profuse sweating and strong acid odor:
  - Articular rheumatism
  - Strong emotional outbursts: uncontrolled anger, fear, jealousy, etc.
  - Spasms in the arteries and veins. Fainting spells.
3. Redness of the skin:
  - Capillaries in the face may have a tendency to burst.
  - Too much blood concentration in a particular area.
  - An abnormal state which can make the individual stroke-prone.
  - If frequent headaches are also present, there may be present some congestion in the brain.
  - When combined with swelling and mild scaling visible on the skin, the skin may be

photosensitive at this time with a more gradual exposure to develop pigment advisable. Extreme saturation of tissues and organs with animal protein wastes.

4. Shiny, tight, skin:

- Due generally to a previous history of high salt intake either in foods such as canned vegetables or applied topically to foods.
- Due, also, to excessive drug taking, both prescribed and over-the-counter drugs are chemical compounds containing sodium, the main ingredient of table salt and the causative agent in most cases of shiny tight skin.

## 5.5 Relation of Cause to Effect

By this time in your studies the student should be convinced that saturation of the fluids of the body, especially the blood, with toxic metabolites and/or other poisons is the underlying cause of all diseased conditions, exempting, of course, those directly attributable to some major trauma. This is true of skin disorders also.

Certainly we can say without fear of contradiction that no person should be considered even reasonably healthy who has a sick skin, especially when the condition persists. The acne of the teenager is a forerunner of more involved diseases to come, while the more serious and vertical skin conditions such as chronic eczema, psoriasis, ichthyosis (fish skin disease) speak a language all of their own and are the visible signs of cellular malfunctioning, organic degeneration and systemic pollution, all of which have been brought about by faulty eating and living habits. They are certainly not the product of a sudden invasion by germs, viruses or other unknown "demon."

Once the real cause of the disorder has been determined and then removed and a more physiologically sane method of eating and living has been established and then maintained for a sufficiently long period of time, the skin disorder, regardless of its nature or origin, usually disappears and thereafter can be kept under control.

Often unnecessarily, over the years, the once beautifully clear complexions of the very young become wrinkled and old-looking, filled with coarse pores and so often marred by disfiguring moles and blotches. Deep-seated wrinkles, once established, cannot be eradicated but, with a well-planned and scientifically-correct total nutritional program including correct food, sunshine, fresh air, cleanliness, exercise, and all the other requisites of our organic existence, then much can be accomplished. The body fluids can be cleansed and the liver and kidneys restored to some semblance of normalcy which will be reflected in a younger looking, more elastic skin.

Frequent attempts have been made throughout modern times to classify the multitudinous numbers of skin disorders, but the task is well nigh impossible. There are numerous divisions and subdivisions in the nomenclature.

When the extreme outer skin is affected, any of the following common skin conditions can develop:

1. Numbness which often accompanies other common skin disorders.
2. Chronic or acute eczema characterized by papules, vesicles, crusts and scales. Generally accompanied by itching and/or burning.
3. Ichthyosis, a condition characterized by a lessening of flow from the sebaceous glands with scaling. Generally accompanied by severe itching. Can afflict any part of the outer skin.
4. Psoriasis, an eruption covered by silvery-like scales which characteristically "flake off." Generally found most prominently on the elbows, knees, scalp and trunk but can also be found around breasts and in the groin area. Rarely does it cover the entire body. (See Case Study—John to follow.)
5. Plus numerous other similar, but slightly differentiated conditions, some of slight concern, others of major concern as the various forms of lupus (an inflammatory condition which may be localized, usually in the face, but also general as in systemic lupus, an idiopathic disease,

meaning of unknown origin, according to medical thinking).

The mucous membranes normally secrete a clear mucus which serves to keep them moist. The outer layer of cells of this part of the skin is equipped with microscopic flagella which are in constant motion. These serve to propel any kind of irritant or foreign substance to some point in the body where they can be more readily eliminated.

All of the activities of the skin are under the control of the thyroid gland located at the base of the neck. Sometimes this gland will direct the mucous membranes to assist in an eliminative effort if the body is under great stress. In such a case, the toxins will be forced out through the mucous membrane cells. During such times polyps or other growths may form. Polyps can appear in the nasal cavities but also in any part of the alimentary canal where they can prove most troublesome. Generally, polyps respond quite well when a sound hygienic program is instituted. We recently were consulted by a young woman schoolteacher who had already had three surgeries for nasal polyps and was anticipating a fourth. We made abrupt changes in her dietary program from the traditional meat and potatoes diet to an all raw diet composed of fruits, leafy green vegetables, fruit vegetables, nuts and seeds and within three months, upon examination by the consulting specialist, an operation was no longer required!

If the elimination process is unsuccessful or only partially so, then the individual may develop a "cold" or a mild case of "catarrh." If the toxicity is permitted to increase, deeper layers of the mucous membranes can become involved and the discharge will consist of a combination of mucus and pus.

When this latter condition develops, we observe such diseases as the following:

- Appendicitis
- Bronchitis
- Cervicitis
- Enteritis
- Gastritis
- Mastitis
- Pyelitis
- Sinusitis
- Tonsillitis

and other "itises" which involve the mucous or serous membranes including, among others, the following: arthritis, bursitis, encephalitis, iritis, meningitis, neuritis, pericarditis, peritonitis, and so on.

While not normally considered as diseases of the skin, the student will readily see that, by the very nature of skin construction, this is exactly what they are, one and all, without exception.

It is interesting in this regard to know that by correctly evaluating the kind of condition which has developed, it is possible to gain a pretty fair idea of which organ in the body is the more involved.

The lungs act as a substitute kidney, the outer skin as a substitute liver, while the pancreas enlarges its normal operations to compensate for a malfunctioning and/or overworked liver.

The worst kind of skin diseases and the hardest to eradicate are those caused by severe protein-poisoning because these are usually longstanding. Studies seem to indicate that it takes about twenty years, at least, of indiscriminate feeding of refined carbohydrates and animal products before the presence of major disorders begins to be revealed. The intervening years are characterized by minor disorders beginning with the first sniffle in infancy and early childhood, the acne of the teenager, the later itches, wheezes and sneezes, and ending up in the mature years with the embarrassment of psoriasis, the pain of rheumatoid arthritis, or other major catastrophic vertical disease (meaning progressive).

Man simply does not possess the metabolic machinery to cope with the modern senseless deluge of sugars and meat, nor with, the heterogeneous concoctions of chemicalized substitutes quaintly described as "food."

To those clients who are afflicted with skin disorders of whatever kind, and especially when these have already established chronicity, it must be made crystal clear that they have a choice: the present skin condition, an unsightly appearance and a constantly diminishing vitality, OR the acceptance of certain restrictions and the introduction of a new way of eating and living, all measures which will help to restore a more normal systemic health as well as clarity and beauty to the skin.

## 5.6 Behind the Scenes

When an unhealthy, scabby-looking animal is killed and then dissected, the organs of the corpse will be seen to be diseased also. A scaly, pimply or ulcerated skin likewise tells us that the entire inner body is, more likely than not, to be in the same state, in a rather advanced state of malnutrition and deterioration. The rashes and pimples so casually treated on the outside also deserve attention to the whole body.

Quite often the very same ulcers and measly appearance visible on the outer skin have been observed in autopsies of humans who have died from "sudden" illness of unknown origin. Dr. Robert W. McCarter, Sr., M.D., at one time stated that autopsies such as these showed that most of these individuals could have died from any one of ten different diseases, so far and to such an extent had malnutrition caused systemic degenerative malformations.

A healthy skin sings of a well-nourished body, of systemic equilibrium, of balance, of homeostasis, of sound living practices, of good inheritance, of vitality, of a clean, free-flowing unobstructed bloodstream and of organs functioning silently and efficiently in a body at peace. But, what causes the sick skin?

If we place a fermenting mass in a bottle and close it up tightly with a cork and then put it in a warm place, some perhaps drastic results may be noted. It won't be very long before the force generated by the gases bubbling inside the bottle will cause the cork either to give way or the bottle to explode?

Dr. Elizabeth well remembers a time forty or so years ago when she was serving as a physical education instructor at a penal institution in the East. She was called upon in an emergency to supervise in the kitchen during the canning season. The inmate temporarily designated to supervise the canning was inexperienced at canning corn, as was Elizabeth, but, since the corn was arriving in truck-loads from the fields, all the inmates went ahead with their own version of the proper way to can corn.

Before the day was done glass jars of corn decorated table after table in the huge kitchen. There were hundreds and hundreds of the two-quart glass jars. The crew went to bed that night happy that their work was successfully accomplished.

In the morning, Elizabeth went to the kitchen to inspect. She found, to her dismay, that most of the jars had exploded! Corn covered the tables, the floors, and was even glued to the ceiling! She said that that was the first and the last time she was ever involved in the canning of corn.

So it is in the human body. When the toxic condition of the body becomes so great, the pressure simply becomes intolerable, the mass swells and becomes intolerably large; the channels which normally dispose of metabolic waste find that the load is beyond their present ability to handle. All organs and systems are being subjected to degenerative poisons. It is then that the liver and kidneys must request assistance to preserve the integrity of the body (its life).

The interpretive and control centers in the brain then redirect body energies and call the skin to urgent duty. It must perform extraordinary vicarious duty as an auxiliary eliminating organ. Otherwise, the system might burn up from the heat generated systemically.

Even though it is the largest organ in the body, the skin is not normally a major eliminating organ. The lungs, however, and kidneys, with the liver being the great body filter and organizer y normally, are entrusted with, this responsibility and well capable of carrying it on successfully. However, in emergency situations, the body will forcefully eject its excess gases, acid sweat, toxic oils and greases out through the pores of the skin and also through temporary exit points devised for the purpose, those being called boils, pimples, rashes, ulcers, and so on. Itching is a typically annoying symptom

characteristic of the exodus.

The client must be made to understand why the abnormal skin condition exists, that it is the outward manifestation of a badly contaminated interior. Not that an infection exists, but rather that undue acid wastes have accumulated with possible damage to the liver, to the nervous structure and perhaps even to all systems and organs with the result that they are no doubt functioning at a reduced capacity as they strive to accomplish their allotted duties while working under greatly enervating conditions.

The outward violent exhibition is the visible evidence of the turmoil that exists within, of the fact that the blood is so saturated with toxic material that the body itself is attempting to eliminate the excess before irreparable damage can be done.

When the skin condition becomes chronic and/or acute, the visible symptoms will, more often than not, be accompanied by fever, as for example, in measles and other so-called "childhood diseases."

When the body vitality is high, the skin eruptions can be very violent but if it is at a lower level (as is generally true in the elderly), then the disorders will be either milder or will have become chronic. The outward manifestation is always dependent upon these factors:

1. The existing vitality.
2. The systemic weakness.
3. The amount and kind of impurities which are present.

When the exodus of toxic material becomes so great that the glands and follicles of the skin themselves becomes obstructed or injured in any way, then we usually witness the development of abnormal growths, such as warts, benign tumors, moles, and the like, some of these being of enormous size. We have observed one such growth which extended some eight to ten inches along one thigh and several inches across. One client had a very noticeable wart which protruded right out from the tip of her nose. After two prolonged fasts and two full years of hygienic living, this disfiguring wart was finally autolyzed.

When the exodus is mild and the symptoms likewise mild, we generally find that there is no fever present.

It is well to know that skin diseases usually become chronic in those persons who develop them early in life and continue to have them periodically throughout life. The periodicity is due to the fact that such individuals begin to develop levels of tolerance which are higher and higher. Indeed, the symptoms may disappear for years and then reappear. As the level of tolerance to systemic poisons increases, the vitality of the individual decreases. From time to time, especially when a person is under unusual stress situations, the poisons which exist begin to exceed whatever level of tolerance has been established and, at such times, a "sudden" eruption can occur.

Once the toxic burden slips again below the existing level of tolerance, then the condition, whatever it may be according to individual weaknesses, the skin begins to clear until there are no further outward signs—until, of course, the next time! No "cure" has been effected. All that has taken place is a certain amount of elimination which has reduced the toxic load to a level whereby the body can function albeit with diminished vitality.

It is worthy of note to observe that those persons with vigorous circulation are more likely to have eruptions on the surface of outer skin; for example, on the face, back, neck or elsewhere, while those possessing a somewhat reduced circulatory power will usually suffer from eruptions on the surface of the mucous membranes, especially those lining the nasal cavities and the digestive tract. Usually these latter persons have highly-inflammatory and catarrhal conditions, with the colon being a frequent location for such. It is common for persons with diminished circulatory powers to be afflicted with all kinds of digestive disorders, often quite serious, these leading, of course, to increasing malnutrition.

The prognosis is always more encouraging when the eliminating effort is made through the outer skin. Generally, if all contributing causes of toxic build-up are removed, and especially incorrect habits of

eating, and this is followed by a more constructive dietary—living regiment, then the eliminating effort should be successful in time.

It is important at this juncture to emphasize most emphatically to all clients who consult with you regarding skin eruptions that, after the cleansing has been accomplished and the healing has taken place, any resumption of old habits of eating and living will, in all likelihood, plunge the individual into an even deeper pathology than before, due to the fact that the body's level of tolerance has been lowered while, at one and the same time, his vitality has been increased. He has already demonstrated his vulnerability!

As we examine the masses more closely we can observe the progression of skin diseases from bad to worse. Young people build their pimpled and mottled oldish skins on their hamburgers, french fries, and cola drinks. School lunch programs add to the problem. Here in Tucson, a "Type A" lunch is made up of a hodge-podge of heterogeneous digestive problems artfully disguised as a protein, fruit or vegetable, bread and milk combination scientifically planned to contain the FOUR BASIC GROUPS.

A meal planned thusly is sufficient to confound the most vigorous enzymatic capabilities even of the very young. In recent years peer drug use has become a serious problem, not only among adults, but also among the high school crowd.

And have you looked at the skins of infants and toddlers? Gray, sicklish products of baby formulas and canned processed baby foods, of soda pop and Kool-Aid and other chemicalized poisons.

Older people gorge on pies, cakes, steaks, soft drinks by the carload, on processed products of every imaginable kind often accompanied by alcoholic drinks; they nibble at all hours and fail to get proper rest: they down all manner of drugs, prescribed and over-the-counter. Like children offered candy, they enjoy and then wonder why they break out with rashes and pimples and are lacking in vitality!

## 5.7 Cosmetics

Probably just about every woman in the civilized world (and in recent years, many men, loo!) has been entranced by the advertised promises of youth eternal as depicted in demographically targeted advertisements. But, contrary to all of the seductive avowals, the skin cannot be fed externally. Its beauty comes from deep within!

We have previously pointed out how the pores act as exit points for certain kinds of waste metabolites. It is vitally important for these cleansing avenues to be kept open and clean so that all toxic material oriented to these exit points can be discharged according to systemic planning.

It should be obvious that using creams, oils, powders, or other common cosmetics can serve only to clog up an important segment of the body's sewer system. Industry makes billions of dollars catering to a woman's natural desire to be young and beautiful and for a man to be a "Number 10," but it is a sad fact that all such concoctions only cause the skin to wrinkle and age prematurely.

The sebaceous glands, which lie deep within the skin are, in fact, excellent cosmeticians and especially so when the entire body is healthy. These glands manufacture a fine face cream which contains various waxes and fatty acids which serve to keep the skin moist, pliable, wrinkle-free and young-looking. They can do a far better job than any product devised by a laboratory technician.

No foreign substance from the outside belongs on the skin. Nature has provided well for the *entire* body. As Dr. Virginia Vetrano so well said in an article entitled, "The Skin. Our Natural Umbrella," featured in *Dr. Shelton's Hygienic Review*, June 1979. "Nature puts there what she wants and that's the way we should leave it."

Thus it is that any extraneously applied substance will annoy, irritate, clog, and eventually wrinkle and age the skin and if the foreign substance should penetrate the membranous barriers of the surface cells, perhaps cause some amount of harm in the body cavity itself.

The living skin cells must cope with the very same problems and challenges common to all living cells. They must secure food from the blood, they must repair or replace any old and worn-out cells. They must take the food supplied to maintain and build on the skin. They must reproduce as and when required to sustain the larger community of cells which they enfold and protect, the entire body. It would appear to be the height of folly to place road blocks in the way of potentially efficient feeding and eliminating processes by applying creams, lotions and the like to block transport.

Certain skin problems have been known to arise from outside applications which have blocked exodus of systemic wastes, conditions such as dry, scaly, itchy skin; red, swollen eyelids, rashes on the neck and behind the ears accompanied by intense itching; abnormal deposits of pigment on exposed areas such as the cheek; and swelling, peeling and rashes around fingernails and even under them. Often such conditions are termed "allergies" and treated topically when simple abstinence from the use of all cosmetics coupled with a Hygienic diet quickly removes the problem.

It is interesting to know that there are about seven million pores (exit passages for wastes) and they represent some seven or more miles of leading duct sewer lines. Each duct acts like a miniature sewer pipe, complete with valves that can be turned on and off according to the conditions at hand, all control being handled by the autonomic nervous system.

The ducts from the glands are built in a spiral from which is so ingeniously designed that it is well nigh impossible for foreign materials, "cosmetic foods," to enter the inner sanctum, through these pore barriers. Oxygen from the air may be the sole exception.

In *Foundations of Health Science*, Second Edition, 1972, authored by Henkel, Means, Smolensky, and Sawry and published by Allyn and Bacon, Inc., Boston, Mass., we read the following: "There is no known substance or combination of substances that can live up to the promises suggested in any of the following names: contour cream, crow's-foot cream, deep pore cleaner, eye wrinkle cream, scalp food, skin conditioner, skin firmer, skin tonic, eyelash grower, or wrinkle eradicator."

However, science marches on—sometimes penetrating into strange uncharted, and perhaps even dangerous, waters. The skin is such an area. Dr. Vetrano again in an article entitled, "The Skin, Our Natural Umbrella." in the *Review* of June, 1979, tells us that "pharmacologists have long been engaged in finding formulas that will penetrate our membranous barriers, either the skin or our mucous membranes, or the cell and its nuclear membrane" and let us add, to date they seem to have had some success. A to be making more and more "progress" in this regard. It would seem that our scientists can never give up tinkering with the nutritive process of the human body.

Some substances are used to convey drugs and other substances through the skin, either for cosmetic or other drugging purposes, the practice increasing with each new discovery. These materials are either damaging to the skin itself and/or to the entire system. In our view, they should be strictly avoided.

[Home](#) > [Lesson 61 - Nutrition And The Skin](#) > 6. The Hygienic Practitioner At Work

## **6. The Hygienic Practitioner At Work**

### **Steps to Take**

#### **6.1 Step One**

On first meeting it is advisable to become better acquainted with your client. To save time, this may best

be accomplished, at least at this time, by having him fill out a form which, in essence, details his medical history and present symptoms. The client should also provide a diet profile, if it all possible, for at least a two-week period. On subsequent consultations, as may be required, give-and-take conversation will provide much insight into the client's more intimate habits of eating and lining, especially as to his emotional health, his knowledge of Hygiene, and so on.

## **6.2 Step Two**

We must begin the treatment of skin disorders, or indeed of any diseased condition, by first keeping OUT of the system anything and everything that could, in any way, contaminate the body. Care must be taken in elimination of possible contaminants and here is where the practitioner must use good judgment. In general, corrective steps can be taken much more quickly with younger clients than with those who are more mature. Sometimes, also, corrective steps are more easily accomplished with one sex than with the other; as, for example, eliminating the use of cosmetics such as face powder with women or certain hair products with both. Experience will broaden one's skill in this area. In this category we include any and all drugs including familiar over-the-counter drugs such as aspirin, Tylenol, and the like; also, salt, sugar, condiments of all kinds; stimulants and depressants, such as alcohol, meat, eggs, cheese, fish and poultry, cereals, and all products made from cereals; and so on including a wide variety of packaged processed foods, candies and the like.

## **6.3 Step Three**

Detoxify the body. A total fast under supervision, preferably at a Hygienic institution, should be instigated as soon as possible as conditions warrant. Most of your clients, at first meeting, will be totally unfamiliar with Natural Hygiene and will come to you by referral. They may be totally "turned off" by fasting. Therefore, it is appropriate to begin a planned educational program using the materials you receive in this course of study and those in your own library.

In many cases a series of short fasts starting with 24-hour fasts and gradually extending the fasting time to 36 hours, then to five days and eventually to seven and, in some cases, to ten days will prove feasible after a suitable period of orientation as to the benefits accruing to fasting. In other cases, especially if your client is elderly, you may have to proceed without the initial detoxification by fasting. In this case the client must be made to understand that the cleansing of the system will require a longer time and that he should not expect immediate results.

## **6.4 Step Four**

Change the diet. There is nothing to be gained by making changes gradually and everything to be gained by changing immediately to a physiologically-correct diet, such as has been outlined in these studies. With new clients, it is well to present them with a specific dietary regimen to follow until they themselves have become familiar with Hygienic principles and food combining rules as based on human physiology.

While abrupt changes are preferable, they may not be feasible for one reason or another. Children are open to change. Some young adults are, also. Rarely are mature adults, especially after the age of forty, either willing or able to make an abrupt about face in their dietary intake. Peer pressure, cultural mores, indeed, any number of societal reasons will make such a transformation difficult. Additionally, too rapid a change may produce a flood of adverse symptoms, including a worsening of the present skin condition, to the discouragement and even dismay, of the client.

Where abrupt change is inadvisable, the client should be placed on an extended detoxification plan; eventually, of course, on a fruitarian diet.

Provide your client with something concrete to take home with him: a change in diet, or in his exercise

program, etc., this at each visit.

## 6.5 Step Five

Make Changes, as advisable, in the client's lifestyle. Among such changes might be the following: a planned exercise program, one commensurate to the client's present capacity with a gradual working toward his potential; sun- and air-baths as well as planned rest periods. Emotional problems may be present or may present themselves during the course of education. These will have to be resolved as best they can by cooperation between the practitioner, his family and friends, and himself. Cleanliness must be emphasized and, if necessary, the client must be instructed in how to take a bath, wash the hair and so on. In fact, the client must be instructed in all phases of Natural Hygiene. It is well to do this by following a planned course of instruction. Here at the ranch, we advise all clients on the first visit that they must embark on a program of education in the principles of Natural Hygiene. Most agree to do so, out of curiosity, in some cases, and because they feel that they must, in others. We advise our clients that the more they learn about how to care for their bodies, the more quickly will they learn to care for themselves in such a way that they will have no future need for medicines, vitamins, or medical advisors. One couple we know took us up on this promise and after the very first year flew to Hawaii and took a tour around the islands on the money they saved by not buying supplements and medicines and making office calls to their former health advisor! Incidentally, by that time, they had both recovered from their illnesses, the wife from the pain of arthritis, the husband from a long-standing skin disease.

## 6.6 Step Six

Expect clients to make errors and to regress. This is understandable and to be expected. Only a very few will go from A to Z in an absolutely correct progression. We have a nurse who regularly comes and confesses her transgressions. She then picks up again, resolves to do better and each time she progresses just a little bit more. In such cases, patience is indeed a virtue. Holding forth the goal of the joyful life, as we like to call it, continuously, if need be, is your best tool. Ask more successful clients to assist you. They are often willing and even delighted to share their experiences with newcomers to the Hygienic way of life. Telephone support can often keep a client on his chosen path, especially if it comes from someone who has also experienced his pain, his embarrassment, his frustrations. Additionally, giving support to others also gives support and confidence to the giver!

We suggest holding meetings from time to time. We occasionally hold a potluck luncheon here at the ranch. Clients and students exchange experiences. They usually leave inspired to reach their individual goals. We also give public lectures and encourage our clients to meet and talk with those members of the public who attend. Most are more than willing to share their experiences. These lectures are usually devoted to a single topic of interest as, for example, psoriasis. The sharing of success stories by your clients helps also to bring new clients to you.

## 6.7 Warts and Moles

In his book, *Getting Well*, Dr. Herbert M. Shelton says that, according to medical "science," little is known about the cause of warts and similar outgrowths of the skin.

In *The New American Encyclopedia*, revised edition of 1939, we note that warts are "due to excessive growth of the skin." No other speculation is given and no explanation of why the skin should evidence such abnormal growth. A 1979 edition of *Funk and Wagnalls Encyclopedia* states positively that warts, or averruca, are caused by viruses and that treatment involves the use of local medication initially and, if they return, by freezing, with dry ice, X ray, burning with an electric needle, or surgical removal. This edition points out that plantar warts, those that develop on the soles of the feet, are especially hard to treat and remove.

Shelton believes that warts and probably other disfiguring skin manifestations of a similar nature, are due to a perversion of nutrition, perhaps due to some local irritation such as dirt, cosmetics (as for example, after shave lotions which contain harmful irritants or drugs), or by internal toxicosis.

Dr. Shelton emphasizes external cleanliness and says that when external cleanliness is supported by all other Hygienic measures—fasting, improved diet, exercise, sun-baths, etc., the wart often disappears.

Occasionally, in stubborn cases, recourse must be had to the blue lens, a device used to concentrate the sun's rays on the affected area(s).

One case we worked with is especially interesting. This woman had a very unusual mole on her back. It was very black and about the size of a half-dollar, sat on a pedestal, elevated about 1/4 inch above the skin surface. It was disfiguring and annoying, even painful should she happen to sit in such a manner as to put the mole in contact with a hard surface.

This woman had been advised to have this mole removed surgically but she was reluctant to do so, so she sought our help. She elected to fast and to follow Hygienic principles. Nothing seemed to happen to the mole but after a time, her other ailments gradually began to improve including what had been a severe sinusitis and frequent aching in various joints.

Little by little, this huge mole began to peel, small pieces breaking off at times. By this time our client was a raw fooder and a fruitarian.

Recently, some fifteen years after her initial decision not to have surgery, she told us that all that remained of this once monstrously disfiguring and annoying mole was an almost invisible dark spot, about 1/4 inch in diameter, a mark that was perfectly flat on the surface of her skin. The mole was no longer a matter of concern.

This case study illustrates McCarter's Law that "sickness begets sickness, but health begets health." In other words, if we are sick and do nothing constructively to improve our living and eating habits, we will grow sicker but. if we improve our health by healthful living and continue to take a positive direction in our lives, we will just keep on getting healthier and healthier. And, experience has demonstrated often enough to us that we are able to say with confidence that this law applies to all skin diseases, too!

## **6.8 Finally**

It is important for all those who suffer from skin disorders, from lupus to eczema to psoriasis to ulcers of the stomach, to realize that they cannot return to their old ways. They have already demonstrated a systemic weakness. Should they regress and return to their former practices, they would soon find that old, and perhaps even new, ailments would appear, some perhaps even more involved and annoying.

The client must be made to realize, that the mouth is an open door either to superior health or to diminished health. It is also the open door to skin diseases of all kinds, particularly when external cleanliness is neglected. He must be impressed with the fact that the ways, of health are not destructive ways; rather that they are most gentle and always in the direction of perfection.

If the student has arrived at the conclusion that the basic treatment for all skin diseases is one of complete body cleanliness, inside and out, coupled with a physiologically correct diet and an appropriate lifestyle, then he is correct. The only way to skin and body health, and the two cannot be separated, is to employ all known means of health.

## **6.9 Case Study—John**

John was a reluctant student of Natural Hygiene. His wife first attended classes here at the ranch while John strolled around outside admiring the desert flora and fauna. His reluctance to consider new methods of healing were understandable. He had suffered from psoriasis for over thirty years, had

consulted innumerable specialists in skin care and had tried all the remedies prescribed and many nonprescription remedies. He had tried many diets and had taken vitamins and other supplements by the carload. His search for a "cure" had borne no fruit. Patches of the dread disease appeared on various parts of his body. His face was almost brick-red.

When Dr. Robert learned that John was on the ranch he persuaded him to come in and at least to give us a fair hearing. That was the beginning of a successful story and of a changed man. From that moment on both John and his wife became ardent students reading everything that we had written and works that we suggested to them. They began slowly to incorporate what they had learned into their daily lifestyle. They gradually reduced their intake of animal products, soon took up golf and hiking. They started their own garden and began to incorporate what they had learned into all phases of their lifestyle.

Gradually they introduced fasting into their program, starting at first with 24-hour fasts and then extending them first to three-day fasts and eventually to five-day fasts. The changeover has been consistent over the last three years.

They did not make sudden or profound changes but rather "grew" into a much improved program for living.

It has been most interesting to watch John's progress. First, the extreme reddish hue of the face began to subside. The lesions grew smaller, the sloughing off of cells less [noticeable on clothing, patchy areas began to recede, some completely disappeared. John's psoriasis is now under control.

It is interesting to know, however, that when John deviates from the Hygienic diet, as he does occasionally, he receives the bill! Most of the lesions now are in obscure parts of the body but on these occasions, almost without exception, a new one will open up on John's face! That soon puts him back on the Hygienic path once again.

## **6.10 Case Study - Sandra**

Sandra came to us about two years ago with diagnosed dermatomyositis, a condition characterized by muscular weakness with a nonspecific eczematous skin eruption or urticaria. According to *Stedman's Medical Dictionary* the "muscles are tender, and owing to weakness the patient is unable to perform normal tasks. The condition is progressive; it commences with erythema (inflammatory condition with redness) and swelling of the eyelids, face and parts of the limbs); muscular weakness succeeds the skin changes. The pathologic changes in the muscles are diagnostic (that is, they identify the condition), but the histopathologic (diseased cellular changes) skin changes are nonspecific (that is, from the condition of the skin alone, diagnosis can not be made)." (Notes in parentheses by the authors.) Sandra's condition was typical and considerably advanced. Her face was covered with reddish, almost black patches. Her entire face was puffy, including the eyelids and nose. Around the nostrils were lesions.

Arms, fingers, calves, and ankles were swollen. Her gait was unsteady and she was subject to falling. Her vitality level was extremely low. The prognosis was very dim, indeed, that anything could be done for her but Sandra was convinced that she could not go on with her present methods of treatment, the drugs causing even more weakness. They also made her nauseous. She was irritable and unable to cope with the daily chores necessitated by her young family. Sandra was willing to learn. She attended classes and read study lessons. We placed her on the McCarter Extended Detoxification Plan (to be outlined in detail in Lesson No. 63). A friend allowed her to work out at the spa. She began with simple resistance exercise routines and learned how to exercise her legs in the pool.

A year has passed. Sandra is a confirmed Hygienist. We recently had some salesmen here at the ranch referred by her. They had approached her regarding the well-known "benefits" of aloe vera and herbs. They wanted to meet us because, as they told us, Sandra would not cough unless we approved! You see, Sandra now has no fear of falling, she can care for her little family and, best of all, she is beginning to look more normal. The patches on her face have all disappeared, melding one into the other until the surface looks as one color. The hue is still somewhat darkened but I much, much lighter than when first

she consulted us. There are lesions still on the inner surface of both hands but these also appear to be receding. Sandra's hands are still quite puffy but the eyelids, nose and face appear much more normal. The change in her attitude toward life and living is worthy of note: she now laughs and looks forward to the years ahead where before she was discouraged, having little hope that the future would bring any change. Sandra knows the many faces of joy that Natural Hygiene can impart to those who follow the laws of life. At age 43, she looks forward to a future filled with bright promise.

## **6.11 Case Study—Mrs: "B"**

Mrs. B. was brought to our attention by her daughter and son-in-law. Her daughter had taken one of our courses of study about a year previous and had talked her mother into at least listening to what we had to say about alternative ways of healing. This had been a rather difficult task since Mrs. B's son was an internist and she had considerable confidence in orthodox methods.

However, she knew that she was now faced with making a major decision that could completely change her life: her own physician was suggesting that he might soon have to recommend amputation of her right leg above the knee.

A widow, the mother of several adult children, Mrs. B. had a history of medical abuse: every so-called "expendable" organ had been removed. For years she had suffered from ulcers of the skin which came and went. They had first appeared in the groin area, then they covered the abdominal area and progressed up and under the arms. At times they made moving the elbows extremely painful due to pus-oozing sores in the crook of that joint. Both legs were puffy and filled with open sores but the right leg was in a frightening state. It was a deep red, tending almost to a deep brownish color. The pain was excruciating. Mrs. B. had almost reached the point of total exhaustion. Both of us were extremely reluctant to handle this case but resolved to see what Natural Hygiene could do.

We made it clear to Mrs. B. that if anything could be done, it would represent a long hard struggle and would require complete adherence to a very strict program. Faced with a more frightening ordeal in the proposed possible amputation of her leg, she agreed to try.

At the time Mrs. B.'s digestion was so deranged that she could not even digest lettuce without suffering stomach cramps. Bowel movements could only be accomplished by using laxatives. The woman was 66 years of age, her living and eating habits well etched. Fasting was not advisable due not only to her weakened condition but also because of her total lack of knowledge of the subject. Abrupt changes in eating styles was not advisable either because we knew that the appearance of any undue symptoms would be immediately attributable to the change in diet, at least in our client's mind.

Therefore, we placed Mrs. B. on the McCarter Extended Detoxification Plan (to be discussed in Lesson No. 63) and made some constructive changes in her lifestyle. For example, the first four days were to be spent prone in bed following which she was to spend two hours resting on a couch or in bed and one hour sitting up with one half-hour during the day spent out of doors sitting in the shade. This was to last for one week after which she was to spend two hours up and one hour resting with one hour sitting out of doors in the shade. Gradually, as her condition permitted, simple flexibility and stretching exercises were introduced. By this time, Mrs. B. was showing a greatly increased vitality. The worried look had departed from her face.

The dietary changes were extremely simple at first. For example, during the first four-day bedrest period, she took only warm to hot soups made of an assortment of vegetables including potatoes, carrots, celery, and other common garden vegetables. It was amazing to watch how Mrs. B.'s nervous structure calmed itself. Even the stomach relaxed with the gas and the cramping disappearing.

Gradually food combinations were corrected and meals acceptable to Mrs. B. were devised. It is now four years later. She can now eat a bowlful of salad greens and fruit by the peck! There is no longer any talk of amputation for she is hiking around the mobile home park where she lives, striding along with her peers, and outdoing most of them! Every ulcer has healed. True, her skin is lull of pock marks where

sores had once been but her face is totally clear and shines with health. Her physician? Well, he told her never to lose sight of her nutritionist, that Mrs. B. had accomplished a miracle! Recently, Mrs. B. told us that she now had a boyfriend and, as she told us about him, we saw a few tears of joy glisten in her eyes. This is what Natural Hygiene can do when given its chance.

On first meeting, older people who consult hygienic practitioners have little or no knowledge of Natural Hygiene. Schooled in orthodoxy, they want healing "now!" They fail to realize that it takes many, many years for chronicity to develop and that it will probably take considerable time for full recovery to take place, if that, indeed, be still possible. In most cases, it will not be. It is often advisable to take photographs of your client on first meeting, photographs with front and side view in a standing position and to keep these in the client's file together with as complete a history as possible, one containing as full a disclosure of symptoms as the client can give.

This is advised, not because we should be overly concerned with symptoms, but because both the pictures and the records are often helpful in reminding clients of just how much improvement has taken place in a given time. Clients are often apt to forget what they looked like when they came and also how they felt! Reminding them from time to time is one means of encouraging them to keep on with a more physiologically sound regimen and not to digress from it.

## **6.12 Case Study—Mickey**

With older clients the progress is often extremely slow with constant prodding and encouragement required. With Mickey, this was totally unnecessary for Mickey, at three years old, was at the other end of the spectrum of life and filled with the vibrant energy of the very young.

In fact, Mickey, according to his parents, had too much energy. He was well described as being "hyper," but with good reason. Mickey was a product of the times, his body saturated with the poison products of cow's milk and formulas fed from birth on. Candy and sweets of all kinds coupled with liberal amounts of Kool-Aid and other goodies had made this little boy break out in a rash which refused to go away in spite of the many medications, prescribed and over-the-counter which had been dutifully applied. His parents brought him to our attention in despair, themselves almost exhausted from sleepless nights and tantrum-filled days.

All medications were immediately stopped, all sweets forbidden. Mickey was taken off milk and placed on a simple diet of raw fruits, vegetables, and nuts. The synthetic food products were relegated to the trash can. In ten days Mickey's parents reported with joy and delight that they once again had a normal boy: the rash had completely healed and, both Mickey and his parents were sleeping the whole night through.

Children recover almost with miraculous speed due to their great store of vitality. This is lacking and often in very short supply in older clients. Expectations of recovery time must therefore often be extended in the elderly to years instead of weeks and months and the extent of the recovery must be expressed realistically in terms of possibility. However let us stress that we ourselves are often amazed at what can be accomplished even in cases of extreme enervation, as was true in the case of Mrs. B. We must keep ever in mind as practitioners that whatever may be possible is not, at early reading, an open book. What will be revealed, given enough time for the body to extend its marvelous healing powers, is an unknown. But this we do know as a certainty: the body can and often does produce a miracle when given the proper tools!

## 7. Questions & Answers

**I have been on a regimen of two fruit meals per day, one in the morning and the other at noon with a raw vegetable plate in the evening at which I alternate a starch food one day with a protein food the next day. But, I don 't seem to be improving. In fact, the rash on my face has actually grown worse. What should I do?**

Your reverse progress is actually evidence of stepped-up body elimination, thus indicating that your vitalities and energies are improving. The body does a general housecleaning first of all when its conditions are improved and you're no exception. If you want to get the elimination over with more quickly, go on a fast. If you want to continue to improve more slowly but faster than now, you might consider an all-fruit diet or meals of a single fruit. If you want to slow your body improvements so that symptoms do not exhibit, replace a fruit meal with another salad and a single concentrated food, thus eating a starch meal with a salad and a protein/fat meal each day with a salad.

**I am a married man and my wife is in total disagreement with me on the advisability of my continuing with the Hygienic program. This keeps me on an emotional roller coaster. Is this at all helpful and how can I handle this situation?**

This is a problem that often arises. In such a case, one has an important decision to make. Which is more important, one's future health or domestic peace at this time? It seems to me that we must separate ourselves emotionally and dietetically from the masses else we will end up as they, more often than not, which is prematurely dead or subject to the "mercy" of the medical establishment warehoused in some institution. If we make the correct choice, which can only be a physiologically-sound way of eating and living, the Hygienic way, then we will enjoy the fruits of a life well lived: superior health for a lifetime.

**Will I ever really enjoy this way of eating? I see an advertisement, for pizza on the television and my mouth waters. I just don't enjoy this food and I have no appetite for it.**

I guarantee you that if you stay on your correct diet, assuming it is Hygienically correct, you will, within a very few months, be totally committed to it, not only because you feel and look better but because you are now discovering new and exciting tastes formerly completely unknown to you. In fact, no one would ever be able to talk you into any other way of eating! Keep on your program. Let nature convince you of its merits and of its delights.

**I have been on this program for two months and I now not only have all the boils I used to have but I also have headaches and occasional pains in my fingers. I am getting discouraged and depressed. Should I keep on?**

By all means! What you are experiencing sometimes occurs and actually should tell you that your program is doing the work. The elimination from the skin is continuing and even accelerating indicating that your vitality is at a higher level than formerly. The pain in your fingers is no doubt caused by poisons entering the bloodstream from that area on their way out of the body. Remember that these acid wastes have a tendency to irritate nerve endings. This may occasion mild pain at times. Hot applications may help. Do not take drugs to relieve the pain. Bear with it. It should be alleviated shortly. Once the poisons have made a suitable exodus from the blood and other body fluids, the pain AND the boils will be no more! Don't give up now when you have proof that your new diet and lifestyle are producing positive results.

## **Article #1: Skin Diseases by William Howard Hay, M.D.**

Like diseases of every other sort, those of the skin are traceable to toxic states of the body. The skin, being wholly visible, is merely the covering of the body, and blends with the mucous membranes, lining the exits and entrances to the body, so that these orifices are merely inversions of the skin. Thus the skin is a most valuable index of internal body condition, when we know how to read its appearance.

Of the emunciories whose duty it is to keep the internal body clear of accumulations, the skin stands in importance. It is therefore mighty important that this organ which covers the body and at the same time takes care of certain of the chemical wastes of the body should be kept as healthy as possible, in order to function properly.

It is not enough that the skin be kept clean in the ordinary sense, for no matter if it is washed thoroughly three times every day, scrubbed with a brush, rinsed thoroughly after a soap bath, it is still in far too many cases a dirty skin, because through it is continually passing all sorts of chemical debris from a body that is throwing off poisonous materials, which, if retained, would cause death in five hours or less.

It is the passage of an extraordinary amount of toxic material through the skin that sets up the irritations and inflammations that we have classified and named through these many years of medical study and research. Seldom do the so-called diseases of the skin arise from outside irritations.

As the toxic material accumulates in the body it must have an outlet or we would soon perish, and it is in seeking such an outlet that the body uses all means available, including acute fevers and colds, indigestion and chills, and tonsiliuses and eruptions of the covering membrane, our external organ, the skin.

Without internal congestion due to intoxications there would never be evidences of the condition visible on the skin.

We so often see eczema alternating with such internal conditions as neuritis or rheumatism, or asthma, and while the skin is broken out, the internal condition is not in evidence, but when the skin ceases to throw off the accumulating debris then it again is manifested in the internal condition. It is a realization of this fact that makes the specialist say that eczema and asthma are merely expressions of the same internal conditions, the one manifesting on the skin and the other through the bronchial mucous membrane. This is all that disease is, one thing, a toxic state of the entire body, and such toxic states do find expression through many and varied symptom complexes or syndromes.

If one doubts this, then use the skin as an index of internal conditions, and no matter what the particular skin disease presents, detoxicate the whole body, keep the laws of nature in the matter of nourishment, and bring the lazy colon up to date and keep it there, and observe that every one of the many and varied skin diseases will disappear as readily as will any other condition that we attribute to internal uncleanliness.

It is the fine delicate skins that are the most subject to eruptions, as we have always known, and when the internal condition is brought back to anything like a normal balance the skin will again be as clear and fine as before it was affected, if you are a victim of eczema or psoriasis, two of the commoner forms of skin eruption, you can very easily prove to yourself that what has before been said is all too true, and that when your internal chemistry is approximately normal so will your skin be. Ichthyosis, or fish skin disease, is a condition of dryness and harshness of the skin that is congenital. The victims of this condition are never handed any encouragement or hope of ultimate recovery, and their health is impaired to the extent to which their skin is deficient in function.

Yet the one case of this condition that has come under direct treatment by this system improved in four weeks to such an extent that normal perspiration was easily obtained through either the hot air bath or exercise, and in six weeks the skin returned to a normal softness and fineness with complete absence of

the usual dryness and harshness and continual scaling...

In the nearly thirty years of application of the principles of natural treatment of disease I have seen no case of psoriasis or eczema that did not recover, even though both conditions had failed to improve under the most "scientific" treatment of many prominent skin specialists.

Acne vulgaris is the commonest of the skin blemishes met with, especially in the young, and every case of acne is merely an expression of an internal condition that is all wrong, and means that the lungs, skin, kidneys, and bowels are among them unable to keep the body clear of its own irritating acid debris. Every boil or pimple means the same thing: every carbuncle, eruptions of whatever nature, except the few caused directly by external irritants such as poison ivy or nettles or the bites of various insects or snakes or the application of chemical irritants to the skin.

Skin allergies, by which we mean those very sensitive skins that will break out with a sort of eczema whenever brought into contact with the primrose or other vegetable irritants, are merely evidences of the internal condition of the body that makes these particular pollens irritating to these particular skins, and "allergies" of every sort will disappear when the body is again in proper chemical balance.

This applies also to foods, and if certain foods are "allergic" today, it does not follow that the same food will disagree next year, even though the so-called "allergy" has been life-long. ...In every case these "allergies" will disappear when the wrong body chemistry has been corrected, and the food that was formerly "allergic" may then become the favorite food and agree better than other common foods that had been the chief items of daily use.

If you have had years of eczema or psoriasis, you can correct the skin irritation in a few weeks or a very few months by detoxicating the body, and with such correction of the dietary habit as will stop the excessive, formation of these irritating acid end products of digestion and metabolism. But when the whole manifestation is fully corrected, this does not mean that your skin will become as resistant as that of someone who has been born with a strong organ instead of a weak one, and it does mean that if you again let yourself get far out of chemical balance you may expect a similar manifestation, for your skin is your weakest organ and its resistance will break down first.

Women consider the skin chiefly from the standpoint of cosmetics, yet mention a woman's skin and its relation to health and you excite her interest almost immediately. The sallow and dry skin lacks the normal elasticity that smooths out all wrinkles. The skin has so much to do with health that next to breathing pure air our second duty in keeping right inside revolves about the function of the skin. Julius Caesar attributed the health of his very efficient army to the fact that every man had to sweat at least once every day. To keep the skin active it should be given the advantage of one real sweat every day, not artificially induced sweating, but the sort that comes from sufficient activity to compel free sweating.

When the pores are thus opened, it gives opportunity for the skin to unload freely the chemical waste matter that is carried in every body, the result of its combustion of fuels, the death of its cells, and the metabolism of food materials taken in every day.

These all produce waste matter of great diversity, and those chemicals that cannot pass out through lungs, kidneys, or bowels must be taken care of by the skin. To accomplish this fully this organ must have the proper cleanliness and exercise, through activity sufficient to produce sweating, aided very materially by a brisk brushing with a bristle skin brush.

### **Article #2: Lupus by Louis Kuhne**

The innumerable successful cures effected by my method, also in the case of lupus, proves that in this disease, as in all others, my doctrine of the unity of disease holds true. I will here cite a case of lupus of general interest.

The patient was a lady, 41 years of age, and had been perfectly healthy until vaccinated in her second year; from that time dated her misery. After the vaccination, obstinate eruption of the skin occurred, which in her tenth year developed into lupus of the face. For over thirty years this lady had suffered from this painfully disfiguring disease, without finding assistance anywhere, notwithstanding that she consulted many famous physicians. Her face was horrible to look at; in fact she could go nowhere without people turning their gaze from her with aversion. In this helpless condition she came to me, all the doctors having pronounced her disease incurable. My diagnosis showed an extremely favorable position of the encumbrance, so that I could assure her of good prospects of a rapid cure. This opinion was confirmed. After only a fortnight the disfiguring lupoid places on the face had undergone considerable change and were no longer quite so repulsive. Her digestion, in particular, which had until now never received any attention, had also improved quite remarkably. The result was abnormal evacuations, whereby the morbid humours were expelled. In seven weeks the patient's skin assumed the normal color.

### **Article #3: The Skin by M.O. Garten, D.C.**

With the lowering of metabolic efficiency, the skin becomes pale, thin and dry with development of many folds. Secretions of perspiration lessen with an increasing difficulty of keeping warm.

During the fast, the skin resumes more effectively its role of body cleanser. Perspiration may become odoriferous as it may carry dissolved particles of uric acid, decomposed cells, etc.

One of the most gratifying effects of the fast is the observance of changes of the skin. The once shiny cigarette paper appearance, particularly on extremities, changes over to a more velvety texture, the skin loses its shine and many folds, and becomes thicker.

*Excerpted from The Health Secrets of a Naturopathic Doctor.*

### **Article #4: The "Hurry-Up" Disease by Elizabeth D. McCarter, D.Sc.**

Don't be a victim of the "hurry-up" disease. Rejuvenation and recovery from sickness do not usually occur overnight. It takes nine months after conception, on an average, before a baby is born! Healing and repair also take time, often considerably more than we anticipate. Dorothy M. found this out, but eventually she, too, received her reward.

When we first came in contact with Dorothy, we found that she was suffering terribly from a fungus which was buried deep in the palms of her hands causing itching so intense that she said it just seemed to burn even into the marrow of her bones. This condition had existed apparently for some time and, needless to say, had almost exhausted her vital power supply. She had wandered from clinic to clinic searching, always searching, for "relief," but without success. At 65 she was still trying caustic solutions, vitamins, ointments, herbs; even steroids. Everything anyone anywhere had recommended, from California to Australia, Dorothy had tried, used for a time, and then discarded as useless. The terrible itching, the painful cracks in her skin and the inflammation persisted.

We explained to Dorothy that parasites live on the effete material within the system—the poison within—and that the only way to get rid of them was to get rid of their food; in other words, to starve them out! Thus, it was that Dorothy embarked on a program of Natural Hygiene that was to extend over many years. She first fasted for a period of about ten days. Then she began a greatly reduced and modified food intake that consisted of about 90% raw fruits, vegetables, and nuts. She learned that these were the kinds of foods which contained all the nutrients of life and contained them in the proper proportion as required by the human body. At suitable intervals she would fast for two or three days, gradually, as she phrased it, "cleaning out the fungus food!"

## **Would Not Give Up**

Months passed with no results—apparently. Almost anyone else would have given up, but not Dorothy! She was convinced that she was now on the right track. You see, it all made sense to her. At long last she realized that obedience to the laws of nature is the only way to find health and that there can be no compromise. Gradually the itching seemed to lessen. Dorothy knew that drugs give only temporary relief, so she endured the terrible itching and persisted in her health program.

Years came and went. She had to wear gloves to take a bath and whenever she put her hands in water. So sensitive were her hands and fingers that even plain water caused her discomfort. Frequently cracks and blisters formed where spores were deeply imbedded.

Four, five, six years passed in review until the day finally arrived when Dorothy first put on the wedding ring so long abandoned. Progress was rapid from that moment on and, before the seventh year had passed she was able once more to take a bath and wash dishes without having to wear rubber gloves. The itching and the pain were now nothing more than a hideous memory.

Dorothy was now almost 73 years of age, but she looked younger than she had when we first saw her! Her complexion was radiantly alive and her vitality that of a much younger woman. She was living proof that age is not necessarily restrictive of improved health. There is an old German proverb which says, "Patience brings roses!" Dorothy had found her roses! It had required patience, perseverance, and a dedication to a firm belief that the ways of health are the natural ways of life.

The lesson, of course, is clear. We, too, must persevere in the ways of health. At any time, Dorothy might have chosen the ways of drugging to relieve the immediate pain. Like so many others, she too could have soothed away the pain and the discomfort with products of the chemist's art, those "instant relief" pills and potions. It would have been so easy, so quick; but Dorothy had learned that drugs only appear to give health, that they present only a false facade.

When we are very young, our bodies are filled to overflowing with vital energy, the return to health may occur with amazing speed; but when we are older, the return may be elusive and taunt us with its tantalizing slowness, as was true in Dorothy's case. But, regardless of our age and our condition, we must remain steadfast in our goal to attain superior health. We must persevere in the ways of health. We must not be victims of the "hurry-up" disease!

### 1. Introduction

"An eye for an eye, and a tooth for a tooth." You've heard this said many times, and no wonder. This old Biblical statement simply reflects the value we place on our teeth and eyes. The eyes and teeth may be the two most vital body parts we have for sensual appreciation. Good teeth allow us to savor and enjoy eating. Good vision allows us to participate more fully in the world.

Old age often has meant that the eyes and teeth rapidly fail us. Dentures and eyeglasses go hand in hand with Social Security checks. But does this mean that poor or missing teeth and weak, failing vision should be the norm for the elderly?

The young, too, have miserable dental health and vision problems. Younger and younger children are forced to wear glasses, and it is a very rare child indeed who does not have at least one dental cavity.

The truth is this: the overall health and well-being of the body is reflected through the health of the mouth and the clarity of one's vision. Dental decay and failing eyesight are signs of a deteriorating body. Yet, it doesn't have to be this way.

The teeth and eyes are built for long years of service—at least for 120 years. There have been stories of people who grow a third set of teeth in old age, and regained eyesight among the elderly is not impossible. So, poor teeth and eyes are never natural. Your teeth and eyes should be as sound at 50 as they were at 20—if you understand and follow the precepts of a healthy lifestyle.

### 2. The Teeth

#### 2.1 Sinking Your Teeth into Good Health

Dental health indicates body health. A proper program of diet, exercise, freedom from stress, and sensible living habits will insure that your teeth will last for a lifetime. Outside of gum disease, the two most common dental problems are caries and malocclusion.

Caries are erosions of the teeth, and are usually called "cavities" by the layman. Malocclusion means that the teeth do not fit together properly, such as in "buck teeth" or other deformities of the jaw and mouth.

Both of these conditions will not occur if a person consumes an optimum diet. Not only the diet of the person involved must be superior, but also the diet of the person's mother as well. Good nutrition for the teeth must begin *before* birth, and the diet of the pregnant mother will shape the child's dental health for the rest of his life. To understand the role of nutrition in dental health and well-being, you must be familiar with the chief causes of dental abnormalities and diseases.

## 2.2 What Is a Cavity?

A cavity is a hole, whether it is in your teeth or in the ground. Holes appear in your teeth when there is a mineral imbalance in the body. Chiefly, the calcium-phosphorus mineral relationship is the determining factor in cavity formation.

When the diet is excessively high in phosphorus, or in foods commonly known as "acid-forming," a calcium deficiency may occur. This deficiency is usually not due to inadequate calcium in the diet (although it may be if the diet is especially poor), but due to such foods as white sugar, refined flour and grains, and other processed carbohydrates that deplete the body of vitamin and mineral reserves (including calcium).

Cavities are *not* created by the external action of bacteria on the surface of the teeth, as is commonly thought, but by the imbalances created in the body by improper foods. Consequently, thorough brushing and flossing of the teeth are ineffective in preventing cavities if a substandard diet is still followed. Healthy teeth can only be built by a healthy diet and lifestyle—not by fluoridated water or "whiter than white" toothpastes.

## 2.3 The Truth About Dental Health

For the truth about nutrition and tooth decay, read the book *Nutrition and Physical Degeneration* by Weston Price, DDS. Dr. Price traveled throughout the world to study the effect of various diets on dental health.

He found, *without exception*, that the people who ate diets free of refined and processed foods were almost completely free of tooth decay. In addition, these people had excellent bone structure, jaw formation, and were well adapted for chewing, singing, and speaking. (In other words, not only were cavities not a concern, but a natural diet does not cause malocclusion, or deformity of the dental bite.)

He also discovered that within so short a time as a single generation, eating refined foodstuffs resulted in narrow dental arches, malocclusion, and rampant tooth decay. His book has pictures of families that show the older generation who ate unrefined and natural foods with perfect "choppers." The younger members of the family who ate the "civilized" foods, like candy, soft drinks, canned foods, and refined grains, had teeth with holes, snags, and decay.

His conclusion: rough, unrefined, whole, unprocessed, and untampered foods promote the highest degree of dental health. Without exception, the eating of modern foods produced dental deterioration.

Although the medical establishment's standard position is that tooth decay is caused by food particles stuck to the *outside* of the teeth, even the *Journal of the American Medical Association* recognized that tooth decay dropped when a more natural diet is followed. In an issue of this magazine, Dr. James H. Shaw reported on the improvement in dental health that occurred when certain countries during World War II had to revert back to a traditional, unrefined diet:

"Careful study of these countries indicates that the nutritional influences imposed on the teeth during development and calcification through the consumption of coarse, unrefined diets of natural foodstuffs

resulted in teeth that were more decay-resistant than those teeth formed during the prewar years."

Notice that emphasis is placed on the formation of the teeth and a good diet. Your mother's diet during pregnancy and lactation provided the foundation of your dental health. Even if you now eat an excellent diet, your teeth may be suffering from poor eating habits of your younger years, or from your mother's prenatal diet.

Still, a diet of chiefly raw fruits and vegetables can make your present teeth last longer. Besides diet, what else can prevent tooth decay? Exercise!

Most people would laugh if you suggest that they exercise their teeth. After all, with all the overweight people in this country, you might think that people need to keep their mouths shut more and exercise their teeth less. Like any other healthy part of your body, however, the teeth require regular exercise. It is a fact: if any part of the body is not exercised or used properly, it will deteriorate. The teeth are no different.

## **2.4 Exercise, Chew, Chomp, and Gnash!**

So, how do you exercise your teeth—by flapping your gums? No, the best exercise for your teeth is to use them for the exact purpose that you have them: chewing food.

Look at the typical American meal: white bread, mashed potatoes, gravy, meatloaf, mushy peas, and a glass of tea. You don't need teeth to eat that kind of food. You could almost swallow the slop in a few gulps with one or two chews. You need a meal you can sink your teeth into. You need to eat food that requires chewing and using your teeth.

Which foods exercise the teeth best? Raw, fibrous, wholesome fruits, vegetables, and nuts. Cooked foods are poorly chewed; raw foods must be thoroughly masticated. The chewing of the firm raw fruits and vegetables give the teeth exactly the kind of exercise they need. In fact, so effective is this exercising of the teeth in promoting good dental health that Dr. Shelton has this story to tell:

"A mother brought her young child to me. She was distressed that his jawbones and mouth were developing poorly. The boy had a terrible bite (referring to the way the teeth fit), and there did not appear to be any room in the crowded mouth for the new teeth to erupt. After discussing the child's diet, I suggested that the mother give the child a raw carrot to chew on at his regular meal and as a replacement for his sweet snacks. Years later I saw the mother and child again. The child had beautiful straight teeth. The hard chewing that was required for the raw carrot allowed the teeth to straighten out as they performed the job for which they were originally intended."

Not only are raw fruits and vegetables beneficial in exercising the teeth, they may be your best Toothbrush! Consider this report made by two British researchers in the *Medical Press*:

Two groups of children were chosen at random. One group ate a raw apple after their regular meal the other group did not. It was found that chewing an apple stimulated the gum tissues, increased the saliva flow to cleanse the teeth, and provided optimum exercise for the jaw muscles. The researchers discovered that the children who ate apples (or any other raw, fibrous fruit or vegetable) with their meals had significantly better gum health and fewer cavities than those children who simply followed a regular program of brushing and a conventional diet.

Dr. Maury Massler, a professor of children's dentistry at the University of Illinois stated that the best way to clean the teeth and gums is not by harsh brushing or chemical toothpastes, but by eating foods which are "natural cleaning agents for the teeth, such as pulpy, fresh, raw fruit, nuts, and vegetables."

Raw food particles do not produce decay or stench in the mouth as does food which has been processed, cooked, or refined. Once a food's composition is altered by cooking or refining, the food particles decay rapidly when left in the mouth and between the teeth. By eating raw fruits and vegetables, your teeth will stay naturally clean and healthy without abrasive toothpaste or excessive brushing.

## 2.5 Here's to Your Teeth—Drink Up!

"Studies have shown," writes Dr. Arthur C. Guyton, "that teeth formed in children who drink water containing small amounts of fluorine develop enamel that is more resistant to caries than the enamel in children who drink water not containing fluorine."

Can fluoridated water prevent decay? Actually, the real evidence proves otherwise. An engineer in Massachusetts has analyzed the official government figures on tooth decay and municipalities that use fluoridated water. His figures have conclusively shown that artificial fluoridation does *not* prevent tooth decay, but only *postpones* it for a few years.

Fluorine does *not* make the enamel of the tooth harder and more resistant to decay. Instead, the fluorine simply displaces certain chemical ions in the enamel which makes it less soluble. The fluorine which is now stored in the tooth's enamel is said to be *toxic* to some of the bacteria in the mouth, which is the original rationale behind putting fluorine in our water in the first place. Bacteria causes cavities; fluorine kills bacteria; therefore, fluorine prevents tooth decay.

Such reasoning is both dangerous and faulty. Bacteria no more causes cavities than they cause any disease. It is true that fluorine will kill bacteria, and that in itself should make you wary and alert.

Remember, any substance that is capable of killing bacteria is an *anti-life* agent. If fluorine is poisonous to bacteria, you may be sure that it is poisonous to you as well. In many locales all over the world, the people have excellent teeth and *there is not a trace of fluorine in the water supply*.

Actually, fluorine in its organic and naturally occurring form as found in small amounts in some foods is a beneficial mineral for the teeth. The fluorine that is dumped into the water supply, however, is a harsh chemical byproduct from industrial manufacturing and fertilizer production. No wonder some people would like us to believe that fluoridated water is beneficial. This simply gives chemical and metal industries a profitable outlet for a hazardous waste. Fluoride toxins are dumped into public water supplies in the name of dental hygiene. In reality, fluoridation is rank pollution of our water supply.

## 2.6 Building Healthy Teeth

You cannot drink a chemical and expect to have healthy teeth. Good teeth are only built through good nutrition, and this means avoiding the harmful foods as well as including the natural fruits, vegetables, and so on.

Which foods are the tooth destroyers? Refined carbohydrates, in the form of sugars, sweets, breads, pastries, cakes, and cooked foods, are the worst foods for the teeth. The white sugar and white flour in these products are nutrient-robbers, and they set the stage for cavity formation. Other poor foods are those high in phosphorus and acid-forming elements such as soft drinks (the chief source of inorganic phosphorus in the American diet) and meat.

The most important person in tooth care today is not the dentist but the mother-to-be. A pregnant woman's diet determines the quality of teeth that her child will have throughout the early years and the entire adult life. After birth, the child should be fed only the optimum foods. If this practice is continued through adulthood, perfect dental health will be a reality.

### 3. The Eyes

#### 3.1 Failing Eyesight and Vision Problems

What causes a person to be near-sighted or far-sighted? Why do so many older people require glasses? What is astigmatism? What are cataracts and how are they caused? Poor eyesight and vision problems affect almost every person alive today. Most of these problems could be prevented or corrected if the causes of poor eyesight are understood. Let's look at the most common complaints about the eyes and sight:

#### 3.2 Is Failing Eyesight Natural?

Your vision often seems to deteriorate as you grow older. People that never wore glasses in their early years often succumb to using reading glasses around the age of fifty. Does the power of vision naturally falter with passing years? Yes and no.

Your eyes can focus on both faraway and closeby objects because the lens of the eye can be "stretched." The lens itself is composed of a strong, elastic capsule of proteinaceous fibers. Ligaments attach to the lens which allow it to be contracted and relaxed. As the lens changes shape by the ligaments pulling on it, the eye adjusts so that it can look at both objects in the distance and those that are close up.

As a person grows older, the lens loses its elastic nature and becomes more and more solidified. This is probably because the protein composing the mass of the lens becomes denatured. As the lens loses its elasticity, it can no longer quickly adjust in its focusing.

Around 45 to 50 years, the lens can only move about one-eighth as much as it could at birth. Finally with advanced age, the lens of the eye loses all elasticity and remains permanently fixed and focused at one distance.

This condition is called presbyopia and it simply means that the person has reached a stage where each eye remains permanently focused at an almost constant distance. The distance that the eyes continually focus on depends upon the physical characteristics of the person's eyes.

What this means is that a person may be able to see moderately well for objects that are three to thirty feet away, but cannot read or see distant objects without glasses. Although similar to "farsightedness" or "nearsightedness," the condition known as presbyopia is strictly speaking not the same. This vision problem affects only the older segment of the population, and occurs as a result of gradual deterioration instead of any congenital defect.

Does this mean that you must have poor vision by the age of fifty? Absolutely not. Although the lens of the eye does gradually decrease in elasticity, it can be slowed down enough so that it is almost imperceptible.

The proteinaceous denaturation of the material that makes up the lens of the eye occurs because the body is focusing its healing and regenerative energies on the more vital body areas. There is no reason why the materials making up the lens cannot be rejuvenated or maintained at their present level.

If the body is unencumbered by toxins, stress, or disease, then it can rebuild its weakest parts—including the eyes. If, however, the individual is in the state of toxicosis or is leading an unhealthy lifestyle, then the body never has a chance to revitalize the eyes. Instead, all the body's energies are directed simply toward keeping itself alive.

As long as the health of the body is in a critical state, then the type of rejuvenation that is required to correct failing vision cannot occur. Perfect eyesight is not an absolute requirement for the survival of the

organism. Consequently, the body always tends to correct the most pressing problems first. For most people, this means that the eyes and eyesight are low on the body's list of priorities for revitalization and healing. Until you can "get ahead" in rebuilding your health, your eyesight will remain at its current level.

The most effective method known for restoring failing eyesight is a *prolonged* and supervised fast. This allows the body to reverse the deterioration and denaturation of the eye lens because the fast provides the necessary physiological rest for this to occur.

Old age doesn't mean poor vision. Perfect eyesight, along with perfect health, is your birthright and heritage. A failing of the senses is not "natural" any more than any illness or disease is natural. Most people believe that poor vision goes along with increased years. Fasting, an optimum diet, and freedom from stress are the only requirements for improving your eyes. No matter what your condition, these steps will give you some noticeable improvement in your vision.

### **3.3 Can You Throw Away Your Glasses?**

A man or woman who lived a thousand years ago would find the twentieth century to be a very strange place. The first thing that such a time traveler would notice is that about one out of every two people walking around his pieces of glass tied together and strapped across the nose. We call these things "eyeglasses" and we take them for granted.

But are they natural? Going through life with a pair of glass lens perched atop your nose or stuck onto the eyeball itself (if contact lenses are used) is the same as using crutches or a cane to walk around with. Why are there so many 'vision cripples?'"

Most people who wear glasses do so usually for one of these three vision problems: near-sightedness, far-sightedness, and astigmatism. Are these conditions natural, and what can we do about them?

### **3.4 Seeing Near and Far**

The most common eye problem is near-sightedness, or myopia. This means that the eyes cannot focus properly on anything beyond a certain distance, and can only see objects that are "near"—hence the term, near-sightedness.

Interestingly enough, near-sightedness most generally occurs in children and gradually worsens until around the age of 20 or so. Why is this? Some researchers have speculated that diet may be the clue in the myopic mystery.

In the *Pennsylvania Medical Journal*, Dr. Hunter J. Turner singles out soft drinks or carbonated soda water as the number one cause of near-sightedness in children. The carbonic acid in these drinks is one of the worst enemies of the eyes, and Dr. Turner believes he has discovered a strong link between soft drink consumption and the incidence of near-sightedness.

What will help a near-sighted person? Exercise. But not only general body conditioning, but a special set of exercises that are performed exclusively for strengthening the muscles of the lens of the eye.

For example, the Bates System of eye exercises has been used for years with moderate success. According to the *International Record of Medicine*, "a specific course in visual training may improve visual acuity, size of visual field, refractive errors, and even reading speed in selected individuals." Additional references to these series of eye exercises are at the end of the lesson. The good news is this: near-sightedness can be overcome by proper exercise of the eyes. Among children, the results are especially impressive. You can throw those glasses away.

What about far-sightedness? Can it be corrected? Farsightedness is also known as *hypermetropia*. In this condition, the person cannot focus on objects close to them (such as a page of a book), but can see things in the distance as normal.

This is rarer than near-sightedness, but it is also caused by a weakened lens system. Both far-sightedness and near-sightedness are "corrected" by placing glasses or contacts over the lens so that the light is refracted in a different way.

Many far-sighted people have corrected their condition by *not* wearing glasses. In other words, they regularly exercise their eyes and try not to rely on any "crutches" or aids that might hinder their progress. Exercising the eyes and following an optimum diet (with periodic fasting) are effective and harmless ways to improve the vision.

If you wear glasses continuously, start off by removing them when it is not essential that you have clear vision. Gradually become used to not wearing glasses, and work your eyes. Focus on objects as far away as possible. Look at mountaintops, faraway trees, or signs. Then turn your eyes to objects less than three feet away. Practice regular rotation and exercise of the eyes for two to three periods a day. At the end of such exercising, press the palms over the eyes and keep them closed and relaxed. If you make a serious effort to exercise and relax your eyes in this manner (along with a regular program such as the Bates Vision System), you should quite literally see some improvement. Don't forget that an excellent diet and fasting program should be used along with your eye exercise program in order to correct near- and far-sightedness.

### **3.5 What is Astigmatism?**

Like myopia (near-sightedness) and hypermetropia (far-sightedness), the eye condition known as *astigmatism* is due to a refractive error of the lens system. People with astigmatism have a "fuzzy vision", and things often appear out of focus, whether near or far.

Due to the nature of this condition, it can never be completely corrected by eyeglasses or contact lenses because an astigmatic eye can never bring the light rays from all angles into focus at one time. The eye is said to be "lazy."

What can you do with a "lazy" or astigmatic eye? Exercise it! Astigmatism responds best of all to a regular eye exercise program. In fact, one method of correcting a single astigmatic eye is to cover the other good eye with a patch for certain periods of the day. This forces the "lazy" eye to do its share of the work and so become gradually strengthened.

### **3.6 Cloudy Vision: Cataracts**

Cataracts are a common abnormality among older people. A cataract is a cloudy or opaque area in the lens of the eye. In advanced cases, the lens may be completely covered by a milky-like coating. Eventually this coating becomes so heavy that light can barely enter the eye, and vision is seriously impaired.

The common medical solution to cataracts is to cut them out. When this is done, *the entire lens of the eye* is also removed. Needless to say, when the eye's lens is removed surgically, the eye loses a large part of its refractive power. To compensate, a convex lens is placed in front of the eye.

There is a better way of dealing with cataracts, and that is to not cause them. To do this, you need to understand what causes cataracts.

Cataracts formation occurs as the protein fibers in the eye lens starts to coagulate with age. As the fibers harden, calcium deposits start to occur in the lens which gives the cataract its milky, opaque color. You can think of a cataract as almost like an "arthritis of the eyes" because inorganic calcium deposits play such an important role in both these degenerative conditions.

Inorganic calcium comes from mineralized waters, cooked foods, and of course, dairy products. Can such food items cause cataracts? There does seem to be an impressive connection. In areas of India where yogurt consumption is the highest, there are also more cases of cataracts than anywhere else. The

*galactose* in the yogurt, along with inorganic calcium, appear to be the culprits in fostering cataract growth.

The solution to cataracts: a strict avoidance of dairy products and all other foods containing inorganic calcium. (Calcium becomes "inorganic" when the foods in which it is present are subjected to high heat. Inorganic calcium is also found in mineral water and in all calcium "supplements.")

### **3.7 Your Keys To Better Eye Health**

Healthy and responsive eyes have the same requirements as any other part of the body: good nutrition, rest, and exercise.

What types of foods build healthy eyes? Carrots? Cod-liver oil? The answer is: none of these. There is no one single food or one single nutrient that insures good eyesight. Nutrition for the eyes is basically the same as good nutrition for the body: an optimum diet of fresh, unprocessed fruits, vegetables, nuts, seeds, and sprouts.

Your eyes do have a definite need for vitamin A, as well as vitamin C and the B vitamins. Your eyes need certain amino acids for their work. But all of these nutrient needs can be *abundantly* supplied in a Hygienic diet of primarily raw fruits and vegetables. You do not need to worry if you're getting the proper nutrients for your eyes if you eat wholesome foods and scrupulously avoid destructive, denatured food products.

Which foods destroy the eyes? Here are, your eyes biggest enemies: dairy products, meat, sugar, alcohol, smoking of any type, white flour products, heated fats and oils and all processed and adulterated foods.

Besides optimum food, your eyes need exercise. Exercise does *not* mean using the eyes continuously for the same task, such as reading or sewing. People who read, write, or perform closeup tasks often think that they are giving their eyes adequate exercise. After all, they use them all the time. Eyes, however, require different types of exercises just as the body responds better to be a varied exercise routine.

As mentioned earlier, the Bates Eye Exercise system is helpful because it requires the eyes to move in certain patterns that are not duplicated by the common tasks of reading, writing, etc.

Eye exercises can be very simple, however. The prime requirement for an affective eye exercise is that the eye must alternately focus between close and far objects. For example, if you are reading outside, take a few minutes every now and then and look at the farthest object you can see. Stare at it for a few minutes and try to bring it into sharper and sharper focus. Now look back at your book and focus on the text. This alternation between close and far objects forces the eye to exercise.

If you now wear glasses, remove them occasionally and try to focus without them. It will be different at first, but if you make regular efforts to get by without your glasses, your vision will slowly improve (be patient!).

Along with exercise comes rest. Your eyes deserve the best lighting possible. Harsh and direct lights do not allow the eyes to rest to relax. Fluorescent lighting is particularly hard on the eyes and soon tires them. How else can you rest the eyes? Here is a method described by Dr. Herbert M. Shelton:

"The eyes may be refreshed by a simple process. Close the eyes and relax them, and then cup the palms of the hands over the eyes. Press the palms against the eyes, with no pressure on the eyeballs for a few minutes. Palming, as this is called, relaxes and refreshes tired eyes as few things will."

### **3.8 The Eyes Have It!**

Vision is one of our most precious senses. To keep your eyes at their peak throughout your life, follow the Life Science diet of chiefly raw fruits and vegetables, exercise the eyes, rest them, and stay free from stress and destructive habits. Your eyes will serve you well as long as you follow the teachings of healthful living.

#### 4. Questions & Answers

**I went to a doctor for a checkup and he said I had the start of two small cataracts in each eye. Later this doctor said he just thought so but wasn't sure and said I should have an eye doctor check my eyes. Up to this point, I never had any problems with my eyes**

**I was very worried about it, so I went to a health food store and they recommended Dr. Christopher's Eyebright. I used it and wrote Dr. Christopher. I told him I started to get floaters and drew a picture of them for him. I received letters that kept telling me I was doing fine, even after ten weeks, and they recommended I continue the Eyebright. I kept telling them my eyes were getting worse and I kept getting the same answers (I have all the letters)**

**During December, I started to see flashes of blue and this scared me terribly. I could not watch a color TV anymore it was so bothersome**

**I went to an ophthalmologist in early February of this year and another one in March. I found out that I had vitreous floaters and the last doctor said the flashes would get better and not to put anything in my eyes. I followed his advice but I still took the Eyebright internally. I know today I should not have done this since I have read your guidance in Healthful Living. But Eyebright was supposed to be good for the eyes**

**Since I stopped taking Eyebright in March the blue flashes bother me less, even if I watch color TV. But the floaters go so bad they were all over my eyes. My right eye is worse than my left eye. So I took stronger doses in that eye. The right eye got even worse. But I was afraid of cataracts. Both eye doctors had told me I had no cataracts. Since I've seen these doctors I've been drinking carrot juice, celery juice, and some parsley. My floaters seem to be improving a little now.**

Yours is a classic case of active "prevention" that causes disease. You are poisoning yourself wholesale! Almost everything you're taking is synthetic and/or inorganic even if the prominent markings on the labels say natural. Your body is poisoned, not nurtured, by non-metabolizable synthetic vitamins and toxic minerals in supplements. The minerals are the same as in soil, rocks, and ores. Selenium, iodine, and chromium are trace minerals that are essential to the body but, in inorganic form, are very toxic. They bear the skull-and-crossbones on commercial preparations. But, as elaborated by plant life, we can readily use them

The grand plan of nature is to leave the body alone. It is fully self-operating and self-sufficient if its needs are furnished. These needs basically, are pure air, pure water, adequate sleep and rest, vigorous activity, sunshine, recreation and play, emotional poise, security of life, and foods which we are biologically and physiologically equipped to utilize. This means we should put into our bodies only water, air, sunlight, and a diet of mostly fruits with a small amount of vegetables, nuts and seeds. Humans are frugivores (fruit-eaters), and in nature we ate fruits, only and exclusively (according to scientific research). Our anatomy has not changed from this in the few thousand years that we've been eating grains, animal products, and plant fare other than fruits

Floaters are caused by toxic materials that destroy and coagulate the protein component of the eye's lens. This causes their opacity. The toxic materials, together with coagulated or

indurated protein tissue, move around in the vitreous fluids of the lens, thus giving the illusion of indistinct objects floating before the eyes

The way to overcome this is to stop those practices that are causing it. Eyebright is a toxic herbal formula containing several virulent compounds. Capsicum is a highly toxic and irritating alkaloid found in cayenne peppers which is in Eyebright. This and other toxins as found in herbs can cause much harm but they have no possibility to help the body. They cannot troubleshoot body problems and correct them. Their only character with relation to the body is as a poison. The body rejects them and tries desperately to protect itself from their destructive factors. We humans have been deluded into believing that we will be helped by supplements, drugs (medicines), and preparations, even if we continue to get worse under their administration

There is only one way back to good health—healthful living. Living healthfully means observing our physiological needs. What you are dosing yourself with is contrary to everything we nourished ourselves with in nature. Instead, you are giving your body drug problems that only further intoxicate and ruin your health. Your eye problems are only a symptom of overall body conditions

I suggest that you consider a fast of a week or more. Then put into your body only fruits as your primary dietary fare with occasional vegetable fruits such as tomatoes, peppers, cucumbers, salads, eaten with nuts, seeds, or an avocado, etc.

### **Should I let my dentist take X rays? Isn't the radiation worse than the decay itself?**

Many times X rays can be avoided. A dentist can examine your teeth visually for signs of decay which may appear on the surface. Unfortunately, most dental decay occurs from the inside out of the tooth, so that by the time it appears on the surface, it may already be quite advanced. An X ray can detect early decay and it can be fixed before more serious problems develop

Nobody likes X rays, and the medical profession overuses them. What you might consider is to have just one set of X rays done of all your teeth for one time only. This initial set will help your dentist evaluate the overall condition of your teeth and the supporting bone beneath them. This will allow correction of any old problems you might have. After these X rays, you should probably never need any more if you stay on a wholesome diet

Should you have this one set of X rays taken, insist on having the X ray technician give you a "lead apron" to protect you from incidental radiation

You don't have to allow X rays at all; that is your right, and you should always refuse "routine" X rays done casually. Sometimes, however, you just might need that one set to get your past problems straightened out.

### **I've got some cavities and decay from before I started a good diet. Should I get these filled or can I fast or let my new diet take care of them?**

While early small cavities may be arrested by proper diet, dental decay should probably be cleaned out and the cavity filled once it reaches a certain size. A cavity does not heal; it is a permanent injury done to the body. Although you can remineralize your teeth with a proper diet and prevent the pain from decay by fasting, you're not going to be able to make that hole in your tooth go away. Sorry

If you have these cavities filled, and you probably should, insist that your dentist does not use silver amalgam fillings. This is the most common type of filling (usually called "silver" filling). Actually, it should be called a "mercury filling" because it is 45% pure mercury which is a potent poison. The saliva in your mouth will interact with silver amalgam fillings and dissolve them so that the mercury enters your bloodstream. Even the FDA recognizes the dangers of "silver" fillings, and had they been developed recently, they probably would never have had a chance for approval

You can have your dentist use gold as an alternative filling. While expensive, gold is the most compatible metal with the fluids of your mouth. You might also be able to use a quartz or porcelain filling for cavities in the front teeth or for small areas. Porcelain used to chip easily on large surfaces, but recently has been improved and is worth investigating as a substitute for the common silver filling.

### **What about novacaine shots and pain killers? Should I take them?**

Although injections are objectionable, it may prove impossible to avoid them under some circumstances. With some dental work, you would jump around from the pains so much that the dentist could not do his or her work, unless the nerve is first deadened

My own recommendations for "pain killers" is to first see if your dentist can use the services of an acupuncturist to deaden the nerve area. Acupuncture involves no drugs or injections, but it may be very difficult to find a dentist that can use this in his practice. The second choice is nitrous oxide ("laughing gas"). Nitrous oxide is taken in by the lungs, introduces no foreign substances to the bloodstream (except for extra nitrogen), and wears off in about five minutes. Some people find it mildly pleasurable and I've noticed no harmful after effects. Finally, if you do have to have a local anesthetic (such as for a root canal or an extraction), ask the dentist for something else besides novacaine. Novacaine has some undesirable after effects and there are other drugs that can be used instead

Understand that we do not encourage the use of any pain killer or injection. Philosophically, all injections and drugs are a compromise in your Hygienic lifestyle; practically, you may have to compromise in this area unless you have an exceptionally high pain threshold. Afterall, you probably wouldn't be getting these injections in the first place if you had followed the laws of Natural Hygiene all your life.

### **What toothpaste should I use?**

Cleaning the teeth, like cleaning the body, is a *mechanical* not a *chemical* process. In other words, your primary concern in cleaning and brushing the teeth is to physically remove the plaque—not to apply some chemical to them than may be included in the toothpaste. In fact, toothpaste is not even necessary. A water-moistened brush is sufficient

Many commercial toothpastes contain sugar (!), fluoride (harmful) and various abrasives. In fact, those glamour toothpastes that promise "whiter white" do their work with harsh abrasive compounds that may actually strip the enamel off the teeth. You'll wonder where the yellow went, and you'll also wonder where your teeth went after a few years of scraping them down

Also be cautious of so-called organic toothpastes. Often they contain sea salt and various herbs which are absorbed through the mouth when you brush your teeth. In general, don't use any toothpaste you wouldn't feel comfortable eating because that's actually what you are doing when you put it in your mouth

One trick for whitening the teeth, is to brush your teeth with strawberries! Rubbing strawberries over the teeth and gums helps remove plaque and yellowing, and then you can eat the strawberries afterwards. Now that's a "toothpaste" I can heartily recommend! Regardless if you use toothpaste or not, a gentle brushing of the teeth and gums is just good hygiene—just like removing the dirt and grime that collects on the skin of the body. Of course, if you eat a predominantly raw diet, less "dirt" will collect around the teeth anyway.

### **What causes cavities?**

A common opinion is that cavities are caused by bacterial formations of acids in the mouth from sugars

The only thing correct about this assumption is that sugars, more particularly, refined sugars, are the culprits

Bacterial fermentation of sugars does result in acids. Milk sugar is fermented to form lactic acid. That is, the acids found in clabber milk, yogurts, buttermilk, scoured milk, cheese, etc. It will not crack enamel. Sucrose is converted to acetic acid and alcohol. Alcohol will not chip teeth. Should any acetic acid form in the mouth (acetic acid is vinegar) it is instantly neutralized by a constantly alkaline saliva

We agree that sucrose is a cause of cavities in those who eat it, but not by the modus operandi popularly ascribed

The eating of sucrose causes osteoporosis of every bone in the body including the teeth. This is so because the body must borrow from its bones the minerals, especially calcium, with which to metabolize the sugar. The sugar of commerce has no mineral or vitamin complement, that having been destroyed by heat and removed by several refining processes

Other causes of cavities are the ingestion of acid-forming foods (such as grains, legumes, etc.) which also cause the body to draw from its alkaline teeth and bone materials as a recourse in neutralizing the acids and maintaining an alkaline pH

Cavities are caused primarily from improper dietary habits. Eating our natural diet of raw foods consisting of mostly fruits with some vegetables, nuts and seeds will not cause cavities.

[Home](#) > [Lesson 62 - Healthy Eyes And Teeth](#) > Article #1: The Eyes

### **Article #1: The Eyes**

The eyes are the principle organs of experience of the material world and should be cared for with great diligence. However, dietary abuses result in direct and indirect impairment of vision, and the eyes are often further abused by the placing in them of irritating substances which purportedly wash them and relieve them of being "bloodshot."

The eyes are humankind's main organ of life's experiences. Vibrations are the source of vision as they are for all of the other senses. The light vibrations of a "perceived" object pass through the transparent

cornea and an opening, the pupil. They are then transmitted through the crystalline lens and semi-fluid content of the inner eye chamber and onto the retina. The retina consists of a thin membrane constructed of optic nerve axons and optic neurons (cells), bipolar cells, and receptor cells (rods and cones) at the back of the retina. Light vibrations pass through the outer two cellular layers onto the rods and cones which convert the vibrations into electrical impulses. These impulses are then transmitted through the bipolar cells to the optic neurons and then to the brain where all of the impulses are consolidated, picked up by the astral brain and relayed to the mind for interpretation and "experience."

Care of the eyes is most important to proper vision. The lacrimal (tear) glands "normally" secrete pure water to lubricate and cleanse the eyeball but in the modern human diet so many contaminants (particularly salt) are consumed and find their way into all body tissues, these glands and all other exocrine glands are forced to continually excrete salt and other contaminating wastes in their fluids. The salt in the tears produces a constant, never-ending irritation to the delicate eye membranes. This results in a perpetual state of some degree of inflammation of the eyeball (bloodshot) and the conjunctiva of the eyelids which grows chronic as people grow older. This weakens the membrane so that any additional irritant will produce severe inflammation.

A salt-free diet leads to clear (whites) bright eyes and improved vision.

In the event of dust or other external irritants entering the eyes, the only suitable eyewash solution is *pure distilled water*. All commercial eyedrops and eyewashes contain substances which are detrimental to tissue by forcing abnormal withdrawal and contraction of cells to "make the eyes clear" and "refresh" them by deadening nerve response to the irritation. These should always be carefully avoided in proper eye care.

Proper eye care also includes daily gentle massage of the eyeballs with the lids closed and exercises to stretch and relax the eye muscles (looking up, down, sideways, crosseyed, etc.).

Good vision is normal and natural. When body contamination and genetic defects combine to distort the vision, the only intelligent solution is to eliminate the cause and restore the vision to normal. The ridiculous practice of using glasses to "compensate" for poor vision is another of the unfortunate "advancements" of a primitive science. Good vision can be restored without glasses by simply observing the rules of proper eye care—proper diet, fasting, daily massage, and exercise.

Glasses for eyes provide the same disservice as perpetual use of crutches. In the case of the eyes, they atrophy and function (vision) becomes constantly progressively impaired. In the case of a weak leg, the muscles atrophy, and function becomes constantly progressively impaired until finally the limb is shriveled and useless.

*Excerpt from "Goldot"*

[Home](#) > [Lesson 62 - Healthy Eyes And Teeth](#) > Article #2: Natural Hygiene - Your Key to Dental Health by Mike Benton

## **Article #2: Natural Hygiene - Your Key to Dental Health by Mike Benton**

Over 98% of the U.S. population suffers from dental diseases.

By the age of sixty, nine out of ten people will not have any teeth of their own. Already more than 32 million Americans are toothless.

Over one *billion* cavities need filling in this country alone each year.

The total amount of money spent by Americans on dental problems is staggering. We have over 140,000

dentists in this country, pay them over six billion dollars a year, and yet 24 out of 25 American children suffer from dental diseases before they are six years old.

Is this normal? Is this natural?

In a region of the world known as Hunzaland, dental disease doesn't exist. Not a single dentist lives there. The people there use no toothpaste, no toothbrushes, and receive no Fluoride treatments. The old folks keep their teeth all their life. Dentures are a curiosity. The children have perfect teeth and healthy gums. The babies suffer no pain or irritation when teething. Sweets, candy, ice cream, and soft drinks are not ingested. Their diet is chiefly fresh raw fruits and vegetables.

Is there a connection? What do you think?

## **The Whole Tooth and Nothing But. . .**

"Teeth are vital parts of the human body," wrote Dr. Fred D. Miller, a dentist of over fifty years, "and they are nourished by the same bloodstream that nourishes the rest of the body. Good dental health is dependent upon good bodily health and vice versa. The mouth is the barometer of the body's general well-being."

Degenerative diseases, poor living habits, improper diet—all are reflected in the health of the teeth and the gums.

An amazing study was done by Dr. Weston Price about fifty years ago. He was a dentist who traveled the world over to investigate the relationship between diet and dental health. What he discovered was that as long as people ate their natural diet of unprocessed and unrefined foods, they enjoyed sound teeth and healthy gums.

Whenever the modern foods of civilization—refined grains, sugars, junk foods, preserved foods, etc.—were introduced, the teeth of the people rotted, their gums became diseased and the actual shape of their mouths changed.

## **Diet Does It!**

"I believe the ideal diet, guaranteed not to cause decay," wrote Dr. Thomas McGuire, a dental researcher, "consists of raw vegetables and fruits." Dental problems do not occur on such a diet for three reasons:

1. When foods are eaten raw, unprocessed and unrefined, food particles that may remain in the mouth do not undergo fermentation. This fermentation, while not actually contributing to tooth decay, can lead to a buildup of harmful materials around the teeth and gums. Living foods—raw foods—do not ferment; dead foods—cooked foods—quickly decay when left in the mouth.
2. Raw foods are naturally fibrous. The fiber in raw foods require chewing and thereby give the teeth and gums beneficial exercise. Circulation is improved around the mouth area when naturally fibrous foods are chewed. The fiber also aids in the removal of food particles from the teeth and gums. After all, if the teeth and gums are not exercised by working on fibrous foods, the result is the same as when any part of the body is denied exercise. For a child, this loss of jaw exercise contributes to a crowded, underdeveloped mouth and crooked teeth.
3. Most importantly, minerals and other nutrients required by the body for healthy teeth (and health in general!) coexist in balanced amounts within natural, raw foods. Processed and refined foods, cooked foods, "junk" foods—all are minerally unbalanced and this is the principle reason for tooth decay: a mineral unbalance.

## **The Important Mineral Balance**

Tooth decay does not occur if the calcium and phosphorus minerals are in proper balance in the body, along with other needed nutrients. The teeth are made primarily of calcium, and phosphorus is needed in

specific amounts to help use this calcium. If too much phosphorus is present in the diet, or if the foods eaten are high in acidic residues, then a calcium loss can occur in the body and weaken the teeth.

Some of the worst high phosphorus foods are meat and grains. People on a grain-based diet or a high-meat diet often exhibit a large amount of dental decay. Carnivores who eat both the organ meat and bone marrow of their prey get a correct balance of phosphorus and calcium since the bones are high in calcium. Humans, however, eat only the mineral-poor muscle meats which disrupt the calcium-phosphorus ratio.

Grains, and especially refined grains, can lead to rapid dental decay. They are soft and sticky, are always cooked and remain on the teeth for bacteria to digest, unless supplemented by high-calcium fresh greens, grains lead to an excessive phosphorus and acid level in the body.

Seeds and nuts, two foods commonly eaten by Hygienists, are also phosphorus-rich. Fortunately, these foods are usually somewhat balanced in calcium as well, but there is an inherent wisdom in eating these foods with leafy greens or citrus fruits—both good sources of calcium.

When a diet high in acid-forming foods (such as meat, legumes, grains, refined foods, etc.) is eaten, the calcium ratio is also disturbed because the acid residue of these foods require the base mineral calcium to neutralize them. When this occurs, calcium is shunted from the body's reconstruction and maintenance activities and is used instead to balance the harmful effects of the acid-forming foods.

We can insure ourselves of the proper mineral balance by eating foods only in their whole, raw state.

Once a food has been tampered with in any way, a nutrient loss occurs. An alkaline diet of fresh fruits and vegetables keeps the calcium in the teeth instead of having it used to neutralize harmful acid wastes that are created by processed foods, cooked foods and foods not suitable to the human dietary (meat, grains, legumes, etc.).

## **By the Skin of Our Teeth**

Tooth decay is the most familiar dental disease, yet it is the degeneration of the gums that is the most serious problem. Most tooth loss in this country occurs not from decayed teeth, but from poor gum health and bone loss.

Bleeding from the gums after brushing or flossing is the first sign of potential gum trouble. Healthy gums do not bleed. They should be a healthy pink, not a bright red, and they should hold the teeth firmly in place with no signs of recession.

Bleeding occurs because the gums have become irritated by a buildup of a substance called *plaque*. What is plaque? Well, if you look closely around the base of your teeth where they join the gum line, you might find a white chalky deposit or perhaps a yellow band. That is plaque and that is what causes most dental troubles in this country.

Plaque is the acid-waste products of bacterial colonies that live in your mouth. As these bacteria eat, they excrete an acid substance which forms the chalky plaque that coats your teeth.

When this plaque is fresh (about one to two days old), it can usually be removed by simply brushing or flossing. If the plaque is left on the teeth, it becomes mineralized into a rock-hard substance called *calculus*.

Calculus is a hardened mineral deposit that forms at the base of the tooth and under the gum line. Eventually it can cover the entire tooth. As it hardens and creeps beneath the gum line, it becomes razor-sharp. The calculus deposits irritate, injure and eventually destroy gum tissue. It's quite simple, usually even quite painless and sometimes quite permanent.

The removal of plaque before it turns into calculus is the main reason for brushing and flossing the teeth. If the plaque has already turned to calculus, your only alternative is to have your teeth professionally cleaned and scraped (or scaled). This is usually painless, involves no drugs and is inexpensive (\$20 to

\$30). If the tartar is already deep below the gums, it may be considerably more expensive, but is worth it if a careful and thorough job is done. It may just save all your teeth.

But why does this plaque occur in the first place? Is plaque buildup "natural?" What did man do before the invention of the toothbrush or of dental floss or of the dental hygienist?

Well, he rarely suffered from this plaque buildup because he ate foods that do not cause this condition. Raw foods do not decay in the mouth—they are still "alive." Only when dead foods, such as cooked foods, are eaten does this decay occur. This is why we are always told to brush after every meal. And this is good advice, especially if our mouths have been turned into cesspools of decay by junk foods, meat, white sugar and so on.

On the occasions that I eat cooked foods, I can hardly wait to brush my teeth. You can almost feel the decay starting immediately. Cooked food particles left in the mouth cause bad breath and a pasty feeling to the teeth. When fruit fibers are left in the mouth, no decay occurs. You can remove a piece of pineapple that may have been lodged between the teeth for hours and it is still fresh. Try doing that with a piece of roast beef and you'll see an obvious difference.

## **What Can You Do?**

To have a healthy mouth, put healthy food into it. An optimum diet can prevent over 95% of all dental problems, and a regular cleansing program (brushing, flossing and scraping, if necessary) can just about solve the rest.

Unfortunately, many of us begin healthy practices and a good diet *after* dental problems have already started. It takes about 25 years or so to grow a healthy tooth. If we ate poor foods during that time period, it's probably going to show up in our teeth and gums at a later age.

So you see, even if you are now eating only the best foods and engaging in all sorts of health-promoting activity, you still might suffer from dental problems created by poor eating habits in your earlier years.

Such serious problems as missing teeth, severe gum disease, poor eruption of the teeth or large decayed areas are going to require some professional attention. Minor dental problems can definitely be arrested by a good Hygienic diet and may even be reversed. If you are already experiencing pain, however, it may indicate that the condition has progressed too far to be remedied by diet alone.

What you need to do is to correct all the old dental problems, stay on a good diet, and clean your teeth regularly and you'll never have any pain or problems again.

If you are currently in pain, have tooth sensitivity, or have some sort of gum disease, find a good dentist who is sympathetic to your healthy lifestyle.

After you find a dentist you can trust, have the major repair work done that you need. A cavity won't heal itself; a broken tooth won't grow back—you just have to have these things repaired as best as possible and then make sure it never happens again. Also, insist on quality materials and quality workmanship from your dentist. Poorly and cheaply done dental work can cause more harm than the conditions they attempt to correct. One dentist said that most of his work comes from "fixing up" other dentists' mistakes and shortcut attempts. Don't compromise or "economize" when you're having permanent corrective work done; after all, you want it to last a lifetime.

After you get your teeth back in shape, stay on a good diet and practice regular dental hygiene. Once these old dental problems are corrected and you eat only wholesome foods, you'll never be bothered by tooth decay, gum disease, or mouth sensitivity again.

After all, good health should be something you can really sink your teeth into!

### **Article #3: How To Conduct A Dental Self-Examination**

1. Start when relaxed and you have at least one hour of free time. Sit at a table that offers a solid arm rest. If you can, purchase a small dental mirror at a drugstore, or use the smallest face mirror that you have. A flashlight or bright overhead light will help you in this examination.
2. Begin your examination with the last tooth on your left side on the lower jaw. Gently pull your cheek away from the back teeth, and with the other hand shine a light on your back teeth. Use the mirror to see the teeth reflected in it. Now starting with this lower left tooth, look for the following things:
3. Dental Checklist:
  - a. Is the tooth broken or does it have a filling?
  - b. Is there a noticeable hole, or a small black spot on the tooth? (This indicates a cavity.) Be sure and look on the back of the tooth as well as between the teeth.
  - c. Is the tooth stained?
  - d. Is there tartar or heavy yellow buildup on the teeth?
  - e. Is the tooth crooked?
  - f. Is the tooth chipped, cracked, or is there an old filling that is cracked or missing?
4. Go slowly all around the mouth, top and bottom, and look at each tooth individually—front, back and in between. For many people, this will be the first time in their lives that they have actually seen the inside of the mouth. Go slowly, and inspect each tooth carefully and critically.
5. Specifically, you should be able to determine the following from this self-examination:
  - a. How many teeth do you have? With all four wisdom teeth, you should have 32. People without wisdom teeth will have 28 teeth. If you have any missing teeth, see if the teeth to the side of the gap are slanted inward.
  - b. Look at the spaces between the teeth. If there are gaps or crooked teeth, then be sure that you are careful about removing food particles that can easily get wedged in these areas.
  - c. See if your teeth are stained. Teeth do become more yellow with age simply because the white enamel of the teeth is gradually worn away by age and abrasive toothpastes. Yellow teeth are not necessarily bad, but you may want to check with a dentist. You may see brown stains on the teeth. This usually indicates smoking. Other stains and colors may appear. If the color of a tooth has changed rapidly, then it may indicate a more serious dental problem.
  - d. Notice if there is some sort of sticky or hard build up around the teeth, particularly at the bottom. This pasty stuff is called tartar and it may eventually harden into a substance called calculus which is sharp and rough. You may want to have your teeth professionally cleaned to remove this buildup. After a cleaning, you should never need another one if you follow a raw diet.
  - e. If you see any holes or black "pinpoints" on the teeth, then you have a cavity. If the tooth is sensitive at all, you may want to have it filled with a harmless substance (do not use silver fillings!). To test for cavity sensitivity, hold ice-cold water in the mouth. If you feel any pain, you have a potential cavity, or perhaps an old or cracked filling.
  - f. The final report of your examination should be around the gums of the teeth themselves. Are the gums red, swollen, or puffy? They shouldn't be. Do they bleed after brushing? They shouldn't. Healthy gums are a pleasant pink, and they cover the base of the tooth without any receding. Now your self-examination is over. What's next? If you are currently experiencing dental pain or discomfort, then you may need professional help. If your teeth appear fine and you are not suffering, then a healthy diet and lifestyle should keep your teeth fit for the rest of your life.

## **Article #4: Eye Exercises**

To strengthen the eye muscles, do these exercises once or more every day:

1. Without moving your head at all, use your eyes to follow an imaginary diagonal line, from the upper left of your vision field and down to the lower right. Feel your eye muscles stretch as you look diagonally upward and then downward. Do this five times, and then repeat from the upper right to the lower left.
2. Now move the eyes to the top and then to the bottom as far as you can without moving the head. Make the eyeball muscles stretch! Do this up and down, down and up movement five times each way.
3. Now blink the eyes rapidly until tears form. Close the eyes in a relaxed manner, then squeeze them, then relax. Place the palms lightly over the eyes.
4. At first repeat these exercises only once. Later, do them twice, and finally three times. Do not strain, and at the end of each exercise part, relax and rest them. Combine these exercises with alternate focusing on far and near Objects.

You may also wish to read other books on eye exercise. The best one is still *Better Eyesight Without Glasses* by Dr. W.H. Bates (Pyramid Books).

### 1. Introduction

Just the other day, while driving across Tucson, we were listening to the comments of Dr. Tony Grant, Ph.D., a well-known psychologist. Dr. Grant remarked that she often gets quite disturbed because medical doctors so often try to advise their patients on matters that rightfully should be referred to a trained psychologist. She went on to say that medical doctors receive little or no training in psychology and that, therefore, they are really not competent to offer advice in that very specialized discipline.

We Hygienists have that complaint, too. Medical doctors, as a group, have little or no training in nutrition. They know nothing of the real nature of disease, nor of how to activate the powerful healing forces resident within the living body. In fact, they have an untrue and totally unscientific foundation for their whole methodology.

In the treatment of diseases of the hair and scalp, we feel especially frustrated because, as a group, persons experiencing diseases in these areas are often subjected to years of senseless tinkering at great expense without any improvement in health of either the localized disorder or within the total body structure. On the other hand, when these same patients are once introduced to the principles of Natural Hygiene and begin faithfully to apply them in their own lives, they often are amazed to find healing taking place, often within a very few weeks.

All persons are much aware of how important it is to possess a fine head of healthy hair. An abundant crop of hair possessing body and sheen is a mark of health and beauty which sets members of both sexes and both the old and the young apart from the crowd. In this lesson we will learn the beauty secrets of the ages. We will learn how to care for the hair the only truly scientific way, the Hygienic way.

## 2. Structure Of The Hair

All mammals possess hair of some kind. Like the nails and the many sudoriferous (sweat) and sebaceous (oil-secreting) glands, the hair is considered to be an appendage of the skin (something which is considered a proper part of a greater whole). Some animals have smooth hair, some stiff bristle-like outgrowths; still others, pointed spines.

Individual hairs are composed chiefly of a rather horny substance, a sclero-protein, a simple protein known as keratin. The amino acids of which keratin is composed are strung together in a more or less straight line, one after another. These lines of amino acids are called polypeptides. Keratin is a fibrous protein and fibrous proteins are strong, sturdy, and tough. This same kind of protein is also found in the fingernails and toenails.

In humans the hair consists of a cylinder 1/400th inch in diameter. At the base of the cylinder, which consists of a shaft and a point, there is a "root" which is embedded in the skin in a kind of pouch-like depression called the hair follicle. Beneath this depression is the papilla, a kind of nipple which fosters the hair and builds new hair cells. The papilla might be called the "connecting link" between the hair, the blood, and the nerves which service it.

The shaft or outer part is pithy (called medullary substance). It is surrounded by a fibrous part containing pigment and this portion is, in turn, covered by a layer of epithelium scaly cells. Near the point, the pith begins to taper off to form the penetrating point of the hair shaft.

In humans the hair begins to develop in the fetal period. By the sixth month, the tiny fetus is literally covered with fine hair which is termed the *lanugo*. Following birth, the lanugo is rapidly shed and is replaced by hair in all the familiar places and in rather precise forms: coarse hair over the cranium and eyebrows and fine, downy-like hair over the rest of the body, the latter often being so fine as to be almost invisible to the naked eye:

At puberty certain changes are evidenced. Coarse hair begins to develop in the armpits and over the pubic or groin area in both males and females. In males the hair begins to grow more coarse over the upper lip and about the lower portion of the face and, if unshaved, quickly forms a beard.

The rate of growth of the hair varies according to age, health of the individual, and the length of the hair. When hair is cut short, for example, it can grow as much as 3/4ths of an inch and even more in a month but by the time it is 12 inches in length, its rate of growth can be reduced by as much as one-half, all other things being equal, of course.

The hair of young people grows faster than that of older people, with the fastest growth being found in women, especially from 16 to 24 years of age, this latter age being about the time when most humans are said to reach full maturity.

The type of follicle determines the identifying characteristics of the hair in different races. The black woolly hair of Blacks, Papuans, and Melanesians grows from a curved follicle which imparts a spiral twist to the hair. This kind of hair growth appears flat or tapelike when cross-sectioned and viewed microscopically.

The characteristic straight, coarse, long, and almost always black hair of the Chinese, Japanese, Eskimo, and American Indian grows from a straight follicle and this type of hair is round in cross section and possesses a plainly visible pithy center.

The hair of other group types, including those of European ancestry, is often wavy and somewhat intermediate in texture between the straight and woolly types. This latter kind of hair also grows from a straight follicle, but it is oval in cross section, this shape giving it a greater or lesser tendency to curl.

Variations in pigmentation among this last group causes the hair to exhibit a wide range of color from

light blonde to various shades of red to black.

Hair grows on the human body where protection is needed. It serves to protect the head area where is housed the control center for all metabolic activity within the entire organic community. It protects the individual from the heat of the sun and from the cold of nights and frigid winters. Body hair helps to retain the heat of the body. When located in ingress passageways as, for example, in the nose and ears, the hair prevents the entrance of foreign matter into the nose, lungs, ears, and other possibly accessible parts.

The hair on the head helps to preserve the brain and nerve centers from shocks, injuries, and irritation from harmful external influences; from blows, for instance. The hair is an organ of touch. It is extremely sensitive and responds quickly to danger. Hair has been observed to stand on end from fear, anger, or when the head has been dealt a blow.

Extremes of heat are believed to induce more rapid growth of the hair than moderate temperatures. This may be due to a kind of incubating effect.

Dr. St. Louis A. Estes, in his book *Raw Food and Health*, gives the following analysis of hair substance:

Carbon	50%
Oxygen	20.85%
Hydrogen	6.36%
Nitrogen	17.14%
Sulphur	5%

and goes on to point out that blonde hair contains lesser amounts of carbon and hydrogen and greater amounts of oxygen and sulphur.

Brown hair, on the other hand, has more carbon and a small amount of oxygen and sulphur, interestingly enough white hair contains high quantities of calcium phosphate. In white hair the pigment ratio is reduced and the pigment replaced by tiny air bubbles.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > 3. Some Common Disorders

### 3. Some Common Disorders

Disorders of the shaft or follicle can cause either of two extremes: abnormal growth of the hair or abnormal or premature falling out of the hair. The latter is often incorrectly, we believe, attributed to the aging process and should, more properly, be attributed to a failure to nourish and take care of the hair.

Sometimes fungi which imbed themselves in and around the mouth of the follicle, can give rise to a variety of hair diseases. Small crusts can form which slough off; or lesions, as in ringworm, can develop and become annoying and very itchy.

Minute insects and mites can take up residence, not only in the hair on the scalp, but also in pubic hair.

Dull or dry hair can be caused by malnutrition, but also by physical or chemical agents. Chemicals used

in permanent waving, or in many shampoos and lotions, especially those which contain alcohol or free alkalis, can cause these conditions and can also give rise to itchy rashes and pimples, some even with pus. Alcohol is an offensive agent to all skin surfaces. It can penetrate the outer membranes of the cells very easily and destroy them.

When the body becomes excessively hairy, it is often, but not always a response to a need for protection from the elements. Carl H. typifies the latter. Carl loved the outdoor life. Years of playing, scantily attired, in and around the waters of the Pacific Ocean at all seasons and for hours on end had caused abnormal hair growth all over Carl's body. The hair on his chest was fully four to six inches long and as much as two inches on his legs and thighs. Carl, now approaching sixty years of age, has so much hair on his body that he finds it most uncomfortable to stay indoors even in the cold of winter and rarely feels the need to wear any clothing except for a pair of scanty shorts. In fact, he is visibly uncomfortable if required to put on a light cotton shirt!

In a few cases excessive hair growth has been traced to a tumor on an adrenal gland or to some malfunctioning of another of the endocrine glands, specifically, the pituitary, the thyroid and/or the ovary. However, medical researchers tend to leave the problem-solving there without tracing the actual cause of such malfunctioning: namely, a toxic condition of the body.

### 3.1 Baldness

It would appear that young men are increasingly bald. Few males seem to reach maturity without some hair loss. In fact, implants and the fitting of toupees is a growing and lucrative business and appears to be a phenomenon of our times. A normal head of hair, thick and luxurious, is indicative of a sound body. The appearance of baldness is believed to be indicative of systemic deterioration being manifested in the cranial area.

Just as clinical study of most individuals suffering from major chronic (vertical) diseases, such as rheumatoid arthritis and cancer, reveals a past history of evolving pathology which begins with acute afflictions characteristic of the very young and ends in progressive chronicity, so does a general decline in the appearance of the hair seem to reveal a similar developing pathology.

Among the more common signs of a progressively serious hair and scalp pathology we can include the following:

1. Persistent dryness of the hair and scalp.
2. Dandruff.
3. Scaling.
4. Tenderness to the touch in certain areas.
5. Itchiness.
6. Falling hair with increasing thinning of the hair.
7. Receding hair line.
8. A bald spot appearing on the top of the head in a limited area (*Stedman's Medical Dictionary* lists over 20 different types of baldness according to precise location and/or its suspected origin.) Alopecia is a general term with prefix or suffix being attached for a more precise identification as, for example, *alopecia liminaris frontalis*, which identifies a loss of hair restricted to the hair line, a condition most commonly seen in members of the black race; or *alopecia universalis*, or total baldness.
9. Excessive oiliness.
10. Discoloration of the hair; streaking, etc.
11. Small bumps or concretions.

Dryness and dandruff appear to be early symptoms of more serious trouble ahead. Itching, of course, provokes excessive scratching with the possible wounding of follicles. Bad combs, brushes made of synthetic fibers, teasing of the hair, burning with caustics and chemicals—all can cause gradual and even

permanent hair loss by damaging the hair roots beyond repair.

Some fifteen years ago Dr. Elizabeth's hair was perfectly straight and very coarse. She decided to have a permanent wave. The beauty operator failed to apply a neutralizing agent to counter the chemicals used in the waving lotion. On the following day, her scalp was covered with a fiery red rash which extended into the ears and down the back of her neck. The hair itself was curled so tightly that it seemed to consist of tiny reddish gray corkscrews! Her condition became so serious that it eventually ended up in the courts with a settlement after considerable testimony offered by the attending physician to the effect that Elizabeth's hair and scalp condition was due to the chemical action of the waving lotions.

As a result of this abuse the hair in the front part of the (head became very thin and a tiny bald spot appeared on the top of the head. It is interesting in this discussion to note, however, that hair has regrown to a remarkable extent in this area and the bald spot is no longer there due, without a doubt, to the fact that the hair cells were not permanently destroyed.

It is interesting to note, too, that during the intervening years during which time Elizabeth's health and general vitality have grown enormously due to incorporating the principles of Natural Hygiene into our living and eating practices, her new crop of hair has changed from its former coarse, bristle-like, straight texture to a much finer texture and it is also now softly curly. Dr. Elizabeth no longer bothers patronizing expensive beauty shops except for an occasional haircut!

We have observed one other case where almost straight hair has become so much more curly and changed in texture that it has attracted the comments of friends and associates. This woman is an athletic instructor in an elementary school. She keeps her hair cut quite short since she has to take frequent showers because of the nature of her work. After a year or so following a greatly-improved dietary intake, her hair is noticeably improved in texture and possesses a lovely natural curl.

Persons who lose their hair, however, more often than not exhibit a past history of catarrhal troubles, nervousness, diseases of other areas of the skin. Their past medical history often shows that they experienced many of the common childhood diseases; some have venereal diseases. Then there are others who may have suffered blows and bruises during childhood. For example, the cuffing of children on the side of the head may lead to baldness in later life. Many participate during the formative teen years in such physical contact sports as football where multiple blows are often sustained.

Dyes, bleaches, excessive shampooing with soaps, the application of chemical poisons in the form of salves, tonics, and various cure-alls advertised for dandruff and itchy scalp—all can be factors leading to falling out of the hair and baldness.

Certain drugs, for example, those used in chemotherapy, especially drugs containing mercury and iodine and most particularly cytoxan (cyclophosphamide) commonly used to treat lymphomas and certain types of leukemia, lead to hair loss, often to complete baldness. Many of these are capable of membrane simple diffusion or can be actively transported to cause cell death. Interestingly, too, is the fact that cytoxan and some of the other drugs also cause nausea, malfunctioning of the liver and drastic reduction in the number of leucocytes (hypoleucocytosis—the loss of white blood cells).

And yet, the vast majority of people, like little lambs following the bellweather lamb to the slaughter, just apply the most widely and glamorously advertised lotions and creams to their hair and scalp and pop all manner of poison pills like children popping "M and M's," and never question their effectiveness or suspect the dangers that may lie waiting in the wings.

It appears that most people who suffer from chronic diseases of the hair and scalp have been constipated for years and, more often than not, the solid-fluid ratio within the body has become deranged to the extent that their bodies lack suppleness and flexibility and the body channel routes have become clogged with abnormal amounts of solid debris accumulated through wrong living and eating habits to such an extent that the circulatory powers of the body have been greatly curtailed. Obviously, such systemic deterioration does not occur overnight. It is one that takes time; such conditions are, no doubt, like all chronic diseases, years in the making.

Normal sexual activity stimulates the flow of the sebaceous glands of the scalp. It is possible that overstimulation of these glands, however, causes them, in time, to produce less and may exhaust the vitality of the hair itself.

Wounds, burns, and excessive heat which again accelerates the action of the sebaceous glands, can cause death of the hair cells and subsequent hair loss.

In all baldness that remains on-going, there has been death, death of the hair cell. As noted, hair cells can die from numerous causes, but all hair loss (barring, of course, loss from some milder external cause) can be traced, in the final analysis, to insufficient or total lack of circulation of the blood to the papilla which houses and feeds the root (the papilla is often called the "mother" of the hair since it is through this organ that the hair is fed).

Most overweight people show pronounced hair loss. People who eat a preponderance of cooked food rarely have healthy-looking hair and often exhibit thin straggly-looking hair. We have noted that persons who are heavy meat eaters quite often have very thin sickly-looking hair.

Overnutrition and the eating of cooked foods "inflate" the body and build toxic-laden adipose tissue.

Nutrients which should be directed to hair follicles do not arrive due to increased blood viscosity (thick blood), a condition which impedes the circulatory powers of the body. The body then stores the available nutrients wherever it can and they are usually used to build fatty tissue which is, in its turn, used to store uneliminated and ever-accumulating toxic debris. Excess fat, therefore, becomes a toxic vault and the possibility is ever present that, under stress, this "vault" can open wide and throw its death-dealing contents into the mainstream to impede and destroy life.

A diseased scalp is an indication of the presence of impurities, toxic metabolites, in the bloodstream. The hair, like every other part of the body is nourished by the blood. Dr. Shelton points out that until the general health is such as to "guarantee to the hair adequate nutrition, through the blood, the hair cannot be improved."

To keep the beauty of the hair throughout life, it must be protected from violence and it must also obtain adequate amounts of all nutrient factors day after day throughout life. For example, a lack of vitamin A in the diet may cause the hair to be coarse and ugly. It is believed also that a lack of some of the B vitamins or of iron, copper, and/or iodine may cause the hair to fall out and that lack of other vitamins, especially pantothenic acid; para-aminobenzoic acid, or PABA; and inositol, may cause the hair to gray prematurely.

Some forms of eczema of the scalp may be due to a lack of essential fatty acids in the diet. All three anti-gray hair vitamins can be produced in the intestinal tract by bacteria that normally, in healthy people, reside there. When the food intake is correct and well-adapted to human needs, there seems to be no deficiency in any of these vitamins.

It is interesting also to learn that experiments at the Good Housekeeping Institute (according to Gayelord Hauser) showed that factors other than vitamin presence also influenced graying of the hair as, for example, a low red blood cell count and other abnormalities in the blood. It is worthy of note here to observe that females more often than men complain of falling hair and many who do so have menstruated copiously for years, a condition demonstrated to be a result of unhygienic living and eating practices. Falling hair is a companion disorder to anemia. Copious menstruation, when prolonged, can result in severe anemia and many women thus afflicted develop gray hair very early in life.

In animal experimentation a lack of even one of the B vitamins can cause animals to lose their hair.

When the food intake is again made optimal, the hair quickly grows in and becomes luxuriant. It is interesting here to note that male animals lose their hair about twice as fast as female animals do and it has been suggested that perhaps baldness in males may have an unexplained sex linkage.

Our own research in this area with our two dogs, one a Doberman and the other a Collie, casts some

doubt on this thesis. Both animals were "rescued," one from the pound and one from a family whose children were abusing the puppy. The fur of both was in terrible condition, thin and very short and dull looking. For a time the animals were fed on ordinary dog food plus scraps obtained from a local slaughterhouse. The Collie was a sad-looking specimen. About three years ago we decided to try a vegetarian diet on the dogs. We fed them sweet fruits in the morning and a combination of cooked and raw vegetables in the late afternoon. We did give them a raw egg every other day.

The results were amazing. In a comparatively short time the Doberman had a shiny soft coat and the Collie was a raving beauty! We lost the Doberman, unfortunately, through an accidental injury, but the Collie's coat of fur is thick, very shiny and of a beautiful tri-color.

It would appear most likely that baldheadedness in both men and women is the result of years of malnutrition, and in using the term "nutrition," we include all phases of nutrition: absorption, assimilation, elimination, etc., as well as the feeding of appropriate food in a correct amount and manner; plus, associate influencing factors, such as the obtaining of sufficient sunlight, etc.

We have already observed that when the diet is improved in humans, new growth can often be observed but again we should point out that such growth would be possible only when the hair cells are still viable and not dead.

Many researchers suggest using isolated vitamins to stimulate the scalp and thus improve the condition of the hair and its growth. Dale Alexander comments how Dr. Herman Goodman, a leading dermatologist, recommends foods which are rich in vitamin A, foods such as carrots. Hygienists, however, know that there are no "target" foods, that we must have the whole spectrum and that this is provided by eating a variety of foods, but eating them in suitable combinations so as to maximize availability to the bioprocesses of the body.

It seems that most dermatologists have little understanding of the fact that we must supply the "whole" of food, not bits and pieces. Dr. Richard W. Muller who practices in several European capitols including Paris and Vienna, recommends foods high in sulfur content but then notes that iron and calcium are also important hair components. We recently had an inquiry via the mails from an individual who had a problem related to nutrition. She said that she was sitting with a box of unopened pills and tablets bearing a total price tag of \$300.00 which had been prescribed for her. These consisted of all manner of vitamin and mineral supplements. She had great doubt that dosing herself this way was the proper approach. We advised her to return the whole batch unopened and begin to eat the Hygienic way.

Certainly, impaired digestion and poor eating habits can cause all manner of body troubles including disorders of the scalp and hair; especially abnormal hair loss, eczema, carbuncles and, no doubt, complete baldness, too. Most people eat too fast and do not chew their food. In excess of 90 to 95% of the foods they do eat are cooked and even these foods are poorly chosen. It is no wonder a minimum of nutrient wealth passes through the cells of the membranes lining the intestinal canal prior to entering the bloodstream for transport to hair cells and all other body cells. The average person pays for food, he eats "food," but the body cells fail to receive the nutrients of life in sufficient quantity and in their original symbiotic proportions to do more than sustain life and this for but a brief span!

It is little wonder that the body begins to sag and that the hair becomes lifeless and lacks suitable pigmentation, or that scalps flake and itch and that eventually the hair falls out.

We recently did a bionutritional analysis and profile for a mother and son. The results were most revealing. The mother has been a faithful follower of Natural Hygiene for almost three years now, the son a faithful follower of his peer group diet of hamburgers, french fries, and coke and, is no doubt, like the vast majority of his age group, "into" drugs and alcohol, also. While the mother's test revealed almost all readings within optimal (not "average") lines, the 17-year-old son's readings were largely either above or below the optimal with a number of them registering in the "dangerous" area. While other facts may account, no doubt, for some deviations, the contrasts in these two instances can rightfully, we believe, be attributed to the differences in nutritional practices noted.

Dr. Lucien Jacques of Paris worked with 71 patients who suffered with disorders of the G.I. tract, all of whom complained of rapidly falling hair. Many of these patients also drank excessive amounts of tea, coffee, and alcoholic beverages. Simply by changing the diet of his patients, Dr. Jacques not only was able to observe better digestion in his patients, but also remarkable changes in the health of the hair, including the coloring.

White sugar, all manufactured sweets such as ice cream, pastries, candy, soft drinks, processed foods of all kinds are acid-producing and nerve-destroying. If we wish to possess a head covered with thick, shiny beautiful hair, we must pay attention to the food and drink. We must drink only the purest of water and eat of those foods to which we humans are adapted: luscious ripe sweet fruits plus limited amounts of young leafy greens and fruit vegetables (non-sweet fruits), sprouts, nuts and edible seeds.

Iron is required for a thick crop of hair. Raisins, lettuce, strawberries, apples, cherries, and many other luscious fruits are well endowed with iron.

Sulphur, an essential food element, is found abundantly in members of the cabbage family, in cucumbers, in potatoes, and figs.

Silicon for strong filaments is found in leafy varieties of green lettuce, especially in romaine; it is also present in strawberries, in cucumbers, and cherries as well as in the skins of apples and other fruits.

Healthy hair requires carbohydrates to supply carbon and hydrogen for composition and the carbon for fuel. Ripe, sweet fruits furnish the finest kind of predigested energy-conserving carbohydrates to be found. This is especially true of the sweet, sweet fruits, the banana being a prime example of an almost perfect food.

Adequate protein and all the essential amino acids are found in many fruits and vegetables. The proteins found in many plant foods are biologically of optimum value.

The Law of the Minimum about which we learned earlier tells us that the absence or short supply of even a single nutrient for any extended period of time can lead to general health debilitation regardless of how well supplied we may be in all other nutrients. Tests on both animals and humans have shown that deficiencies can also reduce the hair quality and health. It would appear that there is a grand pact in nature wherein correct proportions and adequacy of all nutrients are the basic requirements of maximum health. Eating cooked foods, eating foods lacking in nutritional content, failing to chew properly, eating to excess and eating too often, the taking of isolated vitamin and mineral supplements, a lack of exercise or sunshine, long continued emotional stress exposure, indeed, a lack of any of the requisites of organic existence can lead inevitably to diminished health, and any lack of health will be reflected in a lusterless, sick-looking hair which soon starts to lose its color, to thin and fall out in ever increasing amounts. No single food factor or any combination of food factors put together by man and taken in isolation can work hair and scalp magic. The body is a unitized functioning entity. The health of the hair reflects the health status of the totality.

Many excuses are offered from time to time and by many "authorities" for thinning of the hair, for loss of color and sheen, for baldness, excuses like inherited bad genes, wearing hats which are too tight and wearing them too often, shampooing too frequently, and many others. But, these are only excuses. None are based on the known realities which define and limit the life process.

More primitive men and woman have abundant crops of hair. Whole nations of people who have lived for thousands of years on simple diets have thick healthy growths of hair. It is only "civilized" men and women who partake of poor devitalized heterogeneous messes of food in quantities far in excess of body need who suffer hair and scalp problems associated with malnutrition. It is civilized people who show meager crops of hair and damaged scalps.

Dr. Art Mollen, a Phoenix osteopathic physician and a firm believer in the benefits to be derived from regular paced jogging, does not see much prospect of extending the human life span. Pottenger's experiments with cats at Yale showed that it takes several generations to witness the results of good

eating as well as of poor eating. The goal of Hygienists should be to share their knowledge with all peoples so that, generation by generation, the human population can grow into a state of health which we presently can only envisage. Then perhaps we can prove that the Dr. Mollens of this world are wrong. As practitioners we see too many miracles resulting from following after the principles of Natural Hygiene not to believe that we can extend the life span in full health and perhaps more than double its present length.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > 4. How To Care For The Hair

## 4. How To Care For The Hair

The first and primary requirement for improving the condition of the hair and scalp is to cleanse the body fluids, the blood and lymph, of their toxic load, preferably by fasting or, more slowly, by the McCarter Extended Detoxification Method as detailed later in this lesson or by some similar method.

Next, it is essential to begin a new life, to adopt a new way of eating and living: begin to eat and enjoy a fruitarian diet and a lifestyle which provides for all body needs including sunshine, pure water, and so on. Especially important is the cultivation of emotional poise. Remember that constant worry, fear, anger, jealousy can turn the most beautiful hair into a drab-looking gray. It can also make it fall out.

Exercise the scalp daily by manipulating it lightly with the tips of the fingers or the palms of the hand, always in a rotary movement. Press the palms of the hands against the sides of the head and move the scalp gently so as to push it together in folds. Always work gently so as not to irritate the scalp or injure the hair follicles or place stress on delicate nerve endings.

DO wash your hair frequently. However, as a rule we do not recommend using soap or shampoos unless, for one reason or another, the hair has become extraordinarily dirty. Hereward Carrington, in his marvelous book *Vitality, Fasting and Nutrition*, writes as follows, "It has been repeatedly shown, moreover, that frequent washing and extreme cleanliness are as essential to the scalp as to any other part of the body—the effect of water upon the hair being beneficial and strengthening, however frequently applied, provided the hair is thoroughly dried."

Dr. Elizabeth rinses her hair under the shower almost every other day and often every day. Mary Martin, who sang, "I'm Gonna Wash That Man Right Out of My Hair" on Broadway in Rogers and Hammerstein's South Pacific is said to have washed her hair on stage in 1,694 consecutive performances and reportedly observed no adverse effects. Today she displays a beautiful head of hair.

Make frequent rinsing of the hair a part of your personal daintiness program. It is the simple Hygienic physical habits that add up, in time, to major health benefits. Adopt a daily routine of cleanliness and begin to reap its rewards. As Margery Wilson once wrote, "Everyone knows that youth and strength depend on water, vegetables, fruit, exercise, and a high heart and mind." The best beauty treatment for the hair that makes real scientific sense is a combination of a lifestyle and eating regimen best suited to human wellness; in other words, full application of what is presented in this course of study. The discipline of Natural Hygiene is the only discipline that recognizes the fact that nutrition represents the sum total of ALL body processes and cannot accept any attempt to separate or isolate any part of the life process as anything other than foolishness. And, it must be emphasized that proper care of the hair and scalp, just as with the entire body, should begin with the first meal and the life routines of the first day after birth. If these be optimal and continue to be day after day and throughout life, then life itself can be no less.

## **5. Establishing The Client-Practitioner Relationship**

Even though the disorder of immediate concern to the client may be limited to the skin, scalp, or hair, the knowledgeable practitioner well understands that any diseased state affecting these areas indicates an eliminative effort of some dimension. He also understands that the entire system is burdened with a degree of toxicosis which is, at present, unknown and that it is this toxic condition which must first be addressed before the disorder which has brought the client to your office and which is localized outwardly, can be controlled.

At first meeting, the client will probably have no understanding of Natural Hygiene or autointoxication. He must be led to an understanding of life's basic requirements, the requisites of organic existence, because, upon these, full health, including that of the hair and scalp, depends. He must gradually learn that you have a plan for health that works regardless of age, sex, or income! A plan that he can carry out in his own home without the aid of pills, lotions, or doctors. A plan that will not only save him money but will provide superb health for all of life. A plan that has worked for hundreds of thousands of persons, many just like himself, suffering from even the most horrible lesions. And, finally, that it is a plan that may require more time than he now anticipates because how well it works for him will depend on how faithfully he follows your guidance and directions.

It will, of course, be impossible to impart to every client all the knowledge the Hygienic practitioner has garnered as he has studied this course and the many lessons yet to follow, about body detoxification and how this may be achieved. However, we find that a good initial briefing of methodology usually is well received.

We recommend that, on first meeting, the client be given an understanding of the fact that as you work with him you will, in general, proceed with four specific goals in mind, all bearing directly on his present condition.

### **5.1 The Hygienist's and Life's Four-Fold Program for Superior Health!**

1. To discontinue all things, habits, foods, etc., which are acknowledged by the scientific community to be harmful to the human life process; to reduce or completely remove all undue stressors.
2. To improve the lifestyle so that it includes only those practices which are acknowledged by the scientific community to be health-promoting, such requisites of organic existence as:
  - Exercise
  - Pure Air
  - Pure Water
  - Suitable exposure to sunlight
  - Sufficient rest, sleep, and relaxation
  - Protection from violence
  - Emotional Poise
  - The "Pluses of Life," such as friendships, love, etc.
3. To modify the diet slowly or rapidly as the individual client can adapt so that it eventually includes only those foods that are known to be biologically acceptable to humans and to instruct by means of educational materials written in lay terms so that the client will learn how to combine his foods correctly so as to maximize nutrient acceptance and utilization.
4. To detoxify the body; that is, to eliminate from the body any existing abnormal amounts of toxic metabolites (wastes) so that the fluids of the body, including the blood, will again flow free and clean, able to collect, transport, and remove all excess acid waste debris because it itself is no longer so saturated with "sludge" that it lacks the ability to transport waste matter to the

eliminating depots; or because the liver and kidneys are presently so overloaded that they cannot adequately perform their normal filtering and other life-preserving duties.

Dr. Lester Breslow, dean of the School of Public Health at the University of California at Los Angeles, stated in 1975, as follows: "I firmly believe the American people are depending far too much on their doctors to stay healthy." He went on to comment that "all of us must take more responsibility for our own health—the choices we make in our daily life with regard to certain personal habits."

It is this concept that the Hygienic practitioner must convey to his new clients; that the client is now embarking on a wonderful adventure that will not only correct his present annoying symptoms but one that will also open countless numbers of doors and joys to him and provide a future in which he can enjoy a hitherto undreamed of new dimension of health.

We have found that having the four-fold program printed and then given to the client helps him to stay on course. We suggest to our clients that they paste the list on a bathroom mirror or perhaps, even better, on the refrigerator door or some other place where they cannot help but be reminded day by day that they have begun a new way of life, one that has untold promise.

The World Health Organization defines health as "physical, mental, social well-being, not merely the absence of disease or infirmity." We can add that our goal is inner peace and really this is the ultimate goal!

Rarely are diseases of the scalp and hair life-threatening. Perhaps it is for this reason that presentation of the fourfold action plan is so important. It helps clients to understand that their present condition is remedial, not by outwardly or inwardly applied substances, but rather a condition in which the body can constructively redirect its energies and faculties to restoring high-level health. The plan teaches how to provide the tools.

## **5.2 The Consultation**

When the client makes his first contact and requests a consultation, he should be asked to provide you with a diet profile which covers a minimum period of one week plus a personal and medical history. An office form may be mailed to him which he can fill out prior to his appointment. These may then be brought to the office for your consideration.

### **5.2.1 Inquiry**

The first meeting should open with the *inquiry*.

This part of the consultation offers an opportunity for the client to express himself, to present his evaluation of his condition. If the lesions or other conditions are not visible, he can describe them and give his reaction both to them and to past treatments.

The client should have time to express himself, how he is feeling, to give an evaluation of himself, dietetically and perhaps otherwise. Clients have a need to relieve themselves verbally of concerns, to express emotional and other specific needs.

The first meeting is critical. It is at this time that the Hygienic practitioner must impart to the client, both by action and by deed, the fact that he empathizes with the client and also that he has a solution to offer. However, let us point out at this juncture that, while the Hygienic practitioner should listen, should empathize, and then give of his best advice, he must also learn that, once the client leaves his office, the responsibility from that point on rests with the client to put all recommendations into practice; in other words, to carry the ball. If the practitioner does not learn to do this, he will soon "burn out" emotionally.

### **5.2.2 Visual Examination**

Following the inquiry comes the visual examination.

Initial visual examination can be done along gross lines, of course, during the inquiry part of this session. However, psychologically speaking, it is well to take a closer look at all affected parts and note the extent of the afflicted area or areas. Notes should be taken. These will assist the practitioner in noting progress from one meeting to the next.

We recommend that a good quality magnifying glass with a handle be used for this close examination. Notes should be made as to size of pustules, if any, the precise location of any affected areas, and the size of the area affected, not for diagnostic purposes, but rather to assist you in evaluating the on-going improvement in the condition as the client responds to Hygienic measures correctly applied. Such records are also important in the event that you are called upon to explain procedure.

### **5.3 Kinds of Clients**

Clients who consult you regarding diseases of the hair and scalp, generally fall into two types:

1. Those who willingly and cheerfully carry out all suggestions made by you because they have full confidence in your advice. This group is further subdivided into two groups:
  - A. Those who have endured the torments of itching, flaking, or the oozing of pus and watery secretions for so long that they have almost despaired of ever finding relief and are now willing to try even what they may consider as being bizarre and strange suggestions.
  - B. Those who have explicit confidence in you because they have previously witnessed positive results in a similar case under your supervision or have been referred to you by someone in whom they have much confidence.
2. Those who seek your advice with a certain amount of skepticism and/or fear. This group can also be divided into two subgroups:
  - A. The elderly who have long been accustomed to doing things in a certain way. These individuals have well etched habit nerve pathways and require careful handling if success is to be achieved.
  - B. Persons who consider their condition remedial by the use of "medicines," even though they may have met with repeated failures. These individuals are still searching for a "cure." They must be deprogrammed and reeducated in the true ways of health and healing.

Through experience one learns to evaluate the particular category in which a client belongs. Once this has been accomplished, it is possible to proceed in a planned orderly way.

#### **5.3.1 Group One**

All diseases are serious, of course. Milder hair and scalp disorders often represent a beginning, a foretaste of more involved pathologies that will most certainly arise if remedial steps are not instigated. The present condition, mild or serious, represents an attempt by the body to cleanse itself of a burden which is too great for the body to handle by usual eliminating procedures.

Fortunately members of this group have confidence in you and will follow your instructions. For these clients we immediately recommend a prolonged fast, the time suggested depending upon client response, emotionally and physically, to this procedure. We particularly recommend a prolonged fast in cases of psoriasis and chronic eczema and especially when these conditions have seated themselves on the scalp and are accompanied by severe itching and/or flaking. Remedial fasting will do what topical applications can never do, get at the cause of the trouble, whether it be in the constitution of the individual, in a deranged metabolic inner state, simply a state of hypersensitiveness, an injury of some kind, or the presence of imbedded fungus spores. Fasting represents do-it-yourself surgery: cutting out the cause.

According to Otto H. F. Buchinger, M.D., fasting is always the remedy of choice in cases of eczema and psoriasis and that most persons will respond favorably provided that they have not had recourse to many

of such heroic treatments as the constant application of highly-irritating substances over a prolonged period of time or to radiological procedures as, for example, X rays.

Buchinger points out, and we have also observed this same fact, that quite often even following a prolonged fast, patches of eczema and psoriasis will persist, these representing "safety-valves," to quote him, the means whereby the body leaves a way open for exudation of wastes should the need arise. These small patches serve as a reminder to the afflicted person not to relax in the ways of health.

We are reminded of one client whose face and scalp were covered with psoriatic patches before fasting. After several short fasts, the scalp entirely cleared but a minute patch remained behind each ear. This particular person enjoyed golfing and meeting with friends after a match at the "19th hole" to talk about common subjects of interest and to have a beer. Invariably, a day or so later, these patches would enlarge, a silent reminder that obtaining health represents a commitment to a lifetime of correct living.

Most clients who experience the flaking of psoriasis or the extreme itching of eczematous conditions are more than willing to listen to accounts of the benefits that may accrue to them should they decide to undertake an extended fast. However, there are exceptions.

Years ago a close friend who was afflicted with psoriasis came to visit us for a few weeks. Whenever she combed and brushed her hair, the flakes would fly in all directions. Her condition was so bad that we finally resorted to covering the furniture with sheets which we then periodically took outside for a good shaking. We were compelled to vacuum the floor in her bedroom every morning.

For over forty years this woman has tried every "remedy" on the market and every poison that hundreds of medical "authorities" have prescribed. She has tried kinds of diets: with and without fat, with and without salt, she has tried high-protein and low-protein diets, high carbohydrate and low-carbohydrate diets. She has constantly refused to fast. She still has her psoriasis.

Her scalp still sloughs off the sick and wounded cells, do the many patches that cover various parts of her body. In spite of all her futile attempts to find "relief," she still retains faith in "medicines." She still believes that medical "science" will be able to provide the magic "cure." She still refuses to try the one positive step which has been demonstrated in hundreds of cases to be capable of permitting the body to heal the hurt—the simple fast. Contrast this experience with that of John given in Lesson 61!

Clients should be instructed in the merits of the fast and be encouraged to convince themselves of its possible benefits by reading the literature on the subject. If the practitioner himself is qualified to supervise a fast and has the facilities to house fasting clients, he may properly do so. Otherwise, he should encourage his clients to go to an institution where the fast can be professionally supervised by an experienced practitioner and where the client can be isolated from the concerned but unfortunately often uninformed and discouraging comments of relatives and friends.

We presently have a man who is very seriously afflicted with a painful inflammatory condition. He has been placed on a very restricted diet and instructed to take short fasts. He has no family and is dependent upon the services of a paid housekeeper. This woman who weighs well over 200 pounds and is herself under the care of a physician for innumerable ailments, rants and raves at her employer because she is "worried" about his loss of weight and the fact that he is depressed so much of the time! He has finally given in to her, but only temporarily. He has given her notice to leave and in her place has hired someone else. Within a few weeks he expects to make a new beginning under happier circumstances.

However, not all persons have this man's determination. Many unfortunately succumb to the wishes of their misguided relatives and friends and lose their one chance to find a higher plateau of health.

### **When Money Is a Matter of Concern**

In instances where the client is willing to fast but is, for the moment at least, financially embarrassed, it is often possible for the practicing Hygienist to advance credit for a specified time with a contract being signed for future payment of a specified sum; or supervision of the fast can be undertaken in exchange

for services rendered by the client to the practitioner as, for example, typing, addressing envelopes for mailings, yard work, serving in some useful capacity at meetings and lectures, etc. Contracts can work out especially well with those clients who have hair and scalp disorders and especially when visible lesions are present. Photographs of the same may be taken at the onset of the fast and/or other services. When all lesions disappear, payment is due. Such contracts, it goes without saying, are best drawn up by an attorney.

### **The Fast and Apheresis**

The medical community is more and more coming to accept the fact that a toxic condition of the body can cause multitudinous numbers of diverse conditions according to individual tendencies as they may occur in any one person due to his peculiar collection of weak and strong parts, these varying by the very nature of human differentiation. This is why apheresis, the mechanical cleansing of the blood, is being given serious attention by the AMA and insurance companies who can visualize a veritable bonanza if the practice becomes widely accepted.

Apheresis admittedly does "not cure disease, it simply treats the symptoms of illness, and it hasn't been around long enough for scientists to determine how effective it really is," this according to an article by Edward Edelson in the October 1982, issue of *Science Magazine*.

In apheresis a technician taps into the patient's vein, and "blood flows into a machine where the spinning components settle into bands: the heavy red cells first, then the white cells, then the platelets that help blood to clot, and finally the plasma and all the valuable proteins it contains." Components suspected of "harboring the damaging substances associated with the patient's illness are discarded and, in the case of plasma, often replaced with an equal amount of saline solution. The rest of the blood is then returned to the body," supposedly now in a pristine state.

The technique has been used with varying success in such diseases as macroglobulinemia, a condition in which certain plasma components have an unusually high molecular weight, for example, as much as 1,000,000 compared to water with a molecular weight of only 18; multiple myeloma, aplastic anemia, systemic lupus erythematosus, rheumatoid arthritis, multiple sclerosis and myasthenia gravis, to name a few. There have been successes and failures, as well as a few deaths primarily because technicians do not as yet know just what to remove and what to put back! In spite of its acknowledged drawbacks, momentum seems to be accelerating for its use even though a series of "treatments" can cost as much as \$32,000.00, and even more, depending upon the number of "treatments" judged necessary in any particular instance.

We are inclined to suggest fasting as a much simpler procedure, one more in keeping with systemic reality, to say nothing of its relative cheapness and the exactitude of the process, carried out as it is under the watchful and precise guidance of the body's own intelligence, every move being dictated by the body's primary concern for perfect performance on the part of all cells and systems. Unlike manmade machines, the human body does not make errors. We make errors in eating and living and in so doing we may place impediments in the road of perfect performance but the inner workings of the body, the control mechanisms, always turn in a precise and perfect performance.

While medical science waits for controlled experiments to give a stamp of approval to this new medical marvel, fasting has already received its accolades from millions of humans throughout all of history and in all cultures and by other lesser animals who have also benefitted by the cleansing it enables the body to realize. It is little wonder that fasting is so universally recognized as being the almost perfect "cure." However, let us point out here that its benefits accrue best to those persons who are emotionally and mentally prepared and willing to fast. The results to be observed even in severe disorders of the hair and scalp are often no less than spectacular.

## **Following the First Fast**

If the first fast has been extended for a minimum of ten days, the client should, after the initial recovery period, be immediately placed on the fruitarian diet. This is the ideal time for him to adopt a physiologically sound way of eating, the perfect diet, because his system has been cleansed of its former burden of toxic metabolic debris. He should be advised that this is the way humans are intended to eat and that he should follow the fruitarian, diet for a lifetime of health and superb wellness.

Less severe diseases of the scalp and hair will often respond to shorter fasts, often with the scalp becoming quite clean within a matter of three to five days. However, should these persons be immediately placed on the fruitarian diet, it is possible for them to suffer healing crises as the morbid debris, now placed in a state of flux by the short fast, continues to try to find its way to the exit points.

When such healing crises occur, clients often become discouraged because they find that the terrible itching, flaking, falling out of the hair, etc., all seem to intensify instead of improving, as expected: At this early stage in their education in the principles of Natural Hygiene, they fail to understand that this is an entirely normal happening, one that is fully in accord with responsive healing.

With those clients who elect to fast initially for just a few days, it is often advisable to follow the first fast by introducing a planned graduated program, one adjusted to individual differences, especially those of an emotional kind. We suggest the McCarter Extended Detoxification Plan which follows. Such a program may be continued until such time as complete healing has taken place; it may be speeded up or slowed down as circumstances warrant.

The clearing of the scalp and absence of all annoying symptoms will indicate that the toxic load has once again fallen within the toleration level with the usual channels being able to cope successfully with their elimination chores. At this time the client may be encouraged to begin the fruitarian diet. If symptoms should again present themselves too violently, it may be necessary to reduce the fruit intake and place more emphasis on vegetables. Regardless, with improved nutrition, cleanliness, etc., the client will be inspired to continue his Hygienic ways because he will feel and look better than he did at the first meeting.

## **How Exercise Helps to Nourish the Scalp and Hair**

Have you ever noted the beautiful skin and hair of very active, hard-working, healthy people? This is because, when we exercise, the blood rushes to the surface of the skin causing it to take in more oxygen and available nutrients and, in return, give off more of the body's morbidic waste metabolites.

Also, exercise makes us warm. In fact, the temperature of the skin may rise from 86 to 90 and even up to 94 while we are engaged in a really vigorous workout. In Lesson 61 it was shown that one function of the skin is to dissipate heat. The blood acts somewhat as a coolant. The more heat is to be dispersed, the more blood is called up to the skin carrying with it valuable nutrients.

Dr. Albert M. Kligman, professor of dermatology at the University of Pennsylvania School of Medicine says that "the thickness of the skin—the rate at which collagen is synthesized—is probably temperature dependent. So exercise actually may replenish the skin in some way." Hygienists know that nutrients are required for all body synthesis.

According to an article in *Today's Living* of December 1982, Dr. James White, exercise physiologist and coordinator of physical fitness at the University of California in San Diego, says that a study in Finland showed that their daily exercise had beneficial effects on the skin of middle-aged athletes.

"Actual snips of skin from these athletes were found to be denser, stronger, and thicker than skin from sedentary people the same age. The elasticity of the skin was also much better preserved in the athletes."

We have often observed great improvement in the texture of the hair of clients and in its more abundant growth after relatively short periods of Hygienically correct living and eating. When the body has ample

supplies of all required nutrients, healing and replenishment follow. Exercise increases fluid transport of nutrients.

One of our clients, after beginning a greatly improved dietary regimen, found that he began to develop small lumps in several places on his scalp. We suggested he increase his exercise periods and also to include more aerobic exercises. He did so and, within six months, the lumps disappeared. No other changes were made. We believe that the more consistent influx of nutrients to cells and removal of wastes accomplished by consistent and vigorous exercise periods has much to do with improving the condition of the scalp and the texture of the hair. The fruitarian diet, of course, has been shown to provide all the nutrients required by humans for maximum health.

### **5.3.2 Group Two**

In the practical arena of dealing with individuals long accustomed to following after demographically programmed and controlled masses, the new Hygienist will often find many who will seek his services with mental and emotional reservations. Many will have been given false impressions of fasting and relate it to starving. Many of these individuals will have reached their present sorry state after years of medical dependency and mismanagement but, nevertheless, they are literally afraid to undertake a fast and should they try would only do so with great trepidation and fear, a condition which could lead to emotional disturbances which, in turn, could negate the benefits which might accrue to the fasting client if s/he were only better prepared for the experience. In such cases, a more extended approach should be thoughtfully considered and, in many cases, adopted. Such a slower method will accomplish its purpose, detoxification, the cleansing of the body fluids, albeit more slowly. The McCarter Extended Detoxification Regimen represents such a method.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > 6. The McCarter Extended Detoxification Regimen

## **6. The McCarter Extended Detoxification Regimen**

As the name implies, the McCarter Extended Detoxification Regimen is a procedural method which we have found so valuable in leading emotionally hesitant, the more skeptical of our clients, and others who may, for one reason or another, be unable to undertake a fast at this time, on a step-by-step planned program for a body cleansing, but at a slower rate, that we include it for the student's consideration. The regimen may be used to good advantage in all diseased states, as well as with clients who may suffer from skin, hair, and/or scalp disorders. It is especially applicable to new practitioners but useful to all.

This extended action plan tends to lead the client by gradual habits of their past to a Hygienically-correct dietary and living regimen, one intended for immediate remedial purposes but also for lifetime maintenance. In its final stages it provides the client with a state of health previously unknown. It goes without saying that total freedom is achieved from whatever distressing condition presently troubles him and eventually from all diseases of any consequence.

The extended regimen makes important health-promoting changes, but makes them slowly. By so doing, the client's body can accommodate itself in gentle steps to new ways of eating and living without the client having to experience many of the perhaps disconcerting and even painful, and, to some, discouraging symptoms which are sometimes manifested during a prolonged fast or when changes are made too rapidly.

The elderly and the more timid among your clients will appreciate your concern in this area and will, more often than not, willingly accept the simple changes where they might become frightened and even

totally estranged from you by symptoms which might arise with too rapid elimination, losing thereby perhaps their one chance of ever again regaining their health. This bleak prospect is unacceptable to us.

For example, we have one male client in his late seventies who has had an annoying eczema almost all of his adult life. He has taken course after course under our guidance and has attended lecture after lecture. He attends every potluck we have and freely speaks of the benefits of Natural Hygiene. He is now free of his former ailment.

But, let this man partake too freely of some food, especially grapefruit, he almost always begins to experience an annoying twinge somewhere, not unusual in persons who have lived incorrectly, Hygienically speaking, all their lives. At such times, he usually telephones Dr. Elizabeth with panic in his voice to inquire "why am I having this pain?" He is truly frightened by these experiences. At such times, Dr. Elizabeth must explain again how toxins may remain hidden for years, even after several prolonged fasts, and how they can make their presence known even years after the main ailment has been corrected and that the very presence of a symptom shows increased vitality and body power, that the healing going on within is ongoing.

After such assurance, our client remains content—until the next time! In spite of his advanced years, this man's whole body has grown in health. His hair is thick and luxuriant, his skin smooth as a baby's, and his moustache glory to behold! Our satisfaction lies in knowing that by following the extended detoxification regimen this gentleman looks better now than most men twenty or more years younger than he, even though he did not take his first timid steps into Hygienic living and eating until he was well over 70 years of age!

Beginners at practice frequently become discouraged because they tend to lose clients who become disenchanted for one reason or another with whatever program has been devised for them. For example, they may find a recommended food unfamiliar to them and attribute whatever symptoms that may arise to the fact that this food "disagrees with them."

When carefully studied and modified to meet individual differences, the McCarter Extended Detoxification Regimen tends to lessen client loss chiefly because it reduces the number of healing crises experienced and the few experienced are generally less severe.

With too rapid change, on the other hand, the more timid will question why symptoms occur and why they often appear to be getting worse when, in fact, the very symptoms they are experiencing are proof that the new way of eating and living is actually producing curative changes which will prove beneficial in the long run. But, they do not understand this and thus fail to keep their next appointment.

However, once people are persuaded that the easy ways, the painless "remedies," will not solve their problem, then and only then will they consider a long-term program such as we are presently suggesting. You see, most people are content to look on the outside for solutions and do not want to accept responsibility for their present dilemma. Most belong to the "Discounters of Society." Some will insist that no such problem as you may present to them exists as, for example, that they have been eating poor food and must improve their dietary program. Some will say, "Yes, that may be true, but the problem isn't as important as you say it is!"

A splendid example of this last named group is a young girl, age 17, who was brought to us suffering from acne, scoliosis, and a host of other ailments including thin drab-looking hair. Privately, she admitted to "bombing out" on cocaine and other drugs; to excessive sexual indulgence; to using alcoholic beverages; and to the use of the customary teenage diet of sweets, hamburgers, soft drinks, and french fries. Her blood test, on bionutritional analysis, revealed several problem areas of considerable importance. When confronted with these results, she refused to admit that any major problem existed because she "was no different from anyone else!" She refused to accept any negative messages.

Sad to say this same attitude exists with most of our young people. We are told that two-thirds of our high school students try using illicit drugs and that, indeed, the U.S. has the highest use among this age group than any of the nations of the civilized world!

Other discounters will be so discouraged by repeated previous failures that they will admit the problem, the disease, willingly enough but they will, at the same time, believe that you can't help them to solve it because it is unsolvable! Only the more intelligent will recognize that, indeed, the problem exists, that it is vitally important to find solution of the same, that the principles of Natural Hygiene make sense and are fully in accord with all known facts of life and, finally, that only the full application of the same in their own lives will provide the best chance to solve the existing problem even though all other methods and "remedies" may have hitherto failed.

## 6.1 How to Proceed

### 6.1.1 Phase One

In Phase One the diet remains basically the same with no major changes being suggested. However, certain harmful accessory dietary practices are brought to the client's attention and the suggestion made that these may properly be eliminated or the amounts used reduced. These are determined by the practitioner following study of the client's past eating habits.

Obviously, there are multitudinous numbers of possible habitual dietary indiscretions and harmful practices which should be avoided and it would be impossible to list all of them. The practitioner must use his knowledge and good judgment in selecting for first consideration those he considers most critical.

Among the harmful practices which most commonly appear on our diet profiles, we find the following: Drinking beverages with and in-between meals: such beverages as soft drinks, coffee, tea, cocoa, canned chemicalized juices, etc. Some of these drinks contain harmful alkaloids, caffeine, sugar, and other chemicals capable of tissue erosion.

Others lack nutritive substance. To illustrate how some juice products presently marketed are concocted we include a quotation from *Science 82 Magazine* for October 1982 (official publication of The American Association for the Advancement of Science), relative to a product sold by a leading supermarket chain: "Orange juice" on the label means that what's inside is supposed to be pure and unadulterated. Federal standards are clear on the subject.

"But that's not always the case. Consumers unknowingly pay for a product that's often been stretched with a variety of substances from corn or beet sugar to spices to add coloring to spent pulp. Added to pure juice, these adulterants usually aren't harmful, and the resulting drink can be sold—but not as orange juice."

Natural Hygienists would disagree that such products are not harmful if only in that they are substituted for more nourishing foods. Persons in the business of manufacturing fake orange juice used to dilute their product with water, then add extra sugar and citric acid to give their product the taste of citrus fruits. But it seemed that it was fairly easy to detect the diluted product and the fact that it contained sucrose.

In late years it seems that these purveyors of fake orange juice have turned to beet sugar and pulpwash, both somewhat harder to detect. Beet sugar is cheap and when a bad freeze in Florida pushes up the price of oranges, these manufacturers simply take the washed and spent solids left after oranges are squeezed and use these—the pulpwash, as it is called in the trade. The U.S. Food and Drug Administration has seized hundreds of thousands of barrels, cans, and jars of juice made chiefly from pulpwash, extra sugars, and turmeric, a rather pungent spice which just happens to impart the color of orange! It seems that it is difficult to make a positive identification of the pulp and sugars contained in real orange juice, namely fructose and glucose. Since the product tastes remarkably like real orange juice, the public—to save a few cents—buys it because it tastes good, little realizing that when they use this product, they shortchange their own bodies. There are, no doubt, many such products in common use. In fact, we received a long distance call a few days ago from a beginning student of Natural

Hygiene who is about to enter a marathon run asking if it would be "all right" for him to use a product quite frequently used by athletes to impart quick energy. Since it is made almost entirely from chemicals, we told him to "read the label!"

Another harmful dietary practice is the drinking of alcoholic beverages including beer, wine, straight and mixed drinks of all kinds.

Smoking, chewing, sniffing of tobacco and/or other substances of similar nature are known to have a health-destroying effect as, for example, the practice of sniffing glue.

Overeating, probably the most common error of our times, and also, the most harmful.

Using food enhancers such as condiments and spices, especially salt, pepper, sugar, mustard, ketchup, mayonnaise, but also including other less familiar substances, both singly and in combinations, is both unnecessary and unhealthful.

Using packaged processed cereals and bread and products made from wheat and/or other grains is harmful.

The inclusion of flesh meats and/or products derived from animals in the daily food intake, often at every meal, is detrimental to our health.

Using cooked foods, especially fried, barbecued, and boiled, are harmful, and so on.

It is in his initial choice of items to be eliminated that the Hygienic practitioner can alienate the "timid" client, even though the practices selected as being erroneous may have directly contributed to his present scalp and/or hair disorder. For this reason it may be best to make the initial changes minor in kind, gradually encouraging your client to make further constructive changes as he goes along. We are often able to avoid upsetting an emotionally unsure client by assuring him/her that even small changes (which, by the way, may appear major to him/her!) will be curative in kind.

We find, for the most part, that many clients who approach us with hair and scalp disorders (and often, too, with other skin problems) have little understanding of the fact that the immediate problem is simply a reflection of a greater problem, a general systemic toxemia. He will reach this understanding, of course, with careful guidance and education by you in the ways of health. Many clients appear somewhat uneasy about deserting established medical procedure and with such, we proceed with simple changes.

A client who has been accustomed to drinking two or more cups of coffee with every meal understands that this can be harmful and might be a causative agent for whatever ailment now troubles him. With such a person, we might suggest that, for the next two weeks, he reduce his coffee drinking to one cup at the noon and evening meals and permit him his usual two or more cups in the morning to "get him going." In so doing, he will be reducing his coffee intake (or whatever other beverage he is accustomed to drinking) by one-third, a substantial improvement but not one that, might overwhelm him by the appearance of that "all-gone" feeling so often characteristic of the withdrawal from coffee addiction. It goes without saying that clients who are coffee addicts should be made aware of the dangers to health involved in the use of this drug.

Also, if a client has been accustomed to taking two teaspoonsful of sugar with his coffee or tea, he should be advised to reduce his intake by one-half, to one teaspoon per serving, a reduction of fifty percent. If accustomed to having a soft drink as a mid-meal snack, we advise the substitution of a diluted fruit juice of good quality and freshly made if possible; or that he eat a piece of fresh fruit in place of the drink.

### **Initial changes in lifestyle**

Again, the changes which can be advised initially with regard to the lifestyle can be many in kind and number. Among the first that we always recommend are the following:

1. Frequent bathing of affected parts. An easy way to wash the hair and scalp is simply to get under the shower and let the tepid water run through and over the hair. When the scalp is irritated, the fingers should not "dig into" the scalp. A simple striking with the tips of the fingers is sufficient accompanied by a gentle lifting of the hair by running the fingers through it. No soap, medicated or otherwise, should be used. By following this procedure, the natural oils and waxes will be retained but liquid acid wastes will be removed. The hair should be allowed to dry naturally and, depending on the condition of the scalp, it may then be gently combed or brushed with a natural-bristle brush.
2. Sunbathing, the amount of time designated for this purpose to depend on past sun exposure, the texture of the skin, etc.

We find that these few simple changes in the dietary and lifestyle habits of a client are well accepted by him, both emotionally and physically. These are positive health-promoting steps which will not overwhelm the beginning Hygienist and ones which he will recognize as being conducive to better health. Now he is paying you to tell him so and to show him how he can adapt to these changes. We find that most clients are overwhelmed at the simplicity of your advice and cheerfully agree to follow the instructions given. We always advise our clients, however, that this is only the first step and that other instructions will be forthcoming at our next meeting. We recommend that, at this first meeting, whenever possible, that front and side views of the client be photographed for comparison at future meetings. We instruct the client to return for his next appointment in two weeks at which time he will be expected to make a verbal report on how well he has complied with your recommendations.

### **6.1.2 Phase Two**

The client should make his report. Irritated areas should be examined and further changes now suggested, either orally or, preferably in typewritten form. Changes to be suggested might be as follows:

1. No further reduction in beverage or sugar intake at this time. However, the client is now instructed to drink his beverage of choice 15 to 30 minutes prior to his eating and to refrain from drinking even water during the meal or directly after eating. The physiological reasons for this restriction should, of course, be carefully explained.
2. The client should perhaps be instructed at this meeting to eliminate table salt from his diet. The client may be helped to overcome this pernicious habit by suggesting that he substitute Vegebase or some similar product for table salt. However, he should be advised that using substitutes is not to be recommended and that total abstinence from all food enhancers would be a commendable procedure to follow at this time so as to permit recovery of normal taste sensations as well as to prevent further membrane, kidney, and cellular damage.
3. If, according to his diet profile, the client has been accustomed to taking two or more slices of bread with his meals, he should now be restricted to not more than one slice. Most persons find it extremely difficult to eliminate all bread immediately. They seem to crave it. Hygienists know that breads are not only acid-forming but that they also present certain digestive problems. Incomplete digestion of the starch in bread leads to certain fermentative processes which produce alcohol in the system, a fact which possibly explains why it is sometimes harder for the novice Hygienist to give up the bread-eating habit than the use of meat! Unbeknownst to him, he has actually become a victim of vicarious alcoholism! Nervous people are, almost without exception, heavy bread eaters.
4. Introduce distilled water. The client should be instructed to use distilled water for drinking and cooking purposes in place of tap water. He should be informed that he will not be drinking as much water as formerly because he will now be receiving a greater amount of the purest kind of water as contained in uncooked, fresh fruits and vegetables.
5. Change the customary breakfast to one of fresh fruit accompanied by lettuce and/or celery. At first, it may be better accepted by your client if this meal is a rather substantial one. It will tend to

eliminate that "empty" feeling that so often comes on the initial changeover from the popular cereal or bacon and egg breakfast. Remember that clients with hair and skin disorders rarely attribute their condition to malfeeding or to a malfunctioning digestive system, but rather to some unknown "allergy." Therefore, while we certainly must make certain constructive changes as early as possible, it is often advisable to continue the "hearty breakfast" for the time being until the body can accommodate itself to the changes in progress, these being healing in kind. Individual appetites will, at this point, determine just how much food may be desired. We suggest that the first fruit breakfasts be patterned somewhat as follows:

Breakfast No. One

Two bananas, very ripe

10-12 dates

1 apple or pear

Lettuce and/or celery

Breakfast No. Two

Two oranges peeled and segmented

1/2 grapefruit, peeled and seg.

Lettuce and/or celery, 1/2 avocado

Breakfast No. Three

1/2 pound grapes

2 pears

Lettuce and/or celery

Breakfast No. Four

Large dish of fresh or soaked apricots

Dish of berries

Lettuce and/or celery

Breakfast No. Five

One or two apples served with date sauce made by blending a few pitted dates with distilled water

Breakfast No. Six

Fruits in season as, for example: 2 peaches

10-12 dates

Lettuce and/or celery

Breakfast No. Seven

1 whole papaya

2 nectarines

Lettuce and/or celery

Other suggestions: Berry compote served with peach "cream" made by blending peaches and dates (or peaches and banana) in the blender; raw applesauce made by blending apples and raisins (or dates) with celery; or pear sauce made similarly.

This is the proper time to introduce correct food and fruit combining. We suggest that you use the charts supplied in this course. No other dietary changes are required at this time.

6. When practiceable, a simple exercise program should be presented. It should be well within the present capacity of the client to perform. We suggest walking plus, perhaps, simple stretching and flexibility exercises as an excellent first step toward improved physical development.

All previous changes are to be continued. The client should be provided with a typewritten list of his new program and should be instructed to keep a diary of his new breakfasts and also of how much time he has allotted to exercising and the kind of exercise done.

The client is handed an appointment card which specifies the time and date of his next appointment, this to be in four weeks.

### **6.1.3 Phase Three**

With most clients who have consulted you with rather minor hair, skin and/or scalp disorders, it is now possible to make changes somewhat faster. A minimum of six weeks has passed during which time he has become more attuned emotionally to change and perhaps even physically in that he has begun to see some improvement in his overall condition. Therefore, all previous instructions are to be continued and the following new changes introduced as individual differences indicate and/or allow:

1. Luncheons - In the conventional way of eating, luncheons more often than not consist of soup and a sandwich or of a hamburger, french fries, and a "coke." It is time now to introduce the salad plus, perhaps, a simple vegetable broth or soup. A list of possible salads should be given to your client since, with many of them, the salad world is unexplored territory. For salad suggestions, we refer to our book *The Exciting World of Healthful Cookery* which has over two hundred salads to choose from, both vegetable and fruit.
2. Those clients who formerly drank alcoholic beverages should now be instructed regarding the harmful effects of such indulgence. They are either to refrain entirely from any further indulgence (preferable) or to reduce by at least one-half the number of drinks consumed. If the client is accustomed to mixed drinks, he should be encouraged to switch to drinks with a lesser alcoholic content, such as wine and beer. It should be made absolutely clear to the client that by making this suggestion that you are in no way giving your approval to the use of alcohol in any form and that further use by him will only retard and even prevent full recovery.
3. Clients who have been accustomed to using nicotine in any of its forms should be similarly instructed either to reduce or to forego future use. From experience we can say that the easiest and best way to stop this pernicious habit is simply to stop!
4. The number of cups of coffee, tea, or other beverage should now be reduced to no more than three cups per day taken 15 to 30 minutes before the meal with total elimination of the habit now being suggested.
5. Two meat meals per week should now be eliminated. If necessary, the client may be permitted either cottage cheese or eggs in their place. The practitioner should specify the exact day for elimination of meat as, for example, on Friday and Tuesday. Otherwise, certain reluctant clients have a tendency to postpone their meatless days. Where clients are open to total elimination on these two days, they may elect to substitute a baked potato or baked brown rice.
6. Request that your client keep a Diet Diary for the next four weeks. Keeping the diary will help him to adhere more closely to your suggestions since he knows that he will be expected to present the diary to you. A sample report form may be xeroxed and given to the client for this purpose. These forms may be kept on file for distribution.

The alert student will have noted that within a 10-week period, that the client, if he has followed your instructions precisely, will have accomplished the following constructive changes:

1. Reduced his coffee or other beverage intake by 50% or more.
2. Eliminated all fried food.
3. Eliminated all packaged cereals and the traditional ham and egg, bacon and egg, cereal, or pancake breakfast in favor of fresh fruits served usually, with lettuce and/or celery.
4. Has eliminated most condiments and especially salt from his diet.
5. Has drastically reduced or eliminated entirely all alcoholic beverage intake.
6. Has reduced or totally eliminated his former nicotine dependence.

7. Has consistently reduced his protein intake and increased his consumption of simple carbohydrates in the form of sweet fruits.
8. Has increased his consumption of raw foods to approximately 50% or more of his total nutritive package where, prior to his first meeting with you, if his diet was typical of the average American, it probably amounted to less than 4%.
9. Decreased his consumption of flesh food by at least one-third because he no longer has any flesh foods at either breakfast or luncheon and has omitted it from two dinners per week. He has either substituted eggs or cottage cheese or potatoes or baked rice for these two meatless meals.

This has been a period of change during which time the client's body was required to accommodate itself to new practices. The new exercise program has caused more stagnant lazy transport fluids to enter into the mainstream of activity for cleansing by the liver and kidney-filtering mechanisms.

Restorative changes have been silently going on as a result of the improved nutritional intake. These have usually proceeded slowly and quietly, rarely violently. The client has not been emotionally disturbed by rapid elimination of wastes, a process which might and often does intensify already existing symptoms and/or new ones, often to the client's dismay.

Sometimes, of course, even this carefully phased program can lead to minor unsettling symptoms in which case, and especially with nervous clients, it may be well to reassess your client's emotional poise and decide whether to back off and resume an earlier phase or to extend this third phase for another month.

Detached appraisal is often necessary with clients who have diseases of the hair, scalp, and/or skin simply because rarely are these afflictions life threatening. It is difficult sometimes to impart to your client the knowledge you have regarding the methodology of body detoxification. We suggest that with difficult clients that they be given a printout of the procedural method being employed.

#### **6.1.4 Phase Four**

By this time your client should have noted considerable improvement, not only in his overall wellness, but also in the condition for which he sought your help, assuming, of course, that he has faithfully followed all instructions.

Consequently, he will, more often than not, enthusiastically welcome further instructions. If improvement has been slow it may be best to continue Phase Three for another four-week period. Phase Four changes could proceed as follows:

1. The 24-hour fast, usually a major step for most persons. We have found that most clients will adapt well to this short fast if they are instructed to refrain from eating starting after the evening meal of Day One and then not eating again until the evening of Day Two; as follows:

Day One - Eat breakfast, luncheon, and evening meals.

Day Two - Breakfast - none Luncheon - none

Dinner - A light vegetable salad with nuts; or a simple subacid fruit salad served with 1/2 medium avocado.

Throughout the fasting day, distilled water may be used to quench thirst, as needed.

2. Intake of flesh meats is now reduced to three times per week. Baked potato, baked brown rice, nuts, or sunflower seeds may be used in place of the meat. One or two steamed vegetables may be added to this meal, if desired.

This is the perfect time to introduce the subject of correct food combining. The client should be given a food-combining chart for his home use. If you hold regular public classes on nutrition, your client should now be encouraged to enroll in these. The client should now formulate his own meals using the food-combining chart.

3. Introduce aerobic exercises when possible. We suggest to our own clients that they either purchase some good country western music records or turn on their radios to a station which features music with a good "beat." We tell them to encourage other members of the family to join them in free-style movement dancing. This is fun and contributes positively to increased family support. If clients live alone, they should be encouraged to join a Jazzercise class at the "Y" or elsewhere.

The client is again requested to keep a food and exercise diary. Since he is now formulating his own meals, it is important that he present it to you, at the next meeting, for your constructive criticism and suggestions. The intervening period will have been a learning period for him and it is always interesting to see how each client has fared. The client should return for his next appointment in four weeks, or sooner, as circumstances may warrant.

### **6.1.5 Phase Five**

By the time the Phase Five Consultation arrives, some three or four months will have passed. If your client has faithfully followed instructions, he will have accomplished the following steps in his four-fold action plan:

1. Totally eliminated or substantially reduced all major health-destroying habits, including but not limited to: nicotine and alcohol use.
2. Adopted many health-promoting ways of eating and living although he may not have become emotionally or physically fully adapted to them. His mind may tell him that what you suggest in the way of change is sound, that it is scientifically correct but, since his habits have become firmly etched due to the passage of years, they are therefore difficult to modify and/or correct. The practitioner should always be aware of the fact that habit is "a formidable adversary." The Hygienic practitioner should, therefore, be patient but also firm and consistent in his instructions. He must be kind and always encouraging.
3. The client's dietary intake is now approaching an intake of 80% raw food.
4. Your client should be consistently exercising aerobically for from five to fifteen minutes per day and, if he is on target, he should also be walking every day, depending, of course, upon individual capabilities.

At the Phase Five meeting the practitioner should, as the first order of business, examine the food diary for errors and shortcomings, if any. Improvement in condition should be noted in the client's record.

The 36-hour fast may now be introduced and the client instructed to proceed with this longer fast once during this phase, as follows:

Day One - Eat breakfast, luncheon, and the evening meal.

Day Two - Nothing is to be eaten on this day. Distilled water may be used as required to quench thirst.

Day Three - The client now eats a breakfast which consists of a single fruit, preferably a subacid fruit as, for example, two or three peaches or pears. Luncheon - a fruit salad consisting of either subacid, acid or sweet fruits. Dinner - a vegetable salad with nuts, if desired.

All other previous suggestions are to be incorporated in the client's regimen for the next four weeks with steady reductions being made in all remaining harmful practices. For example, all meat eating should now be discontinued with cottage cheese, sunflower seeds, or nuts used as substitutes. The use of cottage cheese should be restricted to no more than one meal per week. (Cottage cheese is not a good food and therefore the client is best persuaded to eat nuts or seeds.)

All coffee and tea should now be totally eliminated with no beverages permitted during or immediately after the meal. Distilled water may be taken 15 to 30 minutes prior to a meal but only if required to quench thirst. The client should have noted by this time a lessening of need for liquids.

A food and exercise diary should again be kept and the client should be advised to return, this time, in

six weeks.

### **6.1.6 Phase Six**

The client's diary should be reviewed. A visual examination may be made and improvements noted. The assessment of condition should be made cooperatively by both the client and the practitioner. All improvements should be emphasized and, if not known to the client, they should be pointed out to him. Small changes for the better may not be noted by the client on a day-by-day basis but they will be observed by the practitioner at the end of extended intervals. A six-week interval may possibly have greatly enhanced the client's condition. All improvements should, of course, be duly recorded in the client's file.

Phase Six is often graduation time! The fruitarian diet should now be introduced. A complete set of suggested menus for a period to encompass at least three weeks should be presented to the client. All cooked food should now be eliminated with a 100% raw food diet adopted.

When possible, the exercise regimen should be expanded to include aerobic, stretching, and flexibility and resistance exercises. We test clients on various weights, starting with five pounds, and suggest that he either purchase whatever weight is most suitable for his present capacity or that he enroll in a physical fitness gym program. We often present clients with a typed list of possible exercises or ask him to purchase a suitable book on exercises.

The weekly 24-hour fast is to be continued with two 36-hour lasts also undertaken in place of two 24-hour fasts as, for example:

Week One - 24-hour fast starting Friday evening after dinner.

Week Two - A 36-hour fast starting after dinner on Friday night and continuing until Sunday morning breakfast.

Week Three - A 24-hour fast as above in Week One.

Week Four - A 24-hour fast.

Week Five - A 36-hour fast as in Week Two.

Week Six - A 24-hour fast.

Most clients will respond favorably to the above regimen. If not, they are requested to return in four weeks having had three 24-hour fasts and ONE 36-hour fast. Most will give their new way of eating and exercising and perhaps the whole fasting schedule a fair trial. If not, then they must continue with Phase Five for another four weeks.

Phase Six should extend for a period of six weeks at which time the condition and response of the client must be carefully evaluated. If all has gone well and if the client has made a satisfactory adjustment to his new way of life, both emotionally and physically, then he should at the discretion of the practitioner, be advised to continue his program as before and to return in three months. When clients feel comfortable on the fruitarian diet, we then have them "check in" with us at three-month intervals, at which time a record of progress, any shortcomings, regressions, symptoms, etc., are recorded.

We find it interesting that many will have fasted for five to seven days. A few will have gone on a prolonged fast at a spa. Some will feel they have made so much progress that they no longer require your services and elect to try to proceed on their own. To others, the practitioner assumes the father or mother role and the regular visit becomes an anchor to hold on to. Regardless, all clients are encouraged to attend lectures, classes, parties, especially potlucks so that they can be reinforced in their new way of life by meeting with other persons of like interest.

We have made no mention other than in passing of the taking of prescribed and over-the-counter drugs, or of vitamin and mineral supplements. These have all been well discussed in other lessons. However, we constantly encourage our clients to discontinue the use of all drugs. By the time a client adopts the fruitarian diet, he has usually come to understand that he is now receiving hundreds of times more

nutrients than formerly. He will also be witnessing in his improved condition the fruits of natural living and eating and will, of himself, realize that he has no further need of chemical crutches. In fact, most will be completely convinced of the merits of their new way of life and will willingly and enthusiastically refer their relatives and friends to you because you are now "their doctor!"

## **6.2 Case Study—Marie**

Marie, a woman aged 39 at her first visit, was troubled with severe itching of the scalp. A rash covered the surface and extended behind the ears and, down the back of the neck and across both shoulders. This condition existed for some time. Numerous prescribed products had been applied with no lessening of symptoms; in fact, they seemed to worsen.

Because of an allied condition (multiple sclerosis), and also for other reasons, it was thought best to put Marie on the Extended Detoxification Plan. It was followed pretty much as detailed in this lesson. No medications were prescribed but Marie was instructed to rinse her hair and scalp with tepid water several times a day and to begin exercising with the assistance of her husband. In this early stage, Marie had a tendency to fall easily.

Marie adapted to the simple changes. A year has passed. The scalp has cleared as have the neck and upper back. She has had other remarkable improvements. She no longer has a tendency to fall. Her hair is much more luxurious. Her energy flow is so great that she now cares for her family and does all her own housework where she once had difficulty crawling out of bed in the morning. She goes every other day now to the spa for a workout. Marie has no doubts that she will eventually recover totally from the multiple sclerosis. It is interesting that from this one success we have had at least 10 other clients referred to us. Throughout the whole year Marie experienced no undue healing crises that might have discouraged her from continuing on with her new way of living. She is now a fruitarian.

The one outstanding drawback to using the Extended Detoxification Plan, that of discouragement because of slow improvement, has been previously pointed out by Mike Benton in Lesson 21. However, we have often found it a useful procedure and especially so with the elderly, the neurotic and in cases where finances prove to be a major consideration. To illustrate:

## **6.3 Case Study—Ellen**

Ellen's story illustrates how it is sometimes advisable to combine techniques when working with certain clients. Ellen was much concerned about the possibility of her becoming completely bald. At only 42, her hair was very skimpy and just seemed to hang lifeless on her head—what there was of it! There were other problems, too, such as a tendency to sweat profusely. During the night, she had to get up at least once to change her night, clothes and often, too, the bedding. She had lumps behind both knees which made walking difficult.

There were other problems too which told us that Ellen's body was saturated with toxic debris. It was obvious that Ellen should be referred to a Hygienic institution at once for fasting but we soon realized that this was impossible. In the first place, Ellen was the neurotic type, high-strung and nervous; and, in the second place, she had spent so much money on medical treatments, on drugs, and all manner of vitamin and mineral supplements, as well as on various kinds of "courses" to, as she phrased it, "get her head on straight," that she just couldn't afford to spend any more money.

So, for a whole year, we resorted to the Extended Detoxification Plan. Gradually, we, introduced Ellen to Hygienic principles and, little by little, she improved both her eating and her living habits. It wasn't long before she was fasting one day a week and soon as long as three days at a time. Her improvement, while not dramatic, was steady. She became less jumpy for one thing and gradually the night sweating lessened and finally became a matter of history.

Then, the time came when Ellen was ready both financially and mentally to go for a prolonged fast. The

first time she fasted for 14 days and then spent another 10 days recuperating. She lost considerable weight and had a difficult time during this first fast, experiencing stomach cramps, chills, nausea, and extreme weakness. In six months, however, she again repaired to an institution and fasted for a similar period. This time, she did not lose so much weight and experienced no unpleasant symptoms other than a coated tongue, bad breath, and a few minor chills.

After three years Ellen has greatly improved. Her hair is much thicker and has luster and sheen to it. Her complexion is beautiful. The lumps behind her knees have long since gone. She is still somewhat neurotic but even this condition has improved. Ellen still checks in about every three months for counseling and is proud of the fact that she has made a new life for herself. She still has her own very private goal: to become the perfect woman, one sound in body and in mind. With her determination, we are sure she will make it.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > 7. Questions & Answers

## 7. Questions & Answers

**I have a breaking out on my scalp and behind my ears. At times it is so itchy that I have to wear gloves to restrain myself from scratching my scalp and making the condition worse. My doctor has prescribed one medication after another but nothing seems to do any good. He said he's going to refer me to a specialist if it doesn't respond to treatment soon. What would you advise me to do?**

By this time you should know that externally applied medications will not help your condition. Your system is so saturated with toxins that it has taken this extraordinary route to relieve itself of its burden. You need to fast. Your body will then take over and cleanse itself. You should be rid of your trouble in a very short time, perhaps even in a week.

**I'm only 19 and already I'm getting bald. What can I do?**

The medical community correlates balding with aging. At only 19 years of age you have obviously just begun your life. Another theory associates balding with inheritance, that one's genes foretell that a person will become bald. Personally, we don't buy this. One thing that makes us hold that balding is related to the overall wellness of a person is that balding has increased in about the same way as man's dietary habits have deteriorated. It will probably take several generations to restore to human males their birthright—a heavy head of beautiful hair—but I am confident it can be done by improving the health of each new generation. As for you, fast, get the accumulated metabolic wastes out of your system, turn over a new leaf, as they say, and live hygienically. If the hair cells are dead, you probably can't revive them, but surely you can prevent further loss.

**My hair is thick enough but it is dull and lifeless-looking. It just hangs. Do you have any suggestions?**

Again we come back to the unity of the body. How is your energy flow? I'm willing to hazard a guess that you probably drink "Cokes" or coffee or tea several times a day to keep going. I see you nodding your head. You, too, need to fast and then to begin eating a human diet, not swallowing messes of chemicals. There is a beautiful black mare in the pasture below us. Her coat glistens in the sun and she runs with great speed around the pasture, her nostrils flaring and every muscle showing its strength. This is a race horse and I can bet my bottom dollar that Bob, the owner, doesn't feed that horse on lollipops and swill. It gets the

finest kind of horse food. You need to feed yourself people food, to get out of doors and walk, to make friends and begin to learn about life and what it takes to live in health. If you'll do this, your body will take care of your hair and it will truly become your crowning glory.

**I'm 67 years of age. As you can see, my hair is thin and it's almost white. I guess, at my age, about all I can do is to buy a wig and wear it, do you agree?**

No way! Dr. Vetrano once noted that many women with wigs can see improvement in their hair's condition, since they are no longer always fussing with it, putting on creams and lotions, teasing, curling and perming it, etc. I would advise you to fast perhaps initially for 24 hours every week, to learn how to combine your food properly, to adopt the hygienic way of eating, to rinse your hair frequently and just let it alone. We ourselves have observed how our hair has darkened. Twenty years ago my hair was a dirty yellow white. As you can see it is now a rather darkish gray and no one can say that I don't have a thick head of hair, can they?

**My hair smells sour. In fact, sometimes it smells so bad that my husband complains about it. What would cause this?**

One of the first things we do when clients come to us with scalp or hair problems is to smell the hair. A foul, sour odor is indicative of a foul, sour body. Your fluids are filled with acid wastes. You need to fast for an extended time; if possible, until the return of hunger. I would advise you to consider going to a spa as soon as possible to undertake a fast. That should end your sour hair problem for good if, thereafter, you adopt a more Hygienic way of living and eating.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > Article #1: Baldness by Dr. Herbert M. Shelton

### **Article #1: Baldness by Dr. Herbert M. Shelton**

Baldness is far more common in men than in women, but it is estimated that there are more than five hundred thousand baldheaded women in the United States, the condition being far more prevalent than is commonly realized. Worse yet, the condition is apparently increasing. Among women who are not bald and who do not become so, the hair is often thin and short, lacking in both vigor and lustre. To compensate for such defects, women buy and wear hair pieces—switches, wigs, braids, chignons, pony tails, clusters, figure eights, etc. Although there is nothing half so becoming to the female face as thick, beautiful hair, fine, luxurious hair is a rarity. Doubtless most men would be astounded to know that many of the tastily arranged tresses worn by the women they see on the streets or that they go out with, originally grew on the head of another. As some wit has said:

*"The golden hair that Gallus wears  
Is hers—who would have thought it?  
She swears 'tis hers! and true she swears,  
For I know where she bought it."*

Medical men talk learnedly about "normal male baldness" and regard it as due to heredity, old age, and an excess of male hormones. The "remedy" is *philosophy*. There is no way to prevent it. Women will continue to resort to wigs and switches, for they cannot prevent it either. Works on beauty often provide their readers with "remedies" for baldness, although no such remedy is known to man. Hair tonics will

neither prevent the development of baldness nor restore hair once it has been lost. Massaging the scalp, pulling the hair, the use of vacuum cups and ultraviolet rays do not save nor do they restore the hair.

In the days when beards were in style it was not uncommon to see luxuriant beards and bald heads. Even today, (Note—published in 1958) men who have bald heads are not bald-faced. Every man would prefer to lose the hair on his face, thus removing the necessity for the daily shave, than to lose that of his head. But no means of saving the hair of the head has yet been found. No means will be found until the genuine causes of baldness are discovered. No preparation will grow hair. Hair tonics and hair foods are frauds.

What, then, is the answer? Shall we accept the hypothesis of the "bad gene" that is alleged to be responsible for baldness; is baldness hereditary? Is the case against baldness and premature graying as hopeless as this indicates?" I doubt the existence of "bad genes" of all kinds. Howard T. Behrman, M.D., a leading medical dermatologist, and author of a five-hundred page medical textbook (1952) on the scalp, says that "there is an evolutionary tendency in the human race to grow less hair—women as well as men.

In 200 years, perhaps more—it may be high fashion in both sexes to have no hair." He declares that "hair is only a vestigial ornament that no longer serves a real purpose. It used to have a protective function. But once we moved out of the trees we no longer needed it." While thus exposing his ignorance and posing as a prophet, this loose-tongued member of the Homo Sapiens stood up on his hind legs and relieved himself of the following bit of cerebral excrement about the future of man: "The eventual human being, man and woman, will have no hair, a longer head, large abdomen and short arms and legs."

Returning to Lamarck and the inheritance of acquired characters and re-asserting the outmoded nonsense of use-heredity, he backs up his prediction that man will evolve into a caricature of his present self by saying: "It's what you'd expect as man becomes more of an indoor animal, sitting on his rear more and spending more time pushing buttons." This is the "easy method" of solving problems. It is that of the arm-chair philosopher, not that of the scientist who would approach the problem directly instead of deducing an explanation from a pet hypothesis. When the cause of the loss of hair is finally discovered, and it will be, it will be found that pathology and not evolution is at the bottom of the loss. Hereditary baldness will go out the window where a lot of other "hereditary diseases" went when their causes were discovered.

Behrman sees the increasing baldness among women today as an evolutionary change, aggravated, he thinks, by lack of proper care. He says that "women who have a tendency to baldness often find it increased after childbirth, because of a temporary loss of female hormones. Treatment with female hormones may bring back the hair, but not necessarily." His thesis is that female hormones grow scalp hair and hinder body hair, while male hormones work just the opposite; they are supposed to be responsible for the growth of body hair and loss of head hair. Strange, if this is so, that head hair in the male is most abundant in youth, when the sex functions are at their highest, and absent after middle life, when the functions of the male sex glands are commonly less efficient. At any rate, the use of hormones to grow hair did not prove satisfactory.

Behrman says of women and their hair, that "they don't brush it vigorously, or wash it as frequently as they did in the old days. Now they dye it, weave it, bleach it—and let it fall into a set pattern. They are afraid to disturb it until their next trip to the beauty parlor." Besides being a gross exaggeration, this view of the need for washing and brushing the hair disregards the fact that washing and brushing the hair is not done among many savage tribes amongst whom baldness is unknown. Important as are these elements of hair care, their lack is not the cause of baldness. Waving, dying, and bleaching may help to produce baldness.

Brushing the hair, although it does cleanse the hair and distribute the oil through it, will not save the hair nor cause it to grow. The solution of our hair problems must be sought in some other and more fundamental direction. Perhaps diet may hold a large part of the solution, but certainly not all of it.

## **Article #2: Your Probing Mind By Dr. Vivian V. Vetrano**

### **Will Fasting Make Your Hair and Nails Grow?**

Both hair, and nails grow well during a fast. Many times people who had brittle nails happily discover that while fasting they become more pliable and less easily broken. Long fasting, in those having disproportionate reserves, may cause the hair follicle to involute while fasting and about a month to two months after the fast these experience a great falling-out of hair. This often frightens them and they think that they are becoming bald. Fasting does not produce baldness. Their hair begins to grow again until they have as many as they had before. It is common physiological process for hair follicles to involute; the hair falls out and subsequently grows again. When a hair reaches its normal potential length, then the follicle shuts down the manufacture of hair for a while and the hair falls out. For the follicles to do so all at once is a conservative process. The same thing happens during acute diseases accompanied with prolonged high fever. The body is conserving its nutritive stores for more important functions.

If this occurs after a fast, no special preparations or dietary changes are necessary unless one has been eating wrongly. Continue eating the Hygienic diet, especially concentrating on eating the nuts and salads, and the hair follicles will begin again to manufacture hair as they normally do. No diet can compare to a diet of nuts, fruits, and green vegetables for luxuriant growth of hair.

### **Are There Any Safe Shampoos? Is Water Alone Sufficient For Washing One's Hair?**

Yes. water alone is sufficient for keeping one's hair clean. In a polluted city, you may have to wash your hair three or four times a week but plain water will suffice. Shampoos have been indicted for causing baldness, excessive oiliness, and excessive dryness of the scalp and hair.

Many women feel that their hair is dirty if they don't use a shampoo of some kind. When I first learned of the effects of shampoos and soaps, I was also fearful that my hair would be dirty without them.

However, once you get used to the new feeling of your hair with its natural oils in it, then you begin to like that feeling better than the flyaway unmanageable hair just after shampooing. Actually, when using water alone plus regular brushing, your hair is much cleaner than when using shampoos. Besides being able to wash it more than once or twice a week, you learn a whole new way of caring for your hair that makes it more beautiful, healthier and cleaner.

To wash your hair without shampoo, scrub the scalp with your fingertips under running water (the shower is best) for about ten minutes. Towel dry it or blow dry it. After it is dry, brush it with a natural bristle brush. The brushing will remove all the loosened dirt and exfoliated scalp tissues while at the same time it distributes the oils evenly throughout the hair. Your hair will shine beautifully and be very manageable. Those with excessively oily hair may wash their hair daily without shampoos without harming it, whereas using shampoos two to three times weekly is extremely hazardous.

### **When I comb my hair I pull out about one fourth of a comb of hair. Is this normal or abnormal?**

It is quite normal for some hair to fall out when being combed. Hair grows to its potential

length, then the hair follicles involute, that is, cease to produce hair for a while, and the hair shaft falls out. Then the hair follicle begins growing a new hair in its place. This is normal. It is abnormal when hair falls out daily by the brushful. This occurs occasionally after long febrile conditions, and in some people after a long fast. In each case the hair grows back.

### **Just how harmful is the repeated use of chlorinated swimming pools?**

Chlorine gas was the gas used in World War I that was so deadly to the Allied soldiers. In hot weather when evaporation occurs, you can smell the chlorine vapors around a pool, which means that you are breathing some chlorine gas. Chlorine is a protoplasmic poison and is damaging to the skin, eyes, hair and mucous membranes. The chlorinated water may accidentally be swallowed and contribute to internal toxemia. If all you have to swim in is a chlorinated swimming pool, make your dips infrequent and stay in the water for no more than ten to fifteen minutes and try not to swallow the water. Don't open your eyes under the water without goggles.

Any amount of chlorine in drinking water is harmful but when more than the prescribed amount is put in, it has been known to cause epidemics of diarrhea. Small amounts can do the same thing in extremely sensitive people, and may even cause colitis. Many so-called allergic symptoms result from the use of chlorinated drinking water. Hives and asthma have disappeared almost overnight in some people when they ceased drinking chlorinated water. Colitis has spontaneously cleared up in many people when they quit drinking chlorinated water. Chlorine has been shown to destroy Vitamins A, B, C, E, and one essential amino acid that is especially important in young children, called tryptophan.

When you add swimming pool water to all the other sources of inorganic chlorine in modern life, it amounts to a pretty high dosage and an increased frequency of disease.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > Article #3: Cutaneous Medicine

### **Article #3: Cutaneous Medicine**

As quoted by Dr. Vetrano in *Dr. Shelton's Review*, June, 1979. Other comments by Dr. Vetrano.

Substances can pass through a hair follicle, when they can't get through other areas of the skin. Soaps, chemicals, and harsh rubbing makes this occur easily. You can demonstrate absorption through a hair follicle by just placing a five percent aqueous solution of histamine or norepinephrine on the hairy forearm. Very soon you will see little blanched bumps around the hair follicles, called wheals, with the hair standing on end. "Washing the skin first with soap and water, or prior defatting with ether or chloroform, somewhat enhances penetrability of the above agents from aqueous solution."

The reason we so often have bad reactions to deodorants, especially while fasting is probably because they are rubbed into a hairy region, such as the axilla; also because the axillary skin is weakened by shaving and soap and water washing. Shaving weakens the skin's protective ability by loosening and disrupting the stratum corneum (for definition see Lesson 61), or the layer of the horn, and soaps wash away our protective oils and other secretions.

Actually there are only two ways that substances can enter the skin. One is by passing directly through the epidermis, the transepidermal route. Certain substances can get into the body via this route but not many. The other way that substances get through the skin is through the orifices of the hair follicles as I

have shown. This is the pilosebaceous route. More substances get into the body through the follicular holes than can pass through the skin itself. This is why you are always cautioned, when using permanent wave solutions or hair dyes, to make a test curl first, because applying chemicals to hair regions can be hazardous to your health. If there were no hair follicles the skin would be even more impermeable than it is presently.

..."By entering the follicular orifices, substances can bypass the epidermal barrier altogether. If miscible or soluble in fat, they can seep down into the sebaceous duct and pass through the sebaceous gland, fanning out from here into the dermis. The pilosebaceous route is the chief means of transit through the skin. Penetration is, therefore, best in densely hairy areas. Conversely, absence of follicles in atrophic or senile skin lowers permeability."

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > Article #4: The Body Beautiful by Max Warmbrand, N.D., D.O.

#### **Article #4: The Body Beautiful by Max Warmbrand, N.D., D.O.**

If you are concerned with your physical appearance., it is important to know that it is only through intelligent living that you can mold a beautiful body and a charming personality.

The sheen of your hair, the smoothness of your skin, unblemished teeth, sparkling eyes, shapely ankles, a buoyant, youthful step—how easily they can be attained when you follow a healthful way of life.

Blotchy aging skin, tired eyes, coarse stringy hair, premature aging, and the weary step are not the inevitable marks of passing years; they are the deteriorating effects of wrong food, bad habits, emotional excesses, abuses of one sort or another.

You can be a charming, vivacious, radiant, and vital person at 70, or dull, bloated, worn out, and depleted at 30. It all depends on how alert you are to the needs of your body and how well you go about taking care of yourself.

The first step toward attaining the body beautiful is to turn to a good wholesome diet. The most valuable foods to help melt away fat or increase weight, smooth out wrinkles, beautify the skin, put life and lustre in the eyes and hair, are the raw fruits and the raw vegetables. These foods should be number one on your diet list.

Excerpted from *The Encyclopedia of Natural Health*

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > Article #5: The Hair by J.J. Tilden, M.D.

#### **Article #5: The Hair by J.J. Tilden, M.D.**

The various pastes, or liquids, on the market for removing hairs are made of arsenic, or calcium sulphate or barium salts, or quick-lime (unslaked lime), or some combination of same.

They remove the hairs by burning them off. No depilatory gets into the roots to prevent more hair coming.

The electric needle is often used to remove hairs by destroying the roots, but it is a dangerous procedure

at its best, for every point that the needle enters must leave a scar. It is a painful operation and leaves many regrets for the operator as well as for the patient.

There is another method of hair-removing that is not fully understood by the public. As it is the public that furnishes the patients, or victims, for any system of treatment or mistreatment, the public should be informed.

This "newer system" is known under many fancy names, but it has for its remover a form of electrical energy or "ray" that destroys the tissues gradually. Many repeat treatments have to be taken, when slowly the hairs wither and dry up and fall off.

As I have had several of these unfortunate victims to treat, I must give a word of warning, for this "unknown-ray" system leaves the skin, so it gradually dries and takes on the appearance of a "raisin skin." (The ray is a form of X-ray.)

In London, England, the authorities have forbidden the use of this "unknown ray" for hair removing. One of the London medical officials claims that cancers are appearing on the faces of many who have had this "unknown ray" system of hair-removing used.

When used under the arms, the "unknown ray" often makes cripples by destroying the blood vessels and withering the nerves.

Other tissues must be destroyed to destroy a hair root.

[Home](#) > [Lesson 63 - Nutrition And The Hair](#) > Article #6: Hygiene of Beauty by Tosca Mariani

### **Article #6: Hygiene of Beauty by Tosca Mariani**

If a child, or anyone for that matter, has dandruff, it is generally because they are on too high a refined carbohydrate diet—too many sweets, too many sugars. It is first necessary to get them off the denatured sugars and high carbohydrate diet to clear up the condition. Let them eat more fresh fruits, less dried fruits, more fresh vegetables and the proper nuts for the protein. They will gradually cease having dandruff. Now, what you can do while you have this condition, is to wash your hair with plain water, because the soaps and shampoos that are said to eliminate dandruff only cause more dandruff. All that's needed is to wash it daily. If the dandruff is very, very bad, wash the head daily and brush with a boar bristle brush. Push the brush in deeply, and then scrub in that spot. Then brush it out. In other areas, just brush out the dandruff. You can get all the dandruff out that way.

A man's hair can be washed just like a woman's hair, and brushed with a boar bristle brush. You can find brushes for males, as you can for females, that are made out of boar bristles. Men can keep their hair nice without using a lot of hair oils or hair preparations. You really don't need them. In fact they aren't too popular any more with most men. Just wash the hair in plain water, let it dry then brush your hair vigorously.

Hair is fed from within, not from without. Whether you get Protein 21 shampoo or any of the other protein preparations, they do not feed the hair, because these cells are nourished by blood only. Hair cells, which are part of the outer layer of the skin, harden in the process of growth. After they are hardened they no longer receive nutrition. They are dead cells. They are kept pliable and soft by the oil secreted by the oil glands. Hair automatically is lost. Every person has a growing span or a particular length or potential length which the hair may reach before the follicle turns under to take a short rest. A hair follicle will turn under every so often and this involution is a natural process.

There are some things that can occasion premature turning under of the hair follicle and a loss of hair.

This is malnutrition and some severe febrile diseases such as typhoid fever, scarlet fever, malaria, etc., and sometimes after a very long fast. This is because the body begins to conserve its reserves and ceases to secrete a lot of oils. The skin becomes a little drier while fasting, and it ceases to grow the hair follicle. They involute or turn under and a month after your fast they may fall out. A new follicle will replace it. This kind of hair loss is only temporary and all of the hair does not fall out. Only some of the follicles involute and you are not completely bald. You are just thin haired for a while. The hair will begin to grow after it has involuted for a while, and you will have a head of beautiful new hair. In some people, believe it or not, their hair has grown back curly instead of straight. Some people think that curly hair is the normal, and straight hair is a loss or an abnormality, but this is a debatable issue.

People almost always want to know what causes graying. When a hair becomes gray, it is because the pigment-producing cells in the follicles have ceased to function and as a general rule, this is an aging process from which there is no return. In some cases, people may turn gray very early, and their hair color has been known to return. This is unusual, and is due to a great fright or some extreme emotional upheaval. These types have been known to regrow the natural color.

It should always be remembered that the care of every part of the body comes from within. It is your total way of life that makes these parts beautiful. Whether it's your skin, or your hair, or your eyes or your teeth, they are all nourished from within. You need sunshine, you need exercise, rest, proper diet and emotional poise, in other words, you need all the requisites of normal physiology. These things are just as "necessary for various parts of the body as they are for your general health. When your general health is good, then nine times out of ten, your hair and your skin will be normal. They will be fed properly because they are fed by the bloodstream. All of the cells use about the same nutriment.

There's not any special nutriment for hair, or special nutriment for teeth, and so forth, but protein is essential in your diet; that is protein supplied from within, not applied on the surface.

- [3. The Life Science Stress-Management Program](#)
- [4. Questions & Answers](#)
- [Article #1: Stress/Unstress By Ken Pelletier, Ph.D.](#)
- [Article #2: In Search Of Emotional Well-Being](#)

### 1. Introduction

The man was berserk. He drove his car through the front doors of an office building, and then leapt out with a shotgun in his hands. He took aim at the picture of the company president in the building lobby, and shot it full of holes before he was wrestled away by the police.

The man was an ex-employee of the company. He had been fired that morning by the man whose picture he blasted away that afternoon. The man was a victim of stress, and he was reacting in a way that let off the anger, frustration, and helplessness he felt.

Stress—it affects us all, and it can kill us as surely as any illness or disease.

We all experience stress every day of our lives. How we handle stress depends upon our current state of health. If we are healthy, we can manage stressful situations in a positive, productive way. If we are sick, depressed, or simply "out of sorts," then stress can trigger the berserk reaction of the man above, or it can send us into a helpless, destructive state of fear.

Stress, however, can be effectively managed by applying the principles of Life Science and Natural Hygiene in these areas: diet, exercise, relaxation, and sleep.

Before we learn how to deal with stress, we need to recognize it in our own lives. If we can identify stressful situations, we can either learn to avoid them or to handle them so that they do not trigger a more serious and harmful reaction.

### 2. The Problem Of Stress

#### 2.1 What Is Stress?

Hold a wooden pencil between your hands. Slowly apply pressure as you try to bend the pencil. Increase your pressure, and the pencil snaps and breaks. That's an example of mechanical stress. Stress is simply a pressure or a strain that tends to distort a body—whether it be a pencil or a person.

Up to a point, we can all take pressure and strain. At some time, however, the stress can become so great that just like the pencil, we "snap." If and when we "snap" depends on the ways we handle stressful

situations.

And, to make it more interesting, all stress is not the same. To handle the stress in your life, you need to understand what type of stresses can be made upon you.

## 2.2 The Types of Stress

Most stress used to be *physical and short-term*. Now in modern times, stress is usually *emotional and long-term*. What does this mean?

All living creatures experience short-term, physical stress almost continuously. Finding food, adapting to weather changes, reproducing, and growth are examples of common, short-term stress situations. As soon as we find our food, or adapt to the season, or reproduce, then the physical stress brought on by these states is eliminated—it was temporary and for a short-term.

This type of stress is normal, natural, and perhaps even beneficial. Without a certain amount of stress, no change, progress, or growth would ever take place. We would be in continuous state of stagnation unless we experienced temporary feelings of stress.

When these stressful situations become long-term, however, then harm results. Also, when the stress becomes more emotional or mental and less physical, we have a harder time of dealing with it. Why? Because the responses to physical stress, such as intense hunger, are already learned. The body has its own way of handling physical stress, and it knows how to best compensate for the temporary demands placed on it.

On the other hand, emotional stress brought about by uncertainties, or feelings of helplessness are difficult to handle. We haven't learned yet how to deal with the type of stress produced by overdue bills or individual shortcomings. And, unlike physical stress, these long-term, stressful emotional states and fears can last for weeks, months, or even years.

## 2.3 The Effects of Stress

You already know how stress affects you personally, perhaps it makes you feel tired, fatigued, nervous, or depressed. Stress may make you feel as if the weight of the world was on your shoulders. Emotionally, stress may make us prone to anger, irritability, or even tears. No matter how you personally react to stress, however, the physiological effects of stress are the same for all living creatures. What happens to your body when you experience stress?

What are the physiological responses by the body to physical stress:

- An increase in arterial pressure.
- An increased blood flow to the muscles with a decreased blood flow to the organs.
- An increased rate of cellular metabolism throughout the body.
- An increase in blood glucose.
- An increase in glycolysis in the muscles.
- Increased muscular strength.
- Increased mental activity.

The overall effect of these responses is to let you perform far more strenuous physical activity than would otherwise be possible. Why is this? Because if a stressful, threatening, situation is present, then you would probably need to flee from it or fight it. This is called the *fight flight reaction* because an animal in a physically stress-state decides almost instantly to stand and fight or to n and run.

Here's an example of how extreme physical stress can activate the energy reserves of the body: In the national newspapers this week is an account of a 80-year-old grandmother who had been on crutches continuously for the last two years. A fire broke out in her neighbor's house and she heard the cries of a

trapped child. Immediately she ran into the house and carried the child to freedom before she realized she had thrown her crutches aside. She then collapsed and had to be removed by ambulance. During a time of great crisis, or stress, her body responded so vigorously that she forgot she was an invalid.

So far, stress doesn't seem to have that destructive an effect, and it doesn't—if it is *short-term, physical stress*. When stress becomes prolonged and internalized, however, it has decidedly negative results upon the person's health.

## 2.4 What Is the Stress Reaction?

It is amazing that almost any type of stress can cause the same reaction in the body. Scientists often refer to two kinds of stress: *physical* and *neurogenic*.

An example of physical stress is being exposed to extreme cold. An example of neurogenic stress is the worry that you won't be able to pay your winter heating bill. A vital body can quickly adapt to physical stress. Neurogenic stress, worry or tension, however, may take their toll.

Regardless if the stress is in the body or in the mind, *the same physiological reaction takes place in the body*. The most noticeable effect of any type of stress is a marked increase of hormone secretion in the body.

The hormone known as ACTH (or adrenocorticotrophic hormone) is released in large quantities whenever stress is present. This ACTH substance activates the secretion of cortisol. Cortisol, in turn, enhances the production of adrenal androgens in the adrenal cortex. The net effect of all these secretions caused by stress is to provide a sharp and immediate stimulus to the adrenal glands.

The adrenal glands sit right above the kidneys, and control many functions. Perhaps you've heard of athletes or other people speak of the "adrenalin rush." Adrenalin is the most powerful stimulant known. Stress causes adrenalin to be released, and we consequently feel "stimulated." If we are constantly overstimulated by stress, we become burnt-out and incapable of responding to true stress situations.

When some people drive in heavy city traffic or experience other intensely stressful situations, their adrenal glands may actually "ache" or hurt from the constant stimulation being received. An older gentleman who complained of lower backaches while commuting in rush-hour traffic believed he had kidney problems. In reality, his adrenal glands were just being overworked by the stress of commuter traffic.

This is the danger in the stress reaction. You can be under stress or overstimulated almost continuously. No one can run on "high" speed all the time, and the body eventually suffers.

The type of stress that can provoke this adrenal reaction is widely varied. Researchers have discovered, however, that the following situations are sufficiently "stressful" to spark a high ACTH release, which means the body becomes highly stimulated.

## 2.5 The Types of Stress That Cause Physiological Reactions

1. Intense heat or cold.
2. Injections of any sort.
3. Surgical operations.
4. Trauma of any type (physical or emotional).
5. Pain.
6. Any debilitating body crisis.
7. Emotional outbursts or anxiety attacks.

It seems as if stress is all around us, and its sustained effects can wear us down and make us vulnerable to negative thoughts and poor living habits. But there is hope.

The Life Science program, which is based entirely upon our natural adaptations, provides the correct

basis for living that allows us to withstand stress far better than if we transgress our own biological requirements and nature.

The Life Science approach to stress management, even long-term and emotional stress, is three-fold: *Exercise, Diet, and Relaxation*. These are three of the essentials of health and well-being. Let's see how they help us overcome stress in our daily life.

### **3. The Life Science Stress-Management Program**

#### **3.1 Sweating Away Stress: Exercise!**

Exercise is your best friend in combating stress. The value of exercise as a stress reducer is well documented by many researchers. Why should exercise, which is a vigorous activity, have the power to *relax* us and eliminate stress? The answer is this:

Exercise channels the excess energy created by stress into a natural and positive outlet. As you learned earlier, stress causes the sympathetic nervous system to prepare for immediate physical action. The muscles become charged with fuel and the entire metabolism quickens. Unless this excess energy is released through exercise, it can overload and "burn out" the body's nervous system.

If stress becomes habitual and no exercise is taken, then the excess energy is internalized as tension within the muscles. When this occurs, the muscles and tendons themselves shorten and thicken. Excessive connective tissue is deposited, and a general consolidation of all the tissues occur. In other words, holding in the stress and tension has destructive effects on the muscles of the body.

When you exercise vigorously, you dispel this muscular energy in a natural and beneficial way. After all, stress produces the "fight-or-flight" reaction. If we can quite literally "run away" from stress by jogging or other forms of exercise, then we use the energy created by stress in a constructive manner.

A young man of my acquaintance was an aspiring body builder who went away to college. He was afraid that the time demands of college study would mean an end to his body-building program. After a year of school, he returned with an amazing physique. I told him that it certainly looked like college agreed with his exercise routine after all.

He smiled, and said: "You know it's funny. I found out that the best way to get rid of tension and anxiety about my college studies and tests was to lift weights. The more anxious I got about my courses, the better it felt to work out with weights. It helped me burn up nervous energy that would have driven me crazy otherwise."

Exercise does reduce stress and aid relaxation. In his book, *Learn To Relax*, C. Eugene Walker concludes that exercise has the specific ability to reduce anxiety and tension. People on regular exercise programs tend to be more healthy, have better vital capacity, and in general, can cope with life in a more satisfactory way.

Regular exercise not only makes you feel better, but also makes you become more optimistic, and have a better self image. So not only does exercise reduce anxiety, it seems to be a good preventive for developing future fears and stress problems.

Some people have downplayed the importance of exercise in stress reduction. They say that stress is "all in the mind" and the only effective way to combat stress is through mental or emotional avenues. Not

true.

In research conducted by Richard Driscoll, groups of people who were suffering from high anxiety and personal stress were given four types of treatment. One group simply used visual imagery and imagined themselves relaxed, happy, and free from stress. Another group used only exercise. A third group used only physical relaxation techniques, and the last group combined exercise with a positive program of mental optimism.

The group which used exercise in addition to positive thinking had the highest success rate in reducing stress. The groups which did not use exercise programs with their other stress-reducing techniques had a much lower rate of success.

The evidence is in: to reduce stress, you must exercise.

### **3.2 Stress Management Through Diet**

"Sure, I use diet to take care of stress. When I get tense, I just stuff my face!" The young man laughed, but his overweight figure showed the truth behind his joking.

Unfortunately, many people respond to stress by overeating or by indulging in drugs or other destructive habits. To make things worse, the types of foods usually favored under stress—ice cream, candy, soft drinks, coffee, alcohol, junk foods—have the effect of making us more susceptible to stress and illness.

Diet and nutrition play an important role in stress management. By simply avoiding destructive foods and following a wholesome diet, you can withstand normal stressful situations in a cheerful and optimistic fashion. A junk food diet, on the other hand, can make us crumble under the slightest bit of tension. Why is this?

### **3.3 How Diet Affects the Stress Response**

A strong and healthy nervous system is our first defense line against stress. Good nerves and a steady disposition allow you to shake away stress and handle tension effectively. Although many factors ensure a healthy nervous system, most nutritionists believe that B vitamins play the vital role in good nerve health.

If you follow the natural Life Science diet of fresh fruits, vegetables, nuts, seeds, and sprouts, you will have a super abundance of all needed nutrients—including B vitamins as well as important minerals and trace elements that build strong nerves.

On the other hand, junk foods, refined sugars and starches, processed foods, nonfoods like alcohol and coffee, and many of the other substandard foods commonly eaten deplete the body of B vitamins during the metabolism of these foods. These types of foods are nutrient destroyers. In this case, the nutrients being destroyed and depleted by junk foods are the exact same nutrients that your body needs to withstand stress.

Perhaps now you can see how the stress junk food cycle gets started. A person feels stressed and insecure; he or she then reaches for a sugary "reward" food, such as ice cream or candy. After the food is eaten, additional B vitamins and other nutrients are depleted. This nutrient loss predisposes the nervous system to more stress attacks, and more junk food is eaten, and so on.

Why do people use food as a refuge from stress? First of food is a very reassuring substance. Our earliest memory of security go back to being fed by our mother. Feeding or eating, then represents a way back to security.

Food or digestion, is also used to deaden the feelings of stress. When the body is loaded down with a mess of food to digest, the mind becomes cloudy, dull, and desensitized. Food is used as a drug to obliterate feelings of tension, obsession, despondency, or stress.

Eating while under stress is actually one of the worst things you can do. Under any type of stress—physical or mental—the digestive faculties are inhibited and digestion ways suspended. What this means is that if you eat when suffering from stress, indigestion will surely result.

A favorite quote from Dr. Herbert M. Shelton is: "Whenever you are uncomfortable in body or mind, skip the next meal." If you ever suffer from feelings of stress or fear, resist the temptation to eat. Fast for awhile. A short fast will do much to dispel feelings of delusion, insecurity, and stress. At the same time, the fast allows the body to rebuild itself and strengthen the nervous system. The result of proper diet and occasional fasting is you receive immediate "stress relief".

The wholesome Life Science diet provides all the nutrients we need to build body and mind that can cope with stress. No foods are included which disrupt the body's balance or deplete the vital nutrients that we need to withstand stress. A proper diet, coupled with exercise can be your best partner in stress management. But there is another important factor in effective stress management, and that is: relaxation.

### 3.4 Relaxation

Rest, sleep, relaxation, poise, equanimity—whatever want to call it—is absolutely essential to the continued health of the organism. In fact, the opposite of stress is recreation. Every muscle, cell, and portion of the body is in a continually alternating state of stress and relaxation. As long as we alternate periods of stress with periods of relaxation, then all is fine. At times, however, stress gets upper hand and relaxation—true and total rest—never occurs, even while asleep.

A young woman who had just accepted a top executive position with one of the nation's leading banks was sitting in a dentist's chair. She had a strange problem, but one this dentist had already seen in dozens of his patients: When she was asleep at night, the woman ground her teeth continually. She had so much tension and was going through so much stress with her new job that she actually ground her teeth down through a gold crown covering, and now grinding away at the tooth underneath.

"It's a common problem of the last ten years," the dentist told me. "People have so much stress in their daily lives that the only way they can release it is by grinding their teeth in their sleep. Some patients have to wear plastic in their mouth when they go to bed so they won't grind the teeth down to the bone."

Just because you get seven or eight hours of sleep does not mean that you are getting adequate rest and relaxation. No, relaxation is different from sleep and strangely enough, you may have to *learn* how to relax in order to offset stress.

Dr. Herbert M. Shelton wrote in his book *Human Beauty: Its Culture and Hygiene*: "Worry, strain, and stress exhaust the nervous system more rapidly than physical activity, producing such danger signals as tension, irritability, and a tendency to worry over trifles. If we neglect the necessity for adequate relaxation and repose, we have no chance to replenish our energies or repair our worn tissues."

Dr. Shelton then concludes that "relaxation is an essential condition of continued healthy existence. Without it, the most vital and necessary processes of life are not carried on or they are conducted with much lowered efficiency."

But how can we relax if we are feeling stress? The trick is to relax *before* stress develops and tension sets in. After all, doesn't it make more sense to use relaxation as a preventive treatment for stress instead of as a "curative?"

Just like regular exercise and a sustained good diet, relaxation and rest should be a normal daily activity that you engage in—whether you need it or not! Modern life can sometimes fool us that we have no time or no need to relax. We feel that we can handle anything, and we take on more projects, more work, and more responsibility. Eventually, the body that has been continually deprived of rest, and relaxation will rebel, and illness may result.

Rest and relaxation must become a daily part of your activities. Give up an hour a day to constructive

rest and contemplation. You may engage in some restful hobby or activity that makes no mental or physical demands. You may take a walk by yourself or listen to some music. There are many ways to relax, but don't fool yourself that you are relaxing when actually you are just doing some other type of work or watching television.

Many people are worried about the "right" way to relax. Some people have been told that meditation is essential, and others believe that relaxation can only come by taking some course or by reading a book.

As far as stress reduction goes, it makes absolutely *no* difference which relaxation method you use. The important thing is that the relaxation be total: both body and mind must be free from tension and stress.

### **3.5 Relaxing the Mind**

Much stress and tension is in the mind, but as we saw, that does not make it any less "real." The mind can also be relaxed in a manner similar to the body. First of all, the mind must be used constructively—"exercised" if you will. Mental laziness breeds anxiety and a lack of self-worth. These feelings lead to stress.

If you diligently apply your mind to new tasks and learning, it will be more eager to relax and let go of the petty worries that sometimes occupy the thoughts.

Along with working or exercising the mind, you must give it time to relax, wonder, and dream. Daydreaming is not bad at all, if it doesn't interfere with our daily lives. Giving the mind free reign to explore and visualize can do much to dispel the mundane worries that can dominate our thoughts.

Listening to fine music, painting, reading inspiring books, and just quietly sitting in contemplation are excellent mind relaxers. Whichever way is best suited for your temperament, find a way to relax your mind and leave your worries behind for at least a small time every single day.

Simply relaxing and "doing nothing" may be very hard at first, but if you give yourself the scheduled time to do it every day, you will eventually look forward eagerly to your "relaxation period."

### **3.6 A Case History**

The man before me should have been at the prime of his life. Forty-five years old, the man had started his own computer company three years ago and was now earning over a hundred thousand dollars a year. Yet he looked distinctly unhappy.

I can't enjoy life anymore. Food I eat doesn't agree with my acid stomach. I worry I'm getting ulcers. After a day of work and dealing with problems, I don't want to even talk to my wife—much less make love to her. I've got everything I want except peace of mind, so I guess I really don't have much at all." The man folded and unfolded a piece of paper in his lap. His hands shook, and he couldn't meet my eyes.

After talking some more, I discovered that his diet was typical for business executives: a breakfast of coffee and orange juice and toast, a fast-food lunch, and a supper of beef and potatoes. His only exercise was taking his sailboat to the lake on summer weekends, and he had no other interests outside of his work.

The first thing we worked on was his diet. He wasn't about to give up meat or some of his "favorite" foods, but he did agree to practice the rules of food combining. He lived about a-mile-and-a-half from his office, and he decided that he would walk there and back at least three times a week, weather permitting. Finally, he renewed an old interest in music, and told me that he was going to start practicing on the piano he had bought for his children.

Two months passed. I met the man again, and noticed his relaxed and smiling expression. "No more ulcers or acid stomach" he told me. "I don't know if I believe that food combining stuff or not, but something sure worked on that diet. And I also realized how much I missed being outside as I walked to

my office. Now I'm riding a bicycle to and from work about every day."

And his new hobby? "Ah yes, music. It sure is soothing my savage beast after a day of work. I gave up on the piano," he confided, "but I got an excellent classical music library now, and I'm taking a music appreciation course."

It all seemed so simple. Just a consciousness about the diet, minimal daily exercise, and a relaxing outside interest were all that was needed to turn the man's stress-filled life around. The Life Science approach to stress management is simple. Only a small amount of commitment and personal effort is required. And the reward? The greatest of all—a stress-free, healthy, happy, and productive life.

[Home](#) > [Lesson 64 - Stress Management: The Life Science Approach](#) > 4. Questions & Answers

## 4. Questions & Answers

### What are the early warning signs of stress?

Irritability and fatigue. If you continually feel tired or short-tempered, then you are experiencing stress. If small annoyances make you angry, or if you become upset for no apparent reason, then you are experiencing stress. In other words, if you even suspect you are under stress, then you most certainly probably are. Stress can "sneak" up on you. Often, people brush aside the early warning signs of stress and continue to push themselves on. Finally, the demands made by stressful situations become so great that the body becomes ill at ease, or "diseased."

The final outcome of stress is a breakdown of the healthy functioning of the body. Be very sensitive to emotional changes and your reactions to your job, family, and surroundings. These types of things can warn us when the stress load is becoming too great.

### Can we "eat" stress away? I mean, is a good diet the main thing you need to avoid stress?

Unless you are following a good diet and a regular exercise regimen and a satisfying relaxation program, then you will be adversely affected by stress. Without an excellent diet, however, all the exercise and relaxation in the world will not overcome stress. Until you are well-established on the optimum Life Science diet, then at least make sure that none of the "stress-promoting" foods, such as junk foods, white sugar, white flour, alcohol, and caffeine, are forever eliminated

You cannot, however, "eat" away stress, "run" away stress, or "sleep away stress. You must combine all three, along with a positive and cheerful mental outlook, to curtail the harmful effects of stress.

### Stress can often come about because of changes in your lifestyle—like getting a new job, moving, becoming married, death of a spouse, and so on. In light of this, wouldn't it be ill-advised for a person suffering from stress to make the types of changes in diet and exercise as you propose?

Most stress that comes from changes in our lifestyle comes about because these changes were made for us. In other words, stress usually arises because we perceive ourselves as "helpless" in face of these changes

Now, if we make positive changes in our life, as a result of a conscious decision, then we

feel that we are in charge of our lives. We no longer feel helpless. We assume control of our destinies. This is one of the greatest values of the Life Science Stress-Management Program. It consists entirely of positive steps that may be undertaken by anyone at any point in their lives

Not only will these changes reduce stress, they will also increase our overall level of health. If you feel overwhelmed by stress in your life, immediately take a positive, constructive step to improving your life. Start an exercise program. Give yourself a time and place to relax. Improve your diet. As soon as you decide to do one or more of these things, you will immediately lower your stress level. Try it. It works!

If stress is not properly managed, illness, disease, depression, and despondency may result. Because of the many mental and emotional demands made upon us by modern life, all of us are susceptible to stress and its negative effects

The best defense against stress is a healthy lifestyle and positive outlook on life. The requirements for effective stress management, are basically the same, as those for health and well-being: a sensible exercise program, wholesome and natural diet, and regular relaxation.

[Home](#) > [Lesson 64 - Stress Management: The Life Science Approach](#) > Article #1: Stress/Unstress by Ken Pelletier, Ph.D.

### **Article #1: Stress/Unstress by Ken Pelletier, Ph.D.**

No one can achieve optimum health so long as they allow stress to dominate their lives. Much of peoples' physical sickness is a result of allowing the autonomic nervous system to get out of control.

Yogis and meditators learn to control their pulse, brain waves, blood pressure, heart rate, skin conductance, muscle tension, peripheral circulation, and respiratory pattern and rate. The subjects' patterns are very coherent—when one goes up they all go up. When one goes down, they all go down.

There are two kinds of stress: short-term and long-term. The short-term we can take. That's the kind we share with every other biological organism. We react in a certain way when we're in a threatening situation.

When there is a long-term stress such as money difficulties, family stress, job stress, emotional conflicts, all bodily functions accelerate as though your life was in danger, and they stay elevated, without release. They continue at a rate of high excitation. This is the kind of biological stress pattern that leads to disease, heart attack or stroke.

Yogis learn to let go of these excess levels and simply quiet themselves down.

You can think of your bodies as being naive. They can't tell if your life is really in danger, or if you're just thinking as if your life is in danger. The fear of losing your job might feel just as threatening as if a speeding truck were coming at you. You might react this way to a nagging creditor or to your income tax coming due.

In someone with a real chronic stress pattern, one thing that may break the cycle is a serious problem or illness such as a nervous breakdown, a heart attack, a stroke, a debilitating headache, or one of any number of such things. During or after a serious illness, a very different set of demands is placed upon you. It's now okay to stay in bed and take it easy.

The same stress that may produce a heart attack in one person might produce only a headache in another. Certain families, both genetically and behaviorally, will predispose to certain illnesses. Your environment will predispose you one way or another. So will your lifestyle.

The most exciting thing about research work in the field of thinking is that once people get moving in the direction of health, they don't want to stop at just being "normal." They keep going toward becoming healthier than the average.

The main ways to break the chronic stress pattern are stress management, diet, and exercise. Exercise breaks up both physical and mental tension.

The physiological effects of light exercise for high blood pressure are comparable if not greater than those brought about by drugs. The information is in medical literature but is not taught in medical schools. How often does a doctor put a hypertensive patient on an exercise program?

Post heart attack victims often undergo a conceptual shift in thinking, so that afterward, things that were considered highly stressful are no longer perceived as so potentially perilous. This process is something like, "I just looked at all the things that used to bug me, and I said to heck with it."

This is the change all patients should strive to produce in themselves—to learn to decide whether a given event is life-threatening or not.

It's a mistake then, to think that all stress is bad. There are times when the stimulus of stress can save your life. The error comes in when you start interpreting relatively nonthreatening situations—like balancing your checkbook or dealing with a certain person—as though they were life threatening. Then you are creating the crisis in that life event. All the same responses take place as if a car was coming at you at 80 miles per hour.

You can achieve the conceptual shift in any number of ways, one of which is the painful, involuntary way through severe illness that forces you to look at your values. Illness can be a very creative experience—a potential source of regeneration and renewal instead of just a breakdown.

There are many symptoms before actual illness strikes. You're being told that you've pushed yourself beyond a level of healthy functioning. Too many people miss the early signals and get the opportunity to examine their lives—perhaps for the first time—at the cost of a serious illness.

Many people recognize a physical symptom and instead of realizing this calls for a change to correct it, they say, "This is something to worry about." This further adds anxiety, and gets them deeper into a chronic stress cycle. You can run from a snarling dog and be attacked or stand your ground, stay relaxed, and relate to the dog.

What can people do to minimize the feeling of stress in their lives? Any activity that you have in your life can be used as a meditation. Prayer, walking, sex, running, singing, listening to Bach—it can be anything. An activity that you invest with prolonged and focused attention can be a form of meditation.

Self care is paying attention to a beneficial way of living your life so that your exchanges and interactions with other people are loving and caring, and your attitudes toward yourself are that way, too. People come to meditation by very different roads. For some people, paying attention to nutrition leads to paying attention to other areas of their lives. Others come at it through exercise.

They realize they can't even run around the block if they're feeling tense, and they get interested in meditation. Another might start meditating and become conscious of being overweight. Meditation leads to self-discovery and self-care.

Pay attention. The unexamined life is the un-lived life. Invest your life with attention. Henry James said, "Try to be someone to whom nothing is lost."

All the things we do to ourselves by eating a nonoptimal diet make us more susceptible to specific disorders so try decreasing your intake of refined sugars which are uniformly destructive; decreasing your fat consumption; diversifying your protein base away from meat into non-meat sources of protein;

and eating more fresh fruits and vegetables.

People who have a slight to extreme overweight problem eat as a form of tranquilization. That relaxed feeling after a large meal is something they seek again and again.

You can get this same feeling from meditating or running several miles a day and this changes your perspective on food. But remember—all things should be fun. Too many people are so *dour*. They're going to become healthy if it kills them.

If you drive yourself to do anything, you're sunk. There must be a spark, an element of vitality, of discovery, that makes it really exciting. You've got to follow the little messages from inside that tell you what's right for you, no matter what any expert says.

[Home](#) > [Lesson 64 - Stress Management: The Life Science Approach](#) > Article #2: In Search Of Emotional Well-Being

## **Article #2: In Search Of Emotional Well-Being**

Mental and emotional well-being is conditioned by far more influences and factors than physical well-being. While physical well-being arises from meeting the physical needs of the body correctly, this is not always enough to assure mental and emotional serenity.

In ascertaining the conditions necessary in achieving mental well-being, we must consider more than the requisites of physical health. We must take into account those elements in our ecosystem that promote mental and emotional health and, likewise, those factors and influences which undermine it.

There are many who assure us that we are responsible for how we feel and act, that we are the architects of our feelings and moods. We can control the factors that affect us or at least so rationalize our attitudes in response to external factors that we are not adversely affected.

Those who are under emotional control are said to be poised: calm, cool, and collected. They respond rationally.

Individuals who do not have strong emotional reactions to stimuli and phenomena, be it adverse or favorable, are rare. Most of us react to unexpected conditions in an involved rather than in a detached manner. This is how almost all creatures of nature react to abnormal situations or extraordinary circumstances.

If there are very few humans who can view affairs in objective fashion, there are fewer nonhumans that have this capability—perhaps porpoises (dolphins) and whales. Where there are immediate and dire threats that require timely action, even the most poised may forego their usual detachment and objectiveness.

In Natural Hygiene/Life Science we teach that every effect is the result of foregoing causes. Hence we need to explore causes—causes over which we can exert control and causes which are beyond our control—in order to improve our mental and emotional condition. Essentially we all seek mental equilibrium, poise, or stability within the context of our respective lives. Within this setting we have certain desires and expectations. Thus we become disturbed and upset when something we expect or want appears to be or is denied to us.

Whatever the causes of depression, all are within the province of our control. We can take several steps to fulfill most of the requirements necessary to live a joyous life.

Some significant areas in which we can exercise control of our emotional and mental well-being are:

1. *Our health regime.* We can adopt and closely observe our biological requirements. Though we may be subject to many of the stresses modern society imposes upon us, we will fare far better if the basics of life are correct. The Life Science/Natural Hygiene program is scientifically correct, for it is based squarely upon our natural adaptations. It is within our province to decide to live healthfully and to pursue it diligently.
2. *Our thoughts.* We can think constructive thoughts instead of destructive ones. If we harbor animosities or the disapproval of others, we injure our minds. We must psyche ourselves into thoughts that are optimistic and positive in nature, and quash our thoughts that are negative in nature. It is said, "As you thinketh, so shall you be." By focusing your thoughts and reflections upon yourself and your relationships with the world, and directing your attention to how you can improve yourself and your interaction with others, you'll be laying the foundation for mastering your own destiny and happiness. Should you feel defeated or depressed, despondent or in despair, you can refuse to indulge in those thoughts that perpetrate these mental states.
3. *Accept the world as it is.* Accept and adapt to changes and look upon them as challenges rather than trying to resist them.

When we are in rapport with the world, we can take advantage of events and conditions rather than lose out by resisting them. In doing so, we create a positive influence on *ourselves* and those around us. We must be committed to what we believe but we must be *realists* and know what we can and cannot do.

We must, finally, address ourselves *honestly* to the limit of our reach. Each personality has its limits—to extend ourselves beyond our capabilities will only lead to self-pressure and our bodies will automatically become stressful. And that mental serenity will escape us.

### 1. Introduction

Many of the methods of treatment that were often prescribed by physicians during the 19th century and before are today considered useless and life-threatening. But the physicians during that time persisted in such practices as bleeding, blistering, purging, and the use of heavy metals, especially mercury, because they witnessed that, in some patients, symptoms would disappear. This, however, was an illusion. Symptoms were suppressed but there was no recovery of health. Indeed, many people died because of the treatment but the physicians did not recognize that the "cure" itself was the direct cause of the deaths.

Since that time, there has been a constant search for that elusive "cure." Harmful results occur when people become so convinced that these "cures" will restore health that they rely upon this illusion instead of looking to their modes of living as the real cause of their ill health. You must, therefore, strive to become more independent thinkers. You must begin to question "cures" and seek the truth by seeing things from a different perspective.

If a certain drug is found particularly harmful and taken off the market, we are told that we should not doubt the effectiveness of all of these agents. However, we should not follow ourselves to be deceived by them. One may feel better for awhile after taking one of these symptom-suppressing agents, but our so-called "cure" is a deception. The "cure" will not last. By seeking the truth, we will be lead to the true cause of disease and from this we may know how to regain our health.

A good example of how the American people have been misled by this delusion of "cures" lies in the practice of immunization. People have been told that vaccines build up antibodies that protect the vaccinated from disease. This is a false claim. Disease is the result of unhealthful living and one cannot

be "immunized" against his errors in living.

Any violation against physiological law always results in sickness. This would include any failure to meet sleep requirements, proper food, air, water, sunshine, exercise, or other needs. The body's ability to adapt is remarkable but freedom from symptoms is a delusion when it is produced by drugs in contravention of physiological functions. Under such circumstances, the body will inevitably become exhausted and more chronic illnesses will ensue.

The adverse effects of drugs were illustrated in a previous lesson and more and more people are realizing the dangers of these poisons and are looking elsewhere for "cures." Thus, we see many drugless practitioners throughout the country promising all sorts of "cures." This lesson will review some of the more popular "cures" and it will be demonstrated that they are harmful and, at best, relatively innocuous.

You should keep in mind that there are no "cures." There is no diet, no herb, no massage therapy that will restore health if the underlying cause of sickness is not removed. As we have stated before, health will result only from healthful living.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 2. Herbal "Cures"

## **2. Herbal "Cures"**

### **2.1 History**

Herbs have been used throughout recorded history as "cures" for various ailments. However, the use of herbs came into the forefront more formally in the late 1700s and early 1800s. Samuel Thomson is credited for the wide spread of this practice during that time in history. During that time, the regular medical practice included harsh bleed, purge, and blister methods. The popularity of the Thomsonian sect arose not necessarily from their success in curing patients' ills but from the fact they seemed to kill fewer patients than did their entrenched competitors—the regular medical practitioners. Thomson's empirical system was based largely on the use of steam and herbs.

Many people opposed the regular profession, but they had no more knowledge of how to remedy its deficiencies than did the regular physician. They found many aspects of regular medicine repugnant but they did not know why or how they were undesirable. The public could only choose among the alternatives available at the time.

Thomson saw his mother die of measles in spite of the care of several local physicians (or was it because of their treatment?); earlier, he felt he had "cured" himself of the same disease through the use of botanics. The illusion is that what appeared to "cure" did not. At best it was less harmful than the regular mode of therapy and therefore the body was able to overcome this drug obstacle and achieved the purposes for which it instituted the healing crises. A year after his mother's death, Thomson's wife became severely ill following childbirth. Several local physicians treated her, but her condition continued to worsen. As she neared death, Thomson wisely dismissed the traditional practitioners and their poisonous treatments. He then called in the local "root doctors." One day later, his wife appeared "cured." Of course, the herbs did not "cure" but the body promptly set about the process of healing when the deadly drugs were removed.

On another occasion, Thomson badly lacerated his ankle with an axe while clearing some virgin land with his father. After a number of treatments, including soaking it in turpentine, he naturally became worse. He then ended up at the home of one Dr. Kitteridge who treated the wound with herbs and was

credited with healing him. The body cannot heal if it is continually assaulted with toxins. When toxic herbs are removed, healing and repair are accelerated. Dr. Kitteridge or his herbs did not assume healing obviously. Herbs cannot help. They present less of an obstacle to the body than the harsh treatment of medical practitioners.

These incidences were enough to convince Thomson that herbs had the power to "heal" and the Thomsonian Sect began to emerge. Thomson became convinced that all disease arose from one general cause and that one remedy could effect a "cure." The cause was cold and the cure, heat. He, like the Greeks believed, "all animal bodies are formed of four elements, earth, air, fire, and water." Any imbalance among these four elements which reduced the power of the heat resulted in illness. To effect a cure, one must restore the balance. Thomson sought to restore the balance through the use of purgatives, enemas and sweat producing botanicals. The chief ingredient was lobelia, an emetic which grew wild in much of North America. To this he might add capsium, hemlock, bayberry, ginger, or pepper, and cloves to make a concoction often referred to as "Composition Tea." What Thomson did not realize is that you cannot poison anyone into health. But he killed fewer people with his method than the regular practitioners and was therefore considered successful.

Thomson patented his system and marketed it through representatives who traveled about the country selling copies of his two volume work, *New Guide to Health; or Botanic Family Physician*.

The treatment that Thomson advocated was rather harsh. As with the regular therapeutics, if the patient recovered, it was in spite of the treatment and not because of it. The following is one patient's account of treatment that he received (Frank G. Halstead, "A first-hand account of a treatment by Thomsonian medicine in the 1830's" *Bulletin of the History of Medicine* 10 (1941): 680-687.):

"The Thomsonian treatment is a steam bath 30 minutes in duration. When the sweat rolls off as thick as your finger the body is washed with cold water and the patient is straight-way put to bed with hot bricks to bring back his heat. Then a powerful vomitive is administered, composed of bayberry, of cayenne (red pepper) and lobelia, which suffer naught impure to remain in the stomach, and all these herbs are mixed in 40 proof brandy, after which warm water is drunk until there has ensued the most extraordinary vomiting. Next, the patient rises and takes a second bath, like the first. He takes again to his bed, after having been laved with cold water and is surrounded with hot bricks and remains in bed for an hour. At the end of this time he takes two injections (enemas) of pennyroyal, cayenne pepper and lobelia and the treatment is over for the day."

The fact that this system was of no value is obvious. It is remarkable that the body could withstand such a treatment. Yet some individuals recovered to a certain extent and, as harsh as this treatment was, it was still less harmful than the heroic treatment that it supplanted.

With the death of Samuel Thomson in 1843, his organization (already split three ways) disintegrated. The principal contending factions came to be known as True Thomsonians, the Physio-pathists, the Physio-medicals, and the Eplectics.

## **2.2 Herbal Medicine Today**

Herbal medicine is still practiced today but not on that formal basis. However, there are several misleading books, organizations, and schools that advocate and teach about herbal "cures." We condemn herbs because, first of all, they have no ability to heal and secondly, they are very dangerous due to their toxicity.

Some authors have been known to advocate the use of the herb squill which is an ingredient often found in rat poison. Mark Bricklin lists some of the most toxic herbs in his book *Natural Healing*.

"In general, it is safe to say that you should never use the following herbs for a home remedy: Jimson weed, daffodils, spurge, arnica, wormwood, mandrake, hellebore, squill, poison hemlock, tobacco, tonka

beans, aconite, white bryony, nux vomica, calabar bean, camphor, ergot, ignatius beans, bittersweet, gelsemium; henbane, celandine, belladonna, foxglove, and may flower."

Tansy is a narcotic and may result in abortion. Valerian in excessive doses may result in headache and even delusions. Goldenseal is extremely toxic if taken in stronger doses than one-quarter of a teaspoon to a cup of water. Even in this dose, the poisoning effects are present but they are not immediately noticeable.

### **2.3 Comfrey (*Symphytum Officinale*)**

Comfrey root will produce a high amount of gummy substance and the root and the leaf are both high in allantoin and pyrrolizidine, substances that are claimed to help with cell proliferation. An increase of cells will occur due to an inflammatory response to the presence of this foreign agent against the skin. Comfrey has no power to heal skin wounds but will interfere with proper healing initiated by the body. When this substance is applied externally to a wound, the outside of the abrasion will close faster than it normally would. This is a response on the part of the body to protect itself so that foreign matter does not enter into the system. As a result, proper healing, from within, is impaired.

It is also claimed that comfrey will help broken bones to knit. This is impossible since healing can only take place from within the body and no agent applied externally or ingested can promote this process.

Many herbalists advocate the use of comfrey as a tea or to be used raw in salads. However, recent studies have proven that this practice may be harmful. According to Dian Dincin Buchman (*Herbal Medicine*, New York: Gramercy Publishing Company, 1979). "Comfrey is in the same plant family as several other plants (Senecio, Croton, Heliotropium), and these plants, investigation now indicates, contain some natural poisons in the form of pyrrolizidine alkaloids. These plants have been implicated in various accidental human and animal poisonings.

"The young leaves of comfrey, thought to be edible and rich in chlorophyll, and used in many natural green drinks, may contain up to 0.15 percent (1,500 parts per million) of the alkaloid.

"Dr. Claude Culvenor of the Animal Health Division of the Australian Commonwealth Scientific and Industrial Research Organization has worked on this subject and studied this alkaloid in pasture weeds. He is particularly conversant with heliotrope, a weed from the same plant family as comfrey.

"He notes, 'At least four of these alkaloids are known to be carcinogens, and it is probable that the type found in comfrey is also carcinogenic. While it is unlikely that anybody eating comfrey in small quantities would suffer serious effects, its regular use as a green vegetable could cause chronic liver damage or worse. Plants in the same family, have caused human poisonings: in the USSR, Africa, India, and Afghanistan after their accidental consumption in bread over a period of one or two years. The evidence of these outbreaks, considering the amount of the alkaloid we have measured in comfrey, suggests that daily consumption of several young leaves of the plant over a similarly lengthy period will lead to serious disease.' "

There are no cures in comfrey and we should eschew this herb. It is, however, useful in the organic garden as an excellent mulch and as an addition to the compost pile as it contains a large amount of nitrogen. Its prolific blossoms also attract honey bees to the garden ensuring proper pollination to all crops.

### **2.4 Ginseng (*Panax Schinseng*)**

Ginseng is an herb with a long, flesh root that is often used as a medicine. It is a low plant with three leaves on the top. Each leaf is made up of five leaflets. Ginseng has small greenish-yellow flowers. Some of these flowers later produce scarlet berries. The Chinese use ginseng to "treat" many illnesses. The name of this plant comes from Chinese words meaning *likeness of a man*, because of the shape of its root. Those shaped most like a human body are said to be the most valuable.

American ginseng is cultivated chiefly in Michigan, Minnesota, Oregon, and Wisconsin. The plant grows wild in parts of the United States and Canada.

Ginseng is a stimulant for the central nervous system. It is often taken as a tonic, a "pick me up," to sharpen the memory, suppress coughs, ward off colds, etc. This drug effect will eventually lead to extreme enervation and chronic diseases due to the constant stimulation and suppression of symptoms.

## **2.5 Cayenne Pepper (*Capsicum Minimum*)**

The official name, capsicum, is derived from the Greek word "to bite," and a single taste of this substance will convince you why it was so named. This "biting" effect on the tongue and mouth will give you a clue as to what effect it has on the internal digestive tract. It is a powerful irritant and poison. It is taken for its stimulant effect which are, in reality, nature's efforts to eliminate this poison as soon as possible. Cayenne pepper should never be taken in any form, in any amount.

## **2.6 Peppermint (*Memha Piperitu*)**

Peppermint is a favourite beverage all over the world. It is taken for a suppressive effect on the digestive system to control diarrhea, spasms, and relieve indigestion. Peppermint is very high in tannin which is a very astringent acid and its use results in enervation and impairment of normal metabolism.

There are many other herbs that are commonly used but we should eschew them all. They do not have any property to "cure" and they contribute to ill health due to their poisonous products.

## **2.7 Aloe Vera**

Aloe vera is a cactus that grows outdoors in tropical and subtropical climates and indoors everywhere else. When you break open one of its leaves, you see a thick, clear liquid ooze out. It is this liquid that is claimed to be a "cure" for burns, ulcers, arthritis, diabetes, high blood pressure, psoriasis, shingles, hemorrhages, post-surgery treatment and more. It is applied topically and taken internally in a liquid form. However, instead of curing anything, it is actually a toxic substance. It contains *allontoin* which results in the same adverse effects as the alkaloid of comfrey. A cathartic, its purgative properties are due to three pentosides (barbaloin, iso-barbaloin, and beta-barbaloin) and to a resin. The resin is aloetin.

*Aloe emodin* occurs in the free state and as glycoside in various species of aloe and is extremely irritating to the delicate linings of the intestinal tract. The body attempts to discharge this poison quickly. Hence, its purgative effects.

But what about the claims? Many people experience that their sores, burns, and ulcers heal almost immediately after applying aloe vera, where otherwise would heal very slowly. The body is continually striving toward health and will do all it can to protect itself from any poisonous substances. When aloe vera is applied to an ulcer, the body closes off that opening as quickly as it can to block the entrance of that poisonous substance thereby protecting itself. This gives the false impression of proper healing. However, when the ulcer was an outlet for toxic materials, this vital outlet is closed off and toxins are kept inside the body. Now a new outlet must be found. Either other ulcers will form or more serious diseases will result.

If you do not interfere with bodily intelligence, healing will take place. To "intelligently do nothing" is the best advice for all ulcers, psoriasis, etc. That is, simply follow the teachings of Life Science/Natural Hygiene and your body will surely be vital enough to heal itself promptly.

### 3. Acupuncture

The principles of acupuncture are based on cell paralysis. The idea on which Chinese medicine is founded is the "Doctrine of the Two Principles: Yang and Yin." According to this philosophy, everything in the universe is governed by these two principles. Yang is the masculine principle, Yin the feminine. They are opposite in all aspects. Yang stands for heaven, Yin for earth. Yang is heat, Yin is cold. Life and death, strong and weak, positive and negative, day and night, dry and wet, hard and soft, light and dark—all these are Yang-Yin—pairs of opposites. Unless these two forces are in exact balance, according to Chinese folklore, health, peace, and well-being are impossible to attain. When the relationship between Yang and Yin get out of balance within a person's body, illness results. The task of the physician, then, is to restore health by renewing the equality of Yang and Yin, according to the Chinese acupuncturist.

The Chinese regard acupuncture as a complete medical system based upon the principle that man is a part of nature. Since nature is precise, then therefore, man is precise. Predictable order reigns in nature and in man. They claim that disturbance in that order results in illness and it is the acupuncturist's work to restore that order and thereby "cure" the illness. By inserting hair-thin needles into certain points on the body, acupuncturists treat disease and malfunctions of every organ of the body. The Chinese people believe that channels of energy, called "meridians" run through the body. In acupuncture, needles are inserted at specific points along the meridians.

Illness is explained in terms of disharmony between man and nature, and in man, between Yin and Yang. Illnesses are either Yin or Yang and the therapy used to "cure" them will be either Yin or Yang.

Ch'i comes into the body at birth and leaves at death. During person's lifetime it flows in a specific and continuous pattern in the forms of Yin and Yang. Ch'i does not inhabit the body at random, although it is present throughout the organism. Instead it flows inside a system of channels called "meridians" that extend into the arms and legs and around the torso beneath the surface of the skin. These meridians are not the vessels of the circulatory system that carry blood. They are not the nerves of the central nervous system.

The Chinese contend that Yin and Yang may not be equal—one rises as the other falls—but their total amount must be properly distributed among the organs for the body to remain healthy. In any organ, Yin and Yang are delicately balanced with each other. Illness results if the balance is disrupted. At certain times of the day, the Yin or Yang "influence" will be stronger than its counterpart, but this is a normal rhythm and will not cause illness or disease. When an imbalance causes sickness, the acupuncturist tries to discover where Yin or Yang has become too strong and with his needles restore the balance, as prescribed in an ancient book called the *Nei Ching*. The illness supposedly disappears when he has done this successfully.

Such treatment based on superstition and opposed to physiology must be discarded. Acupuncturists hold no "cures" and their needles cannot possibly heal. They can do harm if they strike a nerve and damage it. Cleverly-placed needles distress the nerves, resulting in the secretion of narcotizing encephalins, but this procedure cannot possibly restore health. One is anesthetized into relative unawareness of illness.

### 4. Megavitamins

Vitamins resemble enzymes in their catalytic action, producing changes without undergoing any changes

in themselves. They are active in extremely minute quantities.

Vitamins are constant constituents of living tissues and they make it possible for the body to utilize proteins, carbohydrates, fats, and minerals and are essential to growth, regeneration, and maintenance of health. They must be taken in the context of whole foods since there is a distinct relation between the amount of vitamins required and the other food elements. As Dr. Shelton tells us, the efficiency of the vitamins is dependent upon the composition of the food mixture.

Adverse changes take place when an excessive amount of vitamins are taken in concentrated form, especially vitamins A, E, and D. The other vitamins can be harmful, too, but these are the fat soluble vitamins and are difficult to eliminate and oxidize when taken in excess. As a result, you have abnormal changes that take place in the cells.

If the vitamins and minerals have been separated from their natural partners or nutritive elements that stabilize them and work harmoniously with them, they become harmful. There is not an isolated nutritive component that can lead to the same kind of activity that results when nutritional elements are derived from a natural source. In an extracted form, there is some activity but it is not a normal one.

The vitamins that are contained in fruits, vegetables, and nuts are much more available than those derived from other food sources, such as flesh foods or any cooked foods. The vitamins in synthetic form are not utilizable at all.

Even those vitamins derived from raw foods may not be utilized due to certain abnormal interferences such as the inhibiting effects of tobacco upon digestion, the use of coffee, tea, and other such substances. Also, the use of vinegar and condiments inhibit digestion and thus prevent vitamin utilization.

The body uses vitamins and minerals synergistically with one another. For example, the utilization of vitamin C is better with iron and the B complex. The B complex is used better with A and D. Such minerals as zinc, manganese, and magnesium are necessary for best utilization of vitamin C and B complex. In whole raw foods, we receive the vitamins and minerals in correct proportions so that they are used appropriately.

Concerning the use of synthetic vitamins as "cures" Dr. Shelton says:

"The use of certain vitamins is said to 'cure' certain 'diseases.' We must not permit ourselves to be misled by these claims. They have no more validity than the claims that drugs, or other such substances, 'cure' disease. There is no so-called disease that is due to a unitary cause—every disease is the complex effects of a number of correlated antecedents—and no disease is *curable* by a unitary *cure*. On the other hand, practically all of the so-called deficiency states that are said to require vitamins for their cure, will and do get well while the patient is fasting and drinking only distilled water. The wild enthusiasm caused by the discovery of vitamins will sooner or later, give way to sober reflection and it will then be recognized that the research workers and others have permitted their enthusiasm to run away with their judgment."

A study was conducted to determine the link between adequate amounts of vitamins and the ability of the liver to produce a group of enzymes that inhibits the action of carcinogens. Laboratory animals were fed an artificial diet that included sufficient quantities of all known vitamins, minerals, and other nutrients in a highly-purified form. The animals were unable to produce the important liver enzymes. When small amounts of alfalfa were added to the artificial diet, the enzyme production began almost immediately. Other fresh vegetables—cabbage, brussels sprouts, turnips, broccoli, cauliflower, dill, and celery—also enabled their systems to produce the anti-carcinogenic enzymes.

We cannot utilize inorganic vitamins and minerals. All the essential nutrients that we require are provided in abundance in a diet of raw fruits, vegetables, and nuts. If our diet is correct, we do not have to worry about deficiencies of any kind.

## 4.1 The Vitamin E Cure

Vitamin E is widely promoted as a preventive, a treatment, or a "cure" for literally scores of human ailments—ranging from diabetes and heart disease to infertility, ulcers, and warts.

A consumer's report cited an early experiment conducted to determine whether vitamin E was a valid therapy:

"In 1953 M. K. Horwitt, M.D., head of the Biochemical Research Laboratory at Elgin State Hospital in Elgin, Illinois, made the first study of what happens when humans are maintained for protracted periods on low-E diets. The project spanned more than eight years—making it one of the longest as well as one of the most thorough studies of human metabolism under controlled conditions. A total of thirty-eight subjects participated in the study

"The outcome of the project can be simply stated: There was no apparent physical or mental impairment caused by the restricted intake of vitamin E. Low-E patients remained in satisfactory health, despite the fact that blood levels of alpha-tocopherol were lowered by 80 percent. The survival time of their red blood cells became somewhat shorter—on the average, about 100 days instead of 123—than that of the two comparison groups (those on a low-E diet who received vitamin E supplements, and those on a standard diet). But the number of cells remained adequate and no patient became anemic. Nevertheless, the shorter survival time was considered sufficient reason for termination of the experiment. In earlier studies monkeys maintained on diets severely deficient in vitamin E had developed anemia, and Horwitt did not want to risk that possibility with the Elgin patients. In short, the study showed that human beings apparently need some vitamin E, but that the requirement is a modest one and can be easily satisfied by typical, everyday diets."

Vitamin E enthusiasts claim that millions of Americans, especially those whose intake of polyunsaturated fats is low, don't get enough vitamin E in their diet. The deficit, they insist, should be made up by vitamin E supplements. The fact is, however, as the National Research Council made clear in 1973, that vitamin E is available in adequate quantities in the ordinary diet. More than adequate supplies are in vegetables or fruits or nuts.

In a report published in March 1979, a recommendation against the over-the-counter sale of vitamin E supplements on the grounds that deficiencies of vitamin E are "practically nonexistent." Currently, the Recommended Daily Allowance of vitamin E for adults is 12 to 15 International Units, equivalent to approximately 8 to 10 milligrams of natural vitamin E in foods.

Very low levels of vitamin E have been found in patients with cystic fibrosis, celiac disease, nontropical sprue, chronic pancreatitis, and a few other diseases. These disorders are not caused by lack of vitamin E, however, nor can they be helped by vitamin E. All of these ailments have one feature in common: an impairment in the small intestine's ability to absorb fat. Consequently, the vitamin E dissolved in that fat is not absorbed either. Even if such patients eat diets with an abundant quantity of vitamin E, very little of it would reach their bloodstreams.

The doses of vitamin E specified in medicinal use commonly range from 300 to 600 milligrams a day or even higher—from thirty to sixty times the Recommended Daily Allowance. Clinical trials have failed to show any vitamin E benefits for miscarriages, sterility, menopausal disturbances, muscular dystrophies, cystic fibrosis, blood disorders, leg ulcers, diabetes, and a variety of heart and vascular diseases. No drug, including vitamin E, can "cure" these diseases because the causes for them are not dealt with. The 1973 statement by the National Research Council was also negative about the supposed value of vitamin E supplements for the wide variety of ailments for which vitamin E is promoted.

The efficacy of vitamin E in toilet soaps or cosmetics for skin care, despite advertised claims, has not

been demonstrated. We know that no substance possesses any curative properties. Its proposed advantage in a deodorant was ruled out when the distribution of *Mennen E* was halted by its manufacturer because of an unexpected number of adverse reactions in unhappy users.

## 4.2 Vitamin C

Vitamin C has been recommended to combat cancer, atherosclerosis, every "viral" disease, every so-called bacterial disease, poisoning of all kinds, mental illness, colds, injury, temperature extremes, old age, diabetes, allergy, cataracts, kidney stones, radiation sickness, arthritis, headaches, and bee stings.

While vitamin C plays a very important role in human physiology, it does not have the ability to wipe out the effects of unhealthful living that result in numerous acute and chronic diseases.

Since Dr. Pauling declared that vitamin C was a sure "cure" for the common cold, millions of Americans have been running to their neighborhood drugstores to obtain this vitamin. The effect of this practice is really a drug effect. While the body is eliminating excesses of vitamin C, other housecleaning duties (such as debris eliminated during colds) are temporarily halted. Thus, the illusion of "prevention" or "cure."

All fresh raw fruits and vegetables contain several times over the vitamin C that we need. When cooked, however, this vitamin is readily destroyed and is, therefore, not available to us. It is important that we consume all our foods raw and as fresh as possible. Even in the winter, when freshness is lacking in many of our fruits and vegetables, we still receive a more than adequate supply.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 5. Reflexology (Zone Therapy)

## 5. Reflexology (Zone Therapy)

Reflexology is a specialized form of massage and, among the many claims, it is said to be able to restore normalcy of function and give relief from pain to virtually any part of the body. The two basic modes of this therapy are foot reflexology and hand reflexology.

According to reflexology therapists, organs or parts on the right side of the body have their reflex areas on the right foot or hand. Organs on the left side of the body have their reflex areas on the left, foot and hand. Organs extending past the middle or center of the body will have reflex areas on both feet and hands. Where there are two like organs or parts (kidneys, ovaries, etc.), each has a reflex area on its corresponding foot and hand. The lower half of the body has its reflex areas on the lower half of the foot, and the upper half of the body has its reflex areas on the upper half of the foot. The waistline is located approximately halfway between the base of the toes and the lower part of the heel.

It is said that reflexology stimulates the internal organs and increases circulation. It is based on the theory that if the body is in a healthy condition, with no congestion in it, no tender areas should be found on the feet. The tenderness, they say, is caused by crystalline deposits that form at the nerve endings in the feet. The purpose in doing compression foot massage is to break up these deposits (or crush them) so that they may become solvent and be carried away with the rest of the waste material in the body. Once these deposits are dissolved, the congestion is relieved, and the circulation to the body is improved.

This theory sounds reasonable, but like other therapies, it is based on symptomatic relief. It does not restore health because it does not remove the underlying cause of ill health. There can not be any "cures" through this method or any other if the causes of disease are left in force. Calcium deposits that may be deposited in the feet are the result of incorrect living habits. Simply removing these deposits does not create health.

## 6. Relaxation Therapy

When the fight-or-flight response is evoked, it brings into play the sympathetic nervous system, which is part of the autonomic, or involuntary nervous system. The sympathetic nervous system acts by secreting specific hormones: adrenalin or epinephrine and noradrenalin or norepinephrine. These hormones, epinephrine and its related substances, bring about the physiologic changes of increased blood pressure, heart, rate, and body metabolism.

Dr. Herbert Benson (*The Relaxation Response*, New York: William Morrow and Company, Inc., 1975) says:

"While the fight-or-flight response is associated with the overactivity of the sympathetic nervous system, there is another response that leads to a quieting of the same nervous system, indeed, there is evidence that hypertensive subjects can lower their blood pressure by regularly eliciting this other response. This is the Relaxation Response, an opposite, involuntary response that causes a reduction in the activity of the sympathetic nervous system. Since we cannot easily change the nature of modern life, perhaps better prevention and therapy for hypertension and other creases related to the fight-or-flight response might be achieved by actively bringing forth the Relaxation Response."

It is true that stress does affect our health and we should learn to deal with this problem. It is also true that we need rest and relaxation on a daily basis. But this aspect alone will not produce health. All the other requirements for health must also be present in one package of totally healthful living. There are no "cures" in the Relaxation Response. If blood pressure is lowered, or metabolism is lowered through this method, this does not indicate that total health has been achieved. One or two symptoms of ill health may have temporarily disappeared, but that is all.

It has been claimed that people have been "cured" from such symptoms as facial pain after a single session of this therapy. Do not be fooled by this illusion. Ill health is developed after a period of time and the body needs time to heal. It cannot accomplish this task in a few minutes or a few days, it takes time. But when the proper conditions are provided (e.g., through a fast), the body will restore health.

## 7. Ultrasound Therapy

The device used for ultrasound therapy consists of a small box. On its face are a few simple dials and gauges. Attached to a cord running into the unit is a transducer similar in appearance to a small bathtub shower spray extension. This transducer emits a stream of sound waves, at a frequency so high that they are inaudible to the human ear.

When this therapy is applied, a gel is spread on the surface of the body that is to be treated. When the transducer is placed against the injured part, the gel keeps the sound waves from being lost in the air.

On the box of the ultrasound unit is a dial where the ultrasound frequency may be set. It produces heat as the sound waves rub against cell molecules and cause them to vibrate. This heat penetrates just slightly under the skin but the ultrasound can penetrate into the joint.

This therapy is often used for persons with arthritis associated with calcium Deposits. The ultrasound

waves break up the calcium which then disperses. One main problem is that it can also effect healthy bone and cause destruction there. The higher the ultrasound frequency, the greater the risk of bone damage. Since this therapy is still really in experimental stages, it is unknown what is a safe frequency, if indeed, there is. a safe range and also how long to apply the treatment. Besides being risky, no real and long-lasting benefit can be achieved. Calcium deposits may be broken up but the cause for their deposition has not been removed. They will, therefore, once again accumulate. At best, it is palliative. On the other hand, it can destroy healthy tissues and bones.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 8. Radiation Therapy

## **8. Radiation Therapy**

Repeated surveys have shown that those physicians who have the most contact with radiation (radiologists) have a significantly higher incidence of leukemia—at least nine times greater than that among all other males of the same age and at least four times greater than that for other physicians.

### **8.1 Radiation Destroys Cells**

As atomic radiation permeates living tissues, highly-organized units of living matter in the cell are disrupted. Fundamentally, the cell is composed of atoms and molecules which are split by radiation into electrically-charged fragments. This ionization process is completed in less than a trillionth of a second, yet it triggers off a chain reaction of subtle events within the cell leading to its damage or eventual death. Since cells are not inert blobs of matter but living, reproducing, organisms, they react to the radiation-induced injury by repair processes which lead to apparent recovery. If the radiation dose is overwhelming, immediate or only slightly delayed death of the cell ensues when the cell attempts to divide.

Radiation also harms cells by producing changes in the environment. Cells are bathed by solutions from which radiation-produced activated products can reach and damage them. Also, cells can be damaged by interference with their blood supply and the action of poisonous products released by radiation-killed cells themselves.

### **8.2 Tissue Damage**

Since tissues are a specialized population of cells, their exposure to radiation causes damage as a consequence of injury and death of the component cells. The overall effect involves not only the direct action of the radiation on the individual cells but changes in the surroundings of the tissues.

One tissue may give an immediate response to radiation and another no apparent or detectable response. However, the seemingly unresponsive tissue may show injury at a much later date. The recovery of tissues from immediate radiation injury depends on the specific cell types, or the size of the radiation dose, and on the time between repeated irradiations. These factors have been summarized by Doctors E. G. Williams and S. C. Ingraham II in a United States Health report for 1956 (Jack Schubert, *Radiation* NY: Viking Press, 1957):

"The blood-forming organs, the skin, the membranes lining body cavities, and the secreting glands may regenerate completely and resume their normal functions. Muscle, brain, and portions of the kidney and eye cannot regenerate; their repair results only in scar formation. Even those tissues that can regenerate may fail to respond after repeated ionization and cause conditions such as nonhealing ulcers or aplastic anemia (bone marrow destruction). Also,

repeated regeneration may produce cancerous conditions ... These changes have all been observed in animals following radiation exposures at levels corresponding to doses only slightly above the accepted safe limits for man. There are no constant clinical symptoms which can be relied upon to warn of latent radiation injury before life-threatening changes become manifest."

### **8.3 Effects on Genes**

No cell fully recovers from a dose of radiation. While a cell may seem to recover, there is an irreversible effect on the chromosomes and genes. According to Drs. Williams and Ingraham: "Ionizing radiation can alter the genes in the body (somatic) cells and in the reproductive (sexual) cells and cause them to grow or reproduce abnormally. If a gene change occurs in a sexual cell, a mutation will occur in later generations provided that the cell is used in reproduction. If a gene change occurs in a cell of growing or regenerating somatic tissue like skin, liver, or bone marrow, it may cause cancerous or other harmful changes in the exposed individual."

### **8.4 Hormonal Disturbances**

The late effects of radiation are often produced in cooperation with disturbances in body function in general. One of these disturbances in particular—hormonal imbalance—can in itself aid and abet the cancer-producing effects of radiation or even delay years the appearance of the cancer. Consequently, in evaluating the changes wrought by radiation in the body we must also take into account the complex inter-relationship existing between the various organs and the hormones released by the different endocrine glands.

Dr. Schubert theorizes that since hormones influence the regeneration and growth of almost all the cells in the body, it is reasonable to assume that many of the late changes and cancers developed in the body after radiation are related to the impairment of the endocrine glands such as the pituitary, thyroid, gonads, and adrenals, either as a result of the radiation directly on the endocrine organ or, indirectly, because of damage to a distant organ which then brings forth a response from the endocrines.

Since a female child possesses at birth all the ova she will ever use, it is very important to note that exposure of the ovaries to radiation affects eggs which are to be fertilized in the future. Thus, radiation damage is preserved by the ova and may result in defective children. Even if the children appear normal, they may carry defects in their heredity (the genes) which will be manifest in later generations.

### **8.5 Depression of Cells**

A single dose of 50 r to the whole body causes the number of lymphocytes to drop by one-half in about "two to three days. It takes about a week for it to return to the preradiation level. After higher but nonlethal doses of radiation, the lymphocyte drop is abrupt and little or no evidence of recovery may be apparent for several months. In fact, it may take years before the number of white cells returns to normal. Another significant observation is the fact that individuals previously exposed to radiation show a greater depression of cell numbers upon subsequent radiation exposure.

### **8.6 Brain Damage**

The brain is considered to be relatively insensitive to small radiation doses, but this does not mean there is no damage—it means rather that there exists no suitable means of detecting damage, or that it has not been looked for, or that no cases have been followed for a long enough time. One must be suspicious of all tissues to which radiation has been given.

Relatively small doses of radiation to localized regions of the brain give immediate effects. In 1953, two

volunteers were given 100 r to a localized region of the brain (diencephalon). About one and one-half hour; later they complained of ringing in the ears, generalized numbness, and apathy. Shortly thereafter they felt mentally stimulated. Sleep that night was very deep. The next morning they were very active and "high." Then they became unusually quiet. The disturbances lasted about seven to ten days. These effects were confirmed in another experiment involving 120 persons.

There have also been several reports of brain damage in persons given heavy doses of radiation for brain tumors or for scalp lesions.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 9. Laetrile

## 9. Laetrile

Derived from apricot pits, which contain cyanide, Laetrile was considered too toxic for human use by its discoverer, a Californian, Ernst Krebs, Sr., M.D. But years later, after his son, Ernst Krebs, Jr., claimed to have "purified" Laetrile, both father and son advocated it as an effective treatment for cancer. The Krebses patented their promising product as "Laetrile"—an acronym derived from the chemical name Laevo-mandelonitrile, the cyanide-containing substance they extracted from the crushed kernels of apricot pits.

The next step was to explain how Laetrile worked. With a little imagination, the younger Krebs came up with a "magic bullet" theory. Cancer cells, he claimed, contain an abundant amount of an enzyme that releases cyanide from Laetrile. The cyanide, in turn, kills off the tumor cells. Normal cells are low in that enzyme, the Krebs theory went, but rich in another enzyme that detoxifies the cyanide. So normal cells live while cancer cells die.

This theory was proved to be wrong. The supposedly abundant "releasing" enzyme is scarcer in cancer cells than in normal ones, and the "protective" enzyme is found in equal amounts in both kinds of cells. Moreover, cyanide does not have bullet-like precision. Because cyanide diffuses rapidly across intercellular barriers, any destructive effects would spread to both cancerous and noncancerous cells.

Its promoters then took a different course. Laetrile, the drug, was suddenly transformed in 1970 into Laetrile, the vitamin. Cancer, according to the later theory, was a vitamin-deficiency disease. Laetrile, it went on, was "vitamin B-17," the "missing vitamin" needed to prevent and treat cancer.

Besides daily injections or oral doses of Laetrile, the "total holistic metabolic nutritional" regimen includes massive doses of vitamin C and other vitamins, chelated mineral supplements, even coffee enemas. The Laetrile-centered regimen emphasizes a strictly vegetarian diet, free of all animal protein. Often another nonvitamin B-15 or "pangamic acid," is prescribed (B-15 is also the creation of the same Ernst Krebs, Jr., who christened Laetrile "B-17").

Laetrile is one of the most tested substances ever put forward as a remedy for cancer. In 1953, the Cancer Commission of the California Medical Association investigated Laetrile and found it ineffective. As part of that study, the commission discovered that all but one of forty-four patients treated with Laetrile still had an active form of cancer or were dead.

The most comprehensive series of animal tests were done at Memorial Sloan-Kettering in New York City. From 1972 to 1976 approximately thirty-seven experiments were conducted using Laetrile on mouse and rat tumors. Laetrile neither prolonged life, nor reduced tumor size, nor checked the spread of cancer.

Medical records submitted by Laetrile proponents have never substantiated the claims made. Many cancer patients who believe they had been cured by Laetrile find out later that they still have the disease.

Others never had cancer to begin with. Some cancer patients have temporary remissions—periods when symptoms lessen; if Laetrile use coincides with such a remission, the patient may think Laetrile was the cause.

The FDA's pharmacological analysis, in 1977 indicated that Laetrile smuggled or imported from Mexico in the form of oral doses and vials of injectable material under the names of "Laetrile" and "amygdalin" were potentially lethal sources of cyanide. Laboratory tests hinted that amygdalin might even be cancer-causing in its own right.

Jerry P. Lewis, M.D., chief on oncology and hematology at the University of California School of Medicine in Davis, reported late in 1977 the case of a seventeen-year-old in Los Angeles who swallowed approximately 10 1/2 grams (one-third of an ounce) of injectable Laetrile. The young woman had a convulsion ten minutes later, and died without recovering consciousness. In mid-1977, a ten-month-old girl died in an upstate New York hospital a few days after gulping down several Laetrile-tablets. Beyond these documented deaths, the FDA toxicologists suggest that many cancer patients whose death after long-term, high-dose Laetrile medication was attributed to their malignancy actually succumbed to slow cyanide poisoning from Laetrile.

In addition to being deceived, the patients or their families have to pay dearly for the deception.

Laetrile therapy does not come cheap. The cost of 6 month's treatment at a Mexican clinic has been estimated at between \$1,500 and \$2,000. Laetrile smuggled into the United States is priced as high as \$50 for a half-ounce vial for injection, compared with a \$9 price tag in Tijuana. Tablets sell for nearly two dollars in this country, but cost only about three cents to manufacture.

Cancer is the end point of a lifetime of unhealthful living and the accumulated toxins that results from such a lifestyle. Adding more poisons to our body as "medicines" will not produce health.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 10. Spurious Products Sold Through The Mail

## **10. Spurious Products Sold Through The Mail**

Probably the most extensive study of mail-order health advertising was done in the summer of 1977 by the quackery committee of the Pennsylvania Medical Society. The committee screened five-hundred nationally-circulated magazines and found that about a quarter of them carried ads for mail-order health products. Altogether, about one-hundred-fifty such products were offered by fifty promoters. The products included weight reducers, bust developers, blemish removers, hair-loss remedies, longevity formulas, aphrodisiacs, impotency aids, and others.

According to Postal Service estimates, mail-order fraud costs Americans at least \$150 million a year.

In January 1978, some two million copies of a four-page brochure were accepted for insertion into the various editions of eighteen city newspapers from coast to coast. The brochure promoted a handbook, "Modern Solution to Age Old Physical Problems," published by the Midwest Health Research Laboratory. The handbook, it was claimed, "contained a solution or prevention for as many as forty different diseases and illnesses," including arthritis, diabetes, and hardening of the arteries. More than one thousand readers surrendered to the inviting logic of the promotion: "Our special introductory offer of \$9.95 can save you unnecessary visits to the doctor, the hospital, and save you money."

Those who mailed money received a twenty-five-page booklet revealing the secret cure-all and end-all of disease —"colonic irrigation," otherwise known as an enema, preferably "two and three times a week." Coupons were available for those desiring "personal Home Treatment Kits" at \$29.95 apiece.

The *Washington Post* and eleven other prominent publications carried full-page ads for *Thera-Slim-100*, the "diet aid" that supposedly "burns away more fat each 24 hours than if you ran 14 miles a day."

Research conducted by the Consumer's Union resulted in several conclusions concerning some of the more widely-publicized health "cures":

1. Wrinkle removers - No cream or liquid that's safe to put on the skin can do more than temporarily increase the water content of the skin, and then only to the point of masking the most superficial of wrinkles. 'Anti-aging' pills containing RNA, DNA, or other chemicals have no beneficial effect at all.
2. Baldness remedies - Male pattern baldness, the most common type of baldness, is considered to be hereditary. (But other factors are also involved.) Medical science knows of no pill or cream that can arrest that genetically-determined condition. In some instances, loss of hair may also be symptomatic of various emotional and physical disorders.
3. Aphrodisiacs - Most pills and powders with aphrodisiacal pretensions contain 'Spanish fly,' a legendary ingredient celebrated for its purported effect on women. Today's 'Spanish fly' consists mainly of red pepper. It causes nothing more than mild irritation of the urethra. The ginseng root, long used as an Oriental cure-all, has recently acquired a reputation in this country for improving sexual prowess. The FDA has unearthed no evidence to support the root's reputation.
4. Diet pills, protein supplements, reducing devices—there is no proof that such gimmicks are effective for weight loss. Most nonprescription diet pills contain either phenylpropanolamine or methylcellulose. Some evidence indicates phenylpropanolamine can act as an appetite suppressant, but only for short periods. Methylcellulose is a 'bulking agent,' which supposedly expands in the stomach to relieve hunger. There's no evidence that it works. Weight-loss powders are usually accompanied by instructions bidding users to follow a rigid low-calorie diet as well. The diet might very well promote a weight loss, but protein products contribute nothing. Clinical studies by the FDA have shown that 'body wraps'—devices wrapped around parts of the body for selective weight loss—are useless. Some can be harmful.
5. Megavitamins - Everyone recognizes that adequate amounts of vitamins are necessary for good health. But none has ever shown that extra large or 'megavitamin' doses produce better health. Depending on the vitamin, amounts beyond the National Academy of Sciences/National Research Council's Recommended Daily Allowances can be dangerous or just a waste of money. Too much of the fat-soluble vitamins A and D can build up in the body to dangerous levels. Doses of water-soluble vitamins that exceed what the body can use are simply excreted in the urine.

There are many other "cures" being sold through the mail and magazine advertisements, but all are worthless. They are all dishonest attempts to make money from an uninformed or unknowing public. There are no "cures."

[Home](#) > [Lesson 65 - There Are No Cures](#) > 11. High-Fiber Diets

## 11. High-Fiber Diets

It is claimed that this single dietary factor plays a role in such diseases as appendicitis, diverticular disease, polyps of the large bowel, cancer of the bowel, irritable colon, hiatal hernia, gallbladder disease, diabetes, atherosclerosis, coronary artery disease, obesity, hemorrhoids, varicose veins, thrombophlebitis, and dental disease.

Dr. Benjamin H. Ershoff, a research professor of biochemistry at Loma Linda University and the

University of Southern California, points to many studies conducted during the past twenty years that he says indicate the beneficial effects of plant fiber-containing materials when administered to animals fed on low-fiber diets. But the beneficial effects are seen when this fiber is part of the natural food and not separated from it.

In 1943, two American medical investigators observed that immature mice who were being given a compound related to vitamin C—glucoascorbic acid—developed a severe condition characterized by growth failure, diarrhea, hemorrhages beneath the skin, hair loss, and death. But the condition developed only in mice who were being fed on a highly-refined ration. It did not develop at all in mice fed similar doses of glucoascorbic acid in conjunction with a natural food stock ration or in mice fed the refined diet supplemented with dried grass.

In 1954, Ershoff showed that alfalfa meal, when incorporated in the diet was similarly effective. He continued to see if any known nutrient in the alfalfa meal might account for the phenomenon. It was not a nutrient that was responsible. When juice was extracted from the alfalfa, it had no effect. But the whole alfalfa with pulp included provided beneficial results.

It turned out that various grasses—rye, orchard, wheat, fescue, and oat—were also effective. When cellulose was tried, it had a moderate effect, considerably less than that obtained with the fiber—containing alfalfa and varied grasses.

"Nearly all disease," says Denis Burkett, "has more than one causative factor. Not in any of these diseases would suggest that fiber deficiency is a sole causative factor, merely that it may be one important factor. What I would emphasize is that a fiber-depleted diet is a common factor, common to a number of characteristic Western diseases. It is a major factor, I believe, in some, a less important factor in others, but it is common to each of them and offers the only reasonable explanation put forward, I think, why these diseases are associated."

These diverse diseases are related because the underlying cause is the same in each. That is, an unhealthy and unnatural diet plus other poor living habits. A natural diet of fruits, vegetables, nuts, and seeds will provide us with all of the proper nutrients needed to ensure a state of health. The natural fiber will be there in proper amounts and we do not need to think about providing this one ingredient separately. The fiber is the undigestible part of the plant and we receive no nourishment from it anyway. It is certainly not so important as is claimed. It is not any "cure" since it is an inert substance that passes through the digestive tract unchanged. It is discarded by the body in this way because it is nonusable.

The mice fed on an unnatural and refined diet became sick not because of lack of fiber alone but because of the presence of toxins in an unnatural diet. This diet was foreign to their body and was not sufficient to promote health. When some of their natural foods were given, such as alfalfa, health was restored because their organism was once again provided with the nutriment they needed, and healing and normalization took place. This was certainly not due to the fiber present in the diet but due to the many factors in their natural diet that are essential for their particular requirements.

Many human disease conditions are associated with low-fiber diets consisting largely of refined breads, cereals, sweets, etc. However, this again is not due to the lack of fiber alone. Other aspects to take into consideration are the presence of toxic elements and lack of vitamins, minerals, and proteins in 'these refined products. Merely adding fiber in the form of bran will not decrease the toxicity of these foods.

Our natural foods are complete with all nutrients including fiber and these are the foods that will provide the conditions for health.

## 12. Fructose Diet Cure

This diet depends on the periodic ingestion of fructose and a high-protein, low-carbohydrate diet is followed. Dates are eaten between meals to maintain high blood sugar levels.

The foods are divided into seven basic types: 1) "free foods" which can be eaten in any amount since they contain negligible amounts of carbohydrates, fats, or proteins; 2) meat; 3) fat; 4) milk; 5) vegetables; 6) fruit; 7) flour products.

The fructose diet is intended for people who have functional hypoglycemia, for those who wish to lose weight without feeling hungry or irritable, for those who wish to reduce their craving for alcohol, for people who wish to avoid the onset of migraine headaches or premenstrual tension, for hyperactive children, and for persons with certain psychotic tendencies. Do not be fooled by these claims. The Fructose Diet or any diet cannot detoxify and heal. But they certainly can derange the body!

The lists of foods for this diet is as follows:

### List 1 – “free foods”

Bouillon	Pepper & other spices
Clear broth	Pickles
Coffee	Rennet tablets
Cranberries	Salt
Horseradish	Seasonings
Lemon	Vinegar
Mustard	

This list of "free foods" contains the most toxic food elements that we can ingest. Except for lemon, all of the above foods are eliminated on the Hygienic diet not only for their toxicity but because they are irritants, and interfere with normal digestion.

### List 1A (Unlimited in raw state; limit to 1 cup cooked—it is claimed that these foods are most digestible cooked.)

Asparagus	Eggplant	Rhubarb
Bean sprouts	Lettuce	Sauerkraut
Broccoli	Mushrooms	Spinach

Brussels sprouts	Parsley	Summer squash
Cauliflower	Peppers	String beans
Celery	Pimentos	Tomatoes
Cucumbers	Radishes	Zucchini

Sauerkraut, spinach, rhubarb, radishes, parsley, and mushrooms all contain toxins which interfere with normal assimilation of certain nutrients. The other vegetables would be healthful additions to our meals if consumed raw.

## List 2

This list includes meats, fish, cheese, peanut butter, and eggs—each serving contains seven grams of protein. All of these foods are unnatural items in the human diet and contribute to disease.

## List 3 - Fats

Avocado - 1/8	French Dressing - 1 Tbsp.
Butter - 1 tsp.	Mayonnaise - 1 tsp.
Bacon - 1 slice	Nuts - 6 small
Chocolate - 2 tsp.	Oil - 1 tsp.
Light cream - 2 Tbsp.	Olives - 5
Heavy cream - 1 Tbsp.	Shortening - 1 tsp.
Lard - 1 tsp.	Cream Cheese - 1 Tbsp.

Except for the avocado and nuts in this list, these "foods" would result in ill health in anyone consuming them.

## List 4 - Milk and milk products

1 cup of milk or yogurt equals one serving

1/4-cup ice cream equals one serving

Humans cannot digest milk products due to lack of the enzymes rennin and lactase. Ice cream contains many unnatural and toxic ingredients and a high percentage of refined sugar. Yogurt is fermented milk and also may contain high levels of sugar. Humans cannot digest the byproducts of fermentation and putrefaction.

### List 5 - Vegetables - 1/2 cup per serving

Beets	Rutabagas
Carrots	Winter squash
Onions	Turnips
Green peas	Tomato puree
Pumpkin	Frozen mixed vegetables

These vegetables are all served cooked and add little to the value of the diet.

### List 6 - Fruits - servings per day

Apple - 1	Orange - 1
Applesauce – 1/2 cup	Peach - 1
Apricots - 2	Pear - 1
Banana – 1/2	Pineapple - 1/2 cup
Berries - 1 cup	Plums - 2
Cantaloupe -, Vi	Watermelon - 3" x 1 1/2"
Cherries- 10	Grapefruit - 1/2
Fresh figs - 2	Grapes - 12
Nectarine - 1	Honeydew - 1/4

List 6 provides the only major worthwhile contribution to the diet but in such small portions that they are merely "crops in the bucket."

### List 7

Flour products and starchy vegetables.

As was explained in earlier lessons, humans have a limited capacity for starch digestion. In addition, wheat has toxic acids that are harmful and therefore should not be consumed.

For most people following this diet, Dr. Palm recommends that two to three servings of protein foods from List 2 and usually just one serving per meal for the remaining categories be included. Such high amounts of protein will only further endanger your health.

Several recipes include the use of concentrated fructose. In addition, Dr. Palm requires that you eat between 75 and 100 grams of fructose daily—available in tablet or powder form. Fructose is refined from sucrose, ordinary white sugar. The health consequences of such a practice is the same as ingesting the same amount of refined white sugar. This diet is dangerous and could never result in any benefits.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 13. Bland Diet For Peptic Ulcer Patients

## **13. Bland Diet For Peptic Ulcer Patients**

### **13.1 History**

The roots of diet therapy in the treatment of patients with peptic ulcer extend far back in medical history. As early as the first century, Celsus ordered smooth diets free of "acid" food, and practitioners of the seventh century wrote of their belief in "special healing properties" of milk for patients with digestive disturbances. In the first half of the nineteenth century, peptic ulcer became established as a pathologic and clinical entity, and physicians generally advocated a liberal dietary regimen with frequent feedings.

However, in the later part of the nineteenth century, a radical change developed in medical opinion concerning peptic ulcer treatment. The belief spread that food was harmful to the ulcer, and only complete rest—meaning an empty stomach—would allow the stomach to heal itself. When the body is free from the irritation of the presence of food and when the digestive system is given a complete rest, healing will commence. This is the safest known method to regain health and its beneficial results can be documented by anyone who is familiar with fasting.

However, in 1915, an American physician, Bertram Sippy, broke the common practice of fasting and established the beginning principles of continuous control of gastric acidity through diet and alkaline medication. He outlined a program of milk and cream feedings with slow additions of single soft food items over a prolonged period of time, allowing little variation.

### **13.2 Theory**

In general, Sippy's regimen is used today by many physicians and dietitians for gastric ulcer patients. This diet therapy is based on several erroneous principles. The food must be both acid neutralizing and nonirritating, according to this principle.

### **13.3 Acid Neutralizing**

The therapy begins with milk and cream feedings every hour or so, to supposedly neutralize free acid with the milk protein, suppress gastric secretion with the cream, and generally soothe the Ulcer by coating the stomach. However, these assumptions have not been supported by research. In fact, clinical evidence proves them to be worthless.

There are gradual additions of soft bland foods over a period of time, keeping some food in the stomach at all times to mix with the acid to prevent its corrosive action on the ulcer. These bland foods are usually limited to choices of white toast or crackers, refined cereals, eggs, milk, cheeses, a few cooked pureed fruits and vegetables, and later, ground meat.

With such frequent meals, the digestive organs are never allowed to rest, and recovery is prolonged rather than assisted. In addition, many of the foods advocated are toxic and further contribute to the reason for the disease.

### **13.4 Nonirritating**

The therapy is concerned with eliminating chemical, mechanical, and thermal irritation.

### **13.5 Chemical Irritation**

Any food believed to stimulate gastric secretions is prohibited. These include highly-seasoned foods, meat extractives, coffee, tea, alcohol, citrus fruit juices, dried foods, spices, and flavorings.

I could concur with this rule. The above foods are highly irritating for anyone and all except citrus juices contain toxic components that would result in sickness in a well person. For a sick individual who is already enervated, the results are just that much worse.

### **13.6 Mechanical Irritation**

Any food believed to be abrasive in its effect upon the ulcer is prohibited. These include all raw foods, plant fiber (strained fruits and vegetables are used), coarse or rough foods, whole grains, and "gas forming," or strongly-flavored foods.

Hygienists advocate that all foods should be withheld for the gastric ulcer patient. To ensure complete return of health, a fast is in order. After the fast, a diet of the same foods that are prohibited above would be those that would be the best to maintain health. That is a diet that consists of raw foods, mostly fruit.

### **13.7 Thermal Irritation**

Any very hot or cold food believed to irritate the lesion by its effect on surface blood vessels are prohibited. These include hot beverages and soups, frozen desserts or iced beverages.

On this point. I would concur.

### **13.8 The Four-Stage Pattern**

After initial hourly milk and cream only, the diet is gradually increased as the ulcer heals. The routine usually, follows a progressive four-stage pattern as follows:

*Stage 1* - For this initial stage of the dietary therapy, the following foods are permitted: milk, cream, butter, margarine, eggs, cooked and refined cereals, plain custard, Jell-O, rennet, plain puddings, vanilla ice cream, noodles, macaroni, spaghetti, white rice, white bread, soda crackers, cheese, jelly, honey, sugar, white potatoes, and creamed soups

A healthy man could live for a very short time on this diet before he became extremely ill. Why, then, is it advocated for sick individuals? It defies reason.

*Stage 2* - During this second stage of the bland diet, strained fruit juices are allowed to a limited extent (starting with 1/2 cup). In addition to the fruit juice, the following "foods" are added to the diet: plain cake such as angel food, sponge, pound, butter cake; winter squash; strained asparagus, peas, carrots, green beans, beets, spinach; cooked, stewed fruits

The fruit juice would be a welcome addition to the diet if it is served fresh. No individual—healthy or sick—should be served cake as it contains toxic ingredients along with refined white sugar and flour that will result in toxicosis and sickness. Since the vegetables and fruits in the above list are all served overcooked and strained, they contribute little value to this diet.

*Stage 3* - At this stage, flesh foods are added to the diet. These include fowl, fish, and beef that has been ground

As we have stated in earlier lessons, flesh is a terrible food for man. We are not equipped to deal with the many toxic byproducts of flesh and therefore, its ingestion will invariably lead to ill health.

*Stage 4* - At this stage, certain desserts are added such as prune or apricot whip, plain cookies, plain sherbert, water ices, and fine graham crackers. Also, some additional cooked vegetables and fruits are added.

### 13.9 Research Studies

This entire diet is a nutritional disaster and will result only in disease. Recent research studies demonstrate the uselessness of this type of dietary therapy.

A. M. Gill reported a series of studies with chronic ulcer patients, whose ulcers healed in four to eight weeks with placebo treatment of a daily injection of one ml. of distilled water and no diet or exercise restrictions or medications. He concluded that ulcers healed not by manipulation of the various common therapies used but because, "... the man with the ulcer comes under the care of a physician who is able to transmit some of his own confidence to the patient."

Gill's studies were valuable in that he found that the orthodox dietary therapy was useless even though he arrived at some other erroneous conclusions. But his theory that no therapy is better than the bland one, is valid.

Other researchers likewise have found that bland food do not increase the rate of healing, nor was there any particular benefit from avoidance of all foods thought to be commonly irritating (such as fruits and vegetables).

It has been demonstrated that routine omission of any fiber in the diet also seems to have no benefits.

Modes of eating—wrong foods or wrong combinations of foods, improper mastication, and rapid consumption of meals are more involved as sources of irritation. Many physicians, such as Dr. H. J. Shull, contend from their experiences with individual patients that so-called coarse or rough foods; such as lettuce, raw fruits, celery, cabbage, and nuts, do not necessarily traumatize a peptic ulcer when they are properly chewed and mixed with saliva. Grinding or straining of food is needed only when teeth are poor or absent!

[Home](#) > [Lesson 65 - There Are No Cures](#) > 14. DMSO

### 14. DMSO

Barry Tarshis (*DMSO* New York: William Morrow and Company, Inc. 1981) believes that he has found the true panacea for all illnesses. He states:

"... let's say, for the sake of argument, that (somebody—the government, a drug company, a foundation—pulled together a blue-ribbon group of pharmacologists and physicians, presented them an unlimited budget and told them to develop a drug that came closer to being a panacea than any substance now known. Imagine the properties that such a drug, were it ever developed, would embody

"To begin with, the drug would be effective not only against one or two conditions and diseases, but against a broad range of maladies, from simple, everyday problems such as sprains and sinusitis to life-threatening diseases such as stroke or cancer. The drug, in other words, would be far more powerful than aspirin and a good deal more versatile than, say, penicillin

"Apart from its effectiveness, the drug would be safe, keeping in mind that not even aspirin is completely harmless. Physicians who prescribed it wouldn't have to concern themselves with the adverse reactions that may claim as many as 30,000 to 60,000 lives a year in the United States alone. And the people who take it wouldn't have to suffer the myriad side effects—headache, fatigue, blurring of vision, mental disorientation—that come with the territory when you have a chronic disease for which there are only a handful of medications available

"The drug would also be versatile—versatile enough so that, depending on the condition, a physician could administer it orally or topically, by injection or intravenously. And it would be stable enough so that you could ship it anywhere in the world, or keep it on the shelf for months and not have to worry about it spoiling or losing its potency. The raw materials from which the drug was made would be readily available, so that you would never have to concern yourself with a shortage. And, finally, if you had a social conscience, you'd want the drug to be inexpensive enough (somewhat less expensive than, say, the interferon treatments now being offered for cancer in Europe at a price of \$65,000) so that patients who took it on a long-term basis wouldn't have to spend a big chunk of their yearly income for the privilege of living without pain."

The name of this new "wonder drug" is dimethyl sulfoxide or DMSO for short. It is being used for such ailments as sprains and sinusitis to burns and arthritis. Some people claim that it has the ability to stabilize progressively crippling arthritic conditions and to alleviate certain forms of mental illness.

This powerful and toxic drug passes through cell membranes so quickly that you can taste it minutes after it has been applied to the skin. Combined with other drugs, it will carry them through cell membranes that were formerly impenetrable to these drugs when taken alone. Due to this property, DMSO can cause immeasurable damage to all the cells of the body. These cell membranes can become weakened or altered and many other toxins besides DMSO will enter the cell which would not ordinarily enter. Such derangement of the cells may result in serious health consequences—much more serious than the ailment for which it was given.

There is never any "easy way out"—no quick and magical path to health. Many athletes have been using this poisonous drug for years for sprains, pulls, and other soft-tissue injuries. Continued suppression of pain by this drug will eventually result in permanent damage. Besides this, DMSO is now being used regularly by thousands of arthritic patients. People use DMSO for cuts, for sores, for itching conditions. Some people even rub it on their gums.

Do not be fooled by misleading claims. No agent outside of the human body has the ability to heal. The regular use of drugs can result only in greater health destruction.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 15. Mineral Water Therapy

## **15. Mineral Water Therapy**

Certain places of the world are well known for their mineral springs that are said to have therapeutic properties. Sometimes it is recommended that these waters be consumed or bathed in as a "cure" for assorted ailments.

The theory behind all forms of hydrotherapy is that the minerals of the water will, in very small amounts, enter your system through the skin or mucous membranes and help restore your entire system

to a healthier state.

However, these inorganic minerals are inert substances and have no magic about them. They cannot enter the system through the skin and impose any health benefits. If consumed, they cannot be utilized by the body and may prove toxic.

[Home](#) > [Lesson 65 - There Are No Cures](#) > 16. Bee Products

## 16. Bee Products

Honey, bee pollen, bee propolis, and royal jelly are substances collected or produced by bees for their winter food supply, for reproduction, protection, etc.

Honey is a popular product and is essentially sugar (about 1/3 to 1/2 glucose, 1/3 to 1/2 fructose, and the rest water). Bee pollen consists of certain pollen grains of flowers incidentally collected by bees while gathering nectar. It contains protein, vitamins and minerals, and enzymes. It is not a food that bees consume except as a honey contaminant.

Bee pollen is often used by athletes because it is claimed that it will increase their energy and stamina. This effect, however, is an illusion. Its stimulatory effect will first produce a false sense of increased energy, but like all other stimulants will soon have the opposite effect due to enervation of the stimulation of the organs involved.

Neither is propolis one of the bees' food products. It consists of various tree resins, collected and applied to the interior of the hive by them. It acts as a kind of cement to keep their hives intact. When ingested by humans, this substance will have a stimulatory effect due to the response of the body to attempt to eliminate this foreign material. It has no place in human nutrition and has no property to "cure" as is often claimed.

Royal jelly is produced from honey and pollen and fed exclusively to the queen bee. It is made by the bees for the unique dietary needs of developing a queen bee and is excellent food for her.

With respect to honey it cannot be emphasized enough that:

1. It is not a natural food of human's but of bees which created it for their specific needs.
2. Honey is laced with six protective acids. Humans cannot metabolize three of these acids, thus making it a toxic substance.
3. Honey is used as a sweetener. Anything that requires a sweetener to be palatable is not a fit food for consumption in the first place. In the second place, the addition of a sweetener creates an incompatible food combination that vitiates digestion and begets toxic byproducts.
4. Human desecration of the bees' food supply is unnatural, contrary to the symbiotic role of creatures in nature, and unhealthful both to bees and humans.

With respect to pollen keep in mind that, in gathering nectar, the bee performs a symbiotic service for the plant. It becomes contaminated with pollen and spreads it to the female flower, thus fertilizing it. Pollen's role is to create a seed package, not to serve as a food. When the seed package is mature, it ripens a part of the package as fruit which is free food for the creatures that incidentally perform a service in distributing the plant's seeds. That is symbiosis.

Pollen is not unique as a food and has no value. It fails to furnish our foremost need, carbohydrates, for energy. It is only the incipient nutrients and components to fertilize a flower ovary and thus create a seed package of which a part might be edible fruit. In that case we get not only all the nutrients contained in pollen but in a form specifically created to meet our needs. Most important of all we get an easily

absorbable complement of simple sugars ready to convert to energy!

[Home](#) > [Lesson 65 - There Are No Cures](#) > 17. Macrobiotic Diet Cure

## 17. Macrobiotic Diet Cure

The macrobiotic diet consists of 60 to 100% grains. These include brown rice, buckwheat, wheat, corn, barley, and millet. They are eaten raw, cooked, creamed, with or without water, fried, or baked. A maximum of 30% of the diet may consist of vegetables. These vegetables that are considered permissible include: carrots, onions, pumpkin (a fruit), radish, cabbage, cauliflower, and lettuce.

Grain is considered "Principal Food" and is eaten at every meal. The principle behind this diet is based on the same Yin-Yang theory as for acupuncture. Yin and Yang are antagonistic but complementary forces. Certain foods are considered Yang foods and others are Yin foods. There must be a certain balance between Yin and Yang.

When a person becomes ill, it is recommended that he/she eat 100% grains. In addition to this, certain specific beverages and/or foods are used for specific ailments—all based on the superstitious Yin-Yang theory.

This type of diet not only cannot produce health but it can be very harmful if persisted in over a period of time. Humans are not grain eaters—we are frugivores. We are not biologically equipped to digest, assimilate, and utilize large amounts of grains. Fruits contain plenty of sugar, but little or no starch, whereas the cereals are largely starch. Starch requires much more time and energy to digest than fruit. Cereals are among the most difficult of foodstuffs to digest. The protein of most cereals are inadequate. They also contain an excess of acid due to the absence of certain base minerals, especially calcium. The need for calcium of most cereal plants is relatively small so they do not draw much of this mineral from the soil. In the human organism, on the other hand, the need for calcium is very great. Cereals, are therefore, inadequate to support growth.

Oats are deficient in many basic salts. Wheat is deficient in sodium and calcium. Rice is deficient in salts, and especially in calcium. It is also deficient in sodium and chlorine. They are all lacking in iodine. What does this mean when we consume large amounts of cereals? Since cereals are acid forming, they must draw on base minerals from the body to neutralize these acids so as not to create a condition of acidosis within the body. These base salts are withdrawn from the tissues, bones, and teeth, eventually resulting in various pathological disorders such as osteoporosis and dental caries.

Dr. Shelton says, "We have learned that all cereals have certain defects which may be looked upon as characteristic of these nutriment. As regards organic salts, they are deficient in sodium and calcium; they are also poorly supplied with organically-combined sulfur and with bases generally; but they contain a superabundance of acid-formers and of potassium. The cereals are also poor in vitamins A, B, and C. Finally, the proteins of the cereals are always inadequate; they are lacking in essential amino acids, and are especially poor in lysin and cystin."

A study of the human anatomy and physiology will clearly demonstrate which food humans are best suited to eat. For optimum health, we should stick with our biologically-correct fruitarian diet.

## 18. Questions & Answers

### **Are the natural or "organic" vitamins any better than the synthetic ones?**

No, a vitamin is nothing more than a specific compound, whether it is synthesized or extracted from a plant. In either form, they are not usable by the body but may be toxic. All the vitamins that we require are found in our whole natural foods and this is how they must be taken to be utilized.

### **Is choline effective in keeping fat from accumulating in the liver and arteries as claimed by some advertisements that I have read?**

Choline manufacturers may have a difficult time explaining why anyone should swallow choline pills. Choline is widely available in the diet and is also manufactured in the body. It is considered an essential nutrient, but dietary deficiencies have never been demonstrated in man. Although choline has been widely used to treat fatty liver, as well as cirrhosis and hepatitis, it has never been demonstrated that this type of therapy is of any value. It is, in fact, worthless, and should not be used.

### **I have diverticulitis and my doctor told me not to eat fruits and vegetables. Is that good advice?**

Diverticula are outpouchings that can develop in weak spots in the bowel wall. When many of these outpouchings are present and one or more become inflamed causing pain, the condition is known as diverticulitis

This condition was virtually nonexistent in the early twentieth century and is now known as a disease of Western civilization. Its incidence has increased steadily in industrialized countries until between one-third and one-half the population over forty in the United States, Great Britain, France, and Australia suffer from it. Diverticulitis results from the increased use of refined flour and cereals and the substitution of foods containing large amounts of sugar and of meat for fruits and vegetables. In countries where the diet is high in fruits and vegetables, diverticular disease is still nonexistent

The very foods that you were told to avoid are the ones that you should be eating exclusively. It would, however, be advisable to fast first to allow the bowel to heal.

### **Will apple cider vinegar "cure" colds and catarrh?**

Cider vinegar is made by pressing the juice out of the apples and fermenting it, in the same way as making cider. The fermented juice is left to age for about six months and then the process of turning the alcohol into acetic acid begins

Acetic acid is very destructive and corrosive to the tissues of the digestive canal and to all tissues and cells of the body. A small amount will halt digestion completely. This acid is so strong that it will dissolve certain metals and remove rust from steel. Consumption of vinegar will result in ill health and should never be consumed. There is no "cure" for colds. This is a reaction on the part of the organism to rid itself of accumulated toxic debris and should not be interfered with. Vinegar is a drug whose use suppresses the body's vital activity in conducting the eliminative task called a cold.

### **Could you suggest a diet for migraine headaches?**

There are no diet "cures." Foods cannot act as specifics and go directly to the afflicted area to effect a cure. Only the body can heal and will promptly do so when the proper conditions provided. A natural diet of raw fruits, vegetables, nuts, and seeds will provide the proper condition for the body to heal if the other conditions for health are also present.

**What is the difference between white and red Ginseng? Are either forms acceptable to take?**

All ginseng roots are naturally white. The red roots are produced by a special process that includes treating the white roots with other herbs, steaming, and other steps. This process is supposed to preserve the root and prevent insect infestation. As mentioned earlier, ginseng is a toxic substance and should not be consumed. The red root is just that much worse because it has the addition of other toxic herbs. Neither forms are acceptable.

### 1. The Germ Theory Of Disease

Acceptance of the concept of contagion is contingent on acceptance of the germ theory of disease. The germ theory of disease is the reigning premise upon which is superimposed a tremendous network of modern medical procedures.

Simply stated, this is the germ theory: Diseases are due solely to invasion by specific aggressive microscopic organisms; that is, *a specific germ is responsible for each disease*; and microorganisms are capable of reproduction and transportation outside of the body.

The germ theory was founded on the assumption that disease germs are specific and unchangeable in their biological structure and chemical characteristics.

Dr. Rene J. Dubos (eminent modern bacteriologist and 1968 Pulitzer Prize winner) contradicted this assumption by showing that the virulence of microbial species is variable.

Pasteur himself admitted his mistake (around 1880). Dr. Dudaux, a coworker of Pasteur, wrote that, when nearly sixty years of age, Pasteur discovered facts which were not in accord with his previous

conception that disease germs were unchangeable. Pasteur found that microbial species can undergo many transformations, which discovery destroyed the basis for the germ theory.

## **1.1 Dramatic Proof That Germs Do Not Cause Disease**

Reports in the *Journal of Infectious Diseases*, 1914. Vol. 14, pages 1 to 32, describe experiments by E. C. Rosenow, M.D., of the Mayo Biological Laboratories in Rochester, Minnesota. It was demonstrated that streptococci (pus germs) could be made to assume all the characteristics of pneumococci (pneumonia germs) simply by feeding them on pneumonia virus and making other minor alterations in their environment. When the procedure was reversed, they quickly reverted to pus germs. In all cases, regardless of the type of germs, they quickly mutated into other types when their environment and food were changed.

Two New York City bacteriologists, through similar experiments, converted cocci (round, berry-shaped) into bacilli (long, rod-shaped) and vice versa.

So it is obvious that specific bacteria do not produce specific disease symptoms—it is the environment and the type of soil which determines the type of bacteria that proliferate.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 2. Pasteur Becomes Identified As Originator Of Germ Theory

## **2. Pasteur Becomes Identified As Originator Of Germ Theory**

The first "Germ Theory of Infectious Diseases" was published in 1762, by M. A. Plenciz, a Viennese physician. In 1860, Louis Pasteur took the credit for the experiments and ideas of others, "plagiarizing and distorting their discoveries," according to Dr. Levenson of England. Because of Pasteur's strength, zeal, enthusiasm, and convincing personality, and his passionate determination to overcome opposition to the germ theory, he became identified as its originator.

Claude Bernard (1813-1878) disputed the validity of the germ theory, and maintained that the general condition of the patient's body was the principal factor in disease, but this idea was largely ignored by the medical profession and the general public. Pasteur had done his work well as the suave promoter of a plausible "scientific" hypothesis that could bolster the prestige of the sagging medical profession. Bernard and Pasteur had many debates on the relative importance of the microbe and the internal environment.

Pasteur was a chemist and physicist, and knew very little about biology and life processes, but he was a respected and influential man. His phobic fear of infection, his belief in the "malignity" and "belligerence" of germs, and his powerful influence on his contemporaries, had far-reaching consequences, and men of science were convinced of the threat of the microbe to man. Thus was born the period of bacteriophobia (fear of germs) which still exists.

### **3. The Fear Of Infection**

The fear of "infection" of a cut, a bruise, or other injury is widespread. Actually, there is more danger from the drugs and antibiotics administered to "prevent infection." When an injury occurs, the body quickly seals off the area, a scab forms, and repairs are instituted. Suppuration rarely occurs, except in toxic individuals. Devitalizing drugs serve to hinder the cleansing and reparative processes; antibiotics destroy friendly bacteria.

Patients do not have much (or any) choice in the use of antibiotics after surgery. The massive invasive process of surgery (often opening into the body cavity) is quite different from a cut or other wound near the surface of the body. In any event, there is no option. The antibiotics (after surgery) are mandatory (for the "protection" of the surgeon).

### **4. Bacteriophobia**

The universal acceptance of the germ theory, and the consequently widespread bacteriophobia, resulted in a multiplicity of frenzied efforts to escape from the threat of the dreadful and malicious germs by waging a constant war against them in the belief that the alternative was certain death.

The populace was advised to cook all food and boil all water (with the inevitable deterioration in health accompanying raw food deprivation).

The present-day practice of killing germs (inside and outside the body) with poison drugs was initiated, resulting in more and more degeneration and iatrogenic (drug-induced) disease.

Various programs were initiated to confer "immunity" against specific germs by means of vaccines and serums, resulting in the monstrous inoculation system—with horrendous effects, detailed in my book, *Don't Get Stuck!*

Fortunately, the warning against, and horror of, all raw foods as dangerous and bacteria-ridden, has been largely overcome, through the persistent educational efforts of Hygienists and other knowledgeable people, though the ban on unpasteurized dairy products still exists in most areas in the United States.

The acceptance of poison drugs, vaccines, and serums has not waned to any appreciable extent.

### **5. Pasteur Changes His Mind**

As previously mentioned, around 1860. Pasteur discovered facts which were not in accord with his previous conception that disease germs were unchangeable. He found that microbial species can undergo many transformations; this discovery destroyed the basis for the germ theory. Since a coccus (pneumonia germ) could change to a bacillus (typhoid germ) and back again (and, indeed, since any

germ could turn into another)—and since their virulence could be altered, often at the will of the experimenter, the whole theory exploded.

It is frequently overlooked that Pasteur by then had changed his direction, and his more mature conception of the cause of disease, as given by Dr. Duclaux, was that a germ was "ordinarily kept within bounds by natural laws, but, when conditions change, when its virulence is exalted, when its host is enfeebled, the germ was able to "invade" the territory which was barred to it up to that time. This, of course, is the premise that a healthy body is resistant to disease or not susceptible to it.

After the change in his outlook, and numerous experiments along this line, Pasteur was at last convinced that controllable physiological factors were basic in the assessment of vulnerability to disease and concluded, "The presence in the body of a pathogenic agent is not necessarily synonymous with infectious disease." (*The presence of certain germs is not proof that they are the cause of a disease.*)

So Pasteur did finally reverse his position and acknowledge that germs are not the specific and primary cause of disease, and he abandoned the germ theory. He is reported to have said on his deathbed, "Bernard was right. The seed is nothing, the soil is everything."

Although Pasteur abandoned his early immature and erroneous theory in the 1880s, it was accepted, developed, fostered, and perpetuated by others, and the mischief, medical misunderstanding, and error continue to this day (the ultimate irony!).

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 6. A Plausible And Tangible Basis For "Medical Science"

## **6. A Plausible And Tangible Basis For "Medical Science"**

Dr. Shelton says, "Medicine is now claimed to be a science. Before the discoveries and pseudo-discoveries of Pasteur it was a medley of diversified diseases and imaginary causes, treated symptomatically and empirically. Up to this time the evolution of medical thought was but a slow transition from superstition. The profession groped blindly about in search of a tangible basis upon which to base their theories and practices.

"Pasteur, while exploiting the work of Bechamp and other scientists of that period, gave the profession the germ. Here, at last, was a tangible and basic theory which could be developed without a limit. The microscope made it possible to visualize, differentiate, and classify the organisms. With a frenzied and hysterical outburst of enthusiasm, the medical profession seized upon this new theory, since which time practically all medical investigation has been carried on with the germ theory of disease as its basis."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 7. The Unity Of Disease

## **7. The Unity Of Disease**

The unity of disease is not understood by those who insist on relating a specific germ to each disease. As long ago as March 12, 1924, an editorial in the *Boston Medical and Surgical Journal* discussed the trend away from this concept: "The reason ... of an eclipse or partial eclipse of bacteriology may be found in the belief that this branch of medicine, if it has not come exactly to a blind alley, has at least come to a halt ... There are signs, more or less vague as yet, that new conceptions of disease are arising, although

such views are themselves nebulous. It is thought by some that there is more or less a fundamental unity of disease, and that many of the nosological labels attached to them are superfluous and confusing."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 8. Koch's Postulates

## 8. Koch's Postulates

The German scientist, Robert Koch, maintained that for a specific bacteria to be the cause of a disease:

1. It must be found in every case of that disease.
2. It must not be found when the disease is not present.
3. It must be capable of living outside the tissues.
4. It must then be capable of reintroduction into the organism and producing that disease.

As has been repeatedly demonstrated, specific bacteria do not fulfill these prerequisites.

Robert Koch (1843-1910) was a bacteriologist, physiologist and one of Pasteur's contemporaries. The specific requirements of "Koch's Postulates" follow:

1. A culture of the bacteria must be taken from a diseased animal.
2. It must then be grown in pure culture in a laboratory.
3. After this, the culture has to be injected into a *susceptible* animal.
4. It must cause the same disease, and culture must be taken from this animal.

This is a modification of the germ theory, requiring a condition of *susceptibility* to establish a causal relationship between specific germs and specific diseases.

Scientists know that specific bacteria are not found in every case of a specific disease. The eminent Canadian physician, Sir William Osier (1849-1919) found that the diphtheria bacillus is absent in 28 to 40% of cases of diphtheria. Green's *Medical Diagnosis* says that tubercle bacilli may be present early, more often late, or in rare instances be absent throughout the disease condition. Koch's first postulate, "the specific bacteria must be found in every case of that disease" is not fulfilled in tuberculosis, diphtheria, typhoid fever, pneumonia, or any other disease. *Specific bacteria are not found in every case of a specific disease.*

Nor is the second postulate fulfilled, because it is a medically-known fact that bacteria are found in the bodies of humans and animals which exhibit no symptoms of any disease. *Specific bacteria are repeatedly found when the specific disease is absent.*

Further, bacteria are not capable of living outside the tissues; therefore, the third postulate is not fulfilled. Neither Pasteur nor any of his successors have ever induced a complaint by the inoculation of airborne bacteria, but only by injections from bodily sources. The reason is obvious: germs are dependent on human or animal organisms for their survival.

Quoting from "The Germ Theory Reexamined" by Bob Zuraw and Bob Lewanski (*Vegetarian World*, Volume 3, Number 11, September-November 1977): "Koch's Fourth Postulate: *Introducing germ cultures in a healthy body or organism does not produce signs and symptoms of the disease.* The Bio-Chemical Society of Toronto conducted a number of very interesting experiments in which pure cultures of typhoid, diphtheria, pneumonia, tuberculosis, and meningitis germs were consumed by the millions in food and drink by a group of volunteers. The results: no ill effects whatsoever."

But when the condition of *susceptibility* is introduced, this changes the whole concept. Thus we are back to the same point we have been emphasizing: the condition of the host is of primary importance in the production of disease.

## 9. Germs Are Powerless To Cause Disease

Dr. Shelton says (February 1972, *Dr. Shelton 's Hygienic Review*), "The germ alone could no more cause disease than a match alone can produce a fire. Just as the fire, so the microbe, if it is to have any part in causing disease, must find an organism that produces a suitable soil for its activities. We cannot avoid germs. We must be proof against them. We can avoid disease only by keeping ourselves in such a high state of health that they are powerless against us."

Dr. Shelton goes on to tell about numerous experiments in trying to produce various diseases by the feeding of germs, without any disease being produced. Dr. S. K. Claunch, in *Exploding the Germ Theory*, also cites such experiments by the U.S. Navy, again without results. Dr. Claunch says (page 25), "These experiments, conducted under test conditions and under government supervision with such disappointing results should knock the last prop from under the germ theory, as they doubtless would have done if our government doctors had seen fit to make them public property ... would have been a signal government service to the people ... but not good business for the doctors and serum manufacturers."

## 10. Germs Are Not Enemies

Bacteria are ubiquitous—they are with us all the time. Life on this planet would be impossible without them.

Specific "disease" bacteria are commonly assumed to be the primary cause of specific diseases. These much maligned microorganisms are, in truth, friends and scavengers that need nourishment to reproduce. They go into action immediately when there is a dangerous accumulation of toxic materials which is threatening body integrity. They perform the useful function of "cleaning up the mess" and then resume their more passive state, after their work is done.

There is no denying that bacteria are intimately associated with many serious diseases. They contribute secondary or tertiary complicating factors. They elaborate certain powerful toxins. They have factors which add to the primary causes.

There is no denying the importance of bacteria in the evolution of disease. But they are not the fundamental and primary causes, as so many people believe.

It is the disease condition that creates an environment favorable to the mutation of bacteria into those associated with that particular "disease," and favorable to their proliferation and increasing virulence. The disease condition springs from improper living that begets toxicosis.

There is no denying that in the disease process, the work performed by bacteria as scavengers is unpleasant and exhausting to the host, but it is necessary for the preservation of health and life. After the cleansing is complete, the organism again makes its energies available for normal activities.

### 10.1 Diseases Are Not Entities Traveling From One Person to Another

We hear about infectious diseases, contagious diseases, communicable diseases. But nobody has even seen a disease travel from one person to another. There is not an iota of evidence that this happens.

In 1860, the world-famous English nurse, Miss Florence Nightingale, published an attack on the germ theory of disease. She said:

"Diseases are not individuals arranged in classes, like cats and dogs, but conditions growing out of one another. Is it not living in a continual mistake to look upon diseases, as we do now, as separate entities, which must exist, like cats and dogs, instead of looking upon them as conditions, like a dirty and clean condition, and just as much under our control; or rather as the reactions of kindly Nature, against the condition in which we have placed ourselves? I have seen with my eyes and smelled with my nose smallpox growing up in first specimens, either in closed rooms, or in overcrowded wards, where it could not by any possibility have been 'caught' but must have begun. Nay, more, I have seen disease begin, grow up and pass into one another. Now, dogs do not pass into cats

"True nursing ignores infection, except to prevent it. Cleanliness and fresh air from open windows, with unremitting attention to the patient, are the only defense a true nurse either asks or needs ... The specific disease doctrine is the grand refuge of weak, uncultured, unstable minds, such as now rule in the medical profession. There are no specific diseases; there are specific disease conditions."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 11. The Cause, Nature, And Purpose Of Disease

## 11. The Cause, Nature, And Purpose Of Disease

Disease is a process of physiological and biochemical changes within the body, producing certain signs and symptoms which we label as specific diseases.

When diseases are categorized as communicable or infectious, it is not really meant that the disease, per se, is transmitted from one person to another. The concept actually is that an assumed cause of disease—virus, bacteria, etc.—is transmitted.

But disease is the result of many intoxicating causes. The actual process of disease (the fever, the inflammation, etc.) is the action initiated by the body to purge itself of toxic accumulations.

But the causes, the processes, and the effects have the appearance of being intermingled. Toxicity causes change in the processes of the body. These changes result in other changes as the body tries to cope. The situation becomes extremely complicated, with constant interaction between causes, processes, and effects.

But this should not discourage your attempt to discover and pinpoint the fundamental causes of disease. The Hygienic concept is that disease is the result of enervation—due to the bankruptcy of nerve energy, expending more than we are capable of regenerating. The general energy level diminishes and functional efficiency deteriorates. We evolve into a state which we call toxicosis—a condition of body saturation with toxic matters.

Toxicosis, in the Hygienic sense, implies a disturbance of the blood and tissue fluids, and the accumulation of toxic byproducts of metabolism. In recent years, studies of biochemical pathology have shown this disturbance within the homeostatic mechanism of the body, caused by the accumulation of toxic substances.

Dr. John H. Tilden, a Hygienic pioneer, in his book, *Toxemia Explained*, long ago (1926) presented "the true interpretation of disease." Habits of living that fail to supply our needs, that exceed our limitations

—too much food, insufficient exercise, insufficient rest, and so on—produce inner stresses and a chemical burden the body cannot handle.

The causes of disease are multiple and relate to all the facets of our existence—nutrition, exercise, rest mental and emotional factors, relationships with other people—all of life. The most significant causes are those that are related to our fundamental biological needs. Those relating to our fundamental and emotional life complete the total picture. *Most of the causes of disease are within the control of the individual.*

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 12. Disease Is Body Action And Is Self-Limiting

## 12. Disease Is Body Action And Is Self-Limiting

When the toxic level rises above a toleration point, the body takes remedial steps, defensive, and reparative action. Disease is body action, and is limited to the time and effort necessary to rid the organism of injurious substances. Every cell in the body acts in unison with all the other cells for the preservation of the organism. When the work is done and order is restored, the disease symptoms dwindle and disappear, and the organism—although debilitated from the effort made necessary by its toxic condition—regains its powers.

This almost consistent denouement is eloquent evidence that disease is body action and not an attack by proliferating bacteria and viruses. All cases recover without any treatment. If a healthy body is unable to resist an original attack by small numbers of microorganisms—if a healthy body can "catch" a cold, or influenza, due to exposure to cold germs or influenza germs—how then can the subsequently debilitated body ever recover? How can the weakened organism subsequently repel the onslaught by proliferating trillions of microorganisms? If such reasoning were carried forward to its logical conclusion, the inevitable result would be the death of the organism. How can it be denied?—when the healing crisis is completed, recovery begins. People do recover from colds, from influenza, and every acute disease that has not had deadly medical treatments.

Under Hygienic guidance (noninterference), disease symptoms disappear. Those who are "treated" with drugs and nostrums and recover, do so despite the treatment. Often the complication brought on by the treatment are much worse than the symptoms of the disease.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 13. The Vaccination Network

## 13. The Vaccination Network

"Immunization" is based on the idea that it is possible, by chemical or biological means, to make a person disease-proof. If this were indeed possible, it would represent a suspension of the law of cause and effect.

People have been educated to be terrified of bacteria, to believe implicitly in the idea of contagion—that specific malevolent aggressive disease germs pass from one host to another. Even bacteriologists overlook the fact that, instead of the germ population being divided into specific "good" germs and specific "bad" germs, "good" germs have the ability to mutate into "bad" (proliferating and virulent) germs, when the soil is suitable for this change. *Germs have the ability to modify their structure and*

*function, according to the environment in which they find themselves.*

The idea of vaccination is that injection of a specific vaccine of lesser virulence is supposed to confer immunity against a specific disease of greater virulence. Originally, it was maintained that one injection would confer lifetime immunity. After that idea failed, the idea of periodic revaccination was adopted. Read my book, *Don't Get Stuck!*, for the history of the failure of vaccination and the trail of tragedy it has left in its wake.

Dr. Robert Simpson of Rutgers University said (March 1976): "Immunization programs against flu, measles, mumps, and polio may invade the genetic makeup, and may actually be seeding humans with RNA to form pro-viruses, which then become latent cells throughout the body. These could be molecules in search of diseases, which may become activated and cause a variety of diseases later, such as multiple sclerosis, arthritis, or even cancer." While this conjecture is in line with medical reasoning, it is blatant nonsense. Organisms do not work this way.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 14. Immunity Vs. Toleration

## **14. Immunity Vs. Toleration**

Sometimes the injection of a poison into the bloodstream results in toleration of that poison, which is mistakenly labeled immunity. Toleration means the body hasn't sufficient vitality to resist.

The dictionary definition of tolerance is "the power or ability to endure, withstand, or resist the effects of a drug or food or other physiologic insults without showing unfavorable effects." Actually, this is contradictory. If the body endures the insult, it is because of lack of strength to resist. When it resists, it has the energy to institute defensive action: vomiting, sneezing, diarrhea, fever, or any crisis of cleansing and healing.

Dr. Shelton says that toleration is submission; it is broken-down resistance. "The warning voice of self-protection has gradually been put to sleep, while the organism is undermined and premature death comes as a surprise to everyone ... Toleration for poisoning is established by loss of the vitality necessary to resist it. The body pays for this toleration (miscalled immunity) by general enervation and lowered resistance to every other influence. ... It is a sad day for the body when it tolerates poisons. ... If tolerance for tobacco were never established, there would be no tobacco users. The same for alcohol, opium, arsenic, and other poisons. ... The repeated use of a poison gradually overcomes or decreases vital resistance."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 15. Inoculation Is A Disease-Producing Process

## **15. Inoculation Is A Disease-Producing Process**

No vaccine or other similar preparation can confer immunity against the effects of wrong living. On the contrary, more (not fewer) diseases are the inevitable result inoculation with serum and vaccines, which exhaust the vitality and resistance. Inoculation is a disease-producing process, which results in injury to organs, the nervous system and the blood.

Serum inoculations and blood transfusions can dissolve red blood cells in the recipient and damage the

central nervous system, which helps to account for the enormous numbers of servicemen discharged as insane. (*Dr. Shelton's Hygienic Review*, May 1977, page 200).

In an article published in the *United States Naval Medical Bulletin*, May 1, 1943, three naval officers (physicians) reported that inoculations against typhoid, tetanus, and yellow fever are "epidemiological factors" of greatest significance in the history of meningococcal meningitis. They expressed the belief that "immunizing inoculations" may lower body resistance. The occurrence of seventy eight cases of cerebrospinal fever was reported among troops in a camp in Natal after the injection of typhoid vaccine.

The purpose of such inoculations is to produce specific antibodies against specific diseases. Dr. Shelton says that if the body produces antibodies when vaccines and serum are administered, these are the ones required to protect against the injected substances, and not the specific antibodies that would be required to protect it against the contingency of exposure or susceptibility to a specific disease.

The following report appeared in Vol. 93, No. 6, page 482, of the *American Journal of Epidemiology* (observations made by workers conducting a trial of "flu" vaccine):

1. "The overall respiratory illness rates were unaffected by the vaccine.
2. Infections due to agents other than the influenza virus accounted for a larger proportion of illness in the protected (vaccinated) than in the unprotected groups."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 16. Vaccinations And Failure Of Defensive Mechanisms

## 16. Vaccinations And Failure Of Defensive Mechanisms

In their book, *Vaccinations and Immune Malfunction* (published October 1982), authors Harold E. Buttram M.D. and John Chriss Hoffman discuss the fundamental differences between the processes of "natural immunity" and so-called vaccine immunity. They suggest that those who are honestly trying to weigh the pros and cons of vaccines should become familiar with the existing evidence that vaccination does indeed cause lasting damage to the defensive systems of children; and they urgently propose an immediate change from compulsory vaccination programs to absolute freedom of choice.

They take the position that there is a fundamental difference between "natural immunity" (conferred by childhood diseases) and the attempts to confer immunity by introducing massive amounts of antigenic materials in the bloodstream, bypassing the primary defenses, and stressing the body in insidious ways which have previously been largely unrecognized. The body's resistance is lowered through a subtle defensive malfunction and a drastic reduction of the body's ability to defend.

On page 5 of their book, Buttram and Hoffman give an illustration of their concept. "According to the one cell one antibody rule, once an immune body (plasma cell or lymphocyte) becomes committed to a given antigen, it becomes incapable of responding to other antigens or challenges." A hypothetical child passes through "so-called usual childhood diseases with relatively minor and uncomplicated illnesses."

"Considering the extreme efficiency of 'natural immunity,' we may make an educated guess that permanent immunity was gained to these diseases by utilizing only 3 to 7 percent of the total immune capacity. In the case of the routine childhood vaccines, in contrast, it is likely that a higher percentage of the total immune capacity becomes committed, perhaps something on the order of 30 to 70 percent. It should be emphasized that, once an immune body becomes committed to a specific antigen, it becomes inert and incapable of responding to other challenges

"If the reserve immune capacity of children is being reduced by current vaccinations in this

manner, what will be the consequences? No one knows for certain at this time, but it is possible that these consequences could be seen as an increased susceptibility to viruses, to other infections, and to various forms of allergies. A child could be reduced from an expectancy of exuberant, health to a middle state: never entirely healthy, never entirely well."

One of the most extensively documented studies of the indirect effects of vaccines is found in "The Hazards of Immunization" (Oxford University Press, Inc., New York, 1967) by Sir Graham Wilson, formerly of the Public Health Laboratory Service, England and Wales. Dr. Wilson cites documented historical examples of vaccination against one disease seeming to provoke another; for example, fifteen cases of poliomyelitis following inoculation against diphtheria or pertussis.

Reports of twelve cases of multiple sclerosis following inoculations were reviewed in the article, "Multiple Sclerosis and Vaccinations," by Miller and others, *British Medical Journal*, April 22, 1967, pages 210-213. Numerous other reports of apparent immune system-mediated diseases (including Guillain-Barre syndrome) have implicated vaccines.

An overwhelming majority of American medical doctors approve vaccination, on the grounds that occasional direct toxicities are an acceptable risk in terms of assumed control gained over infectious diseases. Although direct toxicities are uncommon (as a result of vaccination), the real danger of vaccination appears to be the indirect effect of impairment of the immune system, first researched in the early 1970s by Dr. Arthric Kalorkerinos and Dr. Glenn Dittman (both of Australia) who uncovered the phenomenon of immune malfunction, lowering the body's resistance as a result of vaccination. The problem is that, because this effect is apt to be delayed and masked, its true nature usually escapes recognition.

Buttram and Hoffman maintain that, in view of the mounting evidence of immune malfunction following current vaccination programs, there must be a public demand for investigation of vaccination methods, and a discontinuation of compulsory vaccination.

These authors say that we are now seeing an increasing social disintegration, with increasing nervous and mental disorders, and that these trends are thought to be related to a subtle biological deterioration of the health of Americans brought about by denatured, devitalized, and adulterated foods; chemical pollution of air, water, and soil; a medical research system oriented toward the use of synthetic drugs and chemicals, and childhood vaccine programs.

"Nature ... created the human biological system, including the immune system, as extremely adaptable so that it could cope with an ever-changing environment. We are now seeing vast numbers of our children who are unable to cope with their environment demonstrating allergic and/or toxic reactions to their foods, to chemicals, to common inhalants such as dust, pollen, and mold, and to environmental pollutants. If this is combined with an immune system which is compromised from the very first by our present compulsory childhood vaccination programs, and in turn, compounded by devitalized and denatured foods upon which many of our children subsist, could we really expect to see anything other than the deteriorating health which is now taking place? "It is possible that many of the nervous, mental, behavioral, and sociological problems occurring today among the younger generation in America may represent a counterpart of the malnutrition-immunization interaction observed by Dettman and Kalokerinos among the Australian aborigines."

Barbara Ann Boruff, in an article, "Immunization: The Risk Factors," says, "The thymus, spleen, and lymph nodes are the main components of the body's immune system. Inadequate nutrition during the time in pregnancy when these organs are developing in the fetus can impair their growth and thereby affect a child's susceptibility to disease, not only in childhood, but throughout his or her lifetime. A

pregnant woman must insure that her diet includes the variety of wholesome foods necessary to the development of her unborn child's immune system.

"Breast-feeding offers the newborn child protection against many diseases. The colostrum present in the first day or so of nursing contains disease-resistant factors

"The long-term effects of breast-feeding are particularly rewarding. In one study at Northwestern University it was found that in comparing children breast-fed six months or longer to bottle-fed children, the bottle-fed children had four times as many ear infections, four times as many colds, eleven times as many tonsillectomies, twenty times as many diarrheal infections, and from eight to twenty-seven times more allergic conditions." (*Nursing Your Baby*, by Karen Pryor.)

"Another recognized guardian of health are the tonsils. A study by Rodrigo C. Hurtado of Georgetown University School of Medicine indicated that the tonsils protect against many diseases, including the common cold, herpes, measles, influenza, and polio

It was also discussed that following the removal of tonsils, there is an increased incidence of malignancy."

This paragraph from page 17 of the book, *Vaccinations and Immune Malfunction*, sounds as though it came straight out of the Hygienic body of literature. "The processes of Nature are always, or almost always characterized by two qualities: efficiency and economy. Attempts of modern science to reproduce or synthesize organic, biological substances and the life-processes of Nature are often grotesquely inefficient, wasteful, and frequently harmful. It is probably a truism that science succeeds only to the extent that it harmonizes with Nature's laws and processes; it fails to the extent that it conflicts with these laws."

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 17. The Body Cannot Be Protected From The Consequences Of Injurious Practices

## **17. The Body Cannot Be Protected From The Consequences Of Injurious Practices**

The body *will not* conduct defensive crises when there is no need for them. Healthy bodies do not require detoxification. The body *cannot* conduct defensive crises if its vitality has been lowered to a point where it no longer has the energy and resources to initiate and conduct detoxification and healing processes.

The suppression of the body's ability to heal itself (by drugging or vaccinating) should not be mistaken for exemption from the consequences of wrong living. On the contrary, the drugs and vaccines constitute additional attacks on the integrity of the organism. They impair structure and function, and hasten degeneration and death.

## 18. Epidemics

Although epidemics diminished as man purified his exterior environment, "it is conceivable that the filth that once beset him in rags, has come forth in a needle to destroy him." —Cash Asher, *Bacteria, Inc.*

Epidemics are mass sickness. In all "epidemics" there are more cases of various other diseases than of the one "epidemic disease."

Dr. Shelton says (*Dr. Shelton's Hygienic Review*, April, 1976, page 171):

"What the epidemic will be will be determined by the public health authorities. The tendency is to diagnose everything as the epidemic disease at the outset and class further developments as complications. A case in point was that of typhoid fever in the American army in France. The whole army was immunized against typhoid, therefore our soldiers could not develop typhoid. A large number of boys v/ho died while being treated for influenza as their cases were diagnosed, were found at autopsy to have died of typhoid fever. The incident was of sufficient importance for the surgeon general of the army to issue a special letter about it and point out to the medical heads of the American Expeditionary Forces in France that inoculation is no substitute for hygiene and sanitation. Physicians were so preoccupied with influenza that they saw a flu devil back of every symptom and could not distinguish between influenza and typhoid fever. Even tubercular flare-ups were diagnosed as influenza

"The high death rate in pneumonia and influenza was not due to any unusual virulence of the two diseases, but to the unusual virulence of the treatment ...  
... Where hysteria rules the mind, treatment is always heroic and the death rate is in keeping, with the treatment. The staff of the Macfadden Healthatorium in Chicago cared for over three hundred cases of pneumonia and influenza during the 1918-19 pandemic without a single death in either disease."

### 18.1 Environmental Improvements, Net Vaccines, Eliminate Epidemics

Concurrent with extensive environmental improvements (including better sanitation) some forms of disease seem to have disappeared. Vaccine promoters have taken the credit for the virtual disappearance of smallpox and diphtheria, but nothing is said about the dwindling of cholera, plague, and leprosy, for which no vaccines exist.

The new rampant plagues of heart disease, cancer, arteriosclerosis and diabetes, are due at least in part to the radical changes in the nature and quality of our foods and living habits. These illnesses can also be diminished by environmental improvements, as well as by ceasing to pollute our bloodstreams with vaccines and drugs.

The relationship of population disposition to develop disease and environmental conditions to influenza epidemics is conceded in a 1976 report by the U.S. H.E.W. Center for Disease Control (page 2): "The occurrence of influenza epidemics depends upon a poorly understood interaction of virus, population susceptibility, and environmental conditions."

Dr. Shelton says (*Dr. Shelton's Hygienic Review*, May 1976, page 197), "If yellow fever disappeared from New Orleans after General Butler cleaned up the city and no vaccine was used, what has sanitation had to do with the disappearance of other epidemic diseases?"

From *Dr. Shelton's Hygienic Review*, April 1976, page 172: "Yellow fever vanished from New Orleans, Cuba, and Panama when these were cleaned up. The medical profession still refuses to admit that

cleanliness did the work. They insist that it is all because they or the sanitary engineers did the St. Patrick act with the mosquitoes. There are still as many mosquitoes in these places as there are in Jersey. I have never been able to figure out how they succeeded in getting just the right mosquitoes to leave, and the harmless ones to remain."

How many people today know about the medical opposition to the early use of the bathtub? They denounced it as the "obnoxious toy from England," and said it would bring on a "whole category of zymotic diseases." In 1842 the Philadelphia physicians submitted a proposal to prohibit by law the use of bathtubs between November 1 and March 15; and in Boston, in 1845, the medical society secured the passage of an ordinance making bathing unlawful "except on medical prescription." The doctors of the time also violently opposed rapid travel on the railroad as being extremely dangerous to public health. Time marches on! The medical profession has adopted and claimed as their own these ideas which others have established as meritorious; but they are still fighting the battle of the poisoned needle; they are still upholding the myth of "contagion" and the role of virulent and aggressive microorganisms as the major cause of epidemics.

L. Tyagaraja Sarma, in an article in *Dr. Shelton's Hygienic Review*, January 1975, page 118, says, "England had repeated—and severe—epidemics of smallpox once every four or five years throughout the last century. The more the British government forced vaccination and revaccination on their people, the more regular were the epidemics. The County of Leicestershire refused to toe the official line; smallpox vaccinations were wholly stopped in this county and all the money that was originally allocated to mass vaccination was spent in improving sanitation. The protagonists of vaccination prophesied that by this step, all the people in the County of Leicestershire would become victims of this dread disease while the rest of England would be saved to a great extent.

"But ... what followed was just the contrary. While smallpox epidemics were raging in the rest of the country, every four or five years as before, Leicestershire was free from this disease."

After the British government introduced a law allowing people to refuse vaccination, the number of people vaccinated (and the incidence of smallpox) kept declining, and ultimately the vaccination law was repealed.

Dr. Shelton says (*Dr. Shelton's Hygienic Review*, October 1970, page 39), "England was the first country in the world to force vaccination on its people by law. After fifty years of rigid enforcement of its compulsory vaccination law, England suffered (1870-71) the largest smallpox epidemic in its history, with the highest death rate in its history. A well-vaccinated, revaccinated and rerevaccinated people suffered a worse epidemic than it had ever suffered under the previously worst sanitary conditions. Vaccination failed and this failure resulted in the rise of an anti-vaccination movement. Today vaccination is no longer compulsory in Britain."

Epidemics of the more virulent types of disease (plagues, etc.) were caused by unsanitary living conditions. The habits of the civilized world have become cleaner, yet more debilitating.

## 18.2 Modern Mass Sickness

Modern mass sickness is basically the result of the debilitating lifestyle and eating habits of the majority of the populace. In 1948, a polio epidemic was proven to have been triggered by excess consumption of sugar, and dramatically stopped when decreased sugar consumption was encouraged by mass media campaigns. (*Don't Get Stuck!*). Of course, vested interests soon reversed the trend by convincing the public to go back to the old habits.

Epidemics are triggered by mass debilitating and prostrating influences, such as prolonged temperature or humidity extremes, great and general worry, fear, grief, and anxiety (war, panic). The most enervated and toxemic people are the first to get sick. Advocates of vaccination (have never attempted to explain why it is often those who have been vaccinated who are the first to get sick, or who often contract the most virulent forms of disease.

The first colds of early winter are not "caught" from someone else with a cold, but are developed by those who have been improperly living and eating. The added stress of cold temperature further checks elimination, adds to the general toxemia, and thus precipitates a crisis.

The more severe diseases develop in people who carry a greater amount of putrescent poisoning, and are more prevalent after holidays and feast days. The enervating excitement and indiscriminate overeating at these times produce the inevitable unwelcome results.

Why does toxemia cause typhoid in one person and pneumonia in another? Dr. Shelton (*Dr. Shelton's Hygienic Review*, March 1972, page 162) says that the answer will have to be found in the laws of heredity, nutrition, and environment. Those tissues offering least resistance to the toxins are the first affected.

The more virulent diseases result from the poisonous toxins in the host. Toxins resulting from protein putrefaction are more virulent than those from carbohydrate fermentation. Flesh foods produce more virulent toxins than plant proteins. There is also a difference in the virulence of poisons produced by different animal proteins, and in various vegetable proteins.

Dr. Shelton says (Dr. Shelton's Hygienic Review, March 1972) that he believes, for example, that tonsilitis is the result of the less virulent plant toxins, while diphtheria results from the more virulent animal toxins. In both these diseases, there is decomposition in the intestinal tract, which may also sometimes cause pneumonia or meningitis or typhoid or other symptoms of disease.

### **18.3 Epidemics Explained**

Why is it that some people who are exposed to those in the throes of these crises subsequently are also "laid low" while others are not? People who have maintained an internal state of cleanliness through correct habits of eating and living do not need the disease process because it cannot develop unless the toxic conditions for disease exist.

As previously indicated, different diseases are different symptom complexes arising out of reduced nerve energy and increased toxicity. Habits of living that waste nerve energy result in inhibition of secretion and excretion—and the consequent self-poisoning. The part of the organism laden with toxins is the first to react, but the effect is general—all the organs and structures of the body suffer the impairing effects.

The body functions as a unit and depends on the continuous cooperation and coordination of all its parts—if one function is disturbed, the health and integrity of the organism and all its parts and functions are affected.

The body ejects its uneliminated waste products by means of a crisis or acute disease, so that the toxins are expelled vicariously, or through channels not normally utilized, e.g., mucous membranes, skin, etc. Thus the disease is a process of detoxification and recovery, and is remedial and beneficial. Although it does expend great reserves of energy, it is a process of self-preservation.

The body ejects uneliminated waste products by means of a crisis or acute disease, so that the toxins are expelled vicariously, or through channels not normally utilized e.g., mucous membranes, skin, etc. Thus the disease is a process of detoxification and recovery, and is remedial and beneficial. Although it does expend great reserves of energy, it is a process of self-preservation.

## 19. Accommodation

There is a body limitation to the vital resistance it can muster against acute disease. When the organism is continually subjected to intoxicating substances (such as tobacco, coffee, drugs, etc.), the body accommodates, and the result is impaired function and chronic disease.

In general, accommodation is thought of as beneficial, but most physiological accommodations are just the opposite. The body accommodates to excessive exposure to sunlight by a deep tan, which cuts off the damaging influence of the sun. Vitamin D needed by the organisms is produced in a much reduced quantity. The skin will also become coarse and leathery because of the defensive accommodations. Normal secretions are reduced, and other departures from the ideal occur.

When calluses form on the hands as a result of manual work, this adaption is necessary—it is the body's defense against a mechanical irritant it can't escape or overcome. Such accommodations preserve life, but they are departures from the ideal.

Accommodation to smoking, drugs or other poisons imposes upon the body higher levels of toxins. The inevitable effect is the multiplication of the toxicity level, with the body actually accumulating additional toxins of its own which it cannot normally excrete. The result is disease. Epidemic diseases are the consequences of the existence of such conditions in the bodies of great numbers of people.

In today's world, it is probably not possible to achieve the degree of health that could be attained after several generations of healthful living Hygienists, we keep striving for improvement, though the true "ideal" may be unattainable.

We may have occasional crises of illness, but we must realize that sickness is not an enemy. Discomforts are our own body signals that we are doing something wrong. If we heed such signals in a timely manner, by fasting and resting, instead of waiting for a full-fledged healing crisis, we will need only a mild and brief cleansing period. If we live our lives in this manner, we do not fear so-called "contagion" and "epidemics."

Natural Hygiene begins in the mind—with understanding. The food regime is a critical factor—exercise is important—but all the other needs of life must be met. It is necessary to get in touch with yourself and be in harmony with your biological requirements.

### 19.1 "Allergic" Symptoms

When, the organism is confronted with toxins which it cannot eliminate and to which it cannot adapt, it may produce "allergic" or even "pan-allergic" symptoms—extreme reactions causing respiratory, neurological, and digestive symptoms, and symptoms involving the muscles, joints, skin, eyes, ears, throat, and elsewhere.

The Environmental Health Center (Dallas, Texas) is a clinic that specializes in treating people for chemical sensitivities, principally by first "fasting patients to cleanse their systems," then testing on various foods and chemicals to determine which cause "allergic" reactions, and then endeavoring to eliminate the offending substances. It is a slow, painstaking, and expensive process.

Dr. William J. Rea, who founded the Center, and Dr. Sprague, a colleague of Dr. Rea's, deal mostly with "ecology" patients—people who have become "pan-allergic" from exposure to insecticides, or from the use of drugs or chemicalized foods.

D.W. Nauss, *Dallas Times-Herald* (reprinted 11/3/82 *St. Petersburg Times*) says: "Dr. Rea said his interest in chemical sensitivities developed after he and his family were incapacitated following a pesticide spraying in their home. I realized then that there were many chemicals, not only pesticides, that were harming people, he said.

"Chemicals are not the root of all disease, Rea said. But he believes many ailments could be prevented if doctors better understood their role in impairing the body's defense systems. The medical community, however, is ill-informed about ecological illness and resistant to learning, he said.

"Clinical ecologists admit they have only scratched the surface in their effort to understand chemical allergies. Researchers say allergies can be inherited, can be caused by a physical or emotional trauma or can result from exposure to various toxins.

"An allergy is produced when the immune system breaks down. In simplified terms, the system is depleted of white blood cells which control the production of antibodies to fight antigens or foreign bodies. As a result the system is overrun by antibodies, creating the allergic reaction. In extreme cases, the body becomes so sensitized that it reacts to even small doses of substances that normally would present no problem.

"Because some chemicals often attack the nervous system, mood swings and personality disorders are not uncommon among ecology patients. Dr. Theron Randolph, a Chicago doctor and pioneer in the theory of clinical ecology, suggests some mental illnesses may be caused by chemical sensitivities, stemming from foods, beverages, dusts, and pollen."

NOTE FROM THE EDITOR: Don't take this medical rationale wholehog. There is no such thing as an immune system or antibodies. There are only regular defensive faculties. Allergies are due to body overreaction to certain substances it overdefends.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 20. The True Explanation Of Contagion

## 20. The True Explanation Of Contagion

M. O. Garten (*Tomorrow's Health*) says, "An average healthy person, with an uncontaminated bloodstream, need not be concerned or apprehensive about being subjected to a 'contagious' disease ... However, this is not true with a person of low vitality and high accumulation of metabolic waste productions ... Bacteria or germs of such a person stimulated into activity by the devitalized elements upon which they thrive, when transferred to the mucous membranes or tissues of another person equally toxemic may be assumed to begin work immediately and in the same manner as on the first-carrier.

"This is a true explanation of 'contagion' and one may say that the germ precipitates the disease or excites it in the person to whom the germs are transferred ... Germs ... could be recognized as contributing factors in all toxic crises in which the localized outside area is exposed to infection or contamination. Serums or drugs will help add to the general toxic load, and instability results in serious harm, even though they" (the serums or drugs) "may apparently modify or suppress a local or general pathological process."

The modification or suppression of normal body function by poisoning (with serums or drugs) is another factor in this picture. Sometimes, when people are too drugged and devitalized, they *cannot* have the healing crisis, even though elimination of a high accumulation of wastes is necessary. Because vaccinations may so reduce vitality as to make it impossible to conduct a simple eliminative crisis, vaccinated people are said to be "immune" against the particular disease they have lost the ability to conduct. In truth, the price of their inability to dispose of the toxins at an early stage, is their accumulation and the insidious development of worse, and more serious, degenerative diseases.

The contagion that actually is prevalent is the contagion of bad habits, producing the same vulnerable and susceptible condition in great numbers of people. Such people conceivably can, through intimate contact, trigger disease symptoms in each other.

But what about the thousands of people who develop colds who have not been in contact with someone with a cold? And what about the thousands who are in intimate contact with someone with a cold who do not develop a cold?

In 1967, after my 29-day fast, I worked in a small office with several other people. Every one of them had repeated colds, some developed flu; I was the only one in the office who never had any such symptoms and lost no time from work.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > 21. Physiological And Ecological Cleanliness Vs. Vaccination

## 21. Physiological And Ecological Cleanliness Vs. Vaccination

### 21.1 Von Hoffman: "Do we really need vaccination?"

Physiological drainage is even more important than drainage of swamps, and infinitely more important than germicides and pesticides. The soil (in the body) is prepared for so-called epidemic disease by failure to keep the fluids and tissues of the body sweet and clean.

In the 1850s, when this country suffered with recurring epidemics of cholera, it developed among the residents of sweltering and crowded cities, and among (as Dr. Shelton puts it) the drunkards and the ill-nourished.

A Hygienist writing in 1851 about cholera (*Dr. Shelton's Hygienic Review*, May 1976, page 196) says, "In New York as in the Old World, the chief victims of the cholera came from the same classes; the destitute poor, the badly fed, the insufficiently clothed, the crowded, the dirty and the intemperate."

The better fed, better housed, clean, and temperate did not get cholera. The same is true today; the enervated and toxemic, the weak and dissipated are sick. Those who live according to the laws of nature are well.

Dr. Shelton says (*Dr. Shelton's Hygienic Review*, May 1976, page 197), "Before the Salk and Sabin vaccines there were great numbers of mild cases of polio and there were a few severe cases. This condition has not been changed, although many cases formerly diagnosed as polio are no longer so diagnosed. But I have yet to learn of a single child of Hygienic or vegetarian parents who has had polio. ... A healthful regime will not cause polio nor cholera, smallpox, and diphtheria."

Scarlet fever declined in incidence and virulence as rapidly as did diphtheria—without a vaccine. Cholera, bubonic plague, English sweat, and typhus fever declined and disappeared at the same time as smallpox—only smallpox had a vaccine! Some common factor must have been responsible for the total decline—not an "immunizing agent," used for diphtheria and smallpox and not for the other diseases. Dr. Shelton asks, "Is vaccination merely a substitute for personal and community cleanliness?"

### Van Hoffman: "Do We Really Need Vaccination?"

Nicholas Von Hoffman, syndicated columnist, after reading *L'Intoxication Vaccinate*, by Fernand Delarue, wrote an article, "Do we Really Need Vaccinations?" (*St. Petersburg Independent*, 9/18/78). He says that the French anti-vaccinationist has some compelling statistics supporting his position.

Von Hoffman continues:

"Swine flu experience or no, no practice of Western medicine is more globally accepted as

safe and efficacious as inoculation. In a quiet way, some few doctors have grown so concerned about the known and unknown harmful effects of inoculation, they have wondered if the prevention of the disease may be more risky than going without protection. Prestigious medical figures have even gone so far as to venture that in recent years more polio may have been caused in the United States by the vaccine than by contracting the disease in the usual contagious manner

"A long list of maladies ranging from blindness to convulsions to eczema to death has been imputed to vaccination, but for well over a hundred years informed opinion has held that the benefits of protection outweigh the risks. Now a small but growing number is wondering if inoculation does confer the protection claimed for it. We know, for instance, that some of the worst epidemics to ravage our kind were not suppressed by vaccination but by achieving a higher level of public cleanliness. Thus it was sanitation, not inoculation, which ended the Black Death. Something of the same thing may have occurred with smallpox

"In the middle of the '70s, the English launched a large public sanitation program and as it went forward the percentage of vaccinated people in the population and the incidence of smallpox both dropped. Moreover, medical records from the time indicate vaccinated people were more, not less, likely to get smallpox than the unvaccinated

"Delarue centers his inquiries in France, where he says, for a long time there has been a number of practicing doctors as well as academicians who've had the gravest private doubts over inoculating people. *They've not wanted to take the catcalls and the damage to their careers which speaking out would bring down on them.*

"Somewhat the same situation probably obtains here. Yet old ideas have to be reexamined and retested from time to time. We have sunset laws for our public institutions so that every so often they must defend themselves and show that they are still necessary. The same should hold for old, long undiscussed scientific principles, especially when they concern the immediate health and well-being of millions."

## **21.2 Dr. Mendelsohn: Now I Am Against All Vaccines**

Dr. Robert S. Mendelsohn's book, *Confessions of a Medical Heretic*, contains three pages (pages 143-145) about the dangers of immunizations, and the fact that "immunized" people may not only be in greater danger of contracting the specific disease against which they were vaccinated (than if unvaccinated), but are also subject to neurological and sometimes fatal conditions caused by the vaccination

Dr. Mendelsohn says, "The entire flu shot effort resembles some massive roulette game, since from one year to the next it's anybody's guess whether the strains immunized against will be the strains that are epidemic. We were all afforded a peek at the real dangers of flu vaccines when, in 1976, the great swine flu fiasco revealed, under close government and media surveillance, 565 cases of Guillain-Barre paralysis resulting from the vaccine, and thirty "unexplained" deaths of older people within hours after receiving the shot."

Dr. Mendelsohn recently told American Natural Hygiene Society member Barry Mesh that "now he is against all vaccines."

## **21.3 "Mistakes" and "Bad Batches" (Contaminated Vaccine)**

When an epidemic occurs on the heels of a mass immunization, the excuse is often given that "it was a

bad batch." Sometimes "mistakes" occur. A recent (fall 1982) report from Sarasota, Florida, is a case in point. "Health officials in Sarasota admitted Tuesday a miscalculation in determining the dosage of a vaccine resulted in 19 youngsters receiving 10 times the recommended amount of Rifampin, a vaccine for hemophilus meningitis. Dr. Robert Laurie, head of the Sarasota County Health Department, said the overdose administered over the weekend resulted in adverse reactions in the 19 children, but none of them had to be hospitalized. The vaccine was given to the parents of 19 children at Grace United Methodist Church Day Care Center at Venice after a three-year-old girl at the center was stricken with the disease." (Craig Basse, Sunrise Digest, *St. Petersburg Times*.) Sometimes the "bad batches" or "mistakes" result in deaths.

In Barbara Ann Boruff's article (referred to previously), she also says:

"In addition to the likelihood of disease, complications, or death, is the possibility of receiving contaminated vaccine. Since 1954, several such incidents have occurred. One is the well-known Cutter scandal, which became the impetus for the establishment of a federal agency to monitor the effectiveness and safety of inoculations for mass immunization. This organization is the Division of Biologies Standards (DBS)

"In the early seventies, the DBS came under severe criticism with regard to its practices. In 1961, several million people received polio and adenovirus vaccines that had been contaminated with a monkey virus known as SV40, known to cause cancer in hamsters. Its effect on humans is not yet known. Instead of taking the remaining vaccine off the market, the DBS continued to allow their usage 'rather than risk eroding public confidence by a recall.' (*Science*, March 17, 1972)."

## 21.4 Let's Look At the Record

Excerpts from *Don't Get Stuck!*

**William Howard Hay, M.D., Pocono, Pennsylvania June 25, 1937, Address before The Medical Freedom Society (published in the Congressional Record) on the Lemcke Bill to Abolish Compulsory Vaccination:**

... "I know of one epidemic of smallpox comprising nine hundred and some cases, in which 95% of the infected had been vaccinated, and most of them recently ...

"A number of years ago, Cook County, Illinois Hospital decided to immunize (against diphtheria) one-half of the nursing staff, and not the other half. Diphtheria broke out soon afterward among the immunized cases, not the others ...

"Within six years of the U.S. takeover of the Phillipines and after 30,000,000 vaccinations, they suffered the worst onset of smallpox, the worst epidemic three times over, that had ever occurred ... and it was almost three times as fatal. The death rate ran as high as 60% in certain areas, where formerly it had been 10% and 15%."

**Report of U.S. Secretary of War, Henry L. Stimson, July 24, 1942:**

"Recent army experience with yellow fever vaccine resulted in 28,505 cases of hepatitis, with 62 deaths, as of July 24, 1942."

### 1957-1959

In 1957, nearly *half* the paralytic cases of polio in children between five and fourteen occurred in vaccinated children. It was admitted that the vaccine had been causing paralysis. There were more polio cases in 1958 than in 1957—6,029 cases, with 3,122 paralytic. In 1959 there were 8,577 cases of polio, with 5,694 paralytic. (The Salk vaccine had been introduced in 1955.) In 1959, the health director of the state of Idaho; Dr. Carl Eklund, one of America's vaccination authorities; and Dr. Florio, the medical

officer of Denver, all spoke out against the epidemic and crippling effects of the Salk vaccine.

**1961 (Chicago Daily News, 9/16/61):**

In 1959, the Sabin Live Virus Vaccine for polio was introduced. "Eleven persons who received Sabin oral vaccine a mass immunizing program in the Syracuse, New York, area have developed paralytic polio, the U.S. Public Health Service reported yesterday."

**1964 (Awake Magazine, 11/22/64):**

"The U.S. Public Health Service recommended that the Sabin oral vaccine for polio be discontinued to adults ... A seventeen-man committee found that 57 cases of paralytic polio have been found that were compatible with the possibility of having been induced by the vaccine. The vast majority ... involved adults."

Read *Don't Get Stuck* or *The Poisoned Needle* for details about the trail of crippling and death left by vaccination. A large volume could be filled with the recorded cases.

## **21.5 The Swine Flu Hoax**

Dr. Shelton said in 1976, "The pain proposed by the president" (Ford) "involves the absurdity of introducing the supposed cause of influenza into the bodies of the people to produce in them mild cases of influenza in the hope that this will cause them to produce protective antibodies and thus enable them to escape more serious disease by the accidental invasion of their bodies by the same supposed causes. Viruses are very accommodating little critters. They introduce mild disease when introduced into the body by physicians and serious disease when introduced accidentally. What an enormous debt the medical profession owes to viruses!"

A student of mine (in 1976) reported to me that her father had been caught up in the swine flu immunizing frenzy, and had died the day after receiving the vaccination.

It may seem incredible that the 1976 Swine Flu Epidemic hoax, with its terrible consequences, has not aroused the public to reject all so-called immunizations. But the government and the medical profession have glib and plausible explanations and continue to sell the idea that the risks involved in "immunization" are small, compared to the potential benefit. And the public still accepts the idea of "contagion" being the cause of "epidemics", and allow their children to stand in the "immunizing" lines.

## **21.6 Compulsory Vaccinations and Exemptions**

Those who doubt the necessity or advisability of vaccination are browbeaten into submission by the "authorities" who insist "it is the law." Actually, the laws vary from state to state.

California allows exemption simply on a written statement that immunization is contrary to his or her belief. But even in Florida, where the media have been screaming, "No child will be allowed to enter school without proof of immunization," it is possible to escape.

Members of the American Natural Hygiene Society can apply to the Society for assistance. Sometimes a firm approach to the school authorities is all that is necessary.

At the October 1982, meeting of our Pasco Natural Hygiene Society, two happy parents (Clearwater, Florida) informed me that all it took was a statement to the school authorities that vaccination is against their religious beliefs. They were told that in case of any outbreak of one of the "vaccination diseases," their children would be required not to attend school until the outbreak was over.

Of course, they were delighted, and repeatedly thanked me for guiding them in the right direction—away from the fear of "contagion" and "epidemics."

## 22. Questions & Answers

**What explanation does the medical profession offer as to the origin of a disease that appears without any possibility of having been caught from another person with that disease?**

I have never heard any "explanation" of this anomaly, but medical people still insist that germs are the primary cause of disease.

**If advocates of vaccination believe that it protects, why are they so insistent that everyone else also be vaccinated?**

They claim that for vaccination to be truly effective, at least 90% of the population must be vaccinated. The rationale is, I believe, that a vaccinated person can infect an unvaccinated person, and the unvaccinated person, being "unprotected," may develop a more virulent form of the disease, and start an "epidemic." When epidemics start among the vaccinated people, the tendency is to blame the unvaccinated people for not participating, so that complete "protection" might be obtained. These specious arguments are the only ones I have ever heard as justification for compulsory vaccination. If there are other more logical reasons for compulsory vaccination, I would like to hear them.

**What causes a germ inside the body to mutate into another type of germ?**

The amount and type of toxins in the body. See (in the lesson) Dr. Shelton's explanation of why toxemia causes typhoid in one person and pneumonia in another, and the relationship to the types of food in the diet. Lack of inner cleanliness and the absence of a clean, Hygienic environment, influence the kind of eliminative crises the body will conduct. Bacteria are scavengers which feed on the materials (soil) available to it in the body of the host. The type (shape) of the bacteria is determined by the kind of soil involved.

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > Article #1: Toleration Means Loss of Vital Resistance by Dr. Herbert M. Shelton

### **Article #1: Toleration Means Loss of Vital Resistance by Dr. Herbert M. Shelton**

Barring violence, perhaps the only cause of death is tolerated poisoning. The slow, gradual, insidious undermining of the organism—the wasting of its nervous energy and the impairing of its functional and structural integrity—by poisons that are harbored and "tolerated" kills sooner or later. Yet, toleration is one of the most misunderstood phenomena in all nature. Very few men and women grasp its true character.

Tolerance for poisoning is established by breaking down resistance to its influence. The body pays for this toleration (miscalled immunity) by general enervation and lowered resistance to every other influence.

It has been objected that the breaking down of resistance should not produce toleration, that it should weaken the organism and render it more susceptible to the influence of poison. This objection arises out of not understanding the phenomena of resistance.

We have seen tolerance defined as the "ability to endure the continued use of a drug." We have also seen

it defined as the ability to resist a drug. There is something wrong somewhere. It is one thing to resist; it is another to endure.

That the vital system resists drug poisons is not doubted. The means of resistance is not well understood. When emesis (vomiting) follows a dose of ipecac and diarrhea follows a dose of calomel, these processes are recognized as evidences of intolerance; but they are not understood to be means of resistance. Resistance is supposed to be some occult power that comes into play after the physiological evidences of intolerance have ceased. This is the reason we are told that tolerance means being inured to poison by habit so that it may be taken without harm.

So long as the body actively resists and speedily expels the poison, it is supposed to produce harm, after active resistance has ceased and rapid expulsion no longer occur, it is supposed to be harmless.

It should be obvious to even a child that its speedy expulsion prevents harm while its toleration permits it to do much harm. If calomel is expelled by diarrhea, it does not get into the blood and cannot damage the blood, nerves, bones, teeth, etc. If it is not expelled by diarrhea, it does get into the blood and does damage all of these structures.

It is a sad day for the body when it learns to tolerate poisons. If intolerance persists, it will force cessation of the use of poison. If tolerance for tobacco were never established, there would be no tobacco users. The same for alcohol, opium, arsenic, and other poisons.

Note that the symptoms of poisoning—pain, nausea, vomiting, griping, diarrhea, vertigo, weakness, inflammation, etc.—are also the symptoms of disease. So-called disease is a process of resistance—resistance to poisons. It expels the cause of disease as surely as it expels calomel or ipecac. This fact is so very obvious we are unable to understand why it cannot be grasped by all.

Drugs are said to lose a degree of their potency by repetition. This does not express what actually takes place. It is not the drug that loses its potency. It is the body that loses power. The repeated use of a poison gradually overcomes or decreases vital resistance.

So long as it was believed that the symptoms following the taking of a poison represented drug action, it was legitimate to believe that when these symptoms, no longer followed a dose of the poison, the drug had lost some of its potency. But when we realize that these symptoms are signs of vital resistance, that they are actions of the living body, we understand that the failure of these symptoms to follow a dose of the poison is due to a loss by the body of power to act.

This weakening of the powers of life, this subduing of the power of resistance, results in establishing what is called toleration. When toleration is established, that is, when the power of resistance is worn out, to produce the same effect—the same degree of resistance—the size of the dose must be progressively increased.

When medical men tell us that drugs lose their "remedial" effects by long continuance, we are to understand that vital resistance has been subdued. For the phenomena of resistance are what medical men mistakenly call the "remedial" effects of their drugs. They have not yet learned that it is the living body, not the drug, that acts (acts to expel the poison).

Toleration and lost resistance are one and the same thing. It is a matter of every day experience that as the body's power of resistance to a particular poison is reduced, it is less able to "react" to that poison.

The first effect of a toxin is always stimulation, which is merely another name for excitement or irritation. This is always followed by actions of the body (the so-called "reaction") to expel the poison. These actions (or "reactions") represent the process of resistance. The body refuses to tolerate the poison.

When "stimulation" is frequently repeated, increasingly large doses of the same poison or toxin are required to arouse a degree of intolerance that equals the intensity of the original "reaction." This lowered "reactive" power, this lessening of the defensive actions of the body, is called toleration.

Diminished resisting power (toleration) is a state of enervation. General enervation, however produced—by drugs, excesses, by toxemia—diminishes resisting power to all poisons or excitants.

This does not, in and of itself, represent a diminished susceptibility to the baneful influence of poisonous drugs. It may, however, represent, in addition to the increased enervation, a change in the methods of self-protection, a shifting from one method of defense to another and let; expensive one—a passive resistance and a slow yielding to the influence of the poison.

This represents the cessation of active resistance, or partial submission to the poison. For submission, or lessened resistance, is what toleration really amounts to.

Passive resistance is doubtless accompanied with or accomplished by changes in the tissue, which, if not identical with those seen in the hands when these are subjected to repeated friction, are analogous to them. The hardening and thickening of the hands, that is the building up of callouses, is not the result of friction, but is a means of resisting friction. The tendency of friction is to wear away the skin, hence this must be continuously built up from beneath.

While the callous guards the underlying structures against the friction, it cripples all the powers of the skin. Such skin is not ideal—does not represent the physiological norm.

If you are not accustomed to using fiery condiments and you undertake to use red pepper, it causes the lips, mouth, tongue, and throat to burn intensely. When swallowed, it produces discomfort in the stomach. There is later a feeling of discomfort in the intestine as the irritating pepper passes along. When, finally, it is expelled in the stools, the anus and rectum burn as much as did the mouth when the pepper was swallowed.

Persist in the use of the pepper and its irritating effect grows less and less until, finally, it produces no burning of the mouth and throat, no distress in the stomach and intestine, no burning of the rectum and anus. The membranes of the entire digestive tract become thickened and hardened in defense against the repeated irritation. The protective thickening impairs their other functions. The sense of taste is dulled, digestion is impaired. Doubtless something similar to this takes place in all the tissues of the body that are subjected to chronic irritation by alcohol, tobacco, caffeine, arsenic, opium, salt, and other poisons and irritants in common use. They, too, must undergo changes to defend themselves.

Adaptation to poisons, that is, the establishment of toleration, is accomplished by changes in the tissues that are away from the idea! and that cripple all the powers of the tissues.

I do not think it can be too strongly emphasized that adaptation to the use of a poison, that is, the establishment of toleration, is accomplished by a depravity of the organism. This fact was, so far as I know, first explained by Sylvester Graham more than a hundred years ago.

The greater the physiological depravity, the more of the poison will be "demanded" by the user and the more his body will tolerate without signs of active resistance. In other words, in precisely the proportion to which one becomes accustomed to the use of any poison is his system depraved and his defensive powers reduced. The ability to use large quantities of tobacco, for instance, without being made sick, instead of being an evidence of strength and physiological fitness, is an evidence of weakness and physiological depravity.

When tobacco is taken into the undepraved organism, it is met with strong vital resistance. There follow in rapid succession distressing dizziness, muscular relaxation, tremor, weakness, perhaps fever, nausea, vomiting, diarrhea, and even convulsions. Such a "reaction" always follows the introduction of tobacco into the undepraved organism; and the more vigorous and undeprived the organism, the more prompt and powerful will be this "reaction."

It is only by commencing a career of depravity, with cautiously measured steps, that we may break down the body's resistance to the poison and, ultimately, bring about a condition in which the body seems actually to call for and embrace, as a friend, its arch foe.

The body may thus be so depraved that the deadliest poison may be habitually taken in considerable quantities and only result in an immediate feeling of apparent well-being. Indeed, there maybe, and usually is, much suffering if the depraved organism is denied the cause of its depravity.

The habitué may be able to take at one dose enough poison to kill six nonusers. Arsenic may be used as freely as table salt, with as little immediate evidence of its poisonous character, once the body has been beaten into submission. Prussic acid, which kills like lightning, when the body is not accustomed to its use, may, beginning with minute doses, and gradually using larger and larger doses, be used with considerable freedom as a means of "exhilaration" and intoxication.

The opium addict can take at one dose sufficient opium to kill several nonusers outright. Instead of producing any immediate symptoms of poisoning in him, the opium results in an immediate feeling of well-being. If he is denied his accustomed dose, he suffers intensely. Give him his accustomed poison and his sufferings vanish as if by magic. The cause of his suffering seems to cure his suffering, but only seems to, for the longer he uses the opium, the more he suffers and the larger dose and the more frequent doses will he require to silence the outcries of his outraged system. The real effect of the dose is to renarcotize his nerves, which can only cry out and reveal his true condition when they are no longer under the influence of the drug.

In the same way coffee will "cure" the headache it produces; tobacco will "steady" the nerves it has unsteadied; alcohol will "strengthen" the man it has weakened; sleeping potions "cure" the sleeplessness they have produced, only to make the sleeplessness worse and require a larger dose to "cure" next dine. Stimulants weaken us by overstimulation, mistaken for "energy."

The ability of the carefully depraved organism to tolerate large doses of poisons and the fact of every day experience that the use of poisons by the physiologically depraved instead of producing immediate symptoms of poisoning, results in the appearance and feeling of well-being, has led even intelligent people to stoutly deny the poisonous character of many poisons in habitual use. Because tobacco, opium, alcohol, arsenic or coffee and tea may be freely and habitually used without producing immediate death, or any of the distressing symptoms that indicate acute poisoning; but, on the contrary, so far as the feelings and actions of the users are concerned, they act as grateful "cordials," men and women are deceived by them. "My experience has shown that tobacco is very kind to me," says the tobacco user, while the opium addict informs us that his "experience has shown that opium is very kind to me."

Such "experience" is based not only on the deceptive appearances of drug habituation, but is defective in that it forgets or ignores both the beginning and the end of the experience with the drug. If we accept the nonpoisonous character of tea, coffee, tobacco, alcohol, opium etc., on the basis of such "experience," we are forced to the fallacious conclusion that there is no such thing as a poison in nature. The body can learn to tolerate most substances, however deadly, by a career of physiological depravity.

The true test of the poisonous or nonpoisonous character of any substance is its introduction into the undepraved—the intolerant—organism. By this test tobacco, alcohol, tea, coffee, opium, arsenic, and all other drugs that are used for "exhilaration" and intoxication are shown to be strongly anti-vital i.e., poisonous.

The beginning of a poison vice is marked by evidences of acute poisoning. Thereafter, there are evidences of acute poisoning. The end—no one disputes the end of opium addiction. Few today will deny the end of arsenic eating. Why close our eyes to the ends of alcoholism, nicotineism, caffeineism, etc.? Not until we include in our "experience" both the beginning and the end of a poison-vice are we justified in drawing conclusions from "our experience."

## **Article #2: Your Probing Mind By V. V. Vetrano, B.S., D.C.**

### **What is the Hygienic viewpoint of viruses and their effects on living cells?**

This question is a little difficult to answer because virology is still in its childhood. Their nature is still not known. Are they plants, chemicals, animals, or parasites? No one knows exactly what they are.

Boyd states that a virus "represents a most minute and primitive form of life. Even this statement may be questioned, for the virus seems to exist in the dim borderland between living things and chemical compounds. It is a submicroscopic unit containing nucleic acid and protein. Unlike bacteria, viruses are not capable of supporting life on their own, owing to a lack of enzymes. In order to exist and multiply, they must occupy living cells, which provide them with necessary material and energy. ... It is evident that a virus is a perfect example of a parasite."

Some viruses live and grow only in man. Others prefer other animals. Some of them like to live only in specific tissues such as nerve tissue (neurotropic), while others prefer the skin, and are called dermatropic. Still others are *viscerotropic*, meaning that they live in the viscera of animals.

The current knowledge of the virus seems to point clearly to its parasitic nature. Knowing the nature of viruses gives us a clue as to how to "defend" ourselves from them, if, indeed, we need defending. They, like bacteria, may end up being our benefactors instead of our enemies. Their outstanding characteristic is that they cannot multiply unless in a living cell. Since they live within the cell, dosing ourselves with antibiotics and other drugs such as the sulfonamides will not destroy them.

Viruses, being mainly proteinaceous in nature, occasion antibody formation when they are in the bloodstream. The body acts against them to destroy them, just as it destroys bacteria. A healthy body can destroy them as rapidly as they are formed. Even though they are somewhat protected within the cell from the antibodies, a healthy cell can keep them under control and prevent them from overwhelming the cell.

A medical differentiation is made between a viral infection and viral disease. A host may be infected with a virus but not manifest a disease. In the case of viral infection multiplication of the virus can proceed without damage to the cell. When there is a viral disease, the cell shows pathological changes, usually in the form of degeneration. Boyd thinks that viral infection is universal but that viral disease is relatively rare. He says, "viral infection is very much commoner than viral disease—indeed it may be universal. Thus polio virus infection is many hundred times commoner than the disease, and adenovirus infection of the tonsils is present in about 90 percent of normal persons, although disease caused by these viruses occurs in a very small percentage.

"In viral infection, a virus may sojourn indefinitely in the comfortable surroundings of the cell. It is more than a boarder, for it has become one of the family, and it can live with the family for generations without causing trouble. Various internal or external agents may upset the harmony and convert the latent virus into a virulent one, which usurps the cell's biosynthetic machinery for the production, almost exclusively, of viral progeny (Swartz and Littlefield). Such factors as age, genetic makeup, nutrition, or hormonal balance may be responsible. So may bacterial infection, one of the best examples being the well-known relation between the herpes simplex ("cold sore" on the lip) and pneumococcal pneumonia. Influenza is believed with reason to predispose the patient to respiratory tract bacterial infection, but it is also possible that such an infection may precipitate an attack of influenza through the conversion of a latent into an active virus.

"It is now known that a protein is produced by virus-treated cells in tissue culture which is capable of inhibiting or interfering with the growth of many other viruses. This material has been named interferon, and it seems to have many of the properties of a viral antibiotic, so that we may hear more of it in the

future (Isaacs and Burke). Recovery, as opposed to immunity, does not depend on the production of antibodies. The factors responsible for recovery are at present unknown.

"The practical importance of the theoretical considerations which have just been outlined lies in the fact that as viral disease is dependent on viral reproduction, and as viral reproduction is dependent on biochemical processes, it may be possible to interfere with these processes and thus inhibit reproduction by chemical compounds. First steps in this direction have already been taken, but we have to face the unfortunate fact that by the time signs and symptoms of disease are apparent, reproduction for the virus is far advanced. It is evident that the control of viral diseases presents the same formidable obstacles as the control of cancer and for the same reason, namely that we are dealing with a disorder within the cell itself."

I quoted extensively from Boyd because I wanted you to read the medical man's words yourself. When analyzing his writing, we learn that a virus can be present without a disease being manifest and without the disease necessarily developing even in the future.

In fact, we learned that 90% of normal persons can harbor a virus and only a few of this percentage develop the disease the virus is supposed to cause. Viral disease, like bacterial diseases, require something else or some other enervating substance or influence to prostrate the body's protective functions permitting the virus to run away with the biological activities within the cell.

We also learned about interferon. This indicates that the body does have a means within the cell of protecting itself, thus preventing the virus from multiplying within the cell. It has always been totally unthinkable to me that a virus could enter a cell, and take over without the least bit of biological protest. Now we have learned that the body protects itself from viruses just like it does from bacteria and their toxins. Our job is to supply our bodies with the necessary materials and influences which promote health and protection.

We learned also that there are "carriers" of viruses just as there are "carriers" of bacteria. A "carrier" is a person in a state of impaired health but not yet sick enough to go to bed. This state of lowered vitality is low enough to permit the virus to exist, but not low enough to permit it to multiply so much that it produces apparent degeneration of the cell. This takes years. Greater health will enable the host to destroy the viruses, and less health will cause the carrier to develop a so-called viral disease.

As Hygienists, we know that there is no such thing as a viral disease. There are simply states of impaired health with cell degeneration. That the virus is an entity and that it occasions cellular degeneration is still a mute question. The so-called viruses may simply be the various toxic debris that Hygienists have been condemning and shouting about for many years. Not wanting to keep the toxin in the bloodstream, the body may find a means of encapsulating it in a protein membrane and injecting it into a cell to get it out of the bloodstream. Eventually these toxins pervert the metabolism of the cell and cause cellular degeneration. The virus may be only encapsulated protein, the body having surrounded it with a membrane to prevent an excess from upsetting the system. The modern high protein diet may be the reason for so-called viral infections.

Another thing we glean from the foregoing quotation from Boyd is the manner in which the medical man thinks. Instead of thinking in terms of improving the person's health with the normal elements of physiology, he thinks in terms of a chemical which will destroy the virus although he previously pointed out the fact that the cell can protect itself with interferon, and although he mentioned the factors which may make a latent virus become active. Instead of telling us to avoid these factors, he searches for a chemical panacea. It has been proven with antibiotic therapy that you can't kill all bacteria with antibiotics and often instead of destroying the bacteria, the drug simply produces a mutant strain that is resistant to the chemical or antibiotic, and the bacteria thrive in the host despite the drug.

But the host's health is destroyed and his ability to destroy bacteria is at the same time depressed by the antibiotic. Instead of making the host immune to disease and bacteria, it makes him more susceptible. The same can be said of any drug, which may be produced, that will kill viruses. If it is destructive to the

virus, it will also be destructive to those taking the drug.

Many important facts have been brought to the surface by modern research. What is so remarkable, is that every time something new is learned it only strengthens and confirms the Hygienic viewpoint of disease.

We have learned that viruses vary just as do bacteria. Something causes them to change from a virulent virus to a nonvirulent one or vice versa. What causes this? In bacteria, it is their environment. If the environment is toxic and the bacteria must live on filth, they become virulent. There is every reason to believe that viruses in a toxic environment filled with an excess of metabolic waste products and environmental poisons, will also become virulent because of their nourishment.

An article from the *Cyclopedia of Medicine* written by Edwin W. Schultz, M.D. clearly points out that viruses change. He states,

"Considerable experimental work has been done on variation in viruses. It is well established that viruses do undergo variations, including variation in virulence, in antigenic structure, and in the character of the lesions induced. Sometimes the variations are of a stable mutation type, at other times, not. While viruses have been compared with self-perpetuating genes, little is known regarding the genetics of viruses

"The capacity of viruses to undergo variation has also been studied in the laboratory. Certain variations have been induced in vaccinia virus and other pock viruses. The conversion of 'street virus' to 'fixed' rabies virus is a classical example of laboratory adaptation. In its passage from brain to brain in rabbits, street virus loses its ability to progress along peripheral nerves; this is a variation relating to its tropism. It occurs without significant changes in antigenic properties. With some viruses, however, appreciable shifts may sometimes occur in the antigenic properties when these are passed long enough in a new type of host. Among the more important variations, which have been induced under artificial conditions, is the transformation of yellow fever virus under tissue culture conditions from a primarily viscerotropic virus to one which has not only lost its viscerotropism, but inherent neurotropism as well, and this without significant alteration of its natural antigenic properties. Strain 17D, now employed in immunizing against yellow fever, has this history."

Again the physician is thinking in terms of using this newfound knowledge wrongly. Instead of learning that a healthy body will destroy the virus and that it can even turn a virulent virus into a nonvirulent one so that it will not cause any pathological degeneration, they are still thinking in terms of immunizing the body against the virus, which is impossible anyway because of the many different strains of the same virus.

That the immunizing process is fraught with great danger is brought out in the following quotation from the the same author. "A certain degree of pliability in a virus can prove a useful property. If a virus can be made to give up its natural virulence without significant change in its anti-genic properties, it may become useful as a vaccine. What will happen when it is placed in a new environment is, however, often unpredictable. Merely carrying it under such conditions for a time gives no assurance that a change in virulence or other properties has been induced. Proof that such a useful change has been effected may require lengthy experimental observations to determine not only the degree of the change, but the stability of the change."

In summary, all the newer knowledge about viruses only strengthens, corroborates, and substantiates the Hygienic viewpoint of all bacteria, parasites, and viruses. The healthy body has its means of destroying and eliminating them from the system. If you are in a state of impaired health, drugs and vaccines do no good whatsoever. They further weaken the organism and intoxicate the system, making it even more susceptible to parasitic and bacterial invasion.

Furthermore, we just learned of the hazards of injecting attenuated viruses. They can backfire and

become virulent again. Many children became paralyzed after taking Sabin and Salk vaccines. The means of health and only the means of health are useful in states of disease. If a substance bears no normal relation to the body and if it is not generally used in any of its biochemical or physiological processes, then it does not belong in the body even if it does kill bacteria and viruses in the test tube. We are dealing with living organisms, not minced tissue growing in a culture in the lab. Let us rely on the only reliable means left, and those are the primordial requisites of life.

*(Editor's Note: While the above article gives credence to medical views, it is, nevertheless an excellent Hygienic presentation. Students should now know that so-called viruses are only cellular debris, being, particularly, the remnants of genetic material from cellular mitochondria. This debris, along with other uneliminated wastes, constitutes the morbid material the body endeavors to expel when it institutes an eliminative crisis called sickness, disease, etc.)*

[Home](#) > [Lesson 66 - Contagion, Epidemics](#) > Article #4: Must I Be Immunized? by Virginia Vetrano, B.S., D.C.

#### **Article #4: Must I Be Immunized? by Virginia Vetrano, B.S., D.C.**

Worried people call the Health School asking if they should have themselves immunized before traveling abroad. They are going to the Far East or Mexico, and should they beware of fresh fruits and vegetables? Is it true that they must drink wine or beer, and shun pure water?

These and other questions come to their mind when preparing for a visit to other countries. They have heard so many scare stories written by the masters of the scare science that they take a trip with great fear and trepidation. Indeed, some remain home for, fear of "catching" some foreign "bug."

On January 4, 1971, the *Arkansas Gazette* carried an article by Dr. Van Dellen alarming the people that a cholera epidemic was spreading through the Middle and Far East, into Africa. "For the first time in 100 years the disease has bridged the Sahara and is in tropical Africa and as far west as Guinea. These areas are densely populated and have poor sanitation—ideal conditions for the spread of the infection. The mortality also has been high.

He goes on to say that the cholera poses "no immediate threat to the United States," but he says this "with his fingers crossed, because any person visiting afflicted countries could bring it back." Then those stow-away germs could pounce on us poor unsuspecting Americans who would then succumb to the disease.

Where was the cholera vibrio all these years? Did it disappear and suddenly return? Travelers are advised to consult the United States Public Health Service to determine which countries demand that they be *immunized* for cholera before entering, making it sound as if many countries demand immunization for this disease before crossing their frontiers. This is not so. Dr. Van Dellen states in the aforementioned article that, "Many countries in Europe, Asia, and Africa demand evidence of vaccination before a person crosses their frontiers. And this is true particularly after the person has been in a cholera-infected area."

I telephoned the United States Public Health Service and was told that it is not necessary to be immunized before going into an infected area; that the countries did not care if you were subjected to the disease when there. It is the other countries that worried when you re-entered them on your way home. I was advised that before making a world trip that one should be immunized for smallpox, cholera, yellow fever, tetanus, typhoid, polio, and hepatitis. Then one month before entering a malaria-infested area I was told to start taking medication and continue taking it as long as there was a chance of being bitten

by the malaria-carrying mosquito.

The World Health Organization, Geneva, is the responsible body for the International Sanitary Regulations. It is clear in Article 83, for all those countries that accept the International Sanitary Regulations, that "objectors to vaccination can refuse the operations without being refused admission into those countries which have accepted the International Sanitary Regulations."

If you have traveled into Asia, Africa, America, other than from the United States and Canada, and wish to enter the United Kingdom, an official vaccination certificate is necessary. In almost all countries, however, you can get in without shots of any kind. It is when you re-enter other countries from an *infected* area that trouble may be given you. Paul-Emile Chevretils, M.D., founder president of *La Ligue Pour Le Vaccine Libre* states that he travels without the yellow certificate, using only Article 83. He states that, "This international by-law gives anyone the right to go around the world by using the medical surveillance for 15 days, *not to be isolated but to go freely.*"

After informing his readers that "there is no good evidence that cholera immunizations are any good ..." Fredrick J. Stare, M.D. (*Arkansas Gazette*, November 16, 1970) urges us to be shot anyway, and then gives us a formula for eating that will supposedly prevent cholera. Do what he says and you probably will develop cholera. Do the exact opposite of his advice which follows and you will probably have more energy, enjoy yourself more and not be troubled whatsoever with "vacation diarrhea."

Stare, according to the dictates of the *infection* myth, gives us this advice: Stick to bottled mineral water, hot tea or coffee, or bottled beer, eat the meat, potatoes, rice, or other well-cooked foods, canned vegetables, bread, butter, and jam; and shun the fruits and vegetables unless you can readily peel them yourself. Wash your hands well before you eat."

This nonsensical plan of eating supposedly prevents the development of cholera by killing the vibrio with heat or chemical processes before introducing it into the body via food and water. Were the vibrio the cause of cholera his reasoning would still be specious. *Vibrio cholerae* are aerobic bacteria, meaning that air is necessary for their growth. There is not an excess of air in the gastrointestinal system. They are also killed by acidity. If food and water, contaminated by *vibrio cholera* are taken, the acid of any good stomach will soon destroy them. Kendall A. Elson, M.D. states in *Cyclopedia of Medicine*, that, "The *cholera vibrio* escapes from the body of the infected individual in stools and vomitus, although if the latter is strongly acid the organisms are immediately killed."

What people should be taught is cleanliness, and to eat moderately of properly-combined foods so that digestion is normal and they need not fear the *cholera vibrio*, if they still believe the concept of disease of the shaman. We must caution our readers against Stare's Middle Ages advice. The *cholera vibrio* does not cause cholera.

Even though he has twice made the statement that cholera *immunizations* do not protect one from cholera, Stare advises getting *immunized* anyway to avoid trouble at ports of entry to other countries which have strict public health regulations. He condemns his peers, who are M.D.s who give the shots when he says, "It is important to have this certificate in order to avoid inconveniences in travel or the threat of serum hepatitis from a dirty vaccinating needle."

To back up his statements about cholera vaccine, Stare quotes Dr. W. B. Greenough, III, whom he says "knows far more about cholera than I know or ever will know," as having written him the following: "Many commercial vaccines do not protect even in populations from endemic areas (where cholera is always present) ... as a measure for disease control immunization is ineffective since the carrier state is not interfered with by the vaccine."

What he is saying in plain English is that if the cholera vaccine protected, then cholera would not be endemic, and those who were protected would not develop the disease even if supposed "carriers" are present. However, we are taught that the "organisms usually disappear from the stools of the cholera patient within five to seven days of the onset of infection. ..." and the carrier state is not supposed to be a significant method of transmission of the disease. Cecil and Loeb's textbook of medicine states "there

are no known instances of chronic carriers among human beings."

Many Hygienists have traveled to the Middle and Far East and into Africa, eating plenty of fresh fruits and vegetables, without developing any trouble, whereas often those who had all the shots and who drank wine instead of water and who didn't dare taste a fresh fruit or vegetable came down with various illnesses, including cholera. I might add, that for the sake of cleanliness, pure distilled water would be best to drink, here or overseas, and for absolute cleanliness of vegetables and fruits, rinse them well in distilled water. The *cholera vibrio* is easily killed by drying, and it dies rapidly in pure water. It is cleanliness that is necessary, not sterility.

Cholera, an acute inflammation of the intestinal canal, is supposedly spread by food and water contaminated with *vibrio cholerae*. It is usually a disease endemic and epidemic in Asia primarily along the Ganges River in India and Pakistan. The bacillus, which is shaped like a comma, and was called the comma bacillus by Koch, its discoverer, releases a powerful endotoxin after death, which contains a mucinase. Mucinase is thought to be responsible for the extreme cellular desquamation of the mucosal epithelium that is so characteristic a feature of cholera. The endotoxin supposedly causes such intense dilatation of all the capillaries along the whole intestinal tract that the fluid leaks out of these into the intestines, thus producing the rice-water stools so typical of Asiatic cholera. Because of the loss of such huge quantities of electrolytes and water, extreme dehydration ensues, and Boyd states that 75% of the untreated patients die.

Since the *vibrio cholera* does such horrible things to a person, by all means, shouldn't we take steps to prevent *infection*? These threats could scare one into being *immunized* despite the poor reports of *immunization*, before going to the Middle and Far East. Who wants to dehydrate and die? So we become immunized and avoid all fresh foods, hoping that we won't develop the disease.

Germs by themselves do not cause disease. Dr. Pettenkofer, Professor of Bacteriology at the University of Vienna, astounded all his students one day by drinking a glass of water containing millions of living cholera bacilli. He had come to the conclusion that germs do not cause disease, and wanted to prove it. As he gulped down a glassful of living vibrio, the bearded Dr. Pettenkofer only growled, "Now let us see if I get cholera." De Kruif said that Dr. Pettenkofer drank enough of the "wiggling comma germs to infect a regiment." Nothing happened to the "mad" Pettenkofer. Many incidents could be cited showing that infecting the body with germs does not cause any specific disease to develop. Perhaps this is why the president was persuaded to dump stockpiles of germs for germ warfare. Perhaps experiments proved them useless and physicians didn't want the lucrative germ theory destroyed just yet. If germ warfare were effective, it is hardly likely that he would have disposed of the stockpile.

As far back 1928, Dr. M. Beddow Dayly, M.R.C.S., L.R.C.P., Medical World, said: "I am prepared to maintain, with scientifically established facts, that in no single instance has it been conclusively proved that any microorganism is the specific cause of a disease."

In Volume VI of the *Hygienic System*, Dr. Shelton says: "In more than sixty years of intensive farming the germ idea, there is not one 'disease' that has been proved to be of germ origin, and not one can be cured according to the germ theory. Unless a germ will cause a disease every time it infects the body, it is not a cause. A cause must be as constant and specific in its influence, or it is not a cause. Germs are omnipresent—this is one of the fundamental truths Pasteur or his contemporary, Bechamp, discovered; but he and his followers appear to have overlooked the fact that germs fail to have a specific influence all the time."

Dr. Shelton further says: "The view I would put before the reader is that 'disease' is not caused by the germ, but by the state of the body that allows the germ to flourish. And this condition of the organism or any part of it which renders possible the growth of the germ therein is the much sought for 'filterable virus.' It is the outgrowth of violations of the laws of life and is no chance or haphazard condition."

Dr. Tilden says that germs are merely adventitious—secondary. If the soil is proper for the growth of bacteria, they will flourish but if tissues and secretions are normal and healthy, pathological germs will

not grow and multiply.

Those who travel and drink alcoholic beverages, smoke, keep late hours, overeat on spicy, cooked dishes, and sight-see until they are about to drop are enervating themselves. They are using up nerve energy in excess. Functions begin to lag. Metabolic waste products mount in the tissues and fluids of the body. Secretion and excretion are impaired. This is the ground work, or the foundation for the development of any disease. Even then, many times the specific bacteria fail to appear. And in numerous other cases the bacteria fail to appear until very late in the stage of the disease. If a cause is a cause, logically it should be present in sufficient numbers before symptoms appear. It cannot be demonstrated that bacteria invariably appear even after the development of a particular disease.

What is the real reason for Fredrick Stare's change in feeling about vaccinations for cholera? Probably, he was given a good lecture by the AMA. Thousands of dollars will be lost to the American medical profession if people do not get their *immunizations* before they leave home. So he castigated his brethren physicians in other countries by telling his public that it is important to avoid the dirty needles in other countries. It would have been better to tell them the truth, that they could rely on Article 83 of the World Health Organization and go freely in other countries, as long as they let the health officials know of their whereabouts. This way a painful shot could be avoided as well as the occasional development of hepatitis from dirty needles in *this* country.

Why the recent outburst of cholera? An item under World Health News, in the September 1971, *Health For All* (England), has a very good answer to this question. It states: "Whenever there is a great social upheaval, with its tragic displacement of people and the consequent crowding of refugees, there is always a medical lesson to be learned. Disease often follows in the wake of such catastrophes, and, as with the most recent one, cholera becomes almost epidemic. According to medical opinion, the causative organism in this case is the *spirillum cholerae* which is found in the stools of patients. Entry into the body is through the alimentary tract, and the source of the infection is polluted water due to a lack of sanitation. To say that the organism is the cause of the disease is, however, to put the cart before the horse. The course of events runs in this order; First the breakdown of social order; then the panic of the population; and then the crowding of the people with the absence of sanitation, with the development of the organism as an associated factor. In this country, as history tells, cholera was widespread whenever people were crowded together and there was a lack of proper sanitation.

"It is interesting to notice that whenever there is a cholera outbreak, the headlines in the newspapers are given over the use of vaccines, to which, also, credit is generally afforded when the epidemic comes under control. The vaccines are rushed from the great pharmaceutical centres with the accompaniment of massive publicity with the result that probably 99 persons out of 100 would affirm the vaccines were effective in controlling the situation.

"It would therefore have come as a surprise to many people to have read on the front page of *Medical News Tribune*, June 11, 1971, the headline: 'Medical science helpless against cholera epidemic' and to have learned that 'medical science is virtually powerless in the face of the cholera epidemic on the India-Pakistan border. Tropical medicine experts can't even estimate how many could die. Better sanitation is the only answer, impossible in the present situation as millions of Pakistani refugees exist in terrible conditions, aggravated by the monsoon... !'"

Boyd's textbook of pathology states that, "The wise Chinese are the only Orientals who do not suffer from cholera; they use boiled water and cooked food, they drink tea and eat hot rice." We have had personal talks with Scott Nearing, who also said that cholera was virtually wiped out in China, but this is attributed to better sanitation and better diets for the Chinese and not due to the fact that everything they eat or drink is boiled or cooked. They have habits of moderation in all things and do not eat extensively of flesh foods.

It is a well-known fact that the Chinese have used human wastes for many centuries for fertilizer. They are still using this method of fertilization. It isn't the boiling or cooking of their foods that protects them; it is the fact that they have a better economy than many years ago, and their people are better fed than

previously.

Recently, in *Organic Gardening and Farming*, an article entitled "Goodbye to the Flush Toilet" pictures the use of human wastes as very ecological and necessary. It demonstrates how unclean our system of purifying water is, and how "even the most modern of sewage plants don't do a perfect job of taking that one part of human excrement out of toilet water." This dirty water, even though sterile, is sent back into the reservoirs for us to drink and wash vegetables in. It clearly shows that the disposal of body wastes is actually cleaner when done the old-fashioned way, by bacteria and filtration through soil. The article states that "clearly, the soil does a much better job of purification than any sewage plant."

The aforementioned article quotes from Dr. F. H. King's book, *Farmers of Forty Centuries*, and shows that all animal wastes are recycled by the Orientals. "Human wastes were almost the life-blood of Oriental agriculture, Dr. King found. Farmers made attractive screens near their fields so passersby would honor them by leaving behind some human fertilizer. All families saved their toilet wastes and sold them to farmers. Cities found their human wastes to be a net profit instead of a liability, as in the U.S. In 1908 Shanghai sold one Chinese contractor 78,000 tons of human waste for \$31,000 in gold."

It just goes to show you that it is not the method of fertilization that harms people. If one fears the vibrio, it may help to know that *cholera vibrio* can survive in sewage for only 24 hours and if the sewage is well composted before using it as fertilizer, there will be no live vibrios to fear.

Cholera is nothing more than a very severe diarrhea commencing high in the intestinal tract. The fluids that are lost during the diarrhea are secreted by the intestinal membranes to rid the food tube of very poisonous and irritating substances, which are *not* the vibrios. Overeating and drinking with the consequent putrefaction of proteins, producing virulent poisons high up in the small intestine are the causes of the diarrhea. It is a disease of poisoning, and because it develops high in the digestive tube, many electrolytes and fluids are lost. This is the danger. But if no food is taken when a malaise is first felt, and the body is permitted to wash the intestines free of the poison, and fear is kept from the patient, and he is freely supplied water when he is thirsty and can retain it, there will be a recovery rate much greater than now.

Graham states in his book on cholera "that the primary and paramount cause (of cholera) is always the peculiar condition of the human system resulting from the violation of the laws of organic life. Its more immediate exciting causes, however, are various; such as atmospheric changes and conditions—quality and quantity of food—excesses of every kind; but more than all, perhaps the use of artificial stimulants, and especially of the narcotic and alcoholic kinds;—in short, anything and everything that reduces the vital powers of the nerves of organic life; and brings the alimentary canal and with it the whole system into a state of extreme, morbid irritability, leaving little power in the system to sustain high irritation, and to resist and throw off things that are noxious or disturbing to it.

"It may, however, with confidence be asserted, that all the causes which obtain, beyond the control of man, would seldom or never develop this disease without the occurrence of those causes which operate through his *voluntary conduct*."

Instead of indulging in beer and wine, and much coffee and cooked food while traveling, if you do the very opposite of this ancient and harmful advice you will be more likely to have a healthy vacation.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 1. Introduction

### **1. Introduction**

Many people, at some time of their life, find themselves in the hospital. Often it is due to an accident of some sort where surgery is necessary or bones must be aligned and set. Some people find themselves being talked into entering the hospital for acute or chronic diseases. This lesson will demonstrate the dangers of hospitalization so that you may be aware and act accordingly. You will learn about various tests and surgical procedures so you will be able to determine whether you wish to undergo these rigors.

As an individual, you have certain rights and these will be enumerated. Be sure to be aware of and assert your rights. Even Hygienists may have to go to a hospital for accident treatment; this lesson will provide some practical advice.

## **2. Choosing A Hospital**

Millions of people are hospitalized each year who need no hospital care whatsoever. Many physicians now admit that at least 10 percent of hospital admissions are not necessary. We know, however, that the true statistics were actually much higher than that, more like 95%. If you feel as though you must go to the hospital, you should ask your physician the names of all hospitals where he has admitting privileges and then discuss with him the pros and cons of each. A lot of your time, energy, and money can be wasted if you let your physician "send" you to a less-than-adequate hospital. If you are not satisfied with your physician's plans for your hospital admission, you should seriously consider finding a physician at the hospital of your choice, or simply going there as a "ward" or "clinic" patient.

Once you have assured yourself about equality, you may wish to consider a hospital's efficiency; its length of stay, occupancy rate, and daily cost. If you have a choice, let's say, between two hospitals you might wish to take these "efficiency factors" into account. You might wish to choose the hospital with the lower daily rate, or length of stay.

If you have been in an accident, you will not have a chance to go through all this decision making concerning an appropriate hospital. It may be worthwhile, however, to go through these steps in the event such a decision would be necessary.

### **2.1 Your Admission**

Some hospitals, on admission, ask you to sign a blanket consent form covering many items, but these vague and indefinite forms have not held up in court. And, even if you do sign such a form, you still have the right to refute any procedure during your stay. Before each major procedure, you will also be asked to sign a specific consent form, once the procedure has been explained to you.

Some hospitals also ask you to sign a form releasing them from legal responsibility in case of negligence. This type of release has not held up in court either. If you object to signing such forms but the admitting clerk insists that you do so, keep in mind that they have not been known to be enforceable.

Most hospitals will want the following five items:

1. The social security card or number of the head of the household (that person who will have the ultimate responsibility for the bill).
2. Your insurance cards or numbers.
3. Your Medicare and/or Medicaid card.
4. Name, address, and phone number of your employer and of your spouse.
5. Name, address, and phone number of the person to notify in case of an emergency.

### **2.2 What to Bring With You**

Take the items that you would need for routine comfort: toothbrush, shaving equipment, pajamas or nightgown, robe and slippers. Optional items might include stationery and stamps, address book, needlework projects, books, etc. However, keep in mind that you should try to discharge yourself as soon as possible and it may be unnecessary to bring many such things with you. Circumstances will dictate. If you have been in a severe accident, it may be necessary to stay in the hospital for awhile. In this case, you may ask friends to bring in reading material and other needs.

### **2.3 Questions to Ask**

Don't be afraid to ask questions. Not only do you have the right to question your care; you owe it to

yourself to do so. Here are some questions you should ask:

1. What do you think is wrong with me?
2. What tests do you recommend? Is there any special preparation for any of these tests?
3. What medication do you suggest? What are their purposes? How will they be administered? How often? (As you know, we do not recommend medications, but if surgery is required for repair of bones or tissues following an accident, you may have to take certain anesthetics and drugs.)
4. Will I see the anesthesiologist before the operation? What preparations are required before surgery? After the preliminary tests are completed, you may ask:
  1. What are the test results?
  2. What did the various consultants think?
  3. Are there any changes in medications?
  4. How long a recovery period is anticipated?

## **2.4 Initial Tests**

You will be given a blood test, during which time blood will be drawn from a vein in your arm and then your blood will be subjected to a dozen or more tests for information about your kidneys, liver, and endocrine glands. Sugar and cholesterol levels will also be measured. You will have X rays if you have been in an accident. Do not allow them to take X rays every day of the same parts.

If you think that the X rays have been excessive, you may refuse further ones until you discuss this situation with your physician. You may also be given an electrocardiogram.

Once you are in your room, a nurse will appear to take what is called a nursing history. She will want to know about any previous hospitalizations and problems. She will take your blood pressure, pulse, respiration, and temperature, and ask for a urine specimen.

If it is a teaching hospital, you may be examined and questioned more than once. If this becomes unbearable, speak up and let them know that you have already been examined and do not want to be again.

## **2.5 Your Room**

The choice of a private or semiprivate room may be left up to you, but sometimes physicians recommend a private room. Some people can't bear the thought of being in a room with strangers; others enjoy the company and would not opt for a private room even if there were no cost differential. Sometimes, however, a roommate or mates can be unbearable (especially if they smoke) and make rest impossible. If that is the case, ask the nurse on the floor to have your room changed.

Most insurance policies cover, semiprivate rooms—usually two patients to a room. In most hospitals semi-private rooms are now two-patient rooms, some are four, and a few still have as many as six. If you wish to have a private room, discuss this with your physicians. If you choose a private room, you will almost surely be responsible for the difference in cost, since insurance coverage is usually limited to semiprivate facilities.

Some hospitals not only give you a choice of semi-private versus private, but also allow you to choose smoking or nonsmoking areas. You will probably not be able to choose your roommate, but if you have serious roommate problems, as mentioned above, you can switch rooms.

## **2.6 If You Want to Leave the Hospital**

What happens if you go in for a particular procedure and then change your mind? What if your doctor recommends an operation, but you decide you don't want to have it? Tell him, and ask that he discharge you. Usually he will do this willingly, but if he feels strongly about your staying put, he may be

resistant. In fact, he may refuse. In that case, you can sign yourself out. Don't be intimidated; trust your instincts and do what makes you feel most at ease.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 3. Dangers Of Hospitalization

### **3. Dangers Of Hospitalization**

Once committed to entering the hospital, you should make you your mind to stay no longer than absolutely necessary. In a recent study by the New York City Health Services Administration, some 30 percent of people hospitalized more than twenty-one days, had no valid reason for being in the hospital. Ask your doctor to estimate your discharge date.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 4. Let The People Beware

### **4. Let The People Beware**

The following are true cases (from *The Great Billion Dollar Swindle* by Dr. K. A. Laski):

1. A person is admitted for cancer surgery on the left leg and the right leg is amputated by mistake.
2. A woman admitted to a hospital for removal of a tumor in her right lung has her left lung removed by mistake. The tumor-filled lung is all she has left to breathe with.
3. A twenty-six-year-old man, about to be married, enters the hospital to have an operation on an undescended testicle. Somehow, his twenty-year-old surgeon inadvertently cuts off his penis.
4. An intensive care unit person falls out of his bed three times, striking his head each time, and afterward dies.
5. A person in intensive care is found out of his bed, not on t'he floor or in a chair, but walking aimlessly in a delirium on the hospital roof eight floors above the ground.
6. During thyroid surgery, one man's whole vagus nerve trunk is accidentally severed, leaving him with permanent paralysis of the voice box. Another man's surgeon accidentally removes all four parathyroid glands, leaving him with a lifetime of life-threatening agony.
7. A comatose diabetic is brought to the hospital emergency room. During his hospital stay, intensive treatment with insulin, intravenous fluid, electrolytes, and all medical means are expended to save the patient. He recovers and becomes fully alert; yet, a day before going home, he collapses and enters a deep coma again. The doctors are stumped. Has he had a stroke? Has he had a relapse? What on earth happened? The answer is that the nurses failed to give the patient his insulin while in the hospital for over three days.
8. The people get someone else's lab tests, someone else's X rays, someone else's surgery, someone else's baby.
9. A person enters the hospital with a bleeding stomach ulcer. The clever intern puts a tube down into the stomach, hooks it up to a vacuum pump, and proceeds to suction the patient's blood continuously, almost bleeding the man to death.
10. Intravenous solutions contain life-threatening contaminants.
11. Blood transfusions induce hepatitis.

12. Halothane anesthetics have caused massive liver destruction.

#### **4.1 To Rule Out Myocardial Infarction**

A person with chest pain, if he is over age twenty-one, can well expect to be stuck in the hospital for at least a three-day "observation period."

The vast majority of these admissions to "rule out acute M.I." (myocardial infarction or heart attack) are unnecessary. The patient goes home and is none the wiser as to why he had chest pain in the first place. The physician does not educate the patient as to how to live so heart disease will not exist.

Even in those very few patients who do get heart attacks after hospitalization to "rule out acute M.I.," there is no evidence that hospitalization is necessary in the overall picture. In Britain, people suffering from heart disease are kept at home, they are not hospitalized. The results in Britain are no different than the results in the U.S. Furthermore, the need for coronary care units is being questioned. No difference exists in mortality or morbidity rates between places where coronary care units are available and places where they are nonexistent.

A more rational care for the person who suffers from heart disease is to fast and rest. This will allow the heart tissue to heal and regenerate. Dr. Shelton has fasted many hundreds of people with heart disease with tremendous success—much more so than any hospital could claim.

#### **4.2 Coronary Care Units**

Many times the physician, to protect himself from any possible risk, will put anyone with any chest pain in the hospital—even if the person is too young for coronary disease.

Physicians dutifully put everyone they see with chest pain in these coronary care units. Of these people, perhaps one out of five have coronary problems.

As mentioned, in England, physicians do not hospitalize patients with heart disease. They send them home to rest. Statistics show no difference between survival of heart attack patients in England and the United States. And Hygienic practitioners have the best survival rate of all because they know how to "intelligently do nothing." They instruct their clients how to live so that neither heart disease nor any other disease will evolve.

#### **4.3 Intermittent Positive Pressure Breathing**

IPPB, or "intermittent positive pressure breathing," is a disputed form of medical treatment that costs the U.S. public a total of \$1.5 billion yearly. Consisting of forced inhalations of air, or air plus a little salt water, given briefly every three hours or so, IPPB is one of the biggest money-makers hospitals have. Costing the patient a hundred dollars or so daily, these IPPB respiratory treatments markedly raise a patient's hospital bills and are one of the major causes for the rise in hospital charges during the past several years.

Yet, occasional deaths have occurred from these treatments. Approximately 50 percent of all pulmonary specialists insist the treatment is useless.

The fact that the individual can still breathe in between IPPB treatments means he never needed the treatment in the first place. A great number of physicians concede this but go right on ordering IPPB anyway. Remember, you have the right to refuse any treatment. You do not have to accept worthless and costly therapies.

#### **4.4 Medical Errors**

Dr. Arthus Levin cites a story concerning hospital errors (*Talk Back to Your Doctor*, New York:

Doubleday & Company, Inc. 1975):

"There is an old story doctors at the prestigious Massachusetts General Hospital used to tell. It seems a little old man walked into the MGH outpatient clinic one day to get a new pair of eyeglasses. By mistake someone directed him to the gastrointestinal clinic. Once there he got into the wrong line. Before he knew it, he found himself on his hands and knees on an examining table, having a sigmoidoscopic exam. During the procedure, the instrument accidentally perforated his bowel. The unlucky fellow was admitted to the hospital, where he underwent surgery to repair his torn bowel, developed peritonitis, and died."

Duncan Neuhauser, a hospital expert now at Harvard, studied thirty Chicago hospitals. He found that some had death rates three times as great as others. Neuhauser estimated that overall, hospital death rates could be lowered by 50 percent.

The National Commission on Medical Malpractice found that nearly 8 percent of hospital patients were the victims of medical errors which made their conditions worse. A larger number, presumably, were victims of errors which—fortunately—did not worsen their health status. At least their health was not immediately noticeably impaired but such treatment can only result in a lowered degree of health. Remember, only the body can heal and any interference will hinder healing and repair.

Medical errors occur frequently. (We condemn all drugs and the reasons were outlined in earlier lessons.) Medication errors occur in all hospitals when people (a) receive the wrong medicine, or (b) the "correct" medicine in an incorrect dose or form, or by the wrong route of administration. These errors make the poisonous effects even worse.

Milton Silverman and Dr. Philip R. Lee, in their book *Pills, Profits, and Politics*, assert that "from two to eight percent of all drugs doses given in hospitals are in error— wrong drug, wrong dose, wrong route of administration, wrong patient."

Medication errors happen for many reasons. The physician makes an error when writing in the "order book." A nurse makes an error when copying the doctor's order from the book into her card file. Or the nurse doing out cups of "medicine" simply gives you someone else's cup. However, any medicine is wrong and what is poisonous for one person is poisonous for another. But the fact remains that certain drugs are more toxic to certain individuals due to their particular state of health at that time.

If you elect to accept the medication your physician has prescribed for you, you should know what it looks like. If a nurse gives you a new medication, you should make sure your doctor's orders have changed (ask her to check the order book). As I stated earlier, drugs are not indicated in disease, but in case of accidents, it may be necessary to accept some, especially if surgery is required for repair.

Dr. Levin cites another case where medication was given in error. "A male construction worker was injured when a nail pierced his right leg and fractured his fibula. On being taken to a hospital, he informed the medical student who took his history that he was allergic to penicillin. This information was passed along to the nurse anesthetist. There was, however, a question as to whether the information concerning his allergy was given to the resident who performed the surgery, and who wrote the postoperative orders. The information was not given to the staff surgeon who was in charge of the resident's activities. The construction worker was given large doses of penicillin postoperatively. He suffered a cerebrovascular accident (stroke) followed by severe physical and personality changes."

This case shows how dangerous drugs are and how crucial facts can get "lost in the shuffle" among the hospital hierarchy. You should be aware that this can happen. You should never assume that what you tell one physician will be communicated to all your physicians. It may be tiresome repeating the same story three or four times, but he assured that it is necessary.

## **4.5 X Rays**

The U.S. Food and Drug Administration estimates that Americans spend \$6.3 billion annually for

diagnostic X rays, most of which are totally unnecessary.

These X rays (exposure may induce cancer) result in profits to hospitals and doctors and may be ordered just to help a doctor protect himself from charges of inadequate work-up in a malpractice case. Here is "defensive medicine" practiced by physicians, for physicians, with total disregard for the safety and pocketbook of the patient, whom the physician fears as a potential malpractice threat. You have the right to refuse to be x-rayed. Defend your rights!

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 5. Health Advocate

## 5. Health Advocate

A health advocate is someone who can represent your interests in dealing with physicians and other health personnel. The job of a health advocate is to make sure you are getting proper care and attention.

Anyone who enters a hospital, or other health care institution, ought to consider having a health advocate. The advocate's sole function is to represent your interests—regardless of what they may be—when you are not totally able to do so yourself.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 6. Your Rights

## 6. Your Rights

When in the hospital, you have the right to:

1. see your hospital record;
2. refuse to be examined by a medical student;
3. refuse a diagnostic test or procedure;
4. refuse treatment;
5. demand that your records be kept a secret;
6. leave the hospital at any time.

Informed consent is one of your most important rights as an individual. This means that, before any procedure or treatment, your physician must inform you of its risks and consequences. He must, after this explanation, have you sign a consent form.

You should not feel obliged to sign a consent form even if you are satisfied that you have been fully informed concerning the procedure or treatment in question.

Do not sign a blank consent form. Do not let the physician convince you to sign a blank form, saying, "I'll fill in the procedure later." Or, "We're not sure exactly what the surgery will be at this time."

Below are your "Bill of Rights" as outlined by the American Hospital Association:

1. You have the right to considerate and respectful care.
2. You have the right to obtain from the physician complete current information concerning his diagnosis, treatment, and prognosis in terms the patient can be reasonably expected to

understand. When it is not medically advisable to give such information to the patient, the information should be made available to an appropriate person in his behalf. He has the right to know by name the physician responsible for coordinating his care.

3. You have the right to receive from the physician information necessary to give informed consent prior to the start of any procedure and/or treatment. Except in emergencies, such information for informed consent should include but not necessarily be limited to the specific procedure and/or treatment, the medically-significant risks involved, and the probable duration of incapacitation. Where medically-significant alternatives for care or treatment exist, or when the patient requests information concerning medical alternatives, the patient has the right to such information. The patient also has the right to know the name of the person responsible for the procedures and/or treatment.
4. You have the right to refuse treatment.
5. You have the right to every consideration of your privacy concerning your own medical care program. Case discussion, consultation, examination, and treatment are confidential and should be conducted discreetly. Those not directly involved in your care must have the permission of the patient to be present.
6. You have the right to expect that all communications and records pertaining to your care should be treated as confidential.
7. You have the right to expect that within its capacity a hospital must make reasonable response to the request of a patient for services. The hospital must provide evaluation, service, and/or referral as indicated by the the urgency of the case. When medically permissible, a patient may be transferred to another facility only after he has received complete information and explanation concerning the needs for and alternatives to such a transfer. The institution to which the patient is to be transferred must first have accepted the patient for transfer.
8. You have the right to obtain information as to any relationship of his hospital to other health care and educational institutions insofar as his care is concerned. The patient has the right to obtain information as to the existence of any professional relationships among individuals, by name, who are treating him.
9. You have the right to be advised if the hospital proposes to engage in or perform human experimentation affecting his care or treatment. The patient has the right to refuse to participate in such research projects.
10. You have the right to expect reasonable continuity of care. He has the right to know in advance what appointment times and physicians are available and where. The patient has the right to expect that the hospital will provide a mechanism whereby he is informed by his physician or a delegate of the physician of the patient's continuing health-care requirements following discharge.
11. You have the right to examine and receive an explanation of your bill regardless of sources of payment.
12. You have the right to know what hospital rules and regulations apply to his conduct as a patient.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 7. Abbreviations

## 7. Abbreviations

While you are in the hospital, you will see various instructions concerning your care that are written in a type of code that would be impossible for you to decipher if you did not know what some of their abbreviations meant. Below are the most common abbreviations used in most hospitals.:

a - before  
a.c. - before meals  
ADL - activities of daily living  
ad lib - as desired  
AMA - against medical advice  
ASA - acetylsalicylic acid (aspirin)  
ASHD - arteriosclerotic heart disease  
b.i.d. - twice a day  
BP - blood pressure  
BPH - benign prostrate hypertrophy (enlargement)  
BRP - bathroom privileges  
Bx - biopsy  
c - with  
CA - cancer  
CAD - coronary artery disease  
CBC - complete blood count  
CBD - common bile duct  
CC - chief complaint  
CCU - coronary care unit  
CHD - coronary heart disease  
CHF - congestive heart failure  
chol. - cholesterol  
CNS - central nervous system  
COPD - chronic obstructive pulmonary disease  
CSF - cerebrospinal fluid  
CVA - cerebrovascular accident  
CVP - central venous pressure  
CXR - chest X ray  
D & C - dilation and curettage  
DM - diabetes mellitus  
D/W - dextrose in water  
Dx - diagnosis  
ECG or EKG - electrocardiogram  
EEG - electroencephalogram  
ER - emergency room  
FBS - fasting blood sugar  
FH - family history  
Fx - fracture  
GB-gallbladder  
GI - gastrointestinal  
GTT - glucose tolerance test  
GU -genitourinary  
Hgb - hemoglobin  
HPI - history of present illness  
h.s. - at bedtime—literally, hour of sleep  
Hx - history  
ICU - intensive care unit  
I & D - incision and drainage  
IM - intramuscular  
I & O - intake and output  
IPPB - intermittent positive pressure breathing  
IV - intravenous

IVP - intravenous pyelogram  
KUB - kidneys, ureters, bladder  
l - left  
LLE - left lower extremity  
LMP - last menstrual period  
L.P - lumbar puncture  
LUE - left upper extremity  
m- murmur  
MI - myocardial infarction (heart attack)  
N-G - nasogastric  
N & V - nausea and vomiting  
NPO - nothing by mouth (non per os)  
NSR - normal sinus rhythm (heart rate)  
o - none  
OOB - out of bed  
OPD - outpatient department  
OR - operating room  
OT - occupational therapy  
p - after  
p.c. - after meals  
P.E. - physical examination or pulmonary embolus  
PI - present illness  
p.o. - (by mouth (per os)  
p.r. - rectally  
p.r.n. - as often as necessary  
pro time - prothrombin time  
pt - patient  
P.T. - physical therapy  
PTA - prior to admission  
Px - prognosis  
q - every  
q.h.-every hour  
q.i.d. - four times a day  
q.o.d. - every other day  
q2h - every two hours  
q4h - every four hours  
q.n. - every night  
q.s. - quantity sufficient  
R - right  
RBC - red blood cell  
rbc - red blood cell  
RHD - rheumatic heart disease  
RN - registered nurse  
ROM - range of motion  
RT - radiation therapy  
Rt - right  
RUQ - right upper quadrant (abdomen)  
Rx - therapy or treatment  
s - without  
s.c. - subcutaneous  
SH - social history  
S1CU - shortness of breath

s.o.s. - may be repeated once if urgently required

S & S - signs and symptoms

stat. - immediately and once only

Sx - symptoms

T & A - tonsillectomy and adenoidectomy

TIA - transient ischemic attack

t.i.d. - three times a day

TRP - temperature, pulse, respiration

TUR - transurethral resection

TURP - transurethral resection of the prostate

Tx - treatment

URI - upper respiratory infection

UTI - urinary tract infection

VS - vital signs

WBC - white blood count

wbc - white blood count

y.o. - year old

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 8. Nursing Care

## 8. Nursing Care

Nursing care is a big part of hospital life. People often feel helpless when faced with rude, incompetent nurses. What can you do if you have the bad luck to encounter a nurse or an aide who is not giving you reasonable care; who is making you wait, for instance, half an hour for a bedpan even though she's not doing anything else? You (or if you are not up to it, your family or friends) should tell the head nurse. In her absence, ask for the nurse in charge. If this does not solve your problems, you can contact the nursing supervisor who is responsible for that unit. If none of these people can resolve your problem, go up the chain of command, which ends with the director of nursing, who is ultimately responsible for all nursing care in that institution.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 9. Food

## 9. Food

You may try to request from the dietary department only fresh fruits and uncooked vegetables. Most, often, however, these foods will not be available in the quantity or quality that you require. You may, then, have food brought in from the outside.

Ask family and friends to bring in your fresh fruits, vegetables, nuts, dried fruits, etc. This is the best way, and probably the only way, that you will be able to obtain good food. As a general rule, do not accept any of the hospital fare. Even their fruit juices should be regarded with suspicion. Most often it is not real fruit juice but a fruit-flavored drink with sugar and other chemicals added. Rely on your outside

sources.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 10. Drugs

## 10. Drugs

No matter what the reason for your hospitalization, chances are you will encounter some kinds of drugs. Sleeping pills are routinely offered on the assumption that you aren't feeling well or you wouldn't be in the hospital in the first place, and that since you are not in your own bed in your own home, you may have difficulty falling asleep. However, no one can force you to take these pills. Simply tell the nurse that you do not want them.

Pain relievers are also given routinely after operations, even minor ones. Again, you have the right to refuse these medications if you feel that they are unnecessary.

There are drugs that result in the depletion of your body's supply of certain chemicals. Diuretics, for one, can cause you to lose a significant amount of potassium. Your doctor may prescribe another drug containing potassium to replace what is lost. However, this inorganic form of potassium is not utilized by the body. Tell your doctor that you prefer to obtain your minerals from the food that you eat. Potassium, for example, is found in large quantities in fine foods such as bananas, apricots, and raisins.

Drugs are administered orally (pills, tablets, or liquids); by injection (intramuscularly or intravenously); or rectally in the form of suppositories. Be firm! Do not let the physicians or nurses talk you into taking drugs that you do not want.

### 10.1 Pills

If you must take pills before surgery or to alleviate excruciating pain from an accident, you must make sure that what the nurse hands you is truly yours. This is what should happen: the nurse who brings the medication should check the nameplate on your bed, ask you your name, check the medicine card against your ID bracelet, and then—and only then—hand you your medication. If she doesn't follow all these steps, let her know who you are before you take the medicine.

Learn what your medication looks like. Most physicians do not change medication without telling their patients. If you have been taking big red pills, and suddenly you are given some small yellow ones, ask the nurse, "How come?" But any drug should not be taken if you can bear the pain without them. The body will heal better without the drug. Using up vital energy expelling drugs will interfere with and delay healing and repair. Your individual situation will dictate what is best.

### 10.2 IV (Intravenous)

IVs are often used routinely as a matter of course. They are almost never needed. You have the right to refuse this unpleasant treatment and I would recommend that you do so.

The IV is usually inserted into a vein in your hand or arm. A tourniquet is first applied to make the vein stand out, and a needle or thin plastic tube is then inserted into the vein. This, in turn, is attached to a bottle which hangs from a pole above your bed or chair. The bottle is kept high so that gravity will keep the solution flowing. It will be kept running all the time with a glucose/saline/water/potassium solution. Other drugs may be added to it.

Sometimes the needle gets dislodged from the vein, and the solution goes into the surrounding tissue.

This is called infiltrating, and your arm or hand will swell. Tell the nurse at once if this should happen. The IV should be stopped and the needle removed. IVs are inherently wrong but may be necessary if you cannot take water any other way.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 11. Tests To Accept Or Reject

## 11. Tests To Accept Or Reject

Many tests require that you sign a consent form. You have the right to understand exactly what a test will entail; how it will feel; what the risks are; and what it will contribute to the physician's knowledge of your condition. Be sure you understand how much you have consented to. Don't agree to anything until you are satisfied on all these scores. Don't be ashamed to ask for a second explanation if the first isn't clear. Don't hesitate to make notes of what to ask and of the answers.

**Angiogram** - This test is performed to get x-ray views of various arteries in order to gain information about those arteries as well as about the organs they supply. For example, areas of bleeding or clotting and any abnormal pathways would be evident. Angiograms can be done of the legs (using the femoral artery), of the kidneys, pancreas, spleen, liver, GI tract, brain, and heart.

The Hygienic approach is to fast all individuals who have any blood clots, clogged arteries, etc., no matter where they are located. During the fast, the body will remove clots and heal those areas that need it. It does no good to locate those areas on X rays when the X rays do harm in themselves.

**Barium Enema** - Used to get an x-ray view of the large intestine. This test is totally unnecessary and enervating to the sick individual. Placed on a Hygienic regime, the bowels will heal and normal function will be restored. **Barium Swallow (Esophagogram)** - This test is used to get an x-ray view of the esophagus. The test may be necessary-only if a mechanical obstruction is suspected. Otherwise, reject this test.

**Bone Marrow Aspiration** - This test is used to withdraw, through a needle, a small amount of bone marrow, which will then be examined under a microscope. Examination of the bone marrow can reveal information about the production of blood cells.

The bone marrow is an important organ for the production of blood cells but this test will not lead to positive results or correction of the problem. The body itself must initiate this production and will do so when and only when the conditions for health are provided. Here again, fasting and the Hygienic program will lead to a normal blood cell count. The test is useless.

**Bronchogram** - This test is used to get an x-ray view of the bronchial tree. A useless and dangerous test—reject it.

**Bronchoscopy** - This test is used to look into the bronchial tubes of the respiratory tract leading to the lungs. This test is not as dangerous as the bronchogram but it is just as useless.

**Cardiac Catheterization** - This test is used to explore the heart's structures, to measure blood pressure and blood gas levels in the heart chambers and associated blood vessels. When the coronary arteries are being studied, the test is called coronary arteriography; when the chambers are studied, the test is called angiocardiology.

Blood pressure can be taken in a much safer and more pleasant manner and if necessary blood tests may be performed without cardiac catheterization. For the person who is living healthfully, this test is unnecessary. Any individual who is willing to begin a more healthful regime, this test is equally

unnecessary for.

**Cholecystogram** - This test is used to get an x-ray view of the gallbladder.

**Cisternal Puncture** - This test is used to obtain a specimen of spinal fluid from the back of the neck in order to gain information about the nervous system (brain and spinal cord). A dangerous procedure that is unnecessary.

**Colonoscopy** - This test is used to examine the upper portion of the colon; to remove polyps; or to perform a biopsy. Reject this test. Removing polyps will not create health. The cause of the formation of the polyps must be removed and only then may health be realized. Likewise, biopsies are unnecessary.

**Computerized Axial Tomography** - To see and localize any abnormalities in the head. Highly-detailed, cross-section, three-dimensional pictures are produced which, because they are of thin slices, or cross sections, establish more precisely than conventional X rays and depth of any abnormality. This test may be necessary following severe injury to the head where surgery may be needed.

**Cystometry** - This test is used to measure the amount of pressure in the bladder and its reaction to hot and cold, and to evaluate the functioning of the nerves supplying it. This is an unnecessary test that is very enervating to the body. The Hygienist has no need for such tests.

**Cystourethrogram, Voiding** - (Also known as voiding urethrogram) - This test is used to view, by X ray, the lower portion of the urinary tract (bladder and urethra) during urination. A useless and dangerous test.

**Electroencephalogram (EEG)** - This test is used to record the electrical activity of various parts of the brain to see if it falls within the normal range. Abnormal electrical patterns are subject to further tests. Everyone's brain gives off minute amounts of electricity. Sometimes a sleep EEG is done, which simply means you are asleep when the recording is done rather than lying awake trying to think pleasant thoughts. This test is unnecessary and meaningless though not dangerous. It is based on a normal range that is derived from people who may be far from normal in their way of living and general health. Do not think that you must submit yourself to this enervating test.

**Electrocytography (EMG)** - This test is used to evaluate the function of nerves and muscles. This test may be rejected as unnecessary.

**Fluorescein Angiogram** (Also known as retinal angiogram) - Used to get information about the blood vessels of the eye. An unnecessary test for the Hygienist. **Gastric Analysis** - Used to analyze a sample of the contents of your stomach, more frequently to check the amount of acid present. This test is totally unnecessary and should be rejected.

**Hysterosalpinography** - (Also known as uterus and fallopian tube test) - Used to examine the uterus and fallopian tubes when there has been an inability to conceive. This is a worthless test. Adherence to a more healthful lifestyle will often resolve problems in conception.

**Intravenous Pyelogram (IVPJ)** - Used to get x-ray views of the kidneys, ureters, and bladder. The only time that this test may possibly be needed is in the case of a severe accident where kidney damage is suspected.

**Knee Arthrogram** - The test is used to get x-ray views of the inside of the knee joint. It is unnecessary except in the case of severe injury and even then it is doubtful.

**Laryngoscopy** - This test is used to examine the larynx (voice box) in order to take a biopsy or to remove a growth. Here physicians are working on symptoms and not causes. The Hygienist should reject this test.

**Liver Biopsy** - This test is used to get a small specimen of liver tissue for examination. A dangerous and unnecessary test.

**Lymphogram** (Also called lymphangiogram) - X-ray examination of the lymph channels and nodes. It

is unnecessary to submit yourself to this test.

**Mammography** - This test is used to get x-ray views of the breasts to detect tumors. This will only give the physician an excuse for operating. Tumors usually autolyze during the fast and this is a much safer way to correct this problem.

**Myelogram** - This test is used to get x-ray views of the spinal canal, the area that surrounds your spinal cord. Abnormalities of the contour of the spinal cord or a protruding disc would show up. It has been clinically proven that healing takes place in the case of a ruptured disc more rapidly if nothing is done and the individual stays in bed and rests. All hospital treatments are worthless in these cases and often delay recovery.

**Oscopies** - In any test the suffix oscopy means "looking into." Another term you may hear is endoscopy; it means the same thing. The rest of the word will tell you what organ or part of the body is being studied. For example, esophagoscopy means, literally, looking into the esophagus; bronchoscopy means looking into the bronchial tubes, and so on. Sometimes, besides looking at an organ, the physician may take a specimen for further examination. This is called a biopsy.

**Pneumoencephalogram** - To view, by X ray, the ventricles of the brain where cerebrospinal fluid circulates. The test can show if any brain substance has been lost, if there are growths, or if the passage of cerebrospinal fluid has been blocked. The only time that this test may possibly be indicated is injury to the head.

**Proctosigmoidoscopy, Proctoscopy, Anoscopy** - This test is used to examine the lower part of the colon (large intestine), to remove polyps, or to perform a biopsy. The difference between sigmoidoscopy, proctoscopy and anoscopy is the length of the instrument and the amount of the intestine that can be seen. Observing the lower part of the sigmoid colon is the highest point of the exam; this is called sigmoidoscopy. Proctoscopy is an examination of the rectum just below the sigmoid, and anoscopy is an examination of the anus. It is unnecessary to submit yourself to these unpleasant probings. They irritate the lining of the intestine and no benefits ever result.

**Renal Biopsy** - This test is used to take a minute sample of renal tissue for study. It is a dangerous and unnecessary test—reject it.

**Scanning** - This test is used to evaluate the structure and function of various organs, including brain, bone, lung, thyroid, liver, kidney, spleen, pancreas. This test would only be indicated if damage to these organs is suspected following an accident.

**Spinal Tap** (Also called a lumbar puncture) - This test is used to obtain spinal fluid for examination which will provide information about the nervous system (brain and spinal cord). It is also done to inject drugs or anesthetic. Damage can occur when needles are inserted into the spine for any reason. Do not accept this dangerous procedure. Only adverse results can be expected.

**Stress Test** - This test is used to see how the heart reacts to exercise. It provides more information than a resting EKG. While not particularly harmful, this test is certainly unnecessary.

**Thoracentesis (Also known as pleural tap)** - This test is used to remove fluid from the space surrounding the lungs just inside the chest wall, called the pleural space. This procedure is based on the theory of removing symptoms to "cure" disease. It just doesn't work that way. Causes must be removed and this fact makes this test worthless. It is harmful as well.

**Ultrasonography** - Ultrasonography uses a very high frequency, inaudible sound wave directed into the body at a specific point. The sound waves are generated by an ultrasonic transducer, a device something like a microphone, which is passed over the area under study. When the sound wave passes through the junction of two types of tissue with differing densities, an echo is produced. The echoes bounding off are converted into a visual pattern on a machine and evaluated by your physician. Ultrasonography is used to gather information about soft tissues, such as kidneys, thyroid, heart, female reproductive organs (particularly for pregnant women), spleen, pancreas, gallbladder, lymph nodes, and aorta.

One major objection to the use of such devices is that the ultrasound waves may cause damage to bones and tissues if used improperly—especially if the frequencies are set too high. I would not take the chance of irreparable damage, especially since the value of this testing in the first place is questionable.

**Upper GI Endoscopy** (Includes esophagoscopy)—looking at the esophagus; gastroscopy—looking at the stomach; duodenoscopy—looking at the duodenum) - This test is used to see the esophagus, stomach, and/or duodenum, or to get a tissue sample for a biopsy. It is unnecessary to submit yourself to such probing. It is likely to cause damage and there is no valid reason for it. The gastrointestinal tract will quickly heal itself when given a total rest.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 12. Chemical Feedings

## 12. Chemical Feedings

You will find that physicians at the hospital have the idea that you must be fed following an operation to "keep up your strength" for healing to commence. Actually, the opposite is correct. All feedings take strength and energy away from the healing process. One would surely recover quickly if allowed to fast for a few days. Hunger will return when the body is ready to accept and digest food.

### 12.1 IVs

One of the most common methods of chemical feedings is through IVs. As described earlier, these are tubes connected to a bottle. The tubes are inserted into a vein and the liquid chemicals are allowed to flow into your vein. Physicians advocate these feedings to be sure that you "do not become dehydrated" and also to supply electrolytes, vitamins, and calories. There are several different kinds of IV solutions and they are supposed to each be suited to individual needs.

The body, however, is not equipped to handle inorganic chemicals. The body detects these substances as poisons and attempts to rid itself of them as best as it can under this stressful condition. Certainly much more harm than good is done by administering IVs.

### 12.2 Hyperalimentation

Hyperalimentation, too, is done intravenously, but into the large vein entering your heart, the superior vena cava, which can dilute the material as it flows into your bloodstream. Because it bypasses the digestive system, this method of feeding is sometimes called total parenteral nutrition (TPN). It is most often used for patients whose intestines cannot absorb nutrients, need a rest, or have been removed. However, if the intestines need a rest, a more sensible approach would be to fast and not subject the body to chemical substances that it cannot utilize anyway.

The solution includes sugar, protein, fat, electrolytes, and vitamins—all inorganic damaging substances. As many as two thousand calories a day can be administered this way. Most often a person stays on hyperalimentation for a minimum of ten days but usually closer to twenty days or more.

Another form of hyperalimentation, less frequently used, is enteral hyperalimentation, in which a special diet is introduced directly into the small intestine. This might be done if for some reason you cannot chew or swallow or if there is a problem with your stomach. It will probably be started right in your room. A thin tube is inserted through your nose and passed into your small intestine. The tube is then connected to a pump which provides high-caloric, high-protein feedings continuously.

It has been proven that high-protein feedings are harmful for relatively healthy individuals. How much more harmful could it be for the sick and weakened person. Do not think that you have to submit to such feedings. Simply tell the hospital staff that you refuse such feedings. They cannot force you to accept any treatment against your will.

### **12.3 Tube Feedings**

If there is some problem with your throat or esophagus, or if you are unconscious, you may get nasogastric feedings. In this case a tube is inserted via the nose directly into your stomach. A diet of pureed or blenderized food is introduced.

Gastrostomy feedings are a way of providing nourishment by surgically creating an opening directly into the stomach through the abdomen. This might be done if, again, the esophagus is obstructed, or if for some reason you cannot swallow. The tube, which is inserted into the stomach, is clamped except during feedings, when a blenderized preparation, warmed to body temperature, is introduced.

Again, you have the right to reject any treatment and this includes tube feedings. You may find resistance but they cannot deny your rights.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 13. Surgery

## **13. Surgery**

Operation rates in this country are double those in England and Wales. If you are hospitalized, the chances you will wind up on the operating table are fifty-fifty (nearly twice as high as in Sweden).

Many physicians look upon surgeons as the only members of their profession who can actually "cure" their patients. More surgery, they feel, means less disease and fewer deaths.

"More surgery," asserts Dr. John Bunker, "means more deaths." Bunker is a Harvard professor and has spent more time studying surgery and surgeons than probably anyone else. Those locales, he points out, where operation rates are highest, also have higher death rates. Indeed, Bunker points out that death rates in the United States are much higher—under age sixty-five—than in most other developed nations. He raises the possibility that these excess deaths may be due to our national love for surgery.

### **13.1 Risks of Surgery**

All surgery carries some element of risk. A so-called "routine" D and C can result in a postoperative uterine inflammation and impairment. The surgeon doing a tonsilectomy may accidentally perforate the internal carotid artery and be faced with a rapidly extinguishing patient.

Below are some of the most common causes of death during and immediately after surgery:

1. Uncontrolled hemorrhage
2. Inflammation and tissue damage
3. Metabolic disorders (abnormal blood sodium, potassium, sugar, etc.)
4. Body temperature disorders
5. Embolism

The most overdone operations include:

- Hemorrhoid repair (hemorrhoidectomy)

- Tonsillectomy (with or without adenoidectomy)
- D and C (dilation and curettage of uterus)
- Hysterectomy (removal of uterus and, usually, ovaries)
- Thyroidectomy
- Varicose vein removal
- Radical mastectomy (removal of breast and surrounding tissue)

You should not go to a general surgeon (or a surgical specialist) for your primary medical care if you feel that you must see a physician. Surgeons tend to have a way of finding things which require surgery. (It is probably no accident that doctors in general, who have the most contact with surgeons, also undergo the most surgery!) On the other hand, "medical men" (internists, family practice specialists, pediatricians, etc.) tend to try to avoid surgery, if possible.

In general, the risk of surgery is less if general anesthesia can be avoided. Many surgical procedures usually done under general anesthesia can be done under another type. You should seriously investigate these other types of anesthesia, in order to lessen the risk of surgery.

You should make certain that your anesthesia will be done by a board-certified anesthesiologist. An anesthesiologist is a doctor who is a specialist in anesthesia. It is his or her job (usually with the surgeon) to select the most appropriate type of anesthesia to be used. During surgery he is also responsible for maintaining all the body's vital functions. In the United States, less than half of all anesthesia is administered by a physician anesthesiologist.

### **13.2 Nausea and Vomiting**

Nausea and vomiting are occasional aftermaths of surgery. General anesthesia may, at times, result in transient stomach upsets. Other causes may be related to the operation itself (if it is an abdominal procedure, for example) and reactions to certain medications. The best solution is to fast until hunger returns and nausea is no longer present.

In some cases a specific cause can be found and eliminated. This is particularly true when a drug is the offender. If you find that after receiving your pain medication, you become nauseated, tell your doctor or simply refuse that medication.

### **13.3 Appetite**

Even those who don't develop actual nausea and vomiting postoperatively may not feel like eating for a few days. A surgical experience dampens the appetite. Here, again, fasting is essential until hunger returns.

The following is the nonsense advice given by Drs. Ronald Gotts and Arthur Kaufman (*The People's Hospital Book*). It exemplifies the approach taken by most hospitals and physicians.

"If you have no dietary restrictions, a favorite delicacy—an ice cream sundae, a milkshake, pizza, or escargots—brought in by a friend or relative may revitalize a temporary sluggish appetite. Another remedy for that no-taste-for-food feeling is a little wine or cocktail before dinner. Many hospitals have wine or hard liquor available. They can be ordered by the physician as a predinner appetite stimulant or a bedtime sedative."

They are advocating the same foods and poisons that resulted in sickness in the first place. It is pure nonsense and demonstrates that any dietary advice given by hospital physicians is best ignored. Either fast or have someone bring in your fruits and vegetables.

## 13.4 Most Common Operations—Are They Necessary?

**Appendectomy** - This operation is performed if your appendix becomes inflamed. Appendicitis was a condition unknown to medicine even in the late 1890s. Diagnosed then as "indigestion," "typhilitis," and "bowel obstruction," some patients died, most likely from heroic drugging. Yet many seemed to survive and do remarkably well without the surgeon's interference.

As many as one-third of the appendices removed today are not inflamed at all. Many of the remainder are inflamed due to improper dietary habits. All would recover if allowed to rest and fast. Appendicitis is not a death-threatening situation.

**Breast Surgery** - If there is a lump in the breast, most physicians feel that the lump must come out to see if it is malignant. They state that the removal of even benign lumps is considered the most prudent approach, because there is some uncertainty about whether or not benign tumors can become malignant. Don't let anyone talk you 'into this surgery. Many thousands of people have had tumors autolyzed during a fast or by merely following a more healthful lifestyle.

**Cataract Extraction** - A cataract operation is performed if the lens of your eye has become opaque, causing a clouding of vision. A cataract is not a growth or a tumor, but the result of a chemical change in the protein of the lens that prevents light rays from passing through. Cataract surgery is the most common eye operation in the U.S.; some three hundred thousand are performed each year. It involves removal of the lens.

The condition of the eyes reflect the health of the entire organism. Merely removing the cataract will not produce health—you are just removing one result of ill health. On the other hand, a healthy lifestyle will produce clear, healthy eyes.

**Cholecystectomy** (Removal of the gallbladder) - If, by some unlucky chance, your indigestion, ulcer pain, or bowel complaint happens to coincide with a moment when Doc is in an X-ray-happy mood, you just may get a gallbladder X ray. And if you are in that 33 percent of adults who happen to have a gallbladder stone—which may just be there minding its very own business—off you go to surgery.

The gallbladder performs a useful function, and one's digestive function is never up to par after the operation.

There is a very interesting name for the incision often used in the performance of this little operation. It is a modest little name for a not-so-modest incision. It is, in fact, based on a particularly violent and fatal mutilation popularized in World War II. It is the descriptive image of how the gallbladder operation is begun. It is called the "hara-Kiri" incision.

**D & C** (Dilation or dilation and curettage) - This operation is performed if you have abnormally heavy bleeding in the uterus; to obtain a tissue specimen for examination, to treat an incomplete abortion or miscarriage, or to terminate a pregnancy.

Do not think that this operation is perfectly safe because it is not. Tissue damage can be done due to this totally unnecessary operation. Any abnormality such as heavy bleeding will be corrected by the body when a healthful regime is begun.

**Gastrointestinal Surgery** (Including gastric resection, intestinal resection, colostomy, ileostomy, and continent ileostomy) - This operation is done for ulcers, tumors, inflammatory diseases of the intestine, or diverticulitis—all of which may be causing pain, bleeding, obstruction or perforation. The only valid reason why this operation should be performed is if there is a mechanical obstruction or for tissue repair following an accident.

Invariably when this operation is performed for the first reasons given, at some point a tube is inserted through your nose and down your esophagus into your stomach or small intestine. These tubes are used for feeding, for administering drugs, and for removing fluid and gas from the stomach or intestines, as well as for obtaining specimens for study. The tube will be an nasogastric tube if it is to reach your

stomach, an intestinal tube if it is to reach your small intestine. The tube is taped in place at your nose or forehead. As it is inserted, you are supposed to help it down by a couple of swallows or a few sips of water through a straw. The intestinal tube has a weight at the end, usually a small, soft plastic bag weighted with mercury, which allows peristalsis, the natural movement of your intestines to carry it along, just as it would carry food.

If the tube is being used for suctioning out fluid and gas, it will be attached to a gentle suction pump, which works intermittently. When it is working, a light goes on.

No one should have to submit themselves to this torture-some treatment.

**Gastrectomy** - This mutilating stomach cutting never was constructive. Instead of telling the patient how to live more healthfully, they simply cut out the stomach.

They sever the vagus nerve to the stomach, the patient not knowing that the nerve almost always grows back. They connect the stomach to the bowel and thereby trade ulcer symptoms for worse symptoms called "dumping syndrome." They cut, stitch, anastomose, sever, remove, and generally make the ulcer patient a lifetime digestive cripple.

**Intestinal Resection** - This operation is performed to remove tumors or portions of the intestine with diverticuli or inflammatory disease. After the affected portion has been removed and the two parts of your intestine are reconnected, a colostomy may be done. It is done temporarily, to allow the intestine to heal and reconnect it in a second operation, or it may be permanent.

If your intestine is inflamed or if you have diverticuli or tumors, the body can and will heal if the causes of disease are removed and a rest is taken. This mutilating operation is unnecessary and will never provide health. Too many of these operations are performed daily, giving the sick individual false hopes of recovery.

**Ileosiomy** - If the colon is diseased, the entire colon and rectum will be removed, and from then on, waste will drain through an artificially-created opening on the abdomen into a plastic pouch.

This operation makes cripples out of hundreds of people every year. It is based on the false idea that if the diseased portion of the body is cut out, then total health will result. This is entirely absurd. Total health only comes from total healthful living. When the Laws of Life are obeyed, all organs of the body will function perfectly, including the bowels.

**Coronary Artery Bypass** - This operation is performed if one or more of the coronary arteries (the vessels supplying the heart) have become clogged by atherosclerosis. The most common conditions for which this operation is done are angina pectoris (severe chest pain) and severe disease of the left main coronary artery. The operation involves using grafts from a leg vein to create new routes around the arteries (hence the term bypass) so that blood can travel freely to the heart muscle. Sometimes the mammary artery is used to create the new route.

First done 14 years ago, it is a controversial procedure today. While there is no question that it relieves the immediate symptoms, it has not yet been conclusively proven that it prolongs life.

**Hemorrhoidectomy** (Removal of hemorrhoids) - This common operation is performed for painful or bleeding hemorrhoids (varicose veins of the rectum). When they are inside the anal sphincter, they are called internal; when outside, external. Internal hemorrhoids frequently prolapse through the anal sphincter and cause pain. If the blood within them clots, they are said to be thrombosed.

Pain, anesthesia, risk of surgery, inflammation, time lost from work, the expense are all consequences of this needless surgery. Most often, the hemorrhoids return because the cause for them has not been removed.

**Hernia Repair** (Called herniorrhaphy) - Performed to repair a weakened muscle through which an abdominal organ, usually the intestine, protrudes. There are several types of hernia, but inguinal—low on the abdomen near the groin—is the most common.

This operation can be done as an outpatient and doesn't require hospitalization or an operating room. The whole cost of the hospital stay, operating room, anesthesiologist, etc., could be dispensed with. The individual rests for a bit afterward and then goes home.

However, hernias can often be corrected through special exercises performed daily at home. Dr. Shelton describes several exercises in his book, *Exercise*. By all means, you should give these exercises a fair try before subjecting yourself to any surgery.

**Hysterectomy** - The removal of the uterus supposedly takes away a so-called "cancer-prone" organ. Thus the gynecologist justifies the operation and the large fees for performing this major surgical procedure.

Along with the uterus, they usually remove the ovaries. This induces an instant "surgical menopause." Often, the women develop years of anxiety, depression, sweats, hot flashes, and a constellation of symptoms of estrogen deficiency. The physician gives her estrogen shots or estrogen tablets once a month. However, the estrogen itself is a cancer-causing agent. Thus a so-called "cancer-prone" organ has been removed so that the woman can get shots of a known cancer-causing agent.

**Prostatectomy** - Sitting at the base of the bladder in the male, a small roundish gland the size of a chestnut circles the male urethra. Sometimes it enlarges a bit and presses on the urethra, causing slow starts and a slow flow on urination. However, this is not a valid reason to remove the gland. As soon as the cause for the swelling is removed, the prostate will return to normal size.

Prostatectomy may leave as its aftermath loss of bladder control (incontinence of urine), impotence, inflammation, impaired ejaculation, sterility, and recurrent return visits to the urologist.

**Tonsillectomy and Adenoidectomy (T and A)** - This operation is most often performed on children under six who have had recurrent sore throats (a symptom of healing), who have difficulty swallowing, breathing, or talking because their tonsils and/or adenoids are enlarged. They enlarge because of chronic toxicosis.

The adenoids shrink as the child grows older anyway, so the surgeon is sure to operate before that naturally occurs. We should not mutilate and cripple our children with this totally unnecessary surgery. Tonsils and adenoids are vital organs of detoxification.

**Thyroidectomy** - The fact that enlarged thyroids, overactive thyroids, and underactive thyroids can be completely healed without medicine or surgery is a fact that has largely been ignored by the general surgeons. They routinely cut out the thyroid gland, trusting to fate that the patient will never know that the operation was unnecessary and that the thyroid could have been left alone to heal on its own.

When the surgeon cuts out the thyroid gland, he renders the patient permanently hypothyroid; that is, for the rest of his life the patient will be dependent on thyroid supplements or else he may go into a coma.

Also, when, the surgeon cuts the thyroid, he may cut the recurrent laryngeal branch of the vagus nerve, which courses through the neck just underneath the thyroid gland. The patient then suffers permanent hoarseness due to the loss of the recurrent laryngeal nerve supply to the voice box.

**Vasectomy** - Vasectomy is male sterilization by cutting the vas deferens (the tube connecting the testes to the penis). Most men who have had vasectomies have subsequently been impotent.

Two reasons why urologists continue doing vasectomies and have not revealed the high incidence of impotence it causes are as follows:

1. Urologists earn a mint doing this operation.
2. So many vasectomies have already been performed, so many men have been made impotent that they are ashamed to admit it or bring up the fact. If the truth should come out, then malpractice cases against urologists would jam every court in the country.

Another aspect of vasectomy that the public has not been made aware of sufficiently is this for practical

purposes it is a nonreversible operation. Rare cases have occurred where surgeons using microscopes have reconnected the severed ends of the vas deferens. However, a successful outcome from this is very rare.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > 14. Intensive Care Unit

## **14. Intensive Care Unit**

The intensive care unit is designed differently from other areas of the hospital. It is a large room, sometimes with curtains between beds, sometimes not. Men, women, and children are all together. There is a central nurses station from which all patients are visible. Specially-trained teams of doctors and nurses are on duty twenty-four hours a day.

The ICU is a room which is definitely not conducive to health. The room is deliberately kept cool to decrease the body's need for oxygen. This creates an additional stress to maintain proper body temperature.

When you first enter the ICU, it looks like something from a spaceship: wires, tubes, lights, pumps are hooked into and onto mostly immobile, white-sheeted figures. There are constantly flashing lights and beeps from monitors. It is eerie and enervating. The light is eerily, intensely bright; there is constant, purposeful movement on the part of the staff. There is rarely an outside window so there is no fresh air and little sense of time of day or season. Beneath all the apparatus it can be hard to recognize (and sometimes even see) the person you know.

### **14.1 Equipment**

People in the ICU are often hooked up to cardiac monitor's that provide records of the heart's activity.

The screens that display these are usually placed at the patient's bedside, as well as at the central nurses station. Tubes or masks often connect them to a respirator or ventilator. If it is believed that you will need help breathing over a long period of time, a tracheotomy (an opening into the trachea through the neck) may be performed. Moistened air or oxygen will be delivered to the area of the tracheotomy through a plastic tube. Since the normal moistening mechanism (your nose and throat) is no longer doing this job, the air must be artificially moistened to prevent the drying of your respiratory passages.

Sometimes, to see how your heart is handling the blood it is receiving, a central venous pressure catheter is used. This is a thin tube inserted into a vein in your arm and threaded up to the large vein (vena cava) entering your heart.

To get a constant and precise measurement of your blood pressure, thin catheters called arterial lines may be in place in arteries in your arm. This makes it possible to check your blood pressure without having to put on the cuff and pump it up the way your doctor or nurse normally would. In other words, the pain and inconvenience experienced by the sick individual with these catheters is for the primary purpose of making the job of the nurse easier.

Often a Foley catheter, to drain urine, is in place in your bladder. It may flow into a bag and be measured from time to time—another unnecessary monitor.

### **14.2 People's Reactions**

Some people simply cannot tolerate being so totally dependent on other people and on machines. Others

can't bear the lack of privacy. Some feel that they'll go mad from the noise, the continuous bright light, the constant attention: temperature, pulse, respiration, and blood pressure are taken every fifteen to twenty minutes. You are burned, checked, made to sit up and cough and take deep breaths.

The people look terrible—pasty-colored, immobile, sometimes unable to talk and, worst of all, often disoriented. Disorientation is common in the ICU because of the constant noise, the lights, the lack of sleep, the fact that patients are seriously ill, may have a fever, and may be sedated so that they won't fight the equipment. People often hallucinate and pass in and out of periods of clarity.

The environment in the intensive care unit is the opposite of what a proper environment for healing should be. These places should be called intensive abuse units. The proper environment should be quiet and peaceful. There should be plenty of windows so that the room is light and airy with plenty of fresh air from outdoors. Since sleep is the prime requirement for all sick individuals, they should never be disturbed when sleeping or resting. There is no equipment or chemicals that can heal—only the body can do that and rest is the primary need.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm: What Treatments To Accept, Reject](#) > 15. The Emergency Room

## **15. The Emergency Room**

The emergency room is an entirely separate unit of the hospital, set up to handle people with an injury or condition that may cause death, disability, or serious illness if not treated promptly.

The person who greets you in an emergency room will have two questions: Do you have insurance? What is the matter? If you do not have insurance and are unable to pay, any hospital that operates a twenty-four-hour-a-day emergency service must still give you emergency care. It does not, however, have to provide follow-up care; and a private hospital has the right, if you cannot pay, to transfer you to a public hospital once you have, received the initial emergency care.

If you do have medical insurance, bring your identification cards with you. It's also a good idea to bring a friend, because the hassle of the emergency room may be more than you can bear alone.

In the hospital, those who get immediate care are usually heart attack cases, women about to give birth, and those with severe bleeding. The rest wait.

### **15.1 Fees**

Don't be shocked by emergency room fees. In large metropolitan hospitals they can be as much as fifty dollars plus charges for such things as X rays. Check your insurance to see if it covers all or a portion of emergency care costs so that you'll be prepared.

## 16. Questions & Answers

### Are there any psychological effects of hospitalization?

Yes, according to Dr. Robert S. Mendelsohn, the psychological dangers of the hospital are every bit as deadly as the physical dangers. He says: "Your hospital stay from the moment you walk in the front door until the moment you walk—or are carried—out has a psychological effect on you similar to a hex or a voodoo curse. Whether you consciously acknowledge it or not, hospital procedures and environment encourage despair and debilitation rather than hope and support. Nobody's optimistic. You see the long faces of the people suffering and dying, and you see the faces of the people who must watch them suffer and die. You see the hospital staff denature their responses and become machines. And then you are denatured at the admissions desk as you are reduced to a collection of numbers and symptoms belonging not to you but to the doctor. You leave your former world and identity behind. You're literally stripped of your former life as you take off your clothes and hide them and your personal belongings in a closet—artifacts of your real life. That past life is kept from reasserting, its ties with you—your relatives—are restricted from spending more than token amounts of time with you.

"The effect of all these psychological pins is that you relinquish any notion you may have had about having control over your health. Your captors isolate you, alienate you, scare you, depress you, and generally make you feel so anxious that you submit to their every wish. Your spirit broken, you are ready to be a "Good Patient."

### What causes gallstones to form? Are operations sometimes necessary?

According to Dr. Shelton, imprudent eating and heavy eating of fatty foods by the enervated and toxic, and a lack of exercise, are chief among the causes that produce gastrointestinal and biliary irritation leading to stone formation. They do not develop in healthy individuals, but in those who have broken down their health by years of wrong living. Nobody would ever have gallstones if he lived right.

Referring to the gallbladder operation, Dr. Shelton says, "In my opinion there is no necessity to operate for gallstones. Normal nutrition is not restored by removing an effect of impaired nutrition. The great and growing army of postoperative invalids attests to the fact that operations on organs of the body do not restore health. Too many organs are removed that could be saved by the simple expediency of draining them by means of the fast. "Instead of surgically draining the gallbladder, a fast will enable the body to perform an excellent job of drainage and do it in a way to leave the gallbladder intact and unharmed."

### Can tumors be dissolved without having to resort to surgery?

Yes they can. Dr. Shelton has had considerable experience on this subject and he says,

"A woman was told that she had" a fibroid tumor of the uterus about the size of a lemon, and that it should be removed at once. This meant that her womb would be removed and that during surgery reasons might be discovered for removing her ovaries.

"But this would not restore health. She would still be a sick woman.

Operations remove effects, not causes. There would probably be a recurrence of tumor. She would also be a physiological cripple. Cutting into the ovaries is like cutting into the brain. The patient rejected the operation and resorted to the fast. Soon the tumor was autolyzed and her organs were saved.

"One case that I cared for was a woman who had a uterine fibroid about the size of a medium-sized grapefruit. Complete absorption of the tumor was brought about in twenty-eight days. This was an unusually rapid rate of absorption and I have never seen it take place so rapidly in another case.

"I have seen tumors in the breast, on the womb, in the abdomen, on the feet and elsewhere absorbed while fasting, and some of these absorptions have been rapid while others have been slow.

"For reasons that are not yet fully understood, some tumors are not affected by the fast, but thousands of tumors, some of them of considerable size, have been completely and permanently removed by fasting. I have had the pleasure of saving hundreds of women from mutilating operations for the removal of the breast, and many more from desexing operations for removal of uterine fibroids. The process is identical with the removal of stores of fat in the tissues. There is nothing mysterious about it.

"Just as fat on any part of the body may be autolyzed and taken up by the lymph stream to be mingled with the blood and used in nourishing the vital tissues of the organism-while no food is being taken, so other tissues may be digested in the same manner and used as food. Muscular tissue, glandular tissue, and other tissues may be called upon to supply nutriment for the more vital tissues, those that have to carry on the most essential functions of life.

"In like manner, the tissues that make up a tumor (neoplasm) are digested and absorbed, the usable portions employed in nourishing the vital tissues, the nonusable portions excreted."

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > Article #1: Is Medicine a Fraud? by Dr. Herbert M. Shelton

### **Article #1: Is Medicine a Fraud? by Dr. Herbert M. Shelton**

A few years ago Dr. Hutchinson, consulting physician to the London Hospital, lectured at Aberdeen University on "The Progress and Present Aspect of Medical Science." The lecture was published in the British Medical Journal. In this lecture Dr. Hutchinson said:

"So few are the diseases that we can really cure, that one is tempted to believe that if all the doctors went on strike for a year the effect on the death rate would be inappreciable. In most cases of illness the doctor is really a mental poultice; he is a source of comfort, confidence,

and consolation to the patient and his friends; but if he is honest with himself he will admit that the number of patients who would have died but for his attendance is lamentably small."

Does this honest confession not brand the practice of medicine as a gigantic fraud and its practitioners as a gang of swindlers? Was anything I ever said about medicine a stronger condemnation of the practice than this coming from one of its honored members? Does Dr. Hutchinson, in the above statement, not, in effect, at least, accuse the members of his profession of accepting money under false pretenses?

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > Article #2: Physician Heal Thyself - Part 1

## **Article #2: Physician Heal Thyself - Part 1**

The frequency with which medical specialists die of the very diseases in which they specialize speaks volumes to the thinking person. If a physician specializes in diseases of the heart for twenty or thirty years and develops heart disease from which he dies, how can such a man be expected to be able to prevent or "cure" heart disease in his patients?

If he does not know enough to save himself, how can he save you? If members of his own family sicken and die of the "disease" that he has made the object of his specialty, what can he do for the members of your family? Is it not about time we demand of these men that they prove in their own lives and in their own families the value of their much boasted "science"?

Heart specialists die of heart disease, lung specialists die of tuberculosis, cancer specialists die of cancer, asthma specialists have asthma, hay fever specialists have hay fever, neurologists become insane—what kind of a science of medicine is this that is good for everyone but its practitioners?

Here is a case in point. It is taken from the *New York Times*:

### **HEART ATTACK KILLS HEART SPECIALIST, 56**

*Dr. John M. Cassidy Stricken While Attending Patient*

JERSEY CITY, N.J.—Dr. John M. Cassidy, a specialist in diseases of the heart, was stricken with a heart attack at the bedside of a patient here yesterday and died within a few minutes. Dr. Cassidy was 56 years old and lived at 1913 Boulevard.

He was born in Paisley, Scotland, and his family emigrated to the United States when he was a boy. He received his early education in the United States and in Scotland, a Bachelor of Science degree from New York University and a degree from Bellevue Medical College, from which he was graduated with Phi Beta Kappa honors.

For fifteen years he was a lecturer on the staff at Bellevue Medical College and for twenty-eight years he was on the staff at the Greenville Hospital in this city. For several years he was associated with Dr. John Wycoff, New York heart specialist.

With all his education, all of his degrees, his connections with famous institutions and his wide experience, he did not know how to care for his own body in a way to keep it healthy and strong. What good is all his store of knowledge, if it cannot be used to help him live?

The sober fact is that he had very little knowledge. He knew a lot; but we would repeat the question that we believe was asked by Josh Billings: "What's the use of knowing so much if what you know isn't so?" This physician had accumulated too much canned ignorance.

## **Article #2: Physician Heal Thyself - Part 2**

"By their fruits ye shall know them" applies as much to "science" as to trees. What are the fruits of modern medical science? What may we expect from this "science" in the future? Do "medical" men really know how to prevent and "cure" disease? Can they really prolong life? Can they help us if we submit ourselves to them for periodic examinations, frequent inoculations, occasional operations, and treatments of many kinds?

If they possess the necessary knowledge and skill to improve, preserve, and restore our health, to prolong our lives and free us from suffering, should we not find evidence of this in the better health and longer life of physicians and the members of their families? If these do not show better health and longer life than that of the lay population, are we not justified in doubting their claim that they possess such knowledge and skill?

A reader sends us a clipping from the *Long Island Star-Journal* telling of the death of a Brooklyn physician who dropped dead in the home of a patient, where he had been called. The physician was only 41 years old. The patient was reported by his wife to be "recovering from his illness."

The physician, Dr. Frank Donigan, died in the home of Joseph McBride, a Great Neck engineer, at 160 South Middle Neck Road.

Were this an isolated case, it might be considered as only a curiosity; but, the fact is that physicians frequently die young, even younger than this one did, and we have known of other cases where physicians have dropped dead while attending their patients. Such facts entitle us to demand, at least, freedom of choice in medical matters.

We cannot reasonably expect medical knowledge and medical methods to do more for us than they do for medical men themselves. Medical men should hesitate before advocating compulsion in the use of their wares when they chalk up such poor records where we have reason to expect their most thorough and conscientious use.

## **Article #3: "Good Drugs"**

In one of his recent syndicated articles, Dr. Irving S. Cutter says that he received a letter that read: "A medical student at Harvard told his father that he was taught that there are only 13 essential remedies. My physician says he is of the opinion that there are only four. Were you to make a list how many would you include?"

After dealing with the old belief that "since the good Lord had sent disease to curse mankind, He had planted in the earth an antidote for every symptom," which we only need to find, and how this led to a search for remedies in everything and, ultimately to the development of shotgun prescriptions, he tells of the development, in the middle of the 19th century, of pharmacology, so that "today every product, before it is applied to human use, must pass the rigid test—what will it do to help the body rid itself of disease?"

Then he adds: "It should be clear that nature is the great healer. All that any medicine can accomplish is

to place the tissues and organs in the best possible condition to repel illness." This is a perversion of the old threadbare statement that "it is nature that heals, medicine only aids nature."

I am certain that Cutter is well aware that "medicines" never "place tissues and organs in the best possible condition." He may not know that the body does not "repel disease," for he still thinks that "disease" is some kind of a mysterious attacking force that must be repelled as any invader should be repelled. But he has studied too much toxicology to believe the mass of lies in the pharmacology about the "physiological action" of poisons.

He tells us of pharmacology, that it deals "with the action of drugs." But he omits to mention the fundamental defect in pharmacology, if he is aware of this glaring defect: that it fails to distinguish between the "action" of drugs and the action of the body. Pharmacology attributes all the action to the lifeless drug—the chief characteristic of which is *inertia*—and none to the living body, the leading characteristic of which is *action*—"action is life."

He believes that epsom salts act on the bowels to produce a diarrhea; and does not understand that the diarrhea is bowel action—that the living thing and not the lifeless thing does the acting. It is the bowels acting on the drug to eject it that produces the diarrhea. Pharmacology is a mass of fallacy simply because it mistakes vital action for drug action.

Drugs do not "place the tissues and organs in the best possible condition." On the contrary they force them to assume a condition of defense. They are compelled to defend themselves against the drugs. Drugs place them either in a condition of excitement, followed by exhaustion, or in a condition of depression, also followed by exhaustion. The excited action of the bowels (diarrhea) that follows a dose of salts, leaves them exhausted. The depression of these same bowels that follows a dose of morphine exhausts them nonetheless.

Cutter uses the term "medicine" and not drug. Medicine is derived from a Greek word meaning heal or healing. There are no medicines. "It should be clear that nature is 'the great healer.'" What is nature? In this instance, nature is the ensemble of the forces and processes of life. It is nutrition, detoxication, drainage, elimination, repair, recuperation—function. Nature is not only the great healer—she is the only healer.

Continuing, Cutter says: "In this connection (that of putting the tissues and organs in the best condition to repel the mysterious attacking force), nursing often is more powerful than all the elixirs in the pharmacopeia." This must depend on the kind of nursing employed. For, nursing may be "medical" nursing, or it may be Hygienic nursing.

Cutter says:

"A few years ago Dr. Shattuck of Boston prepared two lists of drugs. The first enumerated 11 items and was entitled "Very Valuable," the second tabulated 15 under the caption, "Useful." Of the first 11, diphtheria antitoxin is the only serum noted. Nowadays we could scarcely do justice to our patients without antitoxins against lockjaw, gas bacillus, meningitis and pneumonia

"Since Shattuck's pronouncement the sulfonamide derivatives have come into the picture. They are lifesaving in the treatment of meningitis, urinary infections, mastoid, middle-ear disease and pneumonia

"Anesthetics are not even mentioned. I would incorporate also oxygen—so helpful in certain respiratory and heart conditions. When combined with carbon dioxide, this element is of great service in the management of gas poisoning

"The only hormone recorded is insulin. Most experts, I am sure, would demand pituitrin, adrenalin and the sex hormones. There is no reference to glucose or normal salt solution.

Certainly human blood and plasma occupy positions of first importance

"Thoughtful physicians are not generous drug-prescribers, but they must be familiar with the possibilities of their ammunition. To answer the question categorically, I think I would accept most of Professor Shattuck's 26 entries. To these I would add at least a dozen more, with the reservation that no one preparation should be employed unless the doctor who prescribes it knows just what it will do and that his patient needs it."

He includes oxygen and human blood among the "valuable drugs." How did he overlook food and the human brain? Aren't they "valuable drugs," also?

All leading physicians are agreed that there are not many "valuable drugs," but they are not all agreed as to which are the valuable drugs. I have not seen Shattuck's list, but it is safe to say it contained the now discarded specific for "syphilis"—mercury. Most lists of this kind also contain the vaunted specific for malaria—quinine.

A few years ago a prominent New York City physician stated that he could practice medicine successfully with three drugs—mercury, opium, and quinine. I saw a list of "really valuable drugs," prepared by a famous medical authority that contained only twelve drugs. At the present time the Army recognizes epsom salts, C.C. pills, arsphenamine, and sulfanilamide. The U.S. Pharmacopea and the Handbook of New and Nonofficial Remedies each contain a large list—over 45,000 in all—of "curative" drugs.

The simple truth is that there are no valuable drugs. They cure nothing, but kill many. They can cause disease; they cannot restore health. Drugging the sick is a survival of savagery. Increase or decrease the number of drugs in use as they will; it still remains a relic of the voodooism of the medicineman of savage tribes.

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > Article #4: Good Medical Attention by Dr. George E. Crandall

### **Article #4: Good Medical Attention by Dr. George E. Crandall**

In the *New York Times* magazine section several years ago, there appeared an article captioned, "How Healthy Are We?" by Michael M. Davis. It contains some very interesting statements, statistics, and assertions. It is a very graphic tale of a decaying civilization. The contrast between the youth of this country of 1917-1918 and the draftees of 1941-1942 shows conclusively that, in spite of our boasted medical enlightenment and progress, humanity is on a declivitous march. "The March of Time" is undermining our health and sapping our vitality.

The subjects of this article have been examined, reexamined, immunized, reimmunized, and possibly sterilized, yet they are less fit than the youth of two decades ago. Can it be that the advice and knowledge of the family physician, the American doctor, is grossly misleading and fallacious? All these young men have been supervised from birth by the family doctor: in infancy, in the public schools, in colleges and in their athletic pursuits everywhere. Yet approximately 1,000,000 of the 2,000,000 drafted were weighed in the balance and found wanting of the physical qualifications essential to modern war requirements. If I were a logician, an analyst, or stacionian, I would want no more conclusive proof of the incompetency of modern medical science than the comparative health status of the American youth as released in this article.

The cause of our health deficiency as given by the author is that we do not receive "good medical

attention." He does not state the reasons but infers that we are all negligent and fail to employ a physician: TMs, too, in spite of the fact that they are forced on us from birth by custom, coercion, and law. We could not dodge them if we would. We are medicated, vaccinated, innoculated, extirpated, serumized, immunized and figuratively baptized. We are literally soaked and saturated in a medical bath, yet we grow weaker and weaker. Possibly if all the pseudo-science was abandoned, Nature would have an opportunity to develop our youth more normally and more ideally.

There is only one way to build a healthy, sturdy adulthood and that is to observe and follow all the health laws. Be guided by natural instinct rather than live haphazardly and depending on artificial immunity which, itself, is taking a huge national toll in degenerating our manpower.

"The human machine shows more diseases and defects as it gets older, *especially when it does not receive good Medical attention.*" From this quotation it is quite apparent that the author is not familiar with medical practice or such a statement could not have been made. As we grow older, we build and develop all the chronic diseases. These ailments, when once established incurable and not amenable to any known medical treatment. We have been building these diseases for years and even now heart disease (incurable) is taking a greater toll than any other disease, either acute or chronic. Now why are these diseases not prevented by "good medical attention"? The chronic so-called incurable diseases are not respectors of poisons and the wealthy are more frequently afflicted and go down and out more rapidly than the less opulent, in spite of the fact that they can well afford the most renowned physicians and clinics in the land.

If doctors know the cause and cure of these degenerative diseases, why are the American people kept in ignorance? Why do we donate to, endow and build lavish foundations for medical institutions and medical progress and receive no enlightenment or health improvement in return? We are sinking, fellow Americans, into the clutches of disease and death and there is no succor or saviour.

Is American medicine commercialized? Do we need state medicine? Has medical science yet discovered the true cause of disease or have they been totally deceived into following a "Will o' Wisp"—a false philosophy? Is the germ theory a farce and is the practice of modern medicine a burlesque? These are pertinent questions vital to every American and they should be answered truthfully.

We pay annually, over \$2,000,000,000.00 for relief from discomfort, pain, and suffering. This is a staggering sum and should insure health to everyone if we could receive adequate enlightenment along health lines. It should be self-evident that if we build better health, we will develop less disease. If we would pursue our health search far enough, we could eradicate all disease, suffering, and premature death. It is certain that we cannot obtain this knowledge from licensed physicians and it is not taught in hospitals, or clinics, nor by the visiting nurses association.

In time of need, health knowledge is not even supplied by the American Red Cross.

There is only one solution to this vital national problem. It is quite evident that our modern medical knowledge is woefully inadequate, erroneous and ineffective. Even surgery cannot cut health into the body or the cause of disease out of the system. Our only solution to this national problem is to learn "The Laws of Health," and develop enough desire and self-control to practice them. Health cannot be expected from a country of people saturated with tobacco, alcohol, tea, coffee, and drugs.

Doctors and their families indulge in all the bad habits that are so prevalent, suffering with the same degree of impaired health and go to an untimely grave. Frequently, we read of doctors or members of their families dying from twenty to thirty years prematurely so it is a case of the blind leading the blind and all the medical propaganda we read so much in the daily papers is just a game of Blind Man's Bluff.

By a proper regime, consistently and persistently followed, we can in time develop a healthy, strong, and vital people. It will eliminate our weakness and susceptibility to disease. This is a natural immunity and the only dependable safeguard we can possess. It is the function of a health school to impart these laws to the public and create in humanity a desire to have health rather than physician and mental degeneracy and destruction.

Rome has burned but we are still fiddling. Are the needle and the scalpel mightier than the sword (truth)?

[Home](#) > [Lesson 67 - How To Practically Withstand Hospitalization With The Least Harm; What Treatments To Accept, Reject](#) > Article #5: Blood Transfusions by Dr. Herbert M. Shelton

## **Article #5: Blood Transfusions by Dr. Herbert M. Shelton**

We have received numerous requests for information about blood transfusions, blood banks (or, as, one correspondent called them "bloody banks"), and the desirability of donating blood to the sick and wounded. All this curiosity has been aroused by the frequent calls for blood and the many stories carried by the press of the great good accomplished by transfusions and by the use of the blood banks.

Our readers, despite the information they possess, are still very susceptible to voodooism's propaganda. If the propaganda is persistent enough, or repeated often enough, or if its claims are great enough, they think there may be more to it than there is to other forms of propaganda.

That blood-transfusing is a hoax and a swindle; that it is only an expensive and dramatic piece of grandstand play by voodooism's white-robed priests; that it is a damaging and often fatal procedure, have been known for years; yet our readers seem to think there may be good in it.

On the other side of the picture, one of our readers in Rochester sent us what he calls a "good one." He tells us that "the Red Cross is making its rounds in the Rochester industries to replenish its blood bank—or should I call it, its bloody bank? It has just completed its stay at Eastman Kodak Company, Rochester's largest industry. Pressure was put upon all the workers to donate of their substance.

"Here is the procedure: A pint of blood is taken from the arm of each worker. After that, each one is ushered into a sort of traveling cafeteria. The worker is now given a treat for his donation. The treat is supposed to help him recover from his loss of blood. And here it is:

"Sandwiches of white bread and baloney or cheese or peanut butter, coffee, tea, or milk (pasteurized) with white sugar cookies—cigarettes—a shot of liquor!!

"These same blood donors (or suckers) are expected to give a new transfusion within two months. Perhaps the above offerings ought to make this entirely possible. Viva La Red Cross!"

The Red Cross, which is the left hand of the Medical Trust, may always be counted on to build up the blood of its victims with *good* white bread, spoiled meat, coffee, *good* white sugar, pasteurized milk, cigarettes, and booze. When the present world madness has ended and the world is being reorganized in a way to prevent its (mis)leaders from creating another hell on earth, the Red Cross must be sent to the same oblivion to which political organizations will go. The Red Cross must be punished by forcing it to spend eternity in the same padded cell with the A.M.A. Who was it dubbed the old harlot, "The Greatest Mother of Them All"?

The present vogue is to transfuse as often as possible and, if this does not result in death, credit the transfusion with recovery. Every recovery following transfusion is attributed to the transfusion. If the patient "fails to rally" and dies, this is due to *other causes*.

Deaths following transfusions are more frequent than the public is aware of and, while it is positive that the transfusions do often kill outright, there is no unquestionable proof that they ever save a life, or, even that they ever result in positive good.

Apparent successful results of transfusions are usually played up for the public, while the evident failures and damages are not given any great flare of publicity. Front page space is for the spectacular.

Blood transfusions were first made from animals. Later human blood was used. At first the blood was caught in a funnel as it spurted from the artery of the donor and sent through a tube into the veins of the patient. Later a method was devised that conveyed the blood directly from the donor's artery to the vein of the receiver. Still later, instead of direct transfusions, "blood banks" were made by taking the blood, mixing it with an anti-clotting chemical and storing it until used. The latest development is that of "blood dust." The blood plasma is dried in huge sausage skins and stored or shipped. Later this dust is mixed with distilled water and pumped into the veins. Or, if distilled water is unavailable, the unopened skins are immersed in ordinary water. The water passes through the skins, which filter out foreign matters from the water. Enough water passes through the skins to create a fluid "plasma."

It should be recognized that the introduction of the blood of one individual into the body of another is the introduction, therein, of a foreign serum. True, it is human serum and, therefore, theoretically at least, should not produce the symptoms or reactions of serum poisoning—*anaphylaxis*. Actually, however, it does this very thing as we shall show often adding a few symptoms that are missing from serum poisoning.

Let me list the symptoms and evils which follow transfusions as given by these great surgeons—chills, nausea, vomiting, muscular pains, dyspnea (difficult breathing), cyanosis (blueness due to heart and circulatory difficulties), urticaria (nettle rash), headache, fatal hemolysis, (breaking up of the red blood cells), spasm of the un-striated (involuntary) muscles, asthmatic symptoms in the lungs, involuntary voiding of the urine and of the feces, acute edema (dropsical accumulation) of the lungs, hemorrhage, embolism (blood clot), and death. Hemolysis may occur without going far enough to result fatally. Some of these surgeons are convinced that in some conditions in which transfusions are employed, generally, those patients who receive the transfusion "will die sooner than those without."

"Fatal anaphylaxis following blood transfusions," "the deaths following usually in a few hours after transfusion" and occurring often in cases where "previous study of the blood had shown that they were *entirely satisfactory*," should convince everyone that blood shown to be "entirely satisfactory" is not really satisfactory. I am sure that no blood would satisfy me which would kill me in a few hours, or, even in a few days.

The damages to the body listed above, as resulting from transfusions may seem to the reader to be enough. Yet there is no reason to doubt that all the tissue damages throughout the body, which result from all serums (foreign proteins), or serum sickness, also result from blood transfusion. The above-listed damages and symptoms are only the most prominent and most important ones among those that have been studied.

Does it not seem a bit strange that a patient who is very low, who perhaps, is thought to be almost at the point of death, and is fighting desperately with the little remaining strength which he has, should be subjected to such damaging, and deadly treatment? It is stranger still when we consider that the authorities themselves consider it to be valueless in most of the conditions in which they employ it and are hopelessly divided in their opinions about which conditions it is, or may be, of limited value in occasional cases.

Dr. Peterson is evidently correct when he says that "a procedure which lends itself so readily to commercial exploitation is apt to come in for a certain amount of abuse."

## Lesson 68 - First Aid And Natural Hygiene

- [1. First Aid: The Life Science Approach](#)
- [2. Emergency!!](#)
- [3. Specific Injury Treatments](#)
- [4. Emergency Techniques](#)
- [5. Accident Prevention: The Life Science Way](#)
- [6. Questions & Answers](#)
- [Article #1: The Tough Cookie Life Scientist By Peter Gregonis](#)
- [Article #2: First Aid and Hygiene By Dr. Alec Burton](#)

### 1. First Aid: The Life Science Approach

Someday either you or someone you care for may be in a life or death situation. What you do in the next few minutes could either save a life or quickly end it. Should you sacrifice your beliefs and principles at a time like this? Absolutely not. If your beliefs are correct, then your actions will be correct—provided that you have the proper knowledge to act upon.

Unfortunately, some people who think they understand Natural Hygiene or Life Science actually have a mistaken belief when it comes to first aid. One of the first principles of Natural Hygiene is not to interfere with healing. Outside interference with the body's healing processes should always be avoided. In other words, when we are sick or in ill health, we become well again by "intelligently doing nothing."

We don't actually do "nothing" of course. We may fast, improve our diet, take more exercise, or relax. But we don't meddle or interfere with the body by injecting it full of drugs or cutting out diseased organs.

Some Natural Hygienists and Life Scientists make the mistake of believing that "nothing" should also be done in a time of emergency situations where the body might require immediate attention. This is a dangerous belief, and one that may lead to your death.

First aid principles can be applied without violating any of the fundamental facts of Life Science and Natural Hygiene. We must, however, understand what first aid really means in these cases.

#### 1.1 What First Aid Can (and Cannot) Do

First aid simply allows the body a chance to heal itself. Intelligent first aid, quickly applied, can restore the body to its stable state. For example, if you accidentally cut an artery with a knife, you could quite possibly bleed to death if the cut was deep and the artery was a major one. If you "intelligently" do nothing in this case, you're stupid.

Simple first aid would be to apply direct pressure to the artery and stop the blood flow. You would use some type of cloth or clay or even pressure to help the blood clot, and then you might even need to have the artery sewed or reconnected.

Then, after all of this, you would do nothing "intelligently." You may fast or rest and let your body replenish its blood supply and conduct its healing. You would not ask for a blood transfusion or for any drugs to "help" you heal. When the body is restored to its stable state, then it will reestablish health and well-being without any additional aid or interference.

"First aid," wrote Dr. Alec Burton, a Natural Hygienic practitioner, "Represents immediate and temporary care. It is not designed to restore health but merely to avert the possibility of further damage or even death."

If you break your leg, there is no drug, medicine, or injection you can take to make the bone knit and heal. However, if you do not have the bone "set" and the leg immobilized, then the natural healing would not be as effective. First aid is for accidental injuries done to the body, and not for chronic illnesses or disease.

## **1.2 Should "First" Be "Last"?**

First aid is called *first* aid because it is the first attention an injured person receives before being taken to a hospital or a doctor.

In most cases, *first* aid should also be last aid. After you take care of the emergency and restore the patient to a stable condition, no additional outside help is needed or required. The body is now on its own, and will conduct its healing as rapidly as possible. Drugs and various other hospital procedures only interfere with natural healing processes.

"First" aid can save a life. The "second," "third," or "fourth" aid a person receives in the hospital or at the hands of a surgeon can end a life. In many cases, first aid should also be the last aid a person needs.

The Natural Hygienic practitioner and student of Life Science must learn to distinguish between those emergency situations which may require additional professional attention and those that do not.

For example, a dog bite on the leg may often be treated safely at home by letting the wound bleed briefly, cleaning it with water, and then stopping the blood flow with a clean cloth. On the other hand, if the dog attacked the person around the face and actually tore an ear half-off, then surgery should be employed to reattach the ear. In neither case, however, should rabies shots be taken or any other injections be received. Rabies is yet another of the "contagion" myths and shots cannot protect you from a myth.

In many cases, your first aid is also the last aid a person needs before allowing the body to heal itself and restore normalcy. There are times, however, when you may need to seek additional help.

Knowing when to seek help and what type of help should be accepted can be difficult for the Natural Hygienist. How do you know when an emergency situation requires additional help?

Unfortunately, there is no easy and absolute way of answering this question for every situation. In most cases, you will have to use your own judgment and be prepared to accept the consequences of your actions. At such times, it is very handy to have a few phone numbers of professional Hygienic practitioners that you can call in an emergency.

There are some emergency situations, however, that will very often require some additional help beyond the "first" aid that you can give.

## **1.3 When Do You Need Outside Help?**

The most obvious emergency situations that require outside and additional help is when a severe mechanical injury is done to the body. In this case, something is "broken" in the body—such as a broken bone, a severed artery, a deep gashing hole, a crushed organ, or some other acute and violent injury.

When these injuries occur, then constructive or emergency surgery may be required. Setting broken limbs and stitching large wounds up are still valid medical practices that allow the body to expediate its healing processes, these types of surgery do not violate the principles of Natural Hygiene, and may be vital to the well-being of the victim.

Giving the patient antibiotics, pain-killers, "vitamin" shots or other drugs, however, does violate the laws

of nature and is injurious to the body.

In general, we can say that as long as the emergency treatments remain *mechanical* in nature and do not introduce any poisons or drugs into the body, then they may be tolerated.

As a general consensus, some Natural Hygienic practitioners developed a list of conditions that might require "constructive" or emergency surgery. Such treatment may be advisable (or unavoidable) for these types of situations or emergencies:

1. Repair after accidents.
2. Repair of some congenital (birth) defects.
3. Concealed strangulated hernia in an infant.
4. Some Caesarian sections (approach with great care!).
5. Some cataracts (only after fasting has been tried).
6. Repair of extensive damage to joints and cartilage (after an accident).
7. Tubal pregnancy.
8. Some hernias.
9. Large tumors causing obstruction or pressure on nerves or organs (only after an extended fast has first been attempted).
10. Repair of opening in wall of stomach eaten through by an ulcer of long duration.
11. Removal of organ destroyed by accident.
12. Dental surgery, such as tooth extraction or repair after an accident to the mouth.

All surgery and additional repairs to the body should always be viewed with caution, suspicion, and trepidation. Do not always assume that surgery and medical practices are needed for any type of emergency situation. In some cases, a limited amount of professional attention will be entirely adequate.

For example, if a person is knocked out and loses consciousness, then some additional help may be needed beyond the first aid that you can give. In a book called *Management of Trauma: Pitfalls and Practice*, the doctors have this to say about the treatment of head injuries in emergencies:

"If the person is knocked unconscious for less than five minutes, then the patient should be carefully observed for six to twelve hours. Frequently this can be done in the emergency room and does not require hospitalization. Patients who were unconscious for longer than five minutes may need to be hospitalized overnight."

The same doctors also caution us, however, that: "Merely keeping the patient in a hospital bed or in an emergency room does not imply that he is being adequately observed. All too often patients languish in these areas without being seen by a physician at all."

Like it or not, when an emergency or serious injury happens, you may end up in the hospital or an emergency ward. This is especially true if you are a victim of an accident. (See the supplementary material at the end of this lesson for one Life Scientist's experience after a tragic accident.) What do you do if you are the victim of an emergency?

## **1.4 If They Take You To The Hospital...**

You may be unconscious the first time you are taken to a hospital or an emergency room. Some Life Scientists anticipate this situation and wear a medical tag that says: *I am allergic to all drugs and blood transfusions, and I have no medical insurance.*

Having no insurance may be the best safeguard against unnecessary or "elective" medical and surgical procedures. If the hospital suspects that you cannot pay its charges, it will try to have you discharged as soon as possible.

You may also want to give a sympathetic friend who understands your health preferences the "power of attorney" over matters involving your health care. All this means is that you and your friend go to a

lawyer where a letter is drafted that says this person may act on your behalf on matters of health and medical care should you be unconscious or in a coma or unable to speak for yourself. Your friend, then, has the legal right to make sure that the hospital and surgeons do not get to you while you are incapable of making a rational decision.

While you are in the hospital, you cannot be legally forced to take any drugs, shots, transfusions, or whatever. You may be subject to intimidation and threats, and dire warnings that you are "hurting only yourself" by the hospital staff. Stand firm, however; they cannot make you do anything you do not want to do.

You also have the right to *immediate release* from a hospital. To accomplish this, you may have to walk out on your own power, have a friend pick you up, or even get a private ambulance to take you back to your home.

You cannot be forced to sign anything, such as a "discharged against advice" form. In fact, *do not* sign such waivers or forms. These forms serve only to protect the hospital, not you.

You do not need to wait in the hospital while the bill is being drawn up; you can have it mailed to you and you can leave immediately. This is your legal right; do not let empty threats frighten you.

Many times, as soon as a patient is given "bathroom privileges," he is ready to be discharged and nurse the injuries at home.

Make the best of an unavoidable hospital stay. Try to rest and fast. If you eat, try to get only fresh, raw fruits and vegetables. Refuse "feeding" by injection. *Get out as quick as you can.*

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > 2. Emergency!!

## **2. Emergency!!**

First aid is often required at a time of emergency. You need to know two things in an emergency situation: 1) what to do, and 2) how to act. At the end of this section is a general list of things to do for various emergencies, injuries, and accidents. By reading this list and studying other books on general first aid, you can learn *what* to do. But *how* do you act in an emergency?

### **2.1 Act—Don't React!**

You cannot afford to become emotional during an emergency. There is no time for fear, for panic, or emotional outbursts. You must become totally calm, clear, and collected.

Do not panic. Think. Don't react to the blood or pain or tears—act now to save a life.

When you are faced with an emergency, the first question you should ask is: What is the most important thing to do *at the present moment* to help the injured person?

At all times, remain very calm when helping the person. If the victim senses you are afraid, then he too may panic, and cause additional harmful stress. Reassure the injured person.

If possible, send for additional help if you think it necessary. Try to remain with the injured person at all times, and attend to the most life-threatening injuries (such as uncontrolled bleeding, halted breathing, etc.).

Have some phone numbers handy or with you at all times that you can call for advice. Many Natural Hygienists and Life Scientists carry the phone numbers of one or more professional Hygienic doctors

and practitioners that they can call in an emergency. Prepare such phone numbers *ahead of time* so that you may easily call when an emergency does occur.

Realize that even in an emergency, the basic needs for life and health always remain the same: fresh air, pure water, rest, and no drugs. Simply because the body may be seriously injured is no reason to believe that drug use can be safely tolerated.

The one word to describe how to act in an emergency is: think. Use your head, use common sense, and use your knowledge of Life Science. Be confident and be calm and you can handle any emergency.

## **2.2 First Aid Treatments: Doing No Harm**

The following list of emergencies and injuries gives simple and harmless first aid treatments that can be used by anyone. Read the list thoroughly and try to remember as much as you can. Remember, in a real emergency, you will probably not have access to a book or list of things to do. It's important that you know automatically how to act in an emergency.

When faced with an emergency or a seriously injured person, you'll probably first want to take the five basic steps below:

## **2.3 The Five Basic Steps to First Aid**

### **2.3.1 Step One**

**DON'T MOVE THE VICTIM.** The only exceptions are when the victim would be in further danger if not moved immediately, such as a car accident where there is danger of gasoline explosion. Otherwise, leave him alone. You risk aggravating any injuries by improper moving. Wait until trained rescuers arrive.

### **2.3.2 Step Two**

**CHECK FOR BREATHING AND HEARTBEAT.** Put your ear to his face and listen, and at the same time watch for the rise and fall of his chest. If the victim is breathing, his heart is beating. If he's not breathing, blow four quick breaths into his mouth, then check his pulse by putting your finger on his neck, just to the side of his Adam's apple. Feel for a pulse for ten seconds. If you're sure there is no pulse, begin cardiopulmonary resuscitation. (See the end of this section.) If his heart is beating but he's still not breathing, continue mouth-to-mouth resuscitation. (See also at the end of this section.)

### **2.3.3 Step Three**

**SEND SOMEONE FOR HELP.** Don't you go, unless absolutely essential. You're needed to help the victim. Tell the person to call the emergency number for your area or the operator. Give your messenger as much information as possible without causing extensive delay, and tell him to pass everything along.

### **2.3.3 Step Four**

**CHECK FOR BLEEDING.** The best way to stop bleeding is by applying a clean piece of cloth. Hold the cloth or dressing in place with your hand. Once applied, don't remove it. If that's not enough to stop the bleeding, raise the affected area above the heart. If that's not enough, apply pressure with your fingers to a pressure point between the wound and the heart.

### **2.3.1 Step Five**

**TREAT FOR SHOCK.** Any person who's been injured can be in shock. The treatment consists of

keeping the person lying down and as calm as possible. Make sure he's breathing, elevate the legs slightly (unless he has a head injury or fractured leg), and keep him warm, but not hot. Don't give any liquids.

By following these five steps, you do the victim no harm and, in fact, may save his life.

What other aid you give depends on the specific nature of the injury itself. The next section details various treatments and first aid approaches for the more common injuries and accidents.

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > 3. Specific Injury Treatments

### **3. Specific Injury Treatments**

#### **3.1 Blood Hemorrhages and Excessive Bleeding**

For a blood hemorrhage, get a clean dry cloth and cover the area of bleeding. Apply direct pressure. The cloth should make a larger surface to aid in clotting. The blood should start to clot within three minutes if the cut is not too severe. If the cut is deep, and bleeding is severe, then it may take as long as ten minutes for the blood to clot.

If there is massive blood loss, strong spurting of blood, and a weakened pulse or falling blood pressure, then you should carefully apply a tourniquet *between the wound and the heart*. A quick tourniquet can be made from a shirt and belt.

Be careful when applying a tourniquet that you do not cut off *all* circulation beneath the wound. After twenty minutes of tight pressure, you may release the tourniquet gradually for five minutes and then tighten it again. You do not want to leave a tourniquet on for long periods of time as it may damage the tissue beneath the wounded area.

Excessive bleeding can be a very frightening experience, but remember: You can lose up to half of the blood in your body and still be able to function.

A severe cut or wound may require stitches. Accept the stitches but refuse any injections or treatments for "infections."

In all cases, blood transfusions should not be used. A person who has lost over 50% of his blood will produce more new blood faster if a transfusion is not given. Transfusions can cause serious problems or even death. The blood may be contaminated in handling; hemolytic reactions can occur between two different blood types, resulting in a 50% mortality rate; air in the transfused blood can cause death; blood is often obtained from "paid" donors who often have drugs and other toxins in the blood given for use in transfusions.

#### **3.2 Wounds and Puncture Wounds**

Cleanliness is important in treating wounds. Wash the area thoroughly with plain water. Wash or gently scrub to remove all dirt and particles. Do not use soap or antiseptics. If the wound is not too deep or bleeding profusely, leave it open to fresh air and sunlight. If a deep wound, cover it with a porous bandage, such as gauze held with tape. Do not use airtight bandages, or band-aids. Let air circulate through the bandage to the wound.

If the wound is a puncture, such as caused by a nail or glass, you may let the wound bleed freely for a few minutes. If the wound is small and slender (such as made by a nail), gently massage and press

around the wound to encourage a *small* amount of bleeding. There is a purpose to bleeding; it acts to carry away foreign particles from the wounded area. If the wound is large and blood is pouring, then suturing may be required.

In no case, however, are anti-tetanus shots required or any other injections for so-called infection. The introduction of poisons (drugs) or bactericides into the bloodstream cannot be of any help to a wounded body. Considerable harm can be done.

### **3.3 Cuts, Burns, and Scalds**

For immediate relief, immerse the burned or scalded area into cool water. Keep the area clean, and protect any open wound with a light moist covering (such as thick gauze dampened with water). Let the burned or wounded area be open to fresh air and open circulation. Keep burns, however, out of direct sunlight. Salves and ointments should not be used. Cool, fresh compresses should be alternated with exposure to open air. Some Hygienists have reported using freshly-pressed celery juice or a compress made from fresh green plants to alleviate the burning sensation and reduce pain.

### **3.4 Sprains, Strains, and Torn Ligaments**

Rest—do not move needlessly. Fix the limb in one position and immobilize the joint for the initial period. If the limb is dislocated, you may need to see an osteopath or orthopedist to get the limb back into place. In any case, refuse all drugs, including pain-killing pills.

If in pain, immerse the affected joint into cool (not ice) water for one to two minutes and then take out. Repeat this five or six times an hour for as long as there is pain.

After pain leaves, stay off the affected limb or do not use it for a period of time. Gradually start exercising, but do not be in a hurry to put a lot of pressure or strain on the limb.

### **3.5 Poison Ivy, Poison Oak, Skin Rashes**

Bathe immediately. Apply copious amounts of cool to cold (not ice cold) water. Do not rub or scrub area. Do not apply salves or ointments. Do not allow direct or intense sunlight to burn or heat the area. Do keep the rash open to fresh air. Rest and relax—the stress that accompanies a skin rash can often aggravate it. Do not worry. Apply cool compresses for itching and do not scratch.

### **3.6 Snake Bites**

A poisonous snake usually makes fang marks. A non-poisonous snake usually makes a U-shaped mark.

If you are sure that the snake is nonpoisonous, then simply wash and clean the punctured area. Allow a small amount of bleeding to occur. Watch the victim for any reactions.

If the snake is poisonous, immediate action is necessary:

1. First, have the person lay down flat and stay calm. Have him/her breathe long, slow, and deeply to slow down the pulse rate and circulation. It is very important that neither you nor the victim show any signs of panic.
2. Next, apply a tourniquet as quickly as possible around the upper arm, leg, or thigh. Twist the tourniquet tight with a stick until you can feel almost no pulse at all in the limb that the tourniquet is applied to. Leave this on tight for twenty minutes, then release for five minutes. This can be done for up to several hours *if you watch the circulation and do not leave a tight tourniquet on for extended periods with no release.*
3. Transport the victim in a vehicle if at all possible; do not allow him to walk or become excited. The venom may be removed from around the area by a suction cup. Anti-venom shots should not

be used.

4. Fast the victim afterwards.

### **3.7 Spider or Insect Bites**

Most insect bites are only slightly poisonous. Do nothing and forget about them. You may wish to fast if you have multiple stings or swelling.

Some insects, such as scorpions and black widow spiders, can cause a numb feeling for up to 24 hours. In this case, a one- to two-day fast will help restore the body to normal.

If the stinger remains in the skin, carefully remove it. Be cautious, however—many stingers that are left in the skin often have a tiny poison sack at one end. If you press this sack when you remove the stinger, more poison will be shot into your skin. Use tweezers or a razor blade along the surface, taking care not to press the stinger or the poison sack.

The pain and itching will soon cease, and there is no need for salves or ointments.

### **3.8 Poisoning By Swallowing**

After a poison is swallowed, you have only 20 to 30 minutes to neutralize it. After that, the poison will be transported throughout the body.

Be careful about inducing vomiting. Some poisons, such as caustic acids, can actually do more harm when they are vomited back up. It is usually best to try to neutralize or dilute the swallowed poison by drinking large amounts of water. Although milk may not be a fit food, it can certainly be used to good effect in neutralizing poisons. Milk can neutralize both acid and alkali poisons. If milk is available, have the victim drink as much as he can hold.

If spontaneous vomiting starts, don't stop it. Similarly, if diarrhea or fever occur after the poisoning, do nothing to stop them, even if the fever reaches 106 degrees or more. If the person is unconscious or is having convulsions, do not attempt to make him/her vomit the poison. He/she may choke to death.

If the mouth appears burned, or if lye or petroleum (like gasoline) products were swallowed, definitely do not allow vomiting to take place. Any products that are thrown up which contain lye or petroleum products can severely damage the esophagus and lungs.

Since vomiting is not to be encouraged in many cases of poisoning, try the following liquids to neutralize the poison's effects:

For acid poisons, drink either milk, olive oil, egg whites, or water containing baking soda.

For alkali poisons, drink either milk, raw eggs, olive oil, or water containing lemon juice or vinegar.

In some cases, the stomach may need to be pumped or, an antidote given. An antidote is of course a foreign substance, but in most cases, it is less dangerous than the poison swallowed and may be the most expeditious way of saving a life.

After neutralizing the poison, rest and fast for several days. Drink only pure water, and let the body heal any internal damage.

### **3.9 Asphyxiation or Suffocation**

Give artificial respiration. Place the person flat on the back, turn the head to one side, and remove any obstructions from the mouth. Make sure that the tongue is not curled up in back of the mouth. Press the victim's nostrils together, and blow into the mouth every four seconds. Pump the arms and lungs as necessary to get the breathing going again. Even if there is no response, continue blowing into the mouth and try to fill up the person's lungs. People have often been kept alive for long periods by simply giving

them artificial respiration and not giving up.

### **3.10 Choking**

Someone who is choking won't be able to utter a sound. He may also clutch at his throat. Here's what to do:

1. Stand behind the victim and support him in front. Bend forward and slap him soundly between the shoulder blades to dislodge material from his throat.
2. If that doesn't work, try these steps called the Heimlich Maneuver:
  - a. Wrap your arms around the victim's waist from behind.
  - b. Make a fist and push it, thumb in, against the victim's stomach, between the belly button and ribs.
  - c. Grab the fist with the other hand and pull sharply in and up. If necessary, repeat several times.

### **3.11 Electrocuting and Drowning**

Artificial respiration and resuscitation are necessary, just as for asphyxiation. (See the technique on mouth-to-mouth resuscitation in the next section, "Emergency Techniques.")

For an electrocution victim, it may take four to five hours to revive the victim. Do not give up; have someone relieve you, but continue with the artificial respiration until you can get help. For a drowning victim, make sure that the mouth passage is cleared out and that no swallowed water remains in the lung passageway. Continue as above with artificial respiration.

### **3.12 Convulsions**

Make sure that the person cannot injure him or herself. At the first sign of a convulsive fit, place a rolled piece of cloth between the teeth to prevent the tongue from being bitten in the attack. Keep the person under close observation, remove any harmful objects within reach, and simply wait. Convulsions may last from 30 seconds to an hour. Brain damage is more apt to occur because of interference with the convulsions than from the convulsions themselves.

### **3.13 Appendicitis (Acute)**

This is an extremely painful condition, but one that rarely requires surgery unless severely neglected. At the first sign of pain, call a Natural Hygienic practitioner.

Bring the knees up as high as possible to the chest to relieve some of the pain. Do NOT eat. Do NOT drink. Do NOT take enemas. Do NOT press, poke, push, or prod painful area. Do NOT apply heat or cold.

Unless peritonitis develops, you can go through an appendicitis attack without any surgery or outside interference. If, because of neglect and continued dietary errors and excesses, the appendix should rupture, then certain surgery may be necessary to drain the abdominal cavity. When peritonitis does develop, you can tell by the presence of a very high fever and a tremendous rigidity of the abdominal muscles. The stomach area becomes "tight as a drum" and very rigid.

Such an extreme condition would not result if a fast were started at the *first* sign of an appendicitis attack. Most people, however, ignore the first few warnings and continue with their old ways of eating. Appendicitis is due 100% to dietary errors.

### **3.14 Vomiting and Diarrhea**

Do nothing to stop either vomiting or diarrhea. Watch for dehydration if they persist for a long period of time. Drink only water. Stop all food intake. Begin an immediate fast.

### **3.15 Nosebleeds**

Sit the patient in a chair with the head tilted forward.

Moisten a piece of cotton and place inside the bleeding nostril. Press the nostrils together and hold for at least five minutes or more, and have patient breathe through his mouth. After bleeding stops, the cotton should stay in place for several hours.

### **3.16 Stings by Jellyfish, Wasps, Fire Ants, Etc.**

These types of stings are accompanied by a neurotoxin that is injected under the skin. The only serious effect of such an attack is usually great pain. To relieve the pain, try a paste of baking soda and water. In some cases, relief can also be obtained by rubbing lemon juice or vinegar around the bite.

### **3.17 Dog Bites**

Wash the wound well with water only, and let it bleed freely for a few minutes. Clot the blood with a clean cloth. If the area is not so large as to require stitches, then simply forget about it.

Do NOT get rabies shots or treatments. Such treatments are far more dangerous than the bite.

### **3.18 Foreign Particles in the Eye**

Wash your hands and then carefully pull your upper lid down over the lower lid. Wipe the corner of the eye gently with a clean cloth or cotton. Do NOT rub the eye. This may push the particle farther under the lid. Try to get the eye to "cry" or to "tear."

If irritation continues or if a piece of glass is in the eye, then seek professional help in removing it.

### **3.19 Broken Bones**

Do NOT move the victim, unless it is a question of life or death, if the broken bone is in the neck or spine. Wait for outside help if possible. If you cannot wait, make a temporary splint and transport the victim as best you can. For a temporary splint, you can use branches, boards, or even the body itself (e.g., tie broken leg to uninjured one). For a broken ankle, carefully wrap the foot in a pillow, and tie it closed. For any fracture, don't tie anything directly over the wound—tie above and below it. Best procedure, thought, is to wait for help to arrive if you can.

A broken bone is rarely a critical situation; you can usually wait and have it set by an osteopath or orthopedist.

Rolled newspaper splint.

### **3.20 Heart Attack or Stroke**

Some or all of these symptoms can point to a heart attack:

1. Pain, usually in the middle of the chest, or in the left shoulder or arm, or the neck. May feel like a crushing force.
2. Pale and sweaty skin.
3. Feeling of impending doom.

#### 4. Shortness of breath.

Here's what to do:

Place the victim horizontal, and elevate the head slightly. Loosen or remove all constricting clothing. Give artificial respiration and fairly vigorous cardiac massage if the heart appears stopped. (See the "How to Give CPR" in the "Emergency Techniques" section.)

Make sure that fresh air is available, and the patient is kept warm. After the attack, complete resting (including a fast) is essential.

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > 4. Emergency Techniques

## 4. Emergency Techniques

Every person (both child and adult) should be taught the two emergency techniques described below. In the local news was an item about a four-year-old boy who saved the life of his two-year-old brother because he knew how to give mouth-to-mouth resuscitation and CPR. It's never too early (or late) to learn about emergency life-saving techniques.

### 4.1 How to Give CPR

*CPR stands for cardiopulmonary resuscitation.* CPR is the only way to save the life of someone whose heart has stopped. To learn it properly, you should take a CPR course. The American Heart Association and the American Red Cross offer excellent CPR courses.

If you've determined that a person has no heartbeat, you must begin CPR. Here's how:

1. Kneel at the person's side.
2. Find the bottom of the breastbone—the bone in the middle of the chest.
3. About two inches above that, place the heel of your hand.
4. Place the other hand over the first hand and lock the fingers.
5. With arms kept straight, push down on the chest, so that it's compressed about 1-1/2 or 2 inches.  
*You must push fairly hard.*
6. As you push, count out loud: "One, and two, and three, and four, and ..." Keep going a little faster than one push per second until you get to fifteen.
7. After 15 pushes, move quickly back to the person's head, and blow two quick breaths into his mouth.
8. Then go right back to his chest, find the spot two inches above the bottom of the breastbone again, place your hands, and push 15 times again.
9. Keep on with 15 pushes, then two breaths, and so on, until one of these things happens:
  - a. You are relieved by someone who can do CPR, or
  - b. The person's heart starts beating (check his pulse every minute or so). You may still have to continue mouth-to-mouth resuscitation. Or,
  - c. A physician pronounces the person dead.

### 4.2 How to Give Mouth-to-Mouth Resuscitation

When someone stops breathing, no matter whether it happened because of drowning, electrical shock, heart attack, or anything else, you can breathe for him by giving mouth-to-mouth resuscitation. Here's how:

1. Place victim on his back.
2. Check inside of mouth for material that could block the air passage. Clean out if necessary.
3. Kneeling at the side of his head, place one hand on the forehead and the other under his neck. Tilt the head back (unless you suspect a neck injury) so the jaw is pointed up. This keeps the airway open.
4. With the hand that's on the forehead, pinch the nostrils shut.
5. Blow four quick breaths into the victim's mouth, hard enough to fill lungs. If chest doesn't rise, clear the airway by cleaning out mouth, or roll victim on his side and slap between shoulder blades to dislodge material. Then roll him back and try breathing again.
6. After the four initial breaths, remove your mouth and watch for chest to fall.
7. Continue by blowing one breath into victim's mouth every five seconds until he starts breathing again on his own. (For small children, blow into mouth and nose, one breath every three seconds.)

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > 5. Accident Prevention: The Life Science Way

## **5. Accident Prevention: The Life Science Way**

First aid can help you when an accident or injury occurs, just as fasting can help when the body starts a disease or illness process. But wouldn't it be nice if we didn't get sick or never become injured?

If you follow a sensible program of exercise, diet, and other health-building practices, then you will have the best health insurance you can buy. But what about accident insurance? Will the Life Science health regimen prevent us from becoming injured or having accidents?

The answer is YES.

It is a fact. A healthy person has fewer accidents and suffers less injuries than the average individual. Maybe you know someone who is "accident prone" or who always seems to be injuring him or herself. On the other hand, you may know someone (perhaps even yourself) who rarely suffers misfortune or injury.

The majority of all accidents and injuries occur because of an error in judgment. In other words, faulty or unclear thinking leads to accidents. A healthy person can think more clearly, make more correct decisions, precise movements, and avoid many of the minor injuries and accidents that happen to most people.

Most injuries and accidents are self-invited, either consciously or unconsciously. They occur because we are not "on top of things" or when we are not at our best. Haven't you noticed that many accidents happen when we are under stress or have been engaging in negative lifestyle patterns?

When you become more healthy, you take charge of your life on all levels. You become more capable and more in control. You don't become "off-centered" or "spaced out." A healthy body seeks to preserve its health. A sick or diseased body is an intoxicated body. It often hurts onward to self-destruction through negative thought patterns, imprecise actions, poor health habits, and, yes, through accidental injuries.

If you cannot quite believe the truth that healthy people have fewer accidents, then you should at least understand that a healthy body can recover more quickly when an injury does occur.

Melvin Kimmel, a Natural Hygienist, had this to say about staying healthy and injuries in an issue of *Dr. Shelton's Hygienic Review*: "The best safeguard for emergency situations is to stay healthy."

Keeping the cells of our body in optimum condition by following the raw food diet, sensible exercise, and so forth can not only save lives, but can minimize accidental injuries." When the body is injured, a healthy person can recover quickly and without the complications that often send others running to the physician."

Accident prevention should be a major concern of every health-seeker. Besides staying healthy, what else can be done to minimize the risk of injuries and accidents? First, do not take unnecessary risks.

Severe injuries often result from such activities and sports as skiing, sky diving, motorcycle riding, etc. Wouldn't it seem intelligent to avoid those sports and activities that have a high-risk factor? This does not mean that we should be afraid to be active or to exercise. It simply means that when we have a choice, we should choose those activities that have a proven history of fewer injury-related incidents. There is no need to expose yourself to unnecessary risks and potential injuries. A person concerned about health will choose jobs, hobbies, activities, and sports that do not have a high-risk factor or past history of frequent accidents.

Another benefit of healthful living is that you will be relatively immune to accidents and injuries that are alcohol or drug related. Over 50% of all traffic accidents, for example, involve alcohol. Alertness can protect you somewhat from a drunk driver. You can spot and avoid erratic drivers.

If we avoid alcohol and all drugs, both legal and illegal, then we can maintain a clarity of judgment and precise actions that will not subject us to injuries.

First aid is fine *after* the accident or injury. But as with disease and illness, wouldn't it be nicer if we did not have accidents in the first place?

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > 6. Questions & Answers

## 6. Questions & Answers

**I'm confused. First you say that first aid may be the last aid a person needs. Then you say that sometimes emergency surgery could be necessary. What I want to know is when do you go to the hospital and when can you stay at home and treat an injury yourself?**

A visit to a hospital or any type of surgery could be in itself a life-threatening episode. If you sincerely feel that your life is in danger, that your condition is deteriorating, and that your own efforts are not enough, then by all means seek additional help! There are some things that the medical profession is helpful for such as setting broken bones and stitching ruptured arteries

As a general rule, seek additional help when the mechanical injuries done to your body are so great that the body (itself cannot effect a repair without some aid. In other words, you must get the condition of the body stable and whole to start the healing process. If the body is stable, sound, and suffers no major mechanical injury, then do not worry about additional help or aid.

**You say no drugs. But when I broke my leg, I wanted a pain killer! Aren't anesthetics okay at times like that?**

We have to be practical about this sort of thing. Sometimes it would be impossible to set a bone or repair a major injury without some type of pain killer. If the anesthetic is only given initially while the repair is being made, then it would seem that the advantage would

outweigh the disadvantage. If, however, you take pain pills after the operation as a regular course of action, or continue to receive injections to deaden you, then that is drug abuse

Anesthetics are not given to speed up healing or to "cure" anything. They are used (or should be used) as a temporary, one-time measure during a crisis

A normal, healthy, and whole body would never need injections or drugs of any kind. An injured broken body is not normal, and while the repair is being made a mild anesthetic may be a practical necessity

I would also strongly suggest investigating acupuncture as an alternative for anesthetic drugs during surgery or repair. A properly-trained acupuncturist (and there are many more nowadays) can deaden nerve paths more safely than drugs for emergency surgery and repair. Acupuncture and acupressure are techniques for distressing a nerve center to induce brain secretion of its endorphins (endogenous morphine).

[Home](#) > [Lesson 68 - First Aid And Natural Hygiene](#) > Article #1: The Tough Cookie Life Scientist by Peter Gregonis

## **Article #1: The Tough Cookie Life Scientist by Peter Gregonis**

Natural living is difficult to achieve in our society because we are conditioned from birth to be dependent upon authority. How can a person come to trust the body's self-healing ability when we are hammered with the idea that serums, drugs, vitamins, or physicians will bring us health? Trying to fight against this constant barrage of ideas is like swimming against a rushing stream. It takes tremendous strength and willpower to go it alone.

However, once we realize that the bodily intelligence is supreme in all matters of sickness and health, we can take delight in swimming against the tide of mass opinion and even gain nourishment and strength from this opposition.

### **How Terry Did It**

Let us suppose that you were involved in a serious auto accident and you were hauled unconscious to the hospital. Upon awakening, what would you as a Life Scientist do? Would you order that your badly mauled body be taken out of the hospital to your home?

This happened to T. C. Fry several years ago. Tough Cookie Fry came to, and his first thoughts were to flee the hospital and the doctors. Why let these people ride to glory upon the body's ability to heal itself? So Terry's badly bruised body was taken to his home where he immediately began a fast.

For 14 days T. C. refused food in order to give his body a chance to concentrate all of its energy upon the healing process. The healing process took less than a month; it would have taken twice as long under hospital care.

You too can learn to dispense with physicians and their medical treatments. Join the Life Science movement and trust the highest intelligence of your body.

## **Article #2: First Aid and Hygiene by Dr. Alec Burton**

It is important to understand that the basic principles of Hygiene should not be violated in cases of emergency. The body's needs must be met and its capacity recognized. Obviously, there are conditions which result from injury and accidents that require some immediate and skilled mechanical attention.

In cases where such first aid is necessary, we should still avoid violating the fundamental principles employed in the Hygienic system. We should avoid employing procedures which are likely to be damaging in the long term, even if a short-term end is gained.

In certain situations, such as fracturing a bone, dislocating a joint, or severing an artery, which represent mechanical injuries, then mechanical techniques of correction are necessary and justified. However, these mechanical techniques are only justifiable so far as they go. They have no relation whatsoever to actual healing, nor do they remove causes except in the immediate sense. Healing is a fundamental biological process and we employ some of these techniques—like the reduction of dislocations, the setting of broken bones, and minor surgery—in order to facilitate healing, not to perform it. Artificial respiration certainly may prevent a person from dying and in no way could it be considered as harmful, nor does it attempt to usurp the normal and orderly processes of the organism. It is a temporary mechanical procedure that enables the body to perform the functions of life more satisfactorily under the prevailing conditions. Strictly speaking, the "respiration" is anything but artificial.

You may have heard of the millionaire who came running on to the beach to see his wife who had just been dragged from the water and artificial respiration was being administered. The gentlemen screamed at the man, "That's my wife! What are you doing?" "Well," said the young man, "Your wife almost drowned. We're giving her artificial respiration." "Artificial, be damned," was the reply. "Give her the real thing—I can afford it!"

When we have to resort to surgical or mechanical techniques as may be required, and where tissues are severely damaged after serious injury, it is sometimes necessary to relieve pain and consequently the age-old question of the use of anesthetics arises. I think we have to make a distinction between caring for the sick and facilitating surgical intervention. For example, a victim of a motor accident who requires a limb amputation—it would be unthinkable to approach this surgical onslaught without providing, so far as we are able, freedom from pain. In the case of accident or injury, we are not dealing directly with a problem of health and disease. We are not trying to modify symptoms at the expense of the injured person's future health. We are simply trying to restore a certain mechanical facility to the body. We are attempting to mechanically adjust the body.

Constructive surgery does not in any way violate Hygiene and the use of anesthetics may be justified under these conditions. At the same time, we must realize that, having spent the last two or three thousand years discovering the fact that there is no virtue in remedies, drugs do not change their character with circumstances. The fact that wounds heal when ointments are put on them does not mean that the wound would not have healed if an ointment had not been administered. At best, the use of salves and ointments alike can only fall into the dubious category of, perhaps, affording a little protection for the wound. Certainly, they have no power to heal. The power to heal must always be related to the living body itself as an inherent biological function.

It is so easy to think that when we take a remedy or apply an ointment to a wound and it heals, that the extraneous substance has performed the healing. Finally, the cold disappears and the last thing we took before we got well is thought to have "cured" the cold. It is surprising how many people expect wounds to heal when they continually interfere with them, and this particularly applies to the numerous mechanical problems that people have from injuries they suffer. Continuous interference will often delay

and, in some cases, actually prevent healing.

I recall a number of years ago when I had an office practice in England, a gentleman who owned a restaurant on the lower floor of the same building consulted me about his stomach problem. Sometimes in the evenings when I closed my office, we used to walk to the station together. At these times, we used to discuss various things and inevitably his stomach problems would always arise (no pun intended). Never having taken my advice of course, he always had his stomach problems. He used to complain of these severe pains and quite commonly he would stop at the local chemist and get something to relieve the pain in his stomach. He was constantly swallowing antacids and pain relievers.

One day, I put it to him this way, "I don't think your stomach will ever recover. Supposing I were to put my finger on the table and hit it with a hammer and it were to become mangled, bruised, and bleeding, and then were to rub all sorts of ointments over it and bandage it, and then put it back on the table and keep on hitting it with a hammer. How long do you think it would take to heal?" He said, "It would never heal." "Right," I said, "Now, let's take another situation. A man who has a pain in his stomach all the time and continually takes hot, fiery, spicy foods, incompatible combinations, and constantly smothers the various discomforts with powders, antacids, and other drugs that have no business in the stomach whatsoever. How long do you think it would take for that stomach to heal?" My friend did not answer the question and, as far as I know, he continued to take his palliatives.

But I think I made my point that by continual interference, no matter whether the lesion is the evolution of a disease process or whether it is the result of accident or injury, healing cannot be effected. Healing, we must contend, is a fundamental biological process and is directly related to the soundness and general functional vigor of the individual. Certain external factors are required but it must be emphasized that these external factors are secondary to the internal factors. The internal factors are related to our general level of health, our functional efficiency, our basic vitality.

I am sure we all know those people who are in vigorous health and if they suffer an injury, they recover quickly and regain normality. We also know other people who suffer the most serious consequences from what seem trivial wounds and, of course, this is directly related to their degree of health. The fact that we can damage ourselves and recover quickly does not mean that we can violate the laws of life.

The basic principle of cause and effect is always in operation. *There are consequences to every action.*

Now, there are certain objects in first aid. First, to prevent a person from dying and I consider that this is a better way of expressing the fundamental rather than the mendacious euphemism "to save the person's life." Philosophically, I do not believe it is possible to save a person's life. But it is possible to prevent people under certain circumstances from killing themselves. This, then, is the first requisite of applying first aid techniques. We have to try to prevent death from occurring. Secondly, we have to attempt to minimize the suffering. Thirdly, to prepare the sufferer for subsequent care, i.e., to avoid the possibility of complications later.

Some years ago, an acquaintance of mine was involved in a motorcycle accident and dispatched to the hospital. He was discharged some hours later when the initial examinations revealed no serious injury. However, the following day, he collapsed and was returned to the hospital where it was discovered that he had a ruptured spleen. This was not immediately evident but the precaution should have been taken.

When we speak of an emergency, this implies an absolute need for immediate attention. Quite commonly, this is not the case; but an emergency is certainly a time when something actually has to be done.

In Hygiene, we are, I suppose, notorious for our belief in the philosophy of doing nothing intelligently or intelligently leaving things alone; but there are certain conditions, and we are well aware of these, where it is intelligent to do something and that doing something is imperative if we are to prevent deterioration and possible death. However, we must acknowledge that before anything is done, we must be fully aware of what it is that we are doing and what the reasons are for doing it. It is always possible to do something but in many instances whatever we are doing is merely interfering. We are placing obstacles

in the path of the body's processes and this is the very thing we must always attempt to avoid. Nevertheless, there are cases where something actually must be done. I recall a few years ago being at the bedside of a young child whose parents were keen Hygienists. This child had been taken rather sick two or three days before, and the parents had placed him on a fast with absolute rest, and yet he was apparently deteriorating. They called me for advice and I discovered that the young child had a strangulated hernia. Obviously, surgical intervention was necessary. Here we had a mechanical problem that, required a mechanical procedure provide the body with favorable conditions for recovery. Doing nothing in this situation was certainly not intelligent. The use of mechanical procedures and surgical techniques in an attempt to remove immediate causes of trouble does not in any way invalidate the fundamental premises on which the Hygienic system is based.

Following accidents and injury, we are dealing with mechanical problems which require mechanical solutions rather than a pathological evolution which has disturbed the body's chemistry and physiological activity. This requires understanding and the removal of cause. Philosophically, I agree there is a fine line of demarcation, and it is easy for the type of remedy-mentality that is common to extend the therapeutic approach to the vast array of illness or symptom complexes that evolve in the sick as a result of their unhealthy lifestyle.

First aid represents immediate and temporary care. It is not designed to restore health but merely to avert the possibility of further damage or even death. Many of the techniques commonly employed provide nothing but interference. Somebody once remarked that experience is something you get from making mistakes. I have always thought that it is much better if we can learn from other people's mistakes. Of course, this is sometimes difficult as we are not prone to learning from other people's mistakes. We always, like to make them for ourselves, and then we know for sure. But gradually, one by one, many of the stimulants such as alcohol, strong tea, sugary drinks, which were employed as a means of dealing with shock, have been abandoned and no doubt as time passes many other measures which are essentially interference will be abandoned as well.

### **1. Introduction**

Most addicting habits arise from the desire to suppress symptoms or to overcome the feeling of tiredness. These symptoms appear due to an unhealthful lifestyle. Poisons are often resorted to instead of correcting the cause of the symptoms. All drugs and coffee, tea, chocolate, soft drinks, tobacco, etc., stimulate and give the false sense of well-being but this feeling lasts only a short time when depression occurs and the addict resorts to even higher doses of his poison. So the cycle goes on and on.

The Hygienic approach is a very rational one. To break this self-poisoning cycle, a fast is instituted followed by a normal and physiological pattern of eating. With this approach, the addict will find that it is much easier to discontinue his habit than with any other method. Furthermore, there will be no more desire for the former habit.

### **2. Stimulation Effects**

#### **2.1 Alcohol**

Alcohol is absorbed into the blood, principally from the small intestine. It accumulates in the blood because absorption is more rapid than oxidation and elimination. Depression of the central nervous system is a principle effect of alcohol. The CNS is at first stimulated. This is a defensive response by the body to begin action to eliminate this harmful poison. Due to the enervation that invariably follows, exhaustion and depression follow.

People who drink large amounts of alcohol repetitively become somewhat "tolerant" to its effects; later doses seem not to have the same intoxicating effect as earlier ones. This tolerance is not based primarily on changes in drug dispositions or metabolism but is caused by destructive changes in central nervous system cells. Those said to be tolerant to alcohol may have incredibly high blood alcohol concentrations. In this case, the body has become so enervated that it has lost its capacity to react to this drug and eliminate its poisons from the system. The so-called "physical dependence" accompanying tolerance is profound, and withdrawal produces a series of pronounced physical and mental effects. While these symptoms may be severe, the acute period usually only lasts about two days if the alcoholic fasts, but may last as long as ten days under orthodox treatment. Delirium tremens, experienced by many alcoholics, usually ceases after two days on the fast. Since alcohol results in central nervous system stimulation and its eventual depression, it invariably has similar effects on all bodily parts connected with the CNS and this includes everything. Especially effected is the brain and this is demonstrated in the alcoholic's lack of memory, disorientation, slurred speech, etc.

Also, there is a marked prevalence of vitamin B deficiency, especially thiamine, due partly to the poor diet of the alcoholic and partly due to malabsorption of this vitamin by the impaired gastrointestinal tract of such individuals. Many so-called vitamin deficiencies have been corrected during the fast while no food was being ingested. The body normalizes while on the fast and certain food stored vitamins are utilized. On the Hygienic diet of raw fruits, vegetables and nuts, no thiamine deficiency could be possible because all of these foods contain this vitamin in abundance. Thus, the alcoholic is very greatly benefited by this raw diet since his body will be provided the most ideal conditions for normalcy of function to return. Not only will all nutrients be available for utilization but the proper conditions will be provided for healing.

Usual orthodox treatment includes large doses of vitamin C and B-complex vitamins, particularly thiamine. These inorganic vitamins will not provide any benefit to the alcoholic since the body cannot utilize nutrients in this form. The result will be added toxins and additional problems for the body to deal with. In addition, alcoholics are often given fluids if they are thought to be dehydrated. The usual therapy is 1,000 ml of 5% dextrose in a saline solution followed by 1,000 ml of 10% dextrose in distilled water. This practice is totally anti-life and will result in more stimulation if the body is able to respond defensively. In any case, it is harmful practice.

Drugs are used frequently to treat the alcohol withdrawal symptoms. But trading one drug for another never results in health. It only results in additional sickness and destruction of tissues and cells.

Another treatment given to alcoholics is the administration of Disulfiram. This is a drug that interferes with metabolism of acetaldehyde (an intermediary product in the oxidation of alcohol) so that acetaldehyde accumulates, producing toxic symptoms and great discomfort. Drinking alcohol within twelve hours after taking Disulfiram results in facial flushing in five to fifteen minutes, then intense vasodilation of the face and neck with suffusion of the conjunctivae, throbbing headache, tachycardia, hyperpnea, and swelling. Nausea and vomiting follow in 30 to 60 minutes and may be so intense as to lead to hypotension, dizziness, and sometimes fainting and collapse. The reaction lasts one to three hours. Discomfort is so intense that few patients will risk taking alcohol as long as they are taking Disulfiram. This is obvious an extremely dangerous practice.

We take a more rational approach. It is so much more pleasant (and beneficial) to fast in an atmosphere with fresh air, peace and quiet, and then to enjoy the wonderful raw foods that nature has prepared for us. Following a more natural lifestyle, the alcoholic will never crave this poison again.

## **2.2 Addictions to Opiate-Type Drugs**

Use of opiate-type drugs, such as heroin, results in stimulation of the central nervous system and one of the first noticeable signs is a strong psychic dependence on an overpowering compulsion to continue taking the drug. This dependence may be evident as soon as two to three days after beginning use. Thus, so-called "therapeutic" use of narcotics that are given by some physicians often creates some tolerance

and dependence and the user may show symptoms of withdrawal when the drug is discontinued.

The effects of this drug are so damaging and enervating to the nervous system and all systems of the body that a situation is soon created where the body is too enervated to react defensively. In this case, the addict resorts to increased dosages and more frequent dosages until he again achieves the stimulation that he is seeking.

Acute intoxication with opiates is characterized by euphoria, flushing, itching of the skin, abnormal contraction of the pupils, drowsiness, decreased respiratory rate and depth, hypotension, slow heart rate, and decreased body temperature.

The entire body is in an extremely debilitated condition and the only remedy for this situation is rest. That is, total rest until the body can once again begin to function normally. So the addict must fast. Following the fast, the raw foods diet of fruits, vegetables, and nuts will provide the body with the optimum materials to make those desperately needed repairs of the damages that occurred while taking this deadly drug.

Withdrawal symptoms are the opposite of the drug effects (central nervous system hyperactivity). In other words, depression of the CNS occurs. The symptoms may be severe and occur rapidly but are self-limited and the length of their occurrence and their severity will be less while fasting than while eating.

Orthodox treatment often-involves administration of methadone but this results in another type of addiction, so nothing worthwhile has been accomplished. The withdrawal symptoms of methadone are similar to those of heroin.

## **2.3 Caffeine Addictions**

People become addicted to caffeine because of its stimulating effects. Caffeine is a powerful central nervous system stimulator affecting the cortex first, then the medulla, and finally the spinal cord as the dose is increased. Large doses of caffeine may result in impaired motor function. Adverse effects may occur after 150 to 250 mg of caffeine, equivalent to one or two cups of coffee.

Persons who drink large amounts of coffee (fifteen to twenty cups a day) may develop "caffeinism." The symptoms of this illness are insomnia, a slight fever, and irritability.

Children are particularly affected, probably due to their lower body weight.

Caffeine results in stimulation of the heart with tachycardia and arrhythmias. Caffeine also stimulates release of catecholamines from the adrenal medulla, and norepinephrine is released from nerve endings in the heart. Catecholamines have a marked effect on the central nervous system, metabolic rate, temperature, and smooth muscle.

## **2.4 Cigarette Smoking**

Nicotine, in the tobacco, has been found to result in increased heart rate, blood pressure, cardiac output, stroke volume, and velocity of myocardial contraction. An entire lesson was devoted to this pernicious habit so I will not enlarge upon it here, but again, it is a habit endorsed for its stimulating effects.

[Home](#) > [Lesson 69 - Nutritional Approach To Overcoming Addictions](#) > 3. An Illusion

## **3. An Illusion**

According to the Law of Dual Effect, "The secondary effect upon the living organism of any act, habit,

indulgence, or agent is the exact opposite and equal of the primary effect."

This means that when you take a drug of alcohol, caffeine, etc., the first effect will be that of stimulation. But the second and lasting effect will be just the opposite—depression. Enlarging upon this subject, Dr. Shelton states, "Tea, coffee, cocoa, chocolate, spices, meat, etc., which appear to give strength (their first effect), invariably as their secondary and lasting effect, weaken in proportion to the strength they appear to give."

"Alcohol which apparently strengthens and which, for a very brief moment increases function, results in diminished function and weakness. Alcohol, like ether and chloroform, does not add power to the system. It only occasions the expenditure of power already possessed. It is properly classed as a caustic irritant and the exalted function, which first follows its use, is not due to any power it communicates to the body and mind, but to the vital resistance and consequent expenditure of vital power its irritating effects occasion. Its secondary effect is due to the exhaustion of the vital powers and its destructive effects upon the tissues of the body.

"Opium permanently produces sleeplessness, nervousness, and pain because it temporarily relieves these conditions. Give opium to cure a man of pain! Who has pains equal to those of the opium addict? The nomenclature of medicine needs revision. Opium and other anodynes and antispasmodics should be classed as odynes and spasmodics. The whole class of tonics should be classed as atonics. "Stimulants" should be called depressants. These substances should be classed according to their secondary and lasting effects and not according to their primary and temporary effects.

"A cup of coffee will relieve a headache but in so doing it permanently fastens the headache habit upon the patient. It will relieve mental depression, but when the user is deprived of his coffee he becomes doubly depressed. Tobacco steadies the nerves only to unsteady them. Tonics strengthen only to debilitate. Purging produces constipation, diuretics produce inactivity of the kidneys, expectorants result in dryness of the lungs. If the habitual user of any drug will cease its use for a few days, he will experience in their fullness all its secondary effects. If he then returns to his use of the drug, he will be delighted to find that these secondary effects are 'cured' by it. The disease is 'cured' by its cause—coffee appears to cure the headache it produced; whiskey *seems* to restore strength it has wasted; tobacco *seems* to restore steadiness of nerves it has destroyed."

With these facts in mind, we must be sure that our foods do not contain equal stimulating qualities.

[Home](#) > [Lesson 69 - Nutritional Approach To Overcoming Addictions](#) > 4. Foods Must Not Contain Toxins

#### **4. Foods Must Not Contain Toxins**

All refined foods and all flesh foods contain drug-like stimulating qualities. Like all stimulating substances, the stimulation will eventually lead to depression and enervation.

The normal response of the stomach to food is called stimulation. This increased activity of the stomach is necessary for digesting food and it is normal action. But the food contributes to the renewal of the organism and therefore adds more than it takes away.

Dr. Shelton outlined three types of stimulants:

1. Those substances and forces—light, air, water, food—which supply the materials of renewal and prepare the body for increased activity.
2. Those kindly influences—warmth, coolness, good motives, good feelings, joy, enthusiasm, ambition, determination, will, etc.—that invite or inspire increased action; inspire the body to

exert its power and means in a given direction; enable it to mobilize, organize and redirect its forces.

3. Those substances, forces and influences that provoke or excite defensive action

The first two are renewers and are beneficial while the last are irritants and do not provide any nutriment or benefit to the individual

In order for the foods to result in a beneficial renewal of our cells and tissues, they must not contain any toxins.

## 4.1 Condiments

Dr. Shelton says, "Nature has arranged that natural, unseasoned foods, eaten when required by the body and under proper mental or emotional and physical condition, will occasion the secretion of the digestive fluids in a perfectly natural way and the stimulation they afford is never sufficient to impair the functional vigor of the digestive glands. Artificial 'stimulation' is not necessary, and it is harmful."

All condiments artificially stimulate the appetite due to their irritating quality. The desire for food normally arises out of a real physiological need for food. When there is no need, hunger will be absent. Also, in the absence of hunger, the body is not ready to digest food. Appetite should never be stimulated by the use of condiments.

The use of condiments leads to overeating that eventually leads to a number of problems when excess food is taken. In order to recover from any addiction, you must be sure that your food does not contain such artificial and health-impairing stimulants.

All condiments act as irritants and, as a consequence, induce inflammation in the digestive tract. Their continued use results in hardening of the mucous lining of the digestive tract. This hardening renders the membranes less sensitive to the irritating qualities of condiments but cripples the efficiency of digestion. So the real effect of condiments is just the opposite of what it is thought to be. They result in depression and hinder rather than aid digestion.

Mustard, pepper, pepper-sauce, horseradish, cayenne, and other hot and stimulating substances are highly poisonous due to certain oils that they contain. The first effect is stimulation of the stomach due to increased action but latter the gastric juice secretion is lessened and decreased activity of the stomach follows.

Spices, nutmeg, cloves, ginger, mustard, and all irritating sauces and condiments result in the same kind of impairment and do not improve digestion. Food addictions can result from the artificial stimulation through such additives to our food. Just as the drug addict and alcoholic are seeking stimulation, so is the person who is addicted to such stimulating foods.

So we must be sure that our food does not contain destructive stimulants but is eaten as nature has prepared it for us. Once you break away from the habit of using condiments, you will be pleasantly surprised at how good your food tastes without them.

Dr. Shelton quotes Dr. Oswald and he says, "The carnivora digest their meat without salt; our next relatives, the frugivorous four-handers, detest it. Not one of the countless tonics, cordials, stimulations, pickles and spices, which have become household necessities of modern civilization, is ever touched by animals in a state of nature. A famished wolf would shrink away from a 'deviled gizzard.' To children and frugivorous animals our pickles and pepper sauces are, on the whole, more offensive than meat, and therefore, probably more injurious."

The addict must strive to eat only those foods that do not contain toxins. It is well known that cooked foods are less valuable than raw foods and the cooked foods also contain toxins.

## 4.2 Cooked Foods

Protein digestibility is decreased by cooking because the protein molecule is so deranged. Sensitive amines are saponified by heat. The amine group is replaced by the hydroxyl group in the foodstuffs and it has been shown that the hydroxides cannot be reaminized by the animal body.

The organic phosphates in the protein foods are transformed into inorganic and therefore become unusable and toxic. While the body is capable of taking the more complex phosphates and reducing them to lower stages, it is unable to reverse the process. Only plants can do this.

The application of heat to fats and oils of all kinds develops free fatty acids which are not only nonassimilable, but are also toxic. This applies not only to free fats, but also to the fats that are present in all foods. There is a small amount of fat in even vegetables and cooking these foods always renders that fat toxic. Likewise, the minerals and vitamins in the foods are changed from their organic and usable form to inorganic form when heat is applied. Since these inorganic minerals are nonusable, they are toxic.

It becomes clear that cooked foods are not suitable for human consumption. It is even more imperative that the addict not consume these foods since his body is already to very toxic. The body must be given every possible chance for complete recovery and we must provide the correct conditions and not add more poisons to interfere with this healing process.

[Home](#) > [Lesson 69 - Nutritional Approach To Overcoming Addictions](#) > 5. Idealfoods

## 5. Idealfoods

The best food for the addict, and it does not matter what his particular addiction is, is that food that is easy to digest and assimilate, contains no toxins or overstimulating qualities, contains all nutrients needed for health and can be eaten and relished in its raw state.

Fruits fit into this description perfectly. Sweet fruits are especially valuable since they are so easily digested they expend little energy in digestion, thus reserving energy for other bodily processes such as healing and repair. The body will initiate cleansing where accumulated toxins will be eliminated.

Dr. Shelton says, "The best source of sugar for the body is sweet fruits—grapes, dates, bananas, figs, raisins, etc. These sugars come to us almost predigested and well-balanced with minerals and vitamins. These fruits are wholesome, natural, delicious and are full of life-sustaining qualities. No cook, confectioner or manufacturer can even remotely imitate these delicious products of nature's solar-vital laboratory."

This energy conservation is extremely important for the addict. If he first fasts, he will overcome his poison habit. After the fast, however, there will be a period of rebuilding and it is imperative that the proper materials be provided for this repair. A total fruit diet during this time would be ideal. For a time, even such a wholesome food as nuts could be left off the diet because of the larger amount of energy expenditure that they require for their digestion and assimilation. If you would stay on a total fruit diet for a period of time after the fast and include plenty of the sweet fruits, such as bananas and figs, recovery would be rapid. After that time, raw nuts and vegetables may be added (in reasonable amounts) with benefit. Most of the accumulated wastes and poisons of the body are of a protein nature and when we go on a fruit diet that is very low in protein, these excess proteins are eliminated or reorganized more rapidly within the body and utilized.

## 6. Overeating

A person who habitually overeats is no less an addict than the alcoholic. Overeating wears out the vital powers through overstimulation, overworking the digestive organs, the heart, the endocrine system, and the emunctories, by the strain placed on them and gives rise to intoxication through the poisons that these foods generate.

Most people are addicted to overeating on foods that would result in ill health even if they were consumed in moderate amounts. Flesh foods, baked goods—such as pies, pastries, cakes, etc.—bread and all cooked foods are toxic in themselves. Overeating on such foods makes invalids of those who so indulge.

Throughout history, there have been many noteworthy gluttons who always suffered from indigestion and other diseases and soon died from their indiscretions. Dr. Shelton describes a breakfast that was typically eaten by Mr. Bryan, a noted glutton:

"Cantaloupe was first served. Bryan ate a whole one— an immense yellow-meated melon. It was in the fall season—early fall—and quail were on the bill of fare. Bryan ate two. Virginia ham and eggs followed. Bryan ate almost ravenously of this ham in large portions and consumed not less than six eggs, when batter cakes are served, the commoner disposed of a plateful, swimming in butter and then accepted a second helping and got away with that.

"Numerous cups of coffee, potatoes and side dishes of various kinds accompanied the cantaloupe and the ham and eggs and the rest of it."

Bryan had diabetes, hardening of the arteries, heart disease and appoplexy. But the final and real cause of his death was gluttony. He was a sick man who dug his grave with his teeth.

On the other hand, one Dr. Low performed a feat where he lifted 1,000 pounds 1,006 times in thirty-five minutes and four seconds, after a period of training on one meal a day and less. For the first five weeks of his training he ate one meal a day, almost wholly of uncooked foods. During the last three weeks of his training period he ate only four meals a week; the last meal was consumed eleven hours before the lift. It is significant that he abstained from eating 11 hours before the lift as energy was not diverted into the digestive process while needed in muscular activity.

Conservation of energy is the key in health and disease. You must eat enough to supply your body with needed requirements but not so much that there is a great surplus and excessive vital energy is being expended in disposing of this surplus.

## 7. Fasting

Dr. Shelton says, "Nothing enables the alcoholic, the drug fiend, the tobacco addict, to overcome his 'desire' for his accustomed poison and to return to a state of good health, as does fasting."

It becomes easy to understand how and why fasting may be of service in these conditions. It is a period of rest during which the abused organism undergoes needed adjustments and repairs and recuperates its energies. When the fast is ended, the system has been freed of its accumulated toxins, and the nervous system has been restored to health.

Alcoholism is an illness involving structural abnormalities. The thickening and toughening of the membranes of the mouth, throat, and stomach are necessary defensive expediences. Fatty degeneration of the liver or sclerosis of the liver are later developments. When the alcoholic fasts, the thickening membranes are removed and new membranes are formed. The new membrane of the mouth, tongue, throat, and stomach will not be a thickened, seared one, impervious to foods and poisons, but a thin, delicate and sensitive one that permits full appreciation of the fine delicate flavors of foods.

Glands and nerves that have been lashed into impotency by overstimulation, rest into full functional power when given an opportunity. Renewal of their power can come in no other way. The abused organism will heal itself through rest as the broken bone will knit through rest.

When the alcoholic has fully recovered from his illness and hunger has returned, no form of alcoholic drink will tempt him.

Fasting also makes discontinuing the tobacco habit easy. In a few days, the very taste of this poison becomes repulsive. Fasting results in an improved nervous system, and in the regenerated membranes of the smoker's mouth and nose.

Dr. Shelton quotes MacFadden's *Encyclopedia of Physical Culture*: "Fasting is the most valuable of all forms of treatment for overcoming the pathologic conditions of the body brought about by the habitual use of poison. Fasting gives the body an opportunity to readjust itself in a normal way and also hastens the elimination of any poison remaining in the system. The drug fiend has lost his appetite anyway, and by means of a fast will regain a normal condition of the alimentary canal in a fraction of the time that would otherwise be consumed in the process. Especially the mind will clear and gain strength, and he will much sooner find himself in possession of the moral impulse and the will to fight his habit."

Rest—physical, mental and physiological—is the great need. In a remarkably short time, the fasting individual finds his supposed "craving" for drugs or other poisons, has disappeared.

Violent reactions often follow the withdrawal of the drug. For this reason, it is essential to take great care of the individual. Mania following the withdrawal of morphine or opium, or delirium tremens following the withdrawal of alcohol are similar developments. They indicate the gravity of the injury to the nervous system and reveal how important and urgent is the need to get away from the use of the poison.

Violent reactions soon cease as the patient fasts. With the gradual recovery of energy, repair of his damaged nervous system, and regeneration of his membranes, he will soon recover.

Enervation is the basic fact in all addiction. To avoid recultivation of a drug addiction, it is essential that the individual live so that he does not enervate himself. All sources of enervation should be avoided. A well-nourished body, the energies of which are conserved by first-class habits, will not feel the "need" for stimulants and will not "need" to be "relieved" from discomforts and pains.

Dr. James C. Jackson says (*How To Treat the Sick Without Medicine*): "A simple nutrient diet, the use of pure cold water for a drink, and personal cleanliness, with 'abundant sleep, will prove to be the only securities to the reformed drunkard ... Tea, coffee, tobacco, pepper, mustard, salt, and flesh meat will create such a condition of the organic nerves, and of the mucous lining of his stomach, as to reestablish the desire for liquor, and then he will drink, come what may to his pledges or his social position."

## 8. Vital Force

Vital force is behind the stimulating-effect from poisons and stimulation from foods but the purposes are different. The stimulation experienced from foods, taken in proper amounts, is increased action for the welfare of the body in normal activity. The stimulating effects from poisons is *defensive* action. Vital energy is used without being replaced. Vital energy is used up when food is taken but it replaces more than it uses.

In this regard, Dr. R. T. Trall says, "We see how it is that alcohol is an element of force. It occasions force to be wasted, that is all. If a small draught is taken, only a little force is wasted (not supplied) in defending the system from it, and the individual is but slightly excited; that is, a little feverish. If much is taken, a greater amount of force is necessarily wasted (not supplied) and greater excitement is manifested in stimulation, fever, delirium, madness, etc. The system expends its force to get rid of the alcohol, but never derives any force, great or small, good, bad, or indifferent, from the alcohol. *Stimulation does not impart strength—it wastes it.* Vital power does not go out of the brandy into the patient, but occasions vital power to be exhausted from the patient in expelling the brandy."

Explaining the stimulating effects of alcohol and how it occasions the use of vital energy without eventually restoring force, Dr. Hereward Carrington says, "What is stimulation? We know that it is an induced condition in which the organism can, temporarily, perform a greater amount of muscular, vital, or mental work than would normally be performed in the same period of time, and this increase in its ability to work is undoubtedly traceable to the "stimulus" it has received. There is a greater capacity for work (implying a greater nervous force being expended in such action), and it is generally known that there is invariably a "reaction" or prostration, more or less profound and noticeable, following upon such stimulation."

Under all circumstances, however, vitality or energy of any character is invariably manifested or noticed by us in its expenditure, rather than when it accumulates.

Dr. Robert Walter stated it this way in *Life's Great Law*: "Every particle of living matter in the organized body is endowed with an instinct of self-preservation, sustained by a force inherent in the organism, usually called vital force, the success of whose work is directly proportioned to the amount of the force and inversely as the degree of its activity."

So any stimulant, such as alcohol, drugs, etc., will use up this vital energy to the degree that we use these stimulants. When we fast, we reverse this procedure. Vital energy is conserved, not expended. If you feel weak while fasting, it is only because vital energy is being used for healing and not directed toward the musculature or for digestion. In effect, you are getting stronger.

Dr. Carrington says, "The fear of being obliged to wait passively; the lack of faith in the healing powers of Nature, is one of the greatest causes of medical malpractice of today. We must keep in mind, always, that no *action* can possibly occur without an equal and opposite *reaction*; that the pendulum of human energy cannot, by any possibility, swing in one direction indefinitely; but must, at some time, turn and swing in the other. Rest must always follow effort, and effort rest; and this law of rhythm applies, of course to the human body, so far as its energy is concerned. This being so, is it not most obvious that the digestive organs need their periods of rest—just as all our other organ's call for rest? And is it not obvious, also, that the only way in which such a rest can be furnished is by fasting?"

## 9. Beaware

The purer your body, the more aware and sensitive you are to things that are harmful. Former habits will be repulsive especially regarding smoking, alcohol, drugs, junk foods, meat, etc. If you become tempted by some former food addiction, think of the results that will occur after partaking in that unHygienic food. After you have fasted, your body will be pure and you will react violently to foods that are unsuited for consumption. Is it worth contaminating your body and feeling sick? No, it is not worth it.

Our natural foods are so delicious in themselves, that soon no other food or drugs will appeal to you. Certainly anyone's sweet tooth can be satisfied by some delicious figs, dates, bananas or any of the other dried and fresh fruits that you may choose from.

According to Dr. Shelton, our poisonous habits are the major cause of kidney impairment. He says that all poisons from decomposed foods as well as the poisons of tobacco, alcohol, tea, coffee, etc., constantly overtax the kidneys and eventually impair them to such an extent as to result in their disintegration. Coffee drinking by itself results in considerable bodily impairment. This is due largely to the caffeine but also to the other toxic substances that it contains., As a result, the stomach, nervous system, heart and kidneys become impaired. This is especially evident in the kidney/s as coffee drinking temporarily increases the amount of urine expelled since the kidneys must get rid of the poisons. The kidneys then eventually become impaired and damaged due to overuse and enervation.

But it is not only the kidneys but all the organs and all the cells of the body that suffer when we indulge in poisonous habits. With this in mind we should avoid all such poisons. Education and knowledge are a great asset in helping to overcome such addictions. A fast will enable us physiologically to overcome these habits but we must also prepare ourselves psychologically. Be determined. Eliminate all negativity and think positively. You do not have to be sick, it is entirely up to you. If you wish to feel great every day with abundant energy and zest for life, you can feel this way. All you have to do is follow the simple requirements for health in regard to proper food and water, exercise, rest, sleep, sunshine, fresh air, and emotional poise.

## 10. Questions & Answers

### **Can the addict gradually taper off his drugs while on the fast?**

All drugs must be eliminated the first week of the fast. This is an absolute necessity. After the first few days, the artificial cravings will cease and bodily repair will commence.

### **Can a person really become addicted to a particular food?**

Yes, this is quite possible. In fact, it occurs frequently. People become addicted to foods that are especially stimulating such as cooked foods with condiments, white sugar, baked goods, junk foods, flesh foods, etc. However, this temporary stimulation soon leads to depression. Then the "junk-food addict" seeks to relieve this depression through more stimulation via the junk foods. It becomes an endless cycle that eventually results in enervation and disease.

### **Is it true that one stimulating habit often leads to another?**

Yes, this is often the case. Once stimulated by candy, ice cream, cookies, and cake, a person often looks for something more stimulating and turns to cigarettes, or perhaps to coffee drinking, alcohol or drugs. You rarely see fruitarians who also smoke or drink alcohol. It does not occur to a person on such a diet to look for stimulation. They are healthy and enjoy life. No poisons are sought to feel "well" or alter moods.

### **Do certain people have "addictive personalities?"**

The "addictive personality" has been described by behavioral scientists, but there is no scientific evidence that characteristic personality factors exist. Some have concluded that addicts are basically escapist, persons who cannot face confronting the realities and who run away. Others have described addicts as schizoid individuals who are fearful, withdrawn, and depressed, and who have a history of frequent suicide attempts and numerous self-inflicted injuries. Addicts have also been described as basically dependent and grasping in their relations and frequently exhibiting overt and unconscious rage and immature sexuality. These descriptions are often used as excuses for a habit but they are irrelevant. We know that these addictions are wrong and must be discontinued. Under a Hygienic program, everyone can overcome their addictions, whatever their personality may be.

[Home](#) > [Lesson 69 - Nutritional Approach To Overcoming Addictions](#) > Article #1: Coffee, Tea, And Cocoa by Dr. Herbert M. Shelton

### **Article #1: Coffee, Tea, And Cocoa by Dr. Herbert M. Shelton**

In the United States, which appears to be the most drug-addicted nation of the world, about 96 percent of the families drink coffee daily. Eight out of ten adults drink coffee each day, as do one in four children. At the present time Americans are drinking, on the average, 50 percent more coffee than they did ten years ago. Someone figured that Americans are drinking about one thousand million more gallons of coffee a year than milk.

Within recent years the Indian government, in a land that suffers with perpetual famine, has destroyed whole forests of jack fruit trees to make room for coffee trees. The jack fruit, a large melonlike fruit, is delicious. Both pulp and seeds are edible. But it cannot be exported. When I asked an Indian banker why his government was destroying so many food plants to make room for coffee, his reply was: "Coffee brings in American dollars." This is a striking example of the stupidities of an economy in which production is for profits. It is not conceivable that in an economy devoted to production for use such a stupid action could occur.

In our profit-mad world, millions of acres of land are devoted to the production of tobacco, coffee, tea, and similar poison substances. Millions of tons of grains and fruits are converted into alcoholic drinks, in a world that is even now struggling with the spectre of a population explosion and worldwide food scarcity. It is impossible to conceive of such a thing being carried on in an intelligently ordered social system.

Tea drinking has spread over the earth, apparently from China, in much the same way that coffee and chocolate drinking spread. Tea was introduced into Europe about the same time as coffee.

These three substances, coffee, tea and cocoa Or chocolate, all contains an almost identical alkaloid. Called *caffeine* in coffee, *theine* in tea, and *theobromine* in chocolate, this alkaloid can be fatal to man or animal. Classed by pharmacologists as a stimulant, it is taken by those who think they need stimulation.

We frequently hear it said that tea and coffee "excite the exercise of thought."

Although it is customary to include such *narcotic* habits as tobacco, alcohol, opium, and marijuana under the general designation of *stimulant* habits, this does not seem to be the reason these substances are taken. It is not *stimulation*, but *relief* from discomfort that is sought when they are taken.

On the other hand, when coffee, tea, chocolate and cocoa, and the *stimulating* soft drinks are taken, it would seem to be a different type of *relief* that is sought, relief from weakness and exhaustion. When such stomach *stimulants* (irritants) as pepper, mustard, pungent spices, and pepper sauce, are taken, there would seem to be a *need* for stimulation.

Because there is a tendency for discomfort to grow and for the *relief* afforded by these poisons to decrease, there is a natural and inevitable tendency to increase either the size or the frequency of the dose, or both. As this ultimately fails to provide the desired *relief*, a stronger poison is resorted to. This is the reason that employment of one of these substances can lead to the employment of another. The coffee drinker, the cocoa drinker, the addict to chocolate candy, although himself a tobacco chewer or smoker, may condemn his neighbor for his alcohol habits. When we thus choose *narcotics* or *stimulant* addictions, what right have we to assume superiority to those who choose different *stimulants* or *narcotics*? *All are addicts*, regardless of the nature of the addiction.

The search for relief is the essence of drug addiction. There is no craving for poisons; there is only unease, discomfort, and misery which drive the victim to more frequent and larger doses of his favorite poison in his search for relief. Some addicts have been known to take as much as 96 grains of morphine daily without harmful effects, other than the stupefaction which rendered them oblivious to pain. When the drug is withdrawn, obstinate vomiting, violent purging, and other distressing symptoms follow. These are falsely called *withdrawal symptoms*.

They are, in sober reality, symptoms of poisoning, and are present all the time. But they are kept repressed by repeated doses of the drug. Such symptoms follow, in varying degrees of severity, a discontinuance of any poison habit—tobacco, alcohol, morphine, heroin, marijuana, coffee, tea and chocolate.

Untold thousands of people go about their daily duties so tired they hardly know how to work unless driven by stimulants. They mourn their enthrallment to work and business and wish they could omit these. If they knew enough to discontinue eating wrong foods and desist from stimulant habits, and if they knew enough to supply their bodies with adequate nutrients and secure more rest and sleep, in two months they would find themselves new people. The "coffee break" would no longer seem "necessary" to them. They would soon discover the truth of Dr. Samuel Johnson's remark that it is easier to be abstinent than temperate. They have already learned that the tendency of all poison habits is *progressive*.

The fact that almost every tribe of man has been found addicted to some poison habit has been offered as proof positive that there is a *normal* taste for these poisons, and therefore a natural necessity for their use. How absurd! Why not argue that because lying is such a universal vice, it is necessary and good? Every substance man employs in his vain search for relief from self-caused discomforts is to be judged not by any assumed universal taste for it, but by its ultimate effects.

We are frequently reminded that, since the time of Hippocrates, physicians have considered opium invaluable in alleviating acute human suffering. It is customary to add that, "like many others of God's greatest blessings to mankind," opium must be used with reason or with discretion, or "it will be found to be one of man's greatest curses." It never seems strange to these devotees of the drugging cults that God should wrap his greatest curse in the same package as his greatest blessing. Perhaps God made a mistake or, maybe it is man who makes the mistake. Certainly the effects of habitually taking opium are not desirable.

The cocoa chewer is damaged by his practice scarcely less than the opium eater by his. He is known by his uncertain steps, sallow complexion, his hollow, lusterless, black-rimmed eyes, deeply sunk into his head, trembling lips, incoherent speech and stolid apathy. He is irresolute, suspicious and false; in the

prime of life he appears senile and in later years into complete idiocy.

Having asserted that *stimulants* are natural needs of the system, it becomes necessary to find some apology for their employment. So we are told that they are not only foods themselves, but that they aid in the digestion of other foods. That this is false may be seen from the following facts. Even in small quantities, tea completely paralyzes salivary secretion. When the infusion amounts to as much as one-fifth of the contents of the stomach, tea retards stomach digestion. Coffee and cocoa have little effect on salivary digestion, but interfere as much as tea with stomach digestion.

To the alcoholic drinks of the ancients we have added tea, coffee, cocoa, chocolate, tobacco, absinthe, chloral, opium, the pungent spices and a host of other drug habits intended to provide evanescent relief from the discomforts of our wrong eating. The soma drinking, prominently mentioned in the *Rig Veda*, was made from a plant which is today unidentified. The drink was intoxicating and played an important role in the ritual life of early Iranians as well as the Indians. We have gathered our poison habits from all corners of the earth. Every year sees an increase in them.

The feeling of exaltation that follows the taking of a *stimulant* has led to the fallacy that *stimulants* must be good. The depression which follows, and which is in exact proportion to the degree of *stimulation* occasioned, is either ignored or attributed to some other cause. It is likely to be met with another dose of the same *stimulant* that caused it. So imbued are we with the idea that *stimulants* are wholesome, that we are frequently told that "food is a stimulant." This statement is based on a totally wrong conception of the character of *stimulation*.

*Stimulation* is *irritation*; a stimulant is a substance that temporarily occasions an increased vigor of action by means which exhaust the power of action, thereby actually reducing vigor. When this occurs, there must be a corresponding period of rest and sleep. Exhaustion necessitates depression; *stimulation* must be followed by debility. All of our poison habits have debilitating effects on the organism and increase the precariousness and fragility of life.

[Home](#) > [Lesson 69 - Nutritional Approach To Overcoming Addictions](#) > Article #2: Effects Of Stimulants by Sylvester Graham, M.D.

## **Article #2: Effects Of Stimulants by Sylvester Graham, M.D.**

In explaining and illustrating the constitutional laws of external relation, I have stated that every substance in nature from which the human body can derive nourishment, possesses specific and peculiar qualities which the human organs have vital powers to perceive and appreciate. Thus the visual properties of things are perceived by the special sense of sight; the auditory properties by the special sense of hearing; the olfactory properties, by the special sense of smell; the gustatory properties, by the special sense of taste; and the tangible properties by the special sense of touch. These external substances have also certain other properties, which are only perceived and appreciated by the special organic senses residing in the organs belonging to the domain of organic life, or the ganglionic system of nerves. These properties, in all proper alimentary substances, are the natural and appropriate stimuli of those nerves of organic sensibility which are adapted by the Creator to perceive and appreciate them, and to convey the impressions received from them to the special centre which presides over the functions of the particular organ or apparatus, But we have seen that some alimentary substances are much more stimulating than others, in proportion to the quantity of nourishment which they actually afford the system, and that some substances in nature are purely stimulating without affording any nourishment.

The stimulation produced by these various substances is always necessarily exhausting to the vital properties of the tissues on which they act, just in proportion to its degree and duration; and every stimulus impairs the vital susceptibilities and powers, just in proportion as it is un-fitted for the real wants of the vital economy, and unfriendly to the vital interests.

But whatever may be the real character of the stimulus, every stimulation to which the system is accustomed increases, according to the power and extent of its influence, what is called the tone and the action of the parts on which it is exerted, and *while the stimulation lasts, it always increases the feeling of strength and vigor in the system, whether any nourishment be imparted to the system or not.*

Yet by so much as the stimulation exceeds in degree which is necessary for the full and healthy performance of the function or functions of the organs stimulated, by so much the more does the expenditure of vital power and waste of organized substance exceed for the time the replenishing and renovating economy of the system; and, consequently, the exhaustion and indirect debility which succeed the stimulation are always necessarily commensurate with the excess.

Hence, though that food which contains the greatest proportion of stimulating power to its quantity of nourishment causes, while its stimulation continues, a *feeling* of the greatest strength and vigor, it also necessarily produces the greatest exhaustion in the end, which is commensurately importunate and vehement in its demands for relief, by the repetition of the accustomed stimulus; and as the same food, more readily than any other, affords the demanded relief, by supplying the requisite degree of stimulation, our feelings always lead us to believe that it is really the most strengthening.

Hence, whenever a *less* stimulating diet is substituted for a *more* stimulating one, a corresponding physiological depression, or want of tone and action, always necessarily succeeds, varying in degree and duration according to the general condition of the system, and the suddenness and greatness of the change; and this depression is always attended by a feeling of weakness and lassitude, which is immediately removed, and the feeling of strength and vigor restored, by the accustomed *degree* of stimulation, by whatever produced, whether any increase of nourishment is actually afforded to the system or not.

The pure stimulants, therefore, which of themselves afford no nourishment to the system, and only serve to increase the expenditure of vital properties and waste of organized substance, by increasing vital action, cause, while their stimulation lasts, a sense of increased strength and vigor; and thus we are led by our feelings to believe that the pure stimulants are really strengthening; and in the same manner we are deceived by even those pernicious stimulants which not only exhaust by stimulation, but irritate, debilitate, and impair, by their deleterious qualities.

The feeling of *strength* produced by stimulation, therefore, is no proof either that the stimulating substance is nourishing, or that it is salutary, nor even that it is not decidedly baneful.

But we have seen, that those proper alimentary substances whose stimulatory power is barely sufficient to excite a full and healthy performance of the functions of the digestive organs, in the appropriation of their nourishment to the system, are most conducive to the vital welfare of the body in all respects, causing all the processes of assimilation and organization' to be most perfectly performed, without any unnecessary expenditure of vital power, and thus contributing to the most permanent and uniform health and vigor of the body, and to the greatest longevity. For every degree of stimulating power beyond this, necessarily increases the vital exhaustion, without contributing in any measure to the welfare of the body.

With a true application of these well ascertained principles, the physiological evidence in relation to the natural dietetic character of man may be correctly apprehended and accurately estimated; yet the utmost caution and perspicacity and circumspection are requisite at every step, to avoid deception and error in the mazy and delusive paths of human experience and history.

### **Article #3: The Great Delusion By Dr. Robert Walter**

Out of this principle of irritation grows the most important delusion that ever afflicted mankind. Irritation means increased action of the part irritated, and consequently of all parts sympathetically connected therewith, and increased strength. Tonics, nervines, and stimulants produce their effects only through this principle. It is in the this way that alcohol and tobacco increase the action of the brain and nervous system; that calomel and podophyllum apparently improve the functions of the liver; that all other drugs produce their effects; that arsenic and strychnine, nitric, muriatic, hydrochloric, prussic, sulphuric acids, etc., increase the apparent vigor of the whole system, largely through its sympathy with the stomach, which has been termed the great organ of sympathy. For this same reason men often feel more than ordinarily vigorous just previous to a severe attack of sickness: they sometimes retire to bed feeling well, only to wake up in another world. For this reason sudden and violent ailments often follow the most apparently robust health. It is the same delusion that tempts the physician to dose his patient with violent poisons until exhaustion and death close the scene. It is the basis of alcoholic consumption, just as it is the cause of the fearful and monstrous drunkenness, whether by alcohol, opium, or tobacco, which deluges the land. Increased action, apparently increased strength, supposed improved function, the result of the use of irritants deceive both physician and patient, and cause them to become victims of a monstrous delusion.

The delusion pervades all ranks of society, and is the chief explanation of the frequent diseases and sudden and untimely deaths that are everywhere chronicled. When we consider the immense quantities of irritants which are being introduced into human organisms in the guise of food, drink, medicine, etc., the only wonder is that the human constitution endures as long as it does.

But irritation produces a secondary effect, which is quite as important as the primary one, and this is increased flow of blood to the part irritated. Normal exercise does the same thing. Thought induces increased flow of blood to the brain, and labor, to the feet or hands. If this flow be beyond the power of the vessels to send it forward, as in the case of irritation, the blood accumulates, the vessels relax, and we have congestion. This increase of blood at one point of course necessitates a decrease at another point, and hence unbalanced circulation is a concomitant of all diseases.

### **Article #4: Drug Addiction by Dr. Herbert M. Shelton**

*Science*, as medicine is commonly called, is never-ceasing in its search for *cures*. In his syndicated column, Albert Edward Wiggam once wrote that *science* has not discovered a surefire *cure* for alcoholism, but it has found a drug that helps. He said that, after a drunken man sobers up the drug *Equanil* quiets his tense nerves and helps reduce the desire for another drink. This is to say, the drug substitutes for alcohol. The drug is sufficiently dangerous that it can be obtained only upon a physician's prescription.

Drug addiction is frequently an aftermath of the employment of drugs in the treatment of disease. *Sedatives*, *narcotics*, and *stimulants* are employed with which to provide evanescent, but fictional, relief

from discomfort and pain. Somatic awareness, no less than psychic awareness, is benumbed by the taking of sedative drugs and the house-cleaning that is so urgently needed is not undertaken. Each repetition of the dose tends to build a drug habit. A rebirth of awareness follows the excretion of the drug. It is then that the drug user becomes aware of his actual condition. His physician will call his symptoms *withdrawal* symptoms. He should realize that they are the outcries of an organism that has been outraged with poisons. Drug addiction grows out of the search for relief from the unease, weakness, discomfort and pain that result from the employment of drugs and is not a genuine demand for a repetition of the drug. There is no craving for a drug, but a subconscious demand for relief.

For fifty years I have insisted that what is called drug addiction arises out of the search for relief from the unease, discomfort, distress and misery caused by prior taking of a drug. The narcotic addict obtains a brief respite from his misery by *renarcotizing* his nerves. The *stimulant* addict receives a brief illusion of renewed strength by goading his nerves with the *stimulant* the prior taking of which is responsible for his weakness. In July of 1971 a former drunkard was interviewed on television here in San Antonio. When asked what made him drink he stated: "I would drink today to get relief from the misery caused by drinking yesterday." Thus speaking from his personal experience, he confirmed my view.

So persistent and so insistent is the demand for relief from the drug caused misery, the victim of the drug practice finds himself unable to resist the temptation to return again and again to the source of his misery for the temporary "relief" this affords. To provide this "relief" requires a progressive increase both in the size and the frequency of the dose. The standard procedures in such cases continue to revolve around efforts to break the vicious circle by a gradual reduction of the dose, both in size and frequency, and to substitute one addiction for another. Both of these plans have proved very unsatisfactory, for the reason that each of them continues to outrage the nervous system by continuing drugging and the search for relief through drugs. Instead of stopping the drug to which the habitue is addicted, it is continued or an effort is made to substitute another drug—one narcotic for another or one stimulant for another. The addict continues to be smothered in his drug-induced miseries. No effective means of promoting the health of the individual is employed, hence the addict does not recover normal health. In those few cases where apparent recovery from addiction occurs, the tendency to relapse is great.

Diseases and vices, growing out of the same general causes, and being essentially the same, are therefore, to be handled on the same general plan. That mode of care that will restore health to the sick man, will just as effectually relieve the vicious man and *vice versa*. If it fails in one, it will fail in both. When either disease or vice becomes thoroughly matured, it is, to a large extent, beyond control of the will. A proper environment and a *Hygienic* life provide the best hope in this case. It is idle to suppose that a man who has violated nature's laws until his sensations are all abnormal, and the mainsprings of his life are all befouled, representing poor diseased conditions and vicious habits, can merely exercise the will to recover, and even recovery would not be at all sufficient unless good habits and a thorough revolution of life follow. To appeal simply to the intellect and moral sense of a tobacco smoker or an opium eater or a drunkard, as a means of inducing him to relinquish his indulgence is generally about as effective as to ask an ague patient to stop shaking.

When Professor Carlson, who was a habitual cigar smoker, underwent a short fast in his studies of hunger, he found that after the second day of abstinence, he did not enjoy smoking. "In fact," he reports, "smoking tended to produce nausea." It is not an unusual experience for the fast to compel the smoker to discontinue the practice. Many have been able to continue smoking through a fast, but all who discontinue smoking at the outset of fast find that after two to three days without food, they have no more craving for the weed. The same is true of other forms (chewing, for example) of tobacco addiction.

A similar experience is seen in other drug addictions. It is a simple matter to give up coffee, tea, marijuana, alcohol, opium, morphine, and similar addictions by fasting at the same time the drug is discontinued. It is best to abandon all addictions at once and abruptly. For example, the average alcoholic also smokes tobacco and drinks coffee. He will find it easier to discontinue the alcohol if he also abandons both the coffee and the tobacco at the same time. This will be easily understood when the true character of addiction is understood.

Most addicts think it will be easier to give up one drug at a time or to give up one drug habit and continue the others. An organization in California has a home where drug addicts are taken in. By a program similar to that employed by Alcoholics Anonymous, they slowly educate the addict out of his addiction. Frequently two years or more are required to whip the morphine habit. The addicts eat a conventional diet, smoke tobacco and drink freely of coffee. This is the hard way: it is the long way and it probably registers many failures. There cannot be any doubt that their educational program and their cultivation of self-reliance are useful features of the rehabilitation of the addict, but the education program does not go far enough.

Faulty education is the chief, if not the only cause of all drug addiction. It may be and probably is true that individuals with neuropathic tendencies most readily fall prey to so-called habit-forming drugs, but the fact remains that the initial use of drugs arises out of false education. Had the whole population not been wrongly educated from infancy up, they would not turn to drugs to "sustain" them when some unusual circumstance puts a heavy tax upon the nervous system. Pain, sleeplessness, profound and lasting emotions, losses, etc., cause the nervously unstable to turn to those sources of palliation they have been, educated to believe will supply the desired, *relief*. For this false education and all the evils that grow inevitably out of it, we are indebted to the medical profession and to no other.

The legitimate pharmaceutical industry has flooded today's market place with great quantities of addictive drugs which are being sold, especially to the young, through, both legitimate and illegitimate channels. Most of the drugs now being taken by youth are supplied the drug pushers by duly licensed manufacturers of the drugs. If we assume as is popularly done, that these drugs have valid medical usage, we are still faced with the fearful fact that the drug manufacturers are turning out thousands of times more of these drugs than the medical profession can possibly find valid medical use for. So great is their profit hunger that the manufacturers of drugs are willing to destroy the minds of all of today's youth in order to increase their dividends. I marvel at the apathy and indifference of the parents of this country that cause them to sit by and watch the destruction of their children, instead of rising in their collective might and putting an eternal end to the drug industry.

- [Article #3: Influenza](#)

### 1. The Common Cold

Almost as common as the "common cold" is the virtually universal misunderstanding as to what a cold really is.

The condition known as a "cold" is characterized by inflammation of the mucous membrane of the nose and throat; there also may be inflammation of the membrane lining the nasal sinuses, the larynx, the pharynx, or the bronchial tubes.

There is a profuse flow of mucus, initially thin and watery, gradually becoming thicker and whitish or greenish. The nasal lining thickens and interferes with breathing. Sneezing sometimes brings some temporary relief to the stopped-up nasal passages, but it is the inflammation that narrows the openings and makes breathing difficult.

There may be a temporary loss of smell and taste. Often there is a raw, sore throat with a flow of mucus from this membrane, a husky voice, and a cough. The eyes and ears may become involved. The person feels miserable, and may have a fever, often a headache. He may progress from "thinking he is going to die" to "being afraid he won't."

Charles Dickens once described his cold thus: "I am at this moment deaf in the ears, hoarse in the throat, red in the nose, green in the gills, damp in the eyes, twitching in the joints, and fractious in temper, from a most intolerant and oppressive cold."

The most common "common cold" is an acute rhinitis—inflammation of the nasal cavity—with rhinorrhea (nasal discharge), nasal obstruction (due to swelling or edema of the mucous membrane of the nasal passage) and sneezing. A disease that can be aborted to 24 to 48 hours lasts for weeks in many cases.

#### 1.1 Symptomatic Treatment of Colds

Everyone who has had a "cold" (and who hasn't?) will agree as to the nature of the symptoms, and the misery they cause. But it is almost incredible to realize that the misunderstanding of colds, and the type of treatment commonly employed today, have changed very little in the last few hundred years.

In the 1500s, British doctors often prescribed tobacco juice, lime juice and emetics (to cause vomiting) for colds. If that didn't work, the patients were bled. Ronald Kotulak, a *Chicago Tribune* columnist, said, "Those who could not afford these ministrations naturally had a higher rate of recovery."

In the 18th century, another Englishman came up with this remedy, "Hang your hat on the bedpost, drink from a bottle of good whiskey until two hats appear, then get into bed and stay there."

The use of "booze" to ease the symptoms is still widespread, and many drug companies include high levels of alcohol in their cold and cough remedies. Nyquil, for instance, contains 25% alcohol by volume, which makes it equivalent to a 50-proof liquor.

## 1.2 Failure of the Medical Community

The current medical community admits, that it hasn't made much progress in its efforts against the common cold. The American Medical Association and doctors at Harvard Medical School say that colds still resist the best efforts of the world's combined medical research talent.

German scientist Dr. W. Kruse announced in 1914 his discovery that colds were caused by viruses and this was hailed as the first big discovery on colds. After that, research sputtered along, seeking the elusive "cure" that was always just around the corner.

In the 1950s, scientists were hopeful they could develop a vaccine against the "cold virus." But these hopes soon were dashed when more and more cold viruses were discovered. Now there are more than 150 known viruses which are thought (by medical people) to cause the common cold, and a vaccine is admittedly impractical. As Hygienists, we can at least breathe a sign of relief that a "cold vaccine" has not been added to the arsenal of poisonous vaccines being recommended to the gullible public.

Dr. Robert Muldoon, specialist in virology, and professor of medicine at the University of Illinois, said in 1978, "Disgustingly enough, there is not much new about the, common cold. There really isn't much you can do to protect yourself from a cold, and there still isn't anything you can do for it once you get it except to treat the symptoms." (We beg to contradict him!)

Dr. Muldoon took part in a classic experiment at the university with Dr. George Jackson, showing that exposure to cold temperatures or wet feet do *not* increase a person's risk of catching a cold. He said that when a person with a cold sneezes on you, you can expect to receive a direct blast of germs, but your chances of catching his cold are only about one in ten. Dr. Muldoon does not give any explanation as to why he thinks nine out of ten people will not get the cold, even when directly exposed.

A cold research establishment in England has been working for twenty-five years to find a definite cause for the common cold. Everything they have tried has failed, though they have subjected volunteers to every conceivable circumstance in order to find some pattern or combination of factors which produce a cold.

## 1.3 Understanding Colds

Notwithstanding these conclusions (that no one knows the causes of colds)—I must insist that the causes of colds *are* known, and that the proper method of dealing with a cold has been known for many years. As long ago as 1873, Dr. Robert Walter said, "A cold is simply an effort of the system to relieve itself of its accumulated waste particles."

Failure of the medical community to find the *cause* of colds is due to the fact that researchers are looking for something that isn't there. No *cure* for the common cold has ever been found by the researchers for an excellent reason: the cold itself *is* the "cure."

When the state of nervous energy is lowered, excretion, elimination and digestion are impaired. The two great causes of colds are exhaustion and repletion (surfeit).

When the state of bodily clogging which precedes a cold reaches intolerable proportions, the body organizes for a radical eliminative crisis. The temperature rises, the head and nasal passages become congested, appetite may disappear. The cold may go through various stages of eliminative processes, usually regarded as disease symptoms, instead of being understood as *cleansing* efforts of the body to

unburden the vital organs.

If drugs are used to stop these processes, the body may face a more serious situation later on—perhaps influenza, or pneumonia, or possibly problems with other organs or functions.

We have been taught that colds lay the foundation for other more serious diseases. Rather, they are efforts to prevent the development of more serious conditions. The persistence of the causes, or the drug treatment common today, can lay the foundations for future degenerative pathologies. Chronic disease is due to chronic provocation.

Means of eliminating the accumulations must be employed by the troubled organism. Coughing, sneezing, discharge of mucus, all represent efforts on the part of the body to remove the accumulated unexcreted waste. The symptoms represent part of the remedial process, as the body is striving to maintain or restore the status quo—the homeostasis or physiological equilibrium.

When the body produces symptoms of a cold as vicarious elimination of toxic material which is threatening its survival, we should not even consider suppressing them. Why should we try to check a cough that is necessary to remove an obstruction? Why should we try to dam up in the body the noxious matter that the wisdom of the body has determined must be expelled?

#### **1.4 Astronomical Cost of Colds**

Americans suffer more than 600,000,000 colds a year. This is worth several billion dollars annually to the drug industry, physicians, pharmacists, and the huge support industries: packaging, advertising, etc.

*The Harvard Medical School Health Letter* warns that the once common practice of prescribing antibiotics for a cold is useless and potentially dangerous.

Despite the fact that there are no medications available to treat a cold effectively, Americans spend more than five hundred million dollars annually for over-the-counter cold remedies—and that doesn't include aspirin. In addition, coryza (rhinitis), commonly known as a cold, costs the American people untold millions of dollars in loss of time from work and physicians' bills, plus the cost of lowered efficiency and lessened productive power.

But these immediate costs in dollars and cents are dwarfed by the mischief done to the human organism, to some extent by the causes (which produce the necessity for the vicarious elimination), but, primarily, by the treatment.

#### **1.5 Dangers of Cold "Remedies"**

Aspirin is the most commonly used cold remedy. Among so-called "health-minded" people, aspirin is often supplanted by vitamin C. Some people take both aspirin and vitamin C. Antihistamines are commonly used.

Neither "booze," nor aspirin, nor antihistamines, nor vitamin C (nor anything else) can possibly "cure" a cold. Whatever temporary symptomatic relief they may afford is expiated later by accentuation and prolongation of the symptoms, and by insidious damage to the organism.

The most common "side effect" of aspirin is internal bleeding. Most people who experience slight gastric bleeding are unaware that it is occurring. Many people do experience overt, often serious, effects including burning mouth, throat and stomach; breathing difficulties and congestion; dizziness; lethargy; tinnitus (ringing of the ears); vomiting; a decrease in blood circulation; gastric bleeding, or hemorrhaging serious enough to cause ulceration or anemia, or to be life threatening.

Aspirin also interferes with the prostaglandin system, the body's key defense against disease-causing elements, and the key to detoxification.

A study by researchers at the Oregon Health Sciences University in Portland reported that five to ten

percent of permanent kidney failure is due to damage by aspirin, acetaminophen (e.g., Tylenol), and other analgesics (pain killers). I believe this to be a low estimate—Hygienists have been maintaining for years that drugs subject the kidneys (and the liver) to intolerable stress. The report says that taking three aspirin tablets a day for three years causes renal (kidney) disease, and many people are advised to use much more than that as blood thinners for chronic pain or to relieve arthritis and other inflammatory ailments. Dr. William M. Bennett told a National Kidney Foundation seminar that mixtures of drugs appear to cause more kidney damage than each drug alone. Dr. Bennett said it is not uncommon for people to take analgesics daily in the danger-level amounts, sometimes just to "feel good" or for the mild mood-altering qualities they have.

The mood-altering drugs in coffee and tea also have adverse effects on gastric, cardiac and renal function.

Alcohol, aspirin, antihistamines, and all drugs are designed to stop the body from doing what it is trying to do. The drugs form chemical unions with body tissues, fluids and processes, destroy the body's ability to purify itself, dam up the poisons, and multiply the problems. So-called "natural cures" (herbs, vitamin C, etc.) are also used in an effort to thwart the action of the body.

Some people are under the impression that colds can be prevented or "cured" by megadoses of vitamin C. The publicity generated by Linus Pauling's research and writings helped to perpetuate this belief. *It is particularly unwise to use vitamin C if one is also taking aspirin, because vitamin C tablets intensify the effects of aspirin in the body, such as hemorrhaging and anemia.*

It is true that a diet predominating in raw foods is high in vitamin C, and it is also true that such a diet is a good start in not developing disease. *But vitamin C supplements are not food* (contrary to what vitamin pill advocates are fond of proclaiming). The body's reaction to their use is indisputable proof that they are just another form of drug. They are recognized by the body as acids and irritants, to be expelled as quickly as possible. Large amounts of vitamin C supplements trigger an extraordinary detoxification effort of the body (just as do garlic, mustard, camomille, etc.), at great cost in vitality and energy. Some of the toxins which made the cold necessary will often be borne out of the body, riding out on the "fast train" the body is using as an emergency measure to rid itself of the even more intolerable vitamin C supplements. The cold symptoms may disappear, due to the concurrent elimination of some of the toxins, but primarily due to the diversion of the attention of the body from the toxins causing the cold, to the more urgent necessity for getting rid of the acids and irritants in the vitamin C pills.

Viktoras Kulvinskis says, "Fighting colds with vitamin C results in acidification of mucus, which prevents its elimination via the respiratory system. It must instead be expelled by the kidney. The overall effect is strain on the kidney."

The ultimate result of forcing the symptoms "underground" is insidious damage to the organism, and chronic degenerative disease.

## 1.6 Causes of Colds

There is nothing mysterious about a cold—it is the body's own cure for an intolerable condition brought about by the errors and omissions inherent in "civilized living." Overeating; overconsumption of refined carbohydrates; too few fresh, uncooked fruits and vegetables; coffee, tea, chocolate; soft drinks, hard drinks (even copious water drinking); insufficient muscular activity; not enough clean, fresh air; too little rest; excessive stress—the more of these mistakes we commit, the more often our bodies require "colds" or other eliminating crises.

Air-tight homes add to the problem. Modern homes outfitted with double- or triple-glazed windows; air-lock vestibules; weather stripping; insulation and plastic vapor barriers in walls, floors and ceilings make a "residential thermos bottle" which traps dangerous pollutants inside. In older, draftier homes, air is replaced by fresh air about once an hour. In today's tightly-sealed homes, inside air is replaced only about once every ten hours."

The net result of "civilized living" is that every cell in the body is filled with and surrounded by waste material, the blood vessels are lined with excesses of food, and the blood itself is overloaded with waste materials and excesses of food. Hygienists call this condition toxemia, and consider this to be the basic cause of disease.

When the cells, tissues and body fluids contain an abnormally high amount of metabolic waste, it is a threat to the organism. When the body reaches its toleration level, it must employ means of eliminating these accumulations.

## **1.7 A Cold Is Body Action**

Since the cells will, at all times, act in their own best interests, individually and cooperatively, they initiate a process to eliminate the wastes and excess food residues. The body speeds up some activities and reduces the level of others. Elimination is accelerated. The increased burning activity of the body in disposing of the excess materials produces greater heat—the body temperature rises and a fever is experienced. Loss of appetite is a self-protective mechanism.

"A cold is an intense and acute activity designed to rapidly, efficiently, and effectively expel accumulated wastes. ... It is pure insanity to suppress the symptoms of a cold as is commonly done. ... A cold is no more nor less than a period of intense housecleaning." (Dr. Immerman) People speak of "catching a cold." People with colds have not "caught" anything—it is just the opposite—they are getting rid of something: they are getting rid of accumulated foul material. A cold is a cleansing, rejuvenating, renovating process.

## **1.8 Toleration**

A cold, or any disease, usually takes a lot of causation. The bodies of most people have taken so much punishment during the time since infancy, their bloodstreams have become so contaminated, that their levels of toleration have gradually increased. A nontoxic, healthy baby (or a truly Hygienic adult) has a relatively uncontaminated bloodstream. Improper feeding of the infant, too little sleep and rest, too much clothing, not enough fresh air and sunshine, results in a retention of toxic material and the baby develops a cold to eliminate wastes in excess of the toleration level.

As the bad habits continue and the child is dosed and drugged and "immunized," the child's body gradually learns to tolerate more toxins and will develop fewer eliminative colds and fevers. When bad habits force the system to learn to live with poisons, the waste products remain to damage the body and pave the way for the development of degenerative disease.

When the body has established high toleration levels, a cold does not eliminate all the toxemia—it only brings it down to a level at which the body has become adapted to functioning.

This adaptation is accomplished by the body as a means of preservation of life, since it could not survive the tremendous and constant elimination required by the mode of eating and living or the frequent interference with its remedial processes by drugs and treatments. So it adapts, sacrificing its level of vitality to the necessity for survival. Most physiological adaptations are regressive, as explained in detail in Lesson No. 66. The adaptation is not toward health; it is away from health. But the body has no alternative.

*The toleration point can be returned to its pristine low level by fasting and improving the way of life.* The toleration level of the average Hygienist has been reduced. The vitality has been restored to a point where the body will no longer tolerate a large toxic load, and may conduct extraordinary elimination at a level that would allow others to continue insulting their bodies. But if a Hygienist perceives the beginnings of cold symptoms, he knows what to do.

## 1.9 How to Deal With Colds

It is not true that colds are caused by viruses; that there really isn't anything you can do to not cause a cold; or that there isn't anything you can do for a cold once you get it except treat the symptoms (admittedly with scant success).

My grandchildren have known what to do about colds since they were just a few years old. They know that the way to avoid colds is to avoid junk foods and overeating; and they know that a cold can be eliminated by withholding food completely when the first symptoms appear. They know that if one fasts for 36 or 48 hours (or, at the most, three days), the symptoms will usually disappear, and it will not be necessary to contend with a seven- to fourteen-day period of suffering nor the organic damage that can be caused to the respiratory organs or other parts of the body by a prolongation of the causes and the symptoms.

Such cooperation with the self-healing power of one's own body enables the necessary elimination of toxins to proceed with a minimum of discomfort, a procedure which is quickly consummated.

## 1.10 Food Must Be Withheld During Acute Stages

"Laboratory experiments have demonstrated that digestion is impaired during the acute stages of a cold, and indigestion and decomposition are inevitable ... Feeding in a cold, when indigestion is inevitable, insures that putrefactive poisons will be absorbed into the system where they will increase toxemia. Continued eating when there is no power of digestion necessitates a supplementary eliminating crisis to expel the noxious material before vital tissues are harmed. Hence, a common cold may develop into other more serious diseases if eating is not discontinued."

Lesson 22 explained the process of digestion, and what happens when food is consumed under conditions which make proper digestion impossible. Proper digestion reduces food to the diffusible state without depriving it of its organic qualities. During the acute stages of a cold (or fever, or emotional upset, or any condition during which digestion is impaired), putrefaction of proteins and fermentation of sugars and starches are known to occur. Food eaten under such conditions, though rendered diffusible, is reduced to an inorganic, useless and toxic state. Digestion results in solution of the food for utilization by the body. Putrefaction and fermentation result in disintegration into toxic substances.

It is not what we eat, but what we *digest* and *assimilate* that produces health and strength. Conditions which disturb or impair digestion produce decomposition, thus poisoning the body instead of supplying it with nutritional elements from the food eaten. Whether or not the individual is aware of overt symptoms of such decomposition, insidious damage occurs.

## 1.11 Health and Disease

Health and disease are interrelated. Hygienists think of health and disease as fluctuating qualities of the living organism, as a continuum with health at the top. As health becomes less, disease occurs, and, of course, at the bottom of the scale is death. Between health and death are all varieties and conditions.

In a modern environment, it is probably not possible to attain perfect health. The human body is exposed to many toxins daily. Under normal circumstances, it should be possible to eliminate them from the body rapidly. This is the function of the organs of elimination: the kidneys, the liver, the lungs, even the skin. But when the normal level of toxins rises above a certain point, the body is overloaded and the vital energy drops below normal. The organs of depuration, which are regulated by the nervous system, are then unable to maintain their functional efficiency, and the internal environment becomes less stable.

At this point, the condition may be considered a mild functional disturbance, but some remedial steps must be taken to reduce the toxemia. If the individual recognizes the condition and decides to fast and rest, the efficiency and integrity of the body is speedily restored; otherwise, the organism itself takes remedial steps.

## **1.12 Vicarious Elimination**

First, the actions of the normal channels of elimination are intensified. Next, channels of vicarious elimination are employed—most commonly, the mucous membranes, with a deluge of mucus in the upper respiratory tract. When a full-blown remedial activity is in progress, fasting and resting are even more certainly indicated, but recuperation of the body's energies will now require more time.

## **1.13 Acute Diseases Are Self-Limiting**

Acute diseases, such as colds, are debilitating, but they are self-limiting. Most people eventually recover without any treatment, or in spite of the treatment. For that reason, almost anything seems to be a "cure."

When it is fully understood that a cold, or any disease, is body action and not an attack by an external entity, attempts are not instituted to suppress the body's own defensive and remedial processes.

If the body is allowed to continue its cleansing actions, the person will feel much better afterwards. The only helpful means of aborting or shortening the duration of a cold is through fasting, keeping warm, getting plenty of fresh air and as much bed rest as possible.

This methodology will increase elimination of toxic materials through the regular channels of excretion, and will decrease the necessity for vicarious elimination through the nose, throat, eyes, etc. The headache and fever will subside and the other uncomfortable symptoms will be reduced and gradually disappear.

## **1.14 Too Many Housecleaning Episodes Are Exhausting**

People who have frequent colds are conducting beneficial and necessary eliminative processes. Other people, equally toxic (or more toxic) may not have the energy to conduct such housecleaning and may, instead, undergo insidious degeneration.

The wise Hygienist will avoid toxemia, and avoid the necessity for so many housecleaning episodes. If such episodes are too frequent, damage to the channels of vicarious elimination will be inevitable.

Dr. Sidhwa says, "It must be pointed out that too frequent use of the same paths of vicarious elimination will lead to atrophy and degeneration of any path of elimination, as well as a gradual wearing down of the strength of the glands themselves. Although disease, especially acute disease, is a life-saving process, it is also a life-consuming process. Frequent stimulation leads to exhaustion, leading to further enervation of the whole system."

## **1.15 Rationale of Modern Medicine**

The medical profession, for the most part, regards diseases as organized entities that attack the body from without and that must be destroyed. That is why medical students spend such a great percentage of their time studying the pharmacopoeia, the thousands of drugs which are the weapons of choice against the little beasts—the "disease germs" and the mysterious viruses (the drugs that destroy the kidneys, that threaten life itself).

Modern medicine employs the word "virus" to mean an ultra-minute form of life that infects cells and causes maladies. They know not exactly what the viruses are—plants, chemicals, animals or parasites?

Boyd's medical textbook states that "the virus seems to exist in the dim borderland between living things and chemical compounds. It is a submicroscopic unit containing nucleic acid and protein. Unlike bacteria, viruses are "not capable of supporting" life on their own, owing to a lack of enzymes. In order to exist and multiply, they must occupy living cells which provide them with necessary material and energy. It is evident that a virus is a perfect example of a parasite."

Boyd admits that most normal persons can harbor viruses without developing the disease the viruses are

supposed to cause, and that enervating influences overcome the body's protective functions and "permit the viruses to usurp the biological activities within the cell."

## **1.16 Interferon**

Interferon, manufactured within the organism in response to colds and other so-called "virus diseases," is the body's means of protecting itself, but it can only operate when we supply the necessary materials and influences which promote health and protection.

In recent years, interferon has been publicized as the bright new hope to fight cancer and "virus diseases." But, although pharmaceutical firms invested millions in synthesizing interferon, the results (as with other magic bullets) have been disappointing and inconclusive.

In 1978, scientists were hailing interferon as a true miracle drug, a century after it was identified. But it has not lived up to its advance billing. Although the price tag for interferon research has hit four hundred million dollars, an FDA spokesman said (May 1983), "There are no real answers yet ... This drug affects a lot of systems in the body and has produced some side effects that include nausea, vomiting, flu-like pains, fevers and chills, confusion and high blood pressure."

Boyd's writings exemplify the medical attitude. Instead of thinking in terms of health improvement, so that the cells can heal themselves, they are seeking a chemical panacea to destroy the virus. Chemicals only make the host more susceptible and less able to deal with toxins in the organism.

## **1.17 Bacteria and Viruses Are Secondary or Tertiary Factors in Disease**

When the body is undergoing a crisis of elimination, virulent bacteria (or viruses) may become involved as secondary or tertiary factors. The use of drugs may produce mutant, more resistant strains. Edwin W. Schultz, M.D., in an article in the *Cyclopedia of Medicine*, states, "It is well established that viruses do undergo variations ... in virulence, in antigenic structure, and in the character of lesions induced ... sometimes of a stable mutation type."

All the newer knowledge about bacteria and viruses substantiate the Hygienic viewpoint: A healthy body will eliminate virulent or threatening influences, making disease unnecessary. Hygienists understand that disease originates inside the body as a result of poor eating and living habits; of physical, mental and emotional practices which subtly and insidiously weaken the organism."

The true role of germs is as scavengers, breaking up and consuming dead and dying cells and other debris. Bacteria perform the same function in the toxic body as they do everywhere in nature.

Viruses, which the medical profession has been incriminating more and more as the cause of so many diseases, are not even living entities in the same sense as bacteria. Bacteria are microorganisms which have the ability to act. A Virus on the other hand, is not a living entity.

The poisonous materials called viruses have no existence apart from a living organism. They are actually the debris of spent cells—the genetic material or nucleic acid (DNA or RNA) from these spent cells. Viruses are in no sense alive, nor do they have any ability to act, but their presence in the body is as toxic as any other retained body waste material, favoring the surfacing and multiplication of bacteria.

Actually, humans live symbiotically with bacteria. We adapt to, and are dependent on, bacterial flora. Health and disease are not antagonistic to each other. Disease does not attack the body, but rather is produced by it as a means of restoring health.

In Lesson No. 66 it was clearly demonstrated that bacteria do not produce disease; that there are no "disease-producing" bacteria, germs, microbes, bacilli or viruses; and that the opposite is the fact. It is the environment—the host—the disease condition—that determines the type of bacteria that proliferate. The germ does not produce the disease. The disease produces the germ by changing nontoxic bacteria into toxic bacteria in a septic environment. This concept is discussed in detail in

### **1.18 No Bacteria in Early Stages of a Cold**

*During the early stages of a cold, the nasal secretions are completely void of bacteria.* None are found in the thin watery secretion the first two or three days of the cold. When the thick purulent secretion begins, then pneumococci, staphylococci, or streptococci make their appearance.

Dr. Vetrano says, "Since bacteria are so conspicuously absent at the beginning of a cold, another cause had to be found. The unpopular idea that a person could change his life habits and not develop colds was too preposterous to entertain. The virus saved the day." People don't have to change their ways of life as long as they believe their colds are caused because they "picked up" a very malignant virus.

### **1.19 Why More Colds Develop in Cold Weather**

Colds may develop at any time of the year, but the summer months show fewer colds because most people get more fresh air, sunshine, and exercise, and commonly eat less. As indicated in Lesson 66, the first colds of early winter are not "caught" from someone else with a cold but develop in those most susceptible because of the way they have been living and eating. The added stress of cold temperatures further checks elimination, adds to the general toxemia and enervated condition, and precipitates a crisis.

Leslie Thomson says, "To many people a 'chill' and a 'cold' are almost synonymous. It is an easy error, all the more so because it is not a complete fallacy; rather it is a seriously misplaced emphasis. Many people *do* develop a cold after an unpleasant incident in bad weather, but one should ask a few questions. In most cases the feelings of chill and the development of a cold are only different aspects—or successive stages—of a bodily springcleaning. When the body reaches a state in which retained wastes seriously impede normal vital functioning, the process has been so slow that the individual is only dimly aware of being substandard. Then some circumstance presents his system with an unusual challenge and the tolerance of his vital system is exceeded." There is an inability to keep warm because the normal physical and chemical processes are so retarded that the heart is unable to maintain adequately free circulation. The body must, and does, organize for a thorough cleansing and rejuvenating "crisis"—uncomfortable, to be sure—but necessary—and eminently worthwhile. If no stupid interference occurs, "this wonderfully complex process achieves in a few days a massive ejection of waste and a burning up of combustible rubbish."

### **1.20 The True Cause of Colds**

A summation by Dr. Vetrano is concise and eloquent: "Colds develop and are not 'caught.' Bacteria and viruses have nothing to do with the development of coryza. They may be complicating features or function as saprophytes feeding on the debris. They arrive on the scene when tissues and fluids are abnormal and survive as long as the tissues remains abnormal. They help clean up the debris. Our enervating way of life is the true cause of colds."

[Home](#) > [Lesson 70 - Colds, Flus, Upper Respiratory Ailments](#) > 2. Influenza

## **2. Influenza**

Influenza is essentially a magnified version of a cold. If you continue to permit so many adverse factors in your daily life that a couple of colds each year are inevitable, then a bout of flu every second or third

year may also be unavoidable.

Influenza in itself is no cause for panic. Properly understood, and intelligently handled, influenza is a constructive process. The fear with which so many laymen and doctors regard the flu is due to its violent potential when it is mishandled.

## 2.1 Consequences of the Treatment

The severity and after-effects of any cold or flu depend upon the treatment. The terrible developments which are ascribed to flu are almost never due to the basic illness. They are the results of the universally-suppressive treatment, the consequences of the drugging.

Dr. James C. Thomson tells about his experiences during the Great Flu Epidemic of 1918: "Reports collected from naturopaths practicing in all parts of the world after the 1918 wave—the most serious in living memory—gave a death rate of under two percent, whilst around them in the same cities, among the same types of people and under almost identical conditions except for the treatment, the death rate was from seven to over thirty percent. In my own practice, I had personal charge of 87 cases. In 86 of these cases, my instructions were faithfully carried out, and in no case was there either death, complication or any lingering sequel. The majority of these patients spent two or three days in bed, felt somewhat shaky in their walking for a further day or two, and, within a week or two, actually felt better than they had before the attack. In the one remaining case my instructions were willfully ignored, and I was forced to discontinue."

## 2.2 Types of Influenza

Influenza often starts out like a simple cold. Sometimes the first symptoms are vigorous, and arrive without warning,. Suddenly the patient may suffer from fever, nausea, vomiting, severe neuritic pain, severe inflammation, general muscular aching, or other distressing or violent symptoms.

Leslie Thomson (son of Dr. James C. Thomson) describes the four main types of flu. No matter how novel the identifying names given by epidemiologists or immunologists, any particular case consists of either one of these types, or a combination of two or more.

1. *Respiratory*, which starts off with violent, paroxysmal coughing.
2. *Gastro-Intestinal* - nausea, vomiting and abdominal pain are the immediate indications.
3. *Nervous* - headache of unusual severity, often concomitant with pains in neck, chest and upper abdomen. Depression and sleeplessness are common accompaniments.
4. *Febrile* - quite intense fever, sometimes accompanied by disorientation, to the extent of delirium.  
*In this form, it is imperative that no nourishment whatever be given to the patient until the fever has subsided.*

Leslie Thomson says that how individuals have lived, and the relative strength of the various vital organs—the individual physical makeup and the inherited temperament—are dominant and significant in determining the type and severity of the flu episode. Nobody needs to be "infected" by anyone else to develop flu. Flu is something which originates and is directed within the individual system. "The danger in differential diagnosis lies in the orthodox tendency to apply suitable treatment—i.e., aimed at obstructing or neutralizing the particular activity or discomfort predominating."

## 2.3 Dealing with Influenza

A couple of days or more of bed rest with nothing taken in except sips of water, is all that is necessary. Plenty of fresh air should be provided, but chilling should be carefully avoided. No attempt should be made to bring down the temperature by prolonged cold bathing, or by applying ice packs, or alcohol, which can be a dangerous interference in the body's processes.

After perhaps forty-eight hours, if the temperature is more or less normal, fresh fruit or small quantities of green salad may be offered. But the patient must continue to rest. There might be a second phase in a few days, during which food should again be withheld or reduced to a minimum. The patient should continue to rest in bed until the fever and shakiness have cleared.

## 2.4 Vomiting and Diarrhea

If one must vomit, or experience diarrhea, to remove irritants and morbid matter from the body, it is the height of folly to try to block it. The body does not go to the trouble of initiating these modifications in its activities unless they are essential for survival.

Dr. Immernan says, "When vomiting and diarrhea occur, it is because there are substances in the digestive tract that the body recognizes as troublesome, and wishes to eliminate. The material may enter the digestive tract via the liver. The liver is the great filter for the blood. It draws waste material from the blood and shunts it into the digestive tract for elimination. Sometimes this material is so toxic that the body will send it 'upstream' where it will only be exposed to three to four feet of tubing (stomach, esophagus), as opposed to going 'downstream' where it will be exposed to thirty feet of tubing (intestines). Once in the stomach, this toxic material will elicit feelings of discomfort and nausea until the stomach violently contracts and ejects the waste. Following this, there is usually a feeling of relief and improved well-being. Diarrhea fundamentally is of the same origin as vomiting. The body recognizes that there is material in the digestive tract and shouldn't be there. In order to more rapidly eliminate this waste, diarrhea will be initiated."

Some waste is directly transferred from the bloodstream through the walls of the intestines into the alimentary canal, and then eliminated via vomiting and diarrhea. Violent diarrhea and vomiting rapidly clear the digestive tract so that it can be temporarily put to rest, and repair, rejuvenation and cleansing are accelerated. To eat while experiencing the flu is sheer insanity.

## 2.5 Fever

When the body produces fever because of an internal need, why should we panic and seek by heroic means to suppress the fever at all costs? Physicians have prescribed and encouraged the use of antipyretics (fever-reducing drugs) to reduce the temperature as quickly as possible in all cases where the temperature is above the so-called normal temperatures of 98.6 degrees Fahrenheit (37 degrees Celsius). Actually, the medical profession is not universally convinced that fever is altogether harmful. Some medical men have even used fever therapy in an attempt to cure certain diseases.

The human body is delicately balanced and capable of better and safer fever induction than any artificial process of producing fever. Artificially-induced fevers can be dangerous. Artificially reducing fevers interrupts, retards or stops the healing efforts of the body.

The heat of spontaneously-induced fever is produced for the purpose of acceleration of cell activity. When the organism perceives that this is necessary. When there is an emergency, the metabolism is accelerated by increasing the amount of heat available. This is controlled by the hypothalamus, which is sort of a human thermostat.

Metabolism consists of the absorption of nutrients and the excretion of wastes. The heat is necessary to accelerate the excretion of wastes which have accumulated beyond the body's ability to tolerate them, and beyond the body's ability to eliminate without some extraordinary modification. Heat acts as a catalyst which causes the toxins to liquefy and pass into the bloodstream, where they are transported to the organs of elimination, and thus out of the body.

Every now and then we hear from the "scientific" community that "fever may be beneficial." An article in the *St. Petersburg Times*, 1/4/83, says; "For more than a century, we've been told to take aspirin to bring down a fever. Now, researchers aren't so sure that's a good idea. Now studies suggest that a

moderate fever should be allowed to run its course because it may shorten the illness. Scientists have figured out that fever mobilizes the body's defenses against infectious organisms, and, in some cases, directly inhibits their growth."

Of course, what the studies "suggest" and what the scientists have "figured out" are not being correlated with what Hygienists have been teaching for the last 150 years.

Kenneth S. Jaffrey, in his booklet, *Fever, Nature's Own Healing Process*, says, "Nobody has ever been harmed when a self-induced fever has been managed rationally."

He quotes Vincent Priessnitz (1829), the discoverer of Nature Cure; R.T. Trall (1862), a Hygienic pioneer; and Henry Lindlahr (1920), another pioneer in the field of natural healing; as having agreed that fever is part of the healing effort, a process of purification to relieve the system of morbid matter and to repair injury to living tissues.

In 1928, Herbert M. Shelton said, "Fever is a necessary increase in body temperature designed to enable the body, or some part or parts of it, to effectively meet and destroy some foe of life that is threatening the body and to repair damages."

In 1930, another noted Hygienist, Hereward Carrington, described the condition of fever as the result of the forcible recharging of the body with energy, as an emergency measure, to assist in freeing the body from its dangerously-diseased condition.

Eugene F. Du Bois, professor of Physiology at Cornell, University, in his monograph on fever, stated that antipyretics were abandoned in the early part of this century (although later their use was revived). Cold-tubbing in typhoid was also abandoned. Du Bois said, "Clinicians began to regard high temperature as helpful. This belief was strengthened by the realization that many pathogenic organisms (germs and viruses) were inhibited or killed at temperatures that could be tolerated by the human body." The metabolism and chemical reactions of the body, including enzyme activity, are accelerated by a rise in temperature, thus enhancing the healing process. When fasting is employed during a fever, the metabolism and healing process are even more dramatically multiplied.

## **2.6 "Immunization"**

Many advocates of so-called "immunization" procedures freely admit the futility of efforts to immunize against influenza. A 1977 report by the United States Department of Health, Education and Welfare says that the fragmented nature of the genetic material of the influenza virus is believed now to account for the agent's unique and puzzling ability to undergo periodic changes which render available vaccines useless. Although we cannot agree with the basic premise expressed therein, the fact remains that the vaccines are admittedly useless. Obviously, the credibility of the whole immunization theory is moot, if the particular problem can never be identified or dealt with in time—in view of the admitted futility of efforts to immunize against influenza. Yet, even after the Swine Flu Fiasco of 1976, flu vaccines are still being recommended and administered by the medical profession.

In Lesson No. 66, I went into great detail about the futility of so-called "immunization." In January 1983 (some time after preparing Lesson No. 66), I heard Robert S. Mendelsohn, M.D., on this subject. He said, "I lost my faith in immunizations around the end of the 1960s. My patients started to come back to me with the damage that I had previously inflicted on them."

Polio disappeared in Europe without a vaccine. Dr. Mendelsohn said that Salk doesn't like the Sabin vaccine, and Sabin doesn't like the Salk vaccine. Dr. Mendelsohn continued, "I think they're both right."

He said there are hundreds of cases in the courts due to damage from whooping cough vaccine. He said, "Pediatricians are telling me that they are not immunizing their own children, but they give it to their patients!"

Dr. Mendelsohn is a practicing pediatrician. His credentials (conventional, medical, etc.) are

unimpeachable. He has been practicing medicine for about thirty years. He has been national director of Project Head Start's Medical Consultation Service, chairman of the medical licensing committee for the state of Illinois, associate professor of preventive medicine and community health in the School of Medicine of the University of Illinois, and the recipient of numerous awards for excellence in medicine and medical instruction.

*He is also a medical heretic.* He believes that the greatest danger to your health is usually your own doctor. He argues that modern medicine's methods are rarely effective, and in many instances are more dangerous than the diseases they are designed to diagnose and treat. I would recommend that all students of Natural Hygiene read his book, *Confessions of a Medical Heretic*.

In his book, Dr. Mendelsohn says the entire flu shot effort resembles a massive roulette game. He quotes Dr. John Seal, of the National Institute of Allergy and Infectious Disease, as saying, "We have to go on the basis that any and all flu vaccines are capable of causing Guillain-Barre Syndrome."

A study, conducted at the Minneapolis Veterans Administration Medical Center, was published in the November 19, 1981, *New England Journal of Medicine*. Researchers warned that flu shots can cause overreactions to drugs, producing effects similar to "overdoses" of the drugs. The researchers found the influenza vaccine can change human metabolism, hampering the liver's ability to break down and remove drugs from the body, so that the medicines stay in the body longer.

Thus, the potential damage of drugs is multiplied as a result of the influenza vaccine.

## **2.7 The Paradoxical Conventional Weapons Against Disease**

Both of the paradoxical conventional "weapons" against disease have the same result. Injection of noxious material directly into the bloodstream (vaccinations), and the use of drugs to kill the germs which are busily engaged in cleaning up the mess, are not only in opposition to each other, but are also in opposition to the laws of nature, and contrary to common sense.

They are in opposition to each other, because injection of noxious material initiates defensive body action against disease; drugs curtail defensive body action against disease because of the new emergency—the necessity to deal with the drugs. Injection of diseased material into the bloodstream is manifestly in opposition' to the laws of nature, and certainly contrary to common sense.

Both vaccinations and medications not only add more poison to the already overburdened system, they frustrate nature's attempts to help you, and they prolong and intensify your miseries. In addition, they both have the more insidious quality of increasing your susceptibility and vulnerability to future chronic and degenerative diseases.

## **2.8 Frighteningly Impressive Case Histories**

Leslie Thomson says, "It is not surprising that orthodox doctors have frighteningly impressive case histories to report. Delirium, peritonitis, pneumonia, neurasthenia, chronic depression, lymphatic enlargements, pulmonary degeneration, cardiac disorders, kidney disease, arthritis, middle ear deafness, and degeneration of the spinal cord, are only some of the sequelae blamed upon influenza. To us, it is undeniably logical that the more the doctor fills the patient with unwanted and unusable nutrients, and obstructs various vital processes with medication, the greater the inevitability of tragic complications."

I have heard a dark joke, to the effect that, since the treatment of influenza still baffles the physicians but they can "successfully" treat pneumonia with antibiotics, why not let the flu develop into pneumonia and simplify the problem?

But the "humor" is becoming even grimmer, since newer announcements admit that "in recent years, drug resistant pneumonias, especially among hospital patients, have been on the increase."

## 2.9 The Swine Flu Fiasco

Even more ironic is an excerpt from a brochure on flu from the U.S. Department of Health, Education and Welfare: "With identification of a new swine-like influenza virus early in 1976, NIAID (National Institute of Allergy and Infectious Diseases) scientists, grantees, and contractors sprang into action. The technique of recombination was applied to hasten the growth of the vaccine virus; and, in the institute's vaccine centers, medical investigators with years of experience became the nucleus of experts needed to evaluate the new swine flu vaccines in record time. Working closely with the Army, the Center for Disease Control, and the Food and Drug Administration's Bureau of Biologies, NIAID supervised a series of tests to determine the proper vaccine dosages that should give good protection with a minimum of adverse reactions."

They talk about "springing into action," "evaluating the new swine flu vaccines in record time," and "determining proper vaccine dosages for good protection with minimum adverse reactions." *Nothing is said about the fiasco that resulted, or the tragic deaths from the vaccine. Nothing is said about the vaccine-induced Guillain-Barre Syndrome.*

## 2.10 Good Health Is the Only "Immunity"

Hygienists live to have health, not to prevent certain specific diseases. Good health is immunity against influenza and all diseases. Microorganisms only surface when there is a job for them to do—they help to clean up the debris created by atrocious diet and living habits.

[Home](#) > [Lesson 70 - Colds, Flus, Upper Respiratory Ailments](#) > 3. Other Upper Respiratory Problems

## 3. Other Upper Respiratory Problems

Some other upper respiratory ailments are hay fever, sinusitis, postnasal drip, deviated septum, nasal polyps.

Hay fever is not caused by hay and there is no fever. The nasal portion of the respiratory tract is affected, causing the itching, watering, inflamed eyes; nasal obstructions; runny nose; or paroxysms of sneezing. It is usually triggered by pollens from trees, grasses or weeds, or exposure to molds, dust, fur, feathers, animal dander, or orris root, the base of most cosmetics.

The use of nasal sprays for hay fever or colds is a dangerous habit. It produces a rebound nasal congestion, a vicious cycle that is worse than the original problem.

A contributor to Joe Graedon's column made an excellent suggestion for a way to break the habit. She said that the doctor had told her to quit "cold turkey," but she couldn't sleep because she couldn't breathe at night. Instead, she used the spray on only one nostril. After several days, the untreated nostril unclogged. She then repeated the procedure in the other nostril. She said that breaking the nose spray habit was even harder than quitting smoking.

Sometimes hay fever progresses to a more serious condition called asthma. Asthma is not essentially different, except that the bronchial tubes are affected, resulting in labored breathing, wheezing and coughing, slow respiration, sweating, blueness of skin (cyanosis) and coldness of extremities.

When one or more of the four pairs of air-filled cavities in the skull become affected, the condition is called sinusitis.

Nasal polyps are soft, pendulous outgrowths from lining membranes of the nose. If they are of sufficient

size to cause obstructive symptoms, a prolonged fast will sometimes reduce or eliminate them. Sometimes, surgery is necessary.

Sinus headaches and postnasal drip will usually be relieved by short periods of fasting.

Hay fever, asthma, sinusitis and polyps are often associated with so-called allergies. Chronic sinus inflammation can result in the formation of polyps.

Lesson No. 71 will go into detail about allergies, hay fever, asthma, emphysema and other chronic conditions involving the respiratory tract, the bronchial tubes and the lungs.

Actually, the primary causes of all these problems are the same as the causes of all other pathologies—the faulty living habits that lead to toxemia and disease.

[Home](#) > [Lesson 70 - Colds, Flus, Upper Respiratory Ailments](#) > 4. The Hygienic Rationale

#### **4. The Hygienic Rationale**

Dr. Sidhwa eloquently expresses the Hygienic rationale concerning health and disease: "When man does not overstep Nature's limits regarding harmful diet and emotional indulgences; when he does not deplete his nerve energy by late nights, overwork, worry, stress, indulgences or by constant stimulation in the form of chemical, thermal, or physical goads, the balance of the life force is maintained, and, with it, good health. Under such Utopian conditions, it is conceivable that disease would be an impossibility. In other words, living within your means, the individual, under the above circumstances, would be immune to disease."

[Home](#) > [Lesson 70 - Colds, Flus, Upper Respiratory Ailments](#) > 5. Questions & Answers

#### **5. Questions & Answers**

**Why do people, who eat all the wrong foods and get no exercise still seem to get along well and have very few colds?**

Most likely their bodies have developed such a high tolerance level for morbid material that a weakening of the detoxifying organs has occurred, and these individuals no longer have the vitality to conduct necessary and effective eliminative crises. Some people are blessed with superior genes, and it may take a long time for the body to degenerate into an irreversible condition—but wrong living will eventually produce this outcome, especially if necessary housecleaning does not occur, and the toxins are dammed up in the body.

**Why do colds often evolve into more serious illnesses?**

Drugging and feeding produce these sequels to colds. If the individual fasts and rests and takes nothing but water as thirst requires, complications are rare or nonexistent.

**What is the best procedure if I fast for a cold (say, two or three days) and the symptoms return when I start eating?**

The best action would be to stop eating and go back to bed for another day or two. If not possible or convenient, confine your diet to fruits only for a few days, followed by an all-raw-food diet, until the symptoms disappear (or stay on raw food permanently, if possible).

### **Is a diagnosis helpful in determining Hygienic means of caring for a patient?**

Yes, a diagnosis is helpful, but not absolutely necessary. A correct diagnosis supplies clues to the causes of the problem, but it is of very little influence in the management of the illness, except in quite unusual situations. For instance, in acute appendicitis, no water should be taken until the symptoms disappear, but, of course, this would apply to any acute abdominal discomfort.

[Home](#) > [Lesson 70 - Colds, Flu, Upper Respiratory Ailments](#) > Article #1: Coryza, The Common Cold by Virginia Vetrano, B.S., D.C.

### **Article #1: Coryza, The Common Cold by Virginia Vetrano, B.S., D.C.**

Once upon a time there was a beautiful young lady with golden red hair down to her slender waist, and long and shapely legs. Her eyes were a beautiful blue, that scintillated when she laughed. She was lithesome as the fawn in the morning. Her personality sparkled like the cool clear waters of a bubbling spring. There was but one thing that marred the radiant beauty of this lovely young lady. She was continually blowing her nose.

The young lady was well educated. In fact so well "educated" that she could no longer understand the simple things of life. Every new fact or thought had to present itself to her clothed in such heavy scientific garb that anyone trying to comprehend the muss had to peel off layer after layer of nonsense to reach but the core of fallacy. But this type of presentation pleased her. It was scientific, with theory piled upon theory to support a theory, in a long drawn out complicated web of fallacy. It would be highly unbecoming for a woman working on a doctors degree to support or follow any doctrine so simple a child could understand it, even if it would obviate the necessity for rubbing her nose raw blowing all the time.

Let us hope that by the time she receives her doctorate, by wasting so much time with unimportant nonsense such as "proving in what ways mathematically a donut is like a cup," that she will realize that much nonsense passes for science. Let us hope that after so many years of cramming gobbledegook into her head that she will be able to think. Unless she learns that all true sciences always simplify life and thought, instead of complicating them, she is destined to be a snorting horse until some more formidable disease helps her into the henceforth, her life a wasted travesty of education.

We would like to help Miss Nasal Drip but the time is not ripe. She suffers with chronic rhinitis, marked by frequent acute exacerbations, or the common cold. The common cold is an acute rhinitis, or inflammation of the nasal cavities. She suffers with it so often and so long at a time that one can almost say she has a perpetual cold. Her symptoms are typical; rhinorrhea or nasal discharge, nasal obstruction (due to swelling or edema of the mucous membranes of the nasal passages) and sneezing. A disease that may and should abort after twenty-four to forty-eight hours lasts for many weary weeks in this young lady.

In former years Miss Nasal Drip would have said that she "caught" a germ, were it not for the fact that she has learned that the nasal secretions are completely void of bacteria during the early stages of a cold. Many ciliated epithelial cells desquamate and are found in the thin watery secretion the first 2 or 3 days

of the cold, but no bacteria make their appearance until the discharge becomes thick and purulent. When the thick purulent secretion begins then pneumococci, staphylococci, or streptococci arrive upon the scene.

Since bacteria are so conspicuously absent at the beginning of a cold, another cause had to be found. The unpopular idea that a person could change his life habits and not develop colds was too preposterous to entertain. The virus saved the day. Miss Nasal Drip doesn't have to change her way of life as long as she believes she "picked up" a very malignant virus. This time her cold happens to be a very tenacious one, and it is progressing into bronchitis. Her medically-oriented mind attributes this to secondary invaders, not to her continual overeating of starches and sugars.

If all the Miss Nasal Drips in the world could understand that they do not have to develop colds any more than they had to develop measles, chicken pox or any other childhood disease. The simple expedient of refusing to eat at the first sign of a stuffy nose would not only abort colds, but all other acute diseases as well. Since laboratory experiments have demonstrated that in such simple diseases as coryza (common cold) digestion is impaired, it would seem that logic would proscribe eating, when indigestion and decomposition are inevitable.

Since the incipient stages of the childhood diseases (rubella, measles, chickenpox, and whooping-cough) are indistinguishable from the ordinary common cold, if one followed the rule to never eat when he has symptoms of a cold, these and other childhood diseases would never develop. Feeding in a cold, when indigestion is inevitable, insures that putrefactive poisons will be absorbed into the system, where they increase toxemia. Continued eating when there is no power of digestion necessitates a supplementary eliminating crisis to expel the noxious material before vital tissues are harmed. Hence, a common cold may develop into other more serious disease if eating is continued.

Miss Nasal Drip thinks she can't breathe because her nose is obstructed with secretion. She blows all the harder to empty it. Actually in the early stages of her cold, the nasal mucosa is red and swollen due to the inflammatory condition. The choanae (the posterior openings of the nasal cavity into the nasal part of the pharynx) are very narrow. The slightest swelling causes difficult breathing. Also due to the fact that the nasal passages are very narrow interiorly, when the nasal cavities are inflamed, and the membranes are swollen (edematous), Miss Drip's nose feels clogged, even though she empties it every few minutes.

Because of the continuity of mucous membranes, each time Miss Nasal Drip develops a spread to adjoining organs. The nasal cavity communicates with the frontal, ethmoidal, sphenoidal and maxillary sinuses, to which the inflammation may spread. This particular cold of Miss Drip spreads downward to the bronchi, also by way of continuous mucous membranes, and she developed the unpleasant symptom of coughing all night, thus preventing sleep.

Her chest became painful, frightening her, so that she listened to me a slight bit, and stopped eating potatoes swarming in butter one evening for dinner. I couldn't get her to quit drinking milk every morning and noon but she did substitute grapefruit for some of the heavier foods she was eating. On the day she omitted potatoes and butter her symptoms abated markedly and she slept better that night. But the next day with the chest pains gone, she lost her fear and resumed her bad eating habits!

We must be patient, she has a lot to unlearn. Just yesterday, she requested the microscope to analyze the water, because the idea came to her that everytime she visits us she "catches" a cold, so "it's due to bacteria in the water here, to which I am unaccustomed." "You don't 'catch' the cold," she said, "because you are adapted to these bacteria."

Adults generally feel lethargic several days before developing a cold, and may have aches in the limbs or back. Children have a tendency to develop more severe symptoms, with a temperature around 102 degrees F and sometimes higher. They are not hungry generally but are encouraged to eat by their parents, hence the frequent development of more formidable disease in children.

Colds may develop at any time of the year, and do not necessarily develop when a person has been chilled or in a draft. When "epidemics" of colds arise, some extra enervating cause happens to be present

in the lives of the people of the epidemic area. When large masses of people are surveyed, the summer months show fewer colds. Most people get plenty of fresh air, sunshine, and more exercise, which are highly beneficial to digestion and excretion, and commonly eat less during the summer months. Autumn brings less activity, less fresh air and sunshine, and increased eating, so there is an outburst of colds to rid the system of toxic matter. When midwinter comes, around Christmas and New Year's, cold statistics mount again. Toxemia rises to above the toleration point, due to improper living, excessive eating and drinking and late hours. Therefore, more noses start running, more chests begin coughing, and more eyes turn red.

Miss Drip will argue that colds develop in the autumn because of reopening of schools with the massing together of children indoors. How does she explain the development of colds at Christmas vacation when most children are out of school for about 12 to 14 days? As the incubation period for colds is 12 to 48 hours, the germ and virus theory simply does not account for all the facts.

The fact that chilling does not cause colds has been repeatedly demonstrated to physicians who have observed the so-called immunity of travellers in the Arctic and of men compelled to spend many weeks at sea on rafts or in open boats and who never 'caught' cold. This leads the research workers to believe that "in the absence of the virus no amount of chilling can cause a cold." Since viruses are ubiquitous, it cannot be said that there were no viruses present. They are everywhere. Was it too cold or too hot for the activity of viruses under those conditions? Or was it, that there was a scarcity of food, hence, the men couldn't eat their way into a cold?

We are taught that a number of viruses, or a number of strains, cause the common cold. This should lead us to refine the diagnosis still more, to cold type a, type b, type c, etc. The old theory was that there is a specific cause for each specific disease if we could find it. Not so with colds. A number of viruses are said to be guilty. Those infected may be re-infected with the same virus within three weeks after recovery. The so-called immunity is short-lived. Colds cannot be induced experimentally in most animals.

In 1914, the virus theory of the etiology of colds was introduced by Druse, who it was said repeatedly demonstrated that "filterable agents in throat washings obtained from adult patients with acute coryza were capable of producing colds when introduced into anthropoid apes or susceptible human volunteers."

Volunteers, we are told, developed colds when infected by filtrates of nose and throat washings from those who had colds. A poison, a virus is a poison, or any foreign agent, in contact with the nasal mucous membranes, occasions inflammation, rhinorrhea (running of the nose) redness and swelling, and fever in children. An example of which you can perform yourself, is to run a match stick up into the nostril. The nose will begin to run, sneezing will commence, and if kept there longer inflammation will develop to rid the body of the foreign agent.

Another example is the true story of a child who at three years of age repeatedly developed a high fever, and a cold—one right after the other. Her mother took her to a physician each time the cold developed, and the symptoms were quashed by penicillin injections. Two or three days after the suppressive effects of the drug wore off, the cold, high fever and running nose would redevelop. This worried the mother, so she continued taking her child to the pediatrician for more shots. Finally old mother nature won. Despite the continued suppression which interrupted her work, she kept initiating elimination processes until one day, as the child was feverish and nose running still more, the child began picking at her nose in the presence of her mother. To the mother's surprise, a much frayed, and bloody piece of kleenex was pulled out. This was the occasion for the inflammation, fever and runny nose. The three-year-old had undoubtedly pushed the kleenex up her nose at some time in the past and it remained there until the body excreted it. The human organism just doesn't like foreign things in the vital domain, and stubbornly keeps working until it rids itself of them. The child's fever subsided and did not recur.

When viruses are injected to cause colds in "susceptible" individuals, it must be remembered that only certain individuals develop symptoms of coryza, and that the great numbers of viruses present are

treated as foreign agents and expelled by the only method the nose knows—inflammation and sneezing.

So many viruses have been incriminated as causes of colds that research workers are really very puzzled. After a long discussion of the causative agents of colds, they conclude: "From the foregoing it may be concluded that there is no single viral agent to be incriminated in adult colds and that a variety of agents which produce fairly severe disease in non-immune infants may also occasionally cause coryza in adults."

From the foregoing, it appears, that any virus or bacteria that is present when a cold develops is the guilty party. It is stated in Cecil and Loeb's *Textbook of Medicine* that, "It cannot be said with absolute certainty that under certain conditions the common respiratory pathogenic bacteria do not initiate colds, although the evidence is against this possibility." Paul and Freese who conducted studies in isolated communities in Spitzbergen, implied that, in the absence of the virus, colds "almost wholly disappear." He is saying colds almost disappear in the absence of viruses, but they don't actually do so because some colds still exist; these he attributes to bacterial infection as follows: It is then presumed that "the residuum of sporadic, noncommunicable colds may be due to bacterial infection." What sophistry! The colds are gone, and they are still there! The remaining colds are of bacterial origin; but are noncommunicable.

Clinical investigators are still puzzled over the role that bacterial inhabitants of the nasopharynx play in the development of colds. Most of the "basal flora" of the upper respiratory tract, they think, consists of nonpathogenic and inconsequential agents. But since such agents that are thought to be true pathogens are often found in the throat washing of patients with colds this leads them to wonder if they do not play some sort of role in the disease known as coryza, or the common cold. "On the other hand," they reason, "hemolytic streptococci, pneumococci, and hemophilus influenzae are recovered in considerable numbers from a patient with a cold, it is tempting to assume that they are playing a role of some sort."

Were Miss Nasal Drip a diligent student she would see how confused and frustrated the laboratory men really are. One time a bacteria is a proved pathogen and yet the next time it doesn't cause symptoms. With only the germ theory from which to reason, no wonder the confusion. The confusion itself would lead intelligent men to start searching in another direction, were they not so deeply rutted in the germ theory. The surmizing continues: "On the other hand, any of these organisms (Group A hemolytic streptococci and h. influenza) may appear in the normal nasopharynx without causing symptoms, and the mere recovery of one of them from a case of coryza may be of little significance. Most authors tend to designate them as 'secondary invaders,' assuming that the cold virus paves the way for their entry into the mucous membranes."

To further befuddle the physicians, when they give antibiotics to kill the germ invaders, it doesn't shorten the course of the disease one bit. Yale Kneeland, Jr. in Cecil and Loeb's *Textbook of Medicine* states, "Yet when effective antibacterial agents have been used in large-scale controlled experiments on adults with colds, there is little evidence that suppression of the bacterial component alters the average duration of the disease."

Let us review what the physicians are admitting. First, it is not known exactly which virus 'causes' colds. Indeed, it may be numerous ones. Chilling doesn't cause colds in the absence of the virus, yet viruses are ubiquitous. If the virus is sprayed into throats, it causes inflammation in "susceptible" hosts only. The disease doesn't run the same course as it does in those individuals who really develop a cold and whose tissues are not made irritable by foreign agents. So-called respiratory pathogenic bacteria are present in the throat washings of people who never develop symptoms of disease. They are present in some who have colds, but killing them doesn't shorten the period of sickness of the individual. What a mish-mash of contradictions upon which to base a practice.

Yale Kneeland, Jr. sums up the medical viewpoint in the following manner: "It can be stated that the common cold is due to one or more filterable viruses and that only in highly susceptible persons is there an 'etiologic complex,' i.e., a bacterium acting in concert with a virus. The bacterial effect may be either the general intensification of symptoms already referred to or a clear-cut complication, such as purulent

sinusitis or otitis."

How much simpler if physicians' befuddled brains could be washed clean of viruses and bacteria or if they could recognize the beneficial effects of bacteria. How lucid would their day be when they would know the truth. Colds develop and are not "caught." Bacteria and viruses have nothing to do with the development of coryza. They may be complicating features or function as saprophytes feeding on the debris. They arrive on the scene when tissues and fluids are abnormal and survive as long as the tissues remain abnormal. They help clean up the debris. Our enervating way of life is the true cause of colds.

Let us look at the life of Miss Nasal Drip. She is a heavy milk drinker. Never does a day pass that she doesn't drink at least six or more glasses of milk. She is an "early" sleeper, never going to bed before 3 a.m. She overeats on starches, shunning all salads and taking very few fresh fruits. She avoids the sun because it makes her freckle. In general, she leads a very enervating life. When toxemia mounts to above her established tolerance level, which it does quite often, then her nose, like a steam valve, lets out the excess. As she never ceases her heavy starch eating even while she has a cold, but seems to eat even more, sometimes taking as many as eight small red potatoes at a time, and gulping more milk to "soothe" her irritated throat, her colds last anywhere from three to four weeks. They run on and on because cause persists. The fact that her symptoms abated markedly when she ate less food did not teach her anything. Germs and viruses have her complete attention.

When we can control the eating of anyone developing a cold—either get them to cut down or to take only water for a few days—and the symptoms of coryza invariably subside, are we to believe that this invariable phenomenon of nature is due to the whim of a virus? Or, can we safely assume that when you rid the body of the cause, the effect will cease? When favorable results invariably occur, can we not say that we have a truth, or a law of nature? Or, must we continue to bury our heads in the sand and refuse to see the truth because it is not in accord with "scientific" thought?

Shelton, eloquently, gives us the cause of colds: "Toxemia from enervation and excess is the cause of local inflammations. Any enervating influence, any influence that lowers nerve energy, will inhibit elimination and produce toxemia. For this reason, worry or overwork, jealousy or lack of rest and sleep, apprehension or excesses, may help to produce rhinitis.

"Excessive food intake is one of the basic causes of toxemia and its effects. Excesses of starches, sugars, fats and milk are especially likely to result in rhinitis and similar supplementary eliminating processes. Indigestion, whether from food excess, wrong combinations of food, eating when fatigued, eating when worried or under other emotional strain, or eating under other physical, emotional and physiological conditions that inhibit digestion, will produce toxemia."

It is often difficult for people to realize that from their first cold in infancy their tissues and fluids have been saturated with an excessive amount of metabolic wastes. Their way of life prepares their body for a long list of diseases that grow out of an established toxemia. A cold does not eliminate all the toxemia, it only brings it down to a level at which the body has become adapted to functioning.

To make this Hygienic knowledge more clear, let us designate the normal amount of waste products in the body of the nontoxic healthy baby as 1. As the baby grows and is fed improperly, and gets too little sleep and rest, is overclothed, isn't permitted to play in the sun, he becomes toxemic. When toxic material mounts to 1 1/4, the baby develops a cold to eliminate this excess waste material.

As time goes on and enervating habits continue, the baby learns to tolerate more and more toxins in the system. His established toxemia mounts to 2, and he develops a cold only when it rises above 2, then a crisis brings this back to 2, his new toleration point. As he grows older his toleration point continues to mount. He develops fewer and fewer colds and fevers but is paving the way for the development of degenerative diseases. Unfortunately for him, his bad habits of living have forced his system to learn to live with poisons, and only when toxic material rises above his toleration point will he develop a cold. This reduces toxemia to the toleration point or slightly below but doesn't eliminate it completely.

Hence the waste products remain to impair and damage structures. Only by fasting and changing the

way of life can the toleration point be returned to its pristine low.

We should not fear colds in the sense that we fear to sit in a draft, or fear to go swimming, or get our feet wet, lest we "catch" cold, but we should not take the fact that we develop frequent colds too lightly. Once we have an established "toleration" for excess toxic material in the system we are paving the road for the development of more serious forms of disease, unless we change our mode of life radically. An excess of waste material produces pathology, even though it is tolerated. Such waste material causes changes in and about vital organs which are away from the ideal and decidedly detrimental to the welfare of the organism. Toleration is passive resistance. The tissues are forced to live in a state of constant toxic saturation and must resist this in the fashion that tissues do. Hardening of tissues develops and other pathologies which lower the level of health of the individual, eventually leading to disease and death.

Under the present system of medical care, cause is not understood, hence the treatment is directed at palliating symptoms, instead of eliminating cause and supplying the body with the conditions of health.

Fasting must be instituted immediately upon the first symptoms of a cold and should proceed much further than the time it takes for the symptoms to subside. In this manner the tissues will be washed sweet and clean and the long-established toxemia will be eliminated, thus raising the standard of health of the individual. Dr. Shelton states: "We should not be satisfied with a mere disappearance of symptoms. Nothing short of a complete elimination of accumulated toxins, full restoration of nerve energy and a thoroughgoing correction of the mode of living should satisfy the intelligent. This will result in genuine health."

Medical treatment is admittedly suppressive and leads to immediate complications. It lowers the body's functioning powers, causing the retention and toleration of more and more toxic wastes. Kneeland, admits that "Up to the present no specific agent has been developed which is effective against the viruses of the common cold. In consequence, therapy is directed at general management, relief of symptoms and the control of complications."

Under medical care, complications are so common that they are expected. The suppressive treatment is a direct cause of these complications. About ten years ago anti-histimenic drugs were introduced and it was claimed that if used early enough, the disease could be aborted. Kneeland states of these drugs: "Subsequent carefully controlled studies have quite failed to substantiate the original claims."

Fortunately these drugs, in the dosages employed, have been singularly innocuous as far as untoward side effects are concerned. Nevertheless, they are not recommended unless there is an allergic element present."

The fact that they are no longer recommended "unless there is an allergic element present" indicates these drugs were not completely harmless. For symptomatic relief, acetylsalicylic acid (aspirin) is used for the very young. In adults, when the cough is troublesome, codeine is added and administered in the form of a cough mixture or in the form of the traditional "grippe capsule" which contains "codeine sulfate, acetylsalicylic acid, phenacetin, and caffeine citrate." Not one of these substances helps eliminate cause. All are directed at suppressing symptoms, and therefore impair and impede the body's efforts at cleansing itself. With such suppressive treatment of colds, is there any wonder that complications such as laryngitis, tracheitis, tracheobronchitis, sinusitis, or otitis media regularly occur?

Hygiene is so much more simple, direct and effective that it is a wonder that people still run to the physician for his bag of poisons, which only increase suffering and disease. When the living habits of the individual are corrected, he ceases to develop colds. If one feels out of sorts, and thinks a cold may be developing the thing to do is to institute a fast immediately. He should secure more rest, and reassess his way of life. He should try to conform more to the laws of life. In doing this, he is eliminating cause, not suppressing symptoms. By eliminating cause, he obviates the necessity for future colds, and future development of more formidable diseases.

It is hoped that Miss Nasal Drip will see the fallacy of the germ theory and change her mode of living so

that she will not be a T.B., asthmatic, or cancer statistic in the future.

[Home](#) > [Lesson 70 - Colds, Flus, Upper Respiratory Ailments](#) > Article #2: What To Do In a Cold by Dr. Herbert M. Shelton

## **Article #2: What To Do In a Cold by Dr. Herbert M. Shelton**

"A cold is simply an effort of the system to relieve itself of its accumulated waste panicles, said accumulation resulting from overeating or inefficient breathing, or breathing of foul air ... "The foregoing words are quoted from an article by Dr. Robert Walter, which appeared in *The Science of Health* in August 1873, and well sums up the Hygienic theory of the nature of a cold and of its cause. We regard the cold as a remedial effort made necessary by a toxic state of the body. It is not surprising, in view of this, that there is no drug known that will "cure" a cold.

The U.S. Public Health Service says that nearly every person in the United States "catches" at least one cold a year, but that the average is about three colds a year. It says that in January and February some sixty million people in America have colds. The cold is the most common of all the diseases with which man suffers. It is said to disable people in this country to such an extent that two billion working days a year are lost. They are said to cost industry five billion dollars annually in lost production, wages and medical expenses.

The Public Health Service says that there is no known drug that will "cure" a cold. So determined are miseducated people to take drugs that they spend over a quarter of a billion dollars each year for cold and cough "remedies." The so-called wonder drugs—the antibiotics and sulfas—are said by the American Medical Association to have no effect on the "cold virus." It is stated that "most remedies do little more than subtract from the pocket book." Drugs that are called pain killers are said to relieve some of the aches and pains, but "do nothing for the cold."

The U.S. Public Health Service says that the best thing the cold sufferer can do is to stay at home, take a hot bath, go to bed, eat a balanced diet and wait for the body to do the rest. This is not good advice, as we will make clear in this article.

Here is a relatively mild disease that is more prevalent than any other disease with which man suffers, and one with which he has suffered throughout history. Millions of dollars have been spent in research trying to find the cause of colds and a remedy for them. Uncounted thousands of cures for colds have been discovered, given a thorough test and discarded. Today, *medical science*, about which we hear so much boasting, stands empty handed and helpless before the cold and can offer the cold sufferer nothing more than a balanced diet.

The advice of the Public Health Service contains the admission that recovery from a cold is the work of the body itself, unaided by so-called remedies. Whatever may be the nature of the cold, and whatever may be its cause, the sufferer must depend upon his own resources for his recovery. So-called medical science can offer him nothing more more than questionable palliation of some of the more annoying symptoms. Palliation is always directed at symptoms and in all cases represents the suppression of symptoms. Palliation is never an attempt to remove the causes of suffering.

For a long time efforts have been made to find a serum or a vaccine that will "immunize" the recipient against colds. Numerous such vaccines and serums have been found and have been tried and, although much money has been made from the administration of such serums and vaccines, they have one and all failed to produce immunity to colds. Often, indeed, those who have been inoculated have suffered more with colds than the uninoculated. It may seem strange to my readers that a relatively mild disease should

so long and so persistently defy the efforts of the men of "science," while more formidable and less common diseases yield so readily to their vaccines and serums, to their "wonder" drugs, and to their other efforts. The men of "science" have tried to prove that they can protect us against the crunch of a tiger, but are helpless in protecting us against the bite of a house cat.

Colds are preventable; but before we can learn to prevent them, we have to learn their causes. So long as it is assumed that germs and viruses are the causes of colds, and so long as our efforts at prevention are directed at these microscopic and submicroscopic beings, the cold will not be prevented. So long as we hug the old delusion that a cold is something that we "catch" or that "catches" us, and against which we have to defend ourselves by the employment of some anti-vital and unphysiological substance, whether taken by mouth or by injection, just so long will our efforts at prevention prove futile.

The Hygienic conception of the cause of colds is that these remedial efforts are made necessary by the accumulation in the blood, lymph and tissues of unexcreted metabolic waste and by the absorption from the digestive tract of toxic products of indigestion. The ultimate cause of the cold, therefore, consists of those habits of living and eating that reduce digestive power and check excretion. In a sentence, a cold is due to a way of life that produces enervation, thus checking secretion and excretion and permitting the fouling of the internal environment. To use a new phrase, we may call this fouling of the internal environment a physiological smog.

When the toxemic saturation resulting from inhibited excretion and the absorption of toxic materials from the digestive tract reaches a certain intolerable state, the body initiates a process of supplementary elimination, requisitioning the mucous membrane of the nose and throat to do vicarious duty in freeing itself of the accumulated waste. The cold lasts a few hours to several days, depending on the time required to excrete the toxic debris. Due to the fact that the cold is a remedial process the sufferer recovers health in almost every instance and this enables him to credit his recovery to the aspirin he took, to the whiskey he drank, to the quinine he dosed himself with, to the hot foot bath, or to whatever else he did as a "cure." In point of fact, the Public Health Service correctly describes what occurs when it advises the cold sufferer to wait for the body to do the rest.

Aspirin is perhaps the most widely-used drug today for palliating the discomforts of a cold. *Medical News* for November 4, 1966, carried the following statement: "Salicylates (aspirin), phenylbutazone and oral cortisone drugs can cause local erosions of the gastric mucosa by direct contact with the tablet, Dr. M. S. Israel told *Medical News* after the Erasmus Wilson Demonstration at the Royal College of Surgeons of England." For a number of years now it has been admitted that aspirin causes bleeding from the stomach; this discovery that the contact of aspirin with the mucous membrane lining the stomach causes an erosion of this membrane explains why the bleeding occurs. It just does not make sense for a man suffering with a cold to dose himself with a drug that produces such damaging effects, along with many other damages. Certainly, he should be better off if cared for by helpful means rather than by means that are productive of damage. It is certain that the depressing effect of aspirin prolongs the cold.

The duration of a cold may be shortened by means that increase toxic elimination through the regular channels of excretion. These means will also decrease the headache, fever, soreness of the throat, huskiness of the voice, sneezing, running of the nose, watering of the eyes, etc., that constitute symptoms of a cold. The best means of promoting elimination is to go to bed in a well-ventilated room, keep warm, and take nothing into the stomach except water and this only as thirst demands. Fasting and rest will not only make the cold sufferer more comfortable and reduce the likelihood of complications, but they will definitely shorten the duration of the cold and do all of this without the production of unwanted side effects. The advice of the Public Health Service to eat a balanced diet completely ignores the lack of physiological demand for food and the absence of the physiological conditions necessary to the efficient digestion of food. Drugging and feeding are the chief causes of complications in colds and the chief reasons that colds frequently evolve into more serious diseases.

### Article #3: Influenza

The *San Antonio Express*, December 30, 1959, carried the story that the number of cases of influenza in the city had reached near-epidemic proportions. "The old flu bug, and kindred respiratory and intestinal diseases, have reached near epidemic proportions in San Antonio," are the words of the news item. It adds that a check showed that "patients seeking treatment for virus influenza, pneumonia and similar disorders are crowding hospitals to capacity and swelling the emergency load to record highs."

There is nothing unusual about the great increase in colds, so-called "flu," which is a severe cold, pneumonia and intestinal diseases following upon the heels of the gluttony and the indigestible combinations of the holiday season. What is unusual is the public admission that the standby of the medical profession as a preventive of such suffering is a flop. The news account says that William Foster, administrator of the Bexar County Hospital District, said: "13 of the hospital's 259 employees, including the supervisor of the emergency room and the supervisor of surgery, were downed by the flu despite the fact immunization shots were given against the disease."

The city's largest hospital reported a "high incidence of respiratory and intestinal flu cases from Christmas day on." The hospital physicians stated "flatly," that the situation is "abnormal" and is "approaching an epidemic." From fifty to eighty percent of the patients admitted to this hospital were "flu sufferers." More youngsters than adults were ill. Foster reported that of 182 patients with upper respiratory affections 117 were children.

Physicians offered some free advice through the press about how to prevent the "flu" and how to care for yourself, should their preventive advice come too late. It is the usual hackneyed and ineffective advice, such as avoiding contact with "flu" cases, avoiding overexposure to cold, drink plenty of water and guzzle fruit juice—they did not even bother to advise fresh rather than canned fruit juice. Of course, they agreed that while "immunization shots" are not 100 percent preventive, they "are effective."

There was but one sane statement in all that they said, so far as this appeared in the press. "Intestinal flu, the doctors say, comes from overeating and overcelebrating, with a subsequent loss of rest. It is especially prevalent during the holidays." This is old stuff to Hygienists. For lo! These many years we have been telling people that epidemics follow feasting and revelry.

Reread this statement by the San Antonio physicians and then read again, the following paragraph from the December 1959 issue of the *Hygienic Review* where I say: "It is unfortunate that our seasons of good will and festivities are always seasons of overeating (commonly also of drinking), so that they are followed almost inevitably by colds, coughs, 'flu,' and more severe illness. Beginning with the orgy of Thanksgiving, extending through the revelry of Christmas and ending with the bacchanalia of New Year's, our periods of festivity not only result in hundreds of deaths and much mayhem on the highways, but in more suffering and death from indulgence and excess. More bronchitis follows such indulgences than ever follows exposure. Those who are more moderate in indulgence, those who are least enervated and least toxemic escape the evolution of crises at these times, but often, they escape by the 'skin of their teeth.' "

More children than adults are suffering with "flu" in this near epidemic, not because the adults behave themselves very well, but because they have built less toleration. Candies and cookies and soft drinks make up a great part of the burden they impose upon their digestive tracts and their eliminating organs. With the adults, they go to the dining table and gorge themselves on turkey and dressing, on cranberry sauce and plum pudding or mince meat pie. The amount of putrescence thus generated in the digestive tracts of these youngsters would kill a jungle tiger. It is ridiculous to talk of germs and viruses in the presence of so much poisoning.

No digestive tract known to man is capable of efficiently digesting the food mixtures eaten by children and adults alike in our periods of celebration. It is just possible, as was suggested by Tilden, that the

adults save themselves to some extent by their drinking habits. Alcohol inhibits bacterial activity, hence their wine, beer and whiskey prevents more or less decomposition of the indigestible mixtures they swallow at these times.

Late hours, revelry, noise-making, excitement, visits away from home, lack of sleep—these enervating influences inhibit secretion and check excretion. Add the resulting toxemia to the putrescent poisoning from the overloaded digestive tract and you have enough poisoning to produce any so-called disease to which the individual may be diathetically disposed. A people who celebrate the birth of their Savior by getting drunk, making a lot of noise and eating like hogs must expect to pay for their folly, even though they do their celebrating "in a good cause."

To inundate the intestinal putrescence evolved out of such gross eating and out of so much added enervation with large quantities of water and to swill great quantities of fruit juice, these commonly canned and sweetened, is but to add insult to injury.

The physicians advise: "Stay in bed until the disease has run its course. In cases of upper respiratory flu, the sufferer tends to become tired but apparently recovers after a short rest. Arising too soon, he is subject to a serious relapse which makes it easy to go into pneumonia." Rest in bed is vitally important in these cases, but if this is coupled with the water drinking and fruit juice guzzling that is advised, there will be more likelihood of pneumonia evolving out of the putrescence than if a rational plan of care is adopted. Indeed, one may be practically certain that no pneumonia will evolve if he forgets the advice to "drink plenty of water and fruit juice" and will take no food of any kind and will drink only according to the dictates of thirst.

One does not have to come in contact with other cases of "flu" in order to evolve the symptom complex that is labeled influenza when the intestinal tract is a seething mass of putrescence. Nor will avoiding such contact prevent "flu" when the subdiaphragmatic cesspool is filled to overflowing. Colds, pneumonia, intestinal "diseases" and other symptom-complexes are as inevitable under these conditions of acute and chronic poisoning as the explosion of a boiler when the safety valve is stopped down.

How absurd to talk of preventing the evolution of these and similar symptom-complexes in the face of so much poisoning, by the irrational process of shooting more rubbish into the body! Vaccines and serums are efforts to prevent causes from producing their natural effects. They mean that you can be poisoned and not be poisoned. "Immunization" is like trying to prevent drunkenness in the man who drinks. I am reminded, at this point, of the famous serum I invented thirty years ago that I called blisterine. After three inoculations with this serum, a man could sit upon a red hot stove or pass through a fire furnace and not even get hot. He would not burn for he was *immunized*. I was unable to find a manufacturer for my serum, as it was thought that such a serum would put the firefighters out of business.

When we have learned that we are builders of our own miseries, are architects of our own pathologies and makers of our own "diseases," we will be prepared to live sensibly, even during periods of celebration. I enjoyed my oranges on Christmas day and developed no cold or "flu" being out in the cold with only enough clothes on to keep out of jail. More than forty years of going with so little clothes that all of my friends have predicted that I will die of pneumonia (several of them have) and developing no trouble as a consequence has convinced me that "over-exposure to cold" is a minor factor in the evolution of any symptom-complex, unless it is frostbite. I have seen as many as four generations of the same family who suffered with frostbite and am sure that any good geneticist will agree that this was due to a *mutation*.

- [Article #1: Hay Fever and Asthma By Dr. Robert Gross](#)
- [Article #2: Allergy By Dr. Herbert M. Shelton](#)
- [Article #3: Why Suffer With Hay Fever? By Dr. Herbert M. Shelton](#)

### 1. Introduction

An estimated 40 million Americans have hay fever. Another 9 million suffer from asthma; and between 10 and 20 million have had hives at one time or another. An unknown number have food allergies, reactions to insect stings or occupationally-related allergic disorders. Over 80 million people suffer allergies.

Scientists estimate that one in every three Americans will develop hay fever, asthma, hives or some other allergy at some point in their lives. These scientists say that they believe they will have the "cure" for allergies in perhaps five to ten years. While Hygienists have no "cures," allergy sufferers do not have to wait five to ten years to terminate their suffering. The purpose of this lesson is to enable sufferers to rather quickly overcome their problem. It will explain what to do so that allergy symptoms are never again experienced.

Scientists feel as though allergy is now one of the best understood conditions since they discovered the antibody-antigen theory. One might ask, if they understand this condition so well, why is it that one in every three continue to suffer from this disease under their care? Hygienists do not have allergies. The scientists further say that their treatments for allergies are far better than they have ever been and far more effective. How effective can their treatments be when not one of their patients ever regained their health from such treatment? When they are merely holding forth a hope of a "cure" five to ten years down the road? Scientists claim that they understand allergy is proven a lie by the fact they have no solution. If they understood allergy problems, they'd readily solve them as have Hygienists. Sufferers would be guided to a solution in a few days to a few weeks. This lesson presents a comprehensive solution, and any medic who understands less than this really understands nothing.

The medical community is constantly fighting against germs that "constantly wage war on human flesh." This is a completely false idea since germs or bacteria are a normal and integral part of the body and perform important and useful symbiotic functions. They do not attack us. Instead, bacterial flora work for the welfare of the body. Physicians explain that the "immune" system protects and guards against harmful foreign invaders. Allergies occur, they say, when this "immunological" defense system becomes overzealous and tries to protect us from things that don't actually harm us. Dr. Sheldon Spectner, a Los

Angeles allergy physician says, "When the immune system attacks and destroys a dangerous bacterium or virus, that's great; but when it attacks pollen, dog dander or chocolate ice cream, that's an allergy."

White blood cells do have the property to "engulf" and destroy spent cells, viruses, bacteria and other cellular constituents no longer useful to the organism. Unwholesome foods such as chocolate ice cream will eventually result in toxicosis that will soon create the need for an eliminative crisis which is termed "disease." Mucus, secreted due to toxicosis, will sensitize membranes linings, rendering them more sensitive to elements such as pollen, but the body does not turn against itself. The body always strives toward the welfare of the organism.

A recent newspaper article stated that as many as 4000 people die of asthma each year. This article further stated that nearly 200,000 hospitalized patients suffer allergic drug reactions annually and an additional 50,000 are put into the hospital because of drug reactions. As you can see, the "cure" is much worse than the "disease." Below is a quote from the same newspaper article: "Because allergens are basically harmless, why does the body react to them in such a way as to hurt itself?"

"Scientists now think that the IgE antibody defense mechanism originally evolved to protect us from such parasites as hookworm. But, because parasites no longer are a problem for Americans and the peoples of other industrialized nations, the powerful IgE antibodies have turned their attention to pollen and other allergens, mistaking them for parasite-like enemies."

The above statement demonstrates ignorance of physiology and the body's innate wisdom. It is based on superstitious notions from primitive times when it was believed that evil spirits were the cause of illnesses. Our faculties do not turn against us. If they did, every human and animal would demonstrate these symptoms as we all possess the same mechanisms within our bodies.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 2. Allergies

## 2. Allergies

Most people welcome spring and summer and look forward to these months as the best time of the year. To most people, the first signs of spring brings joy and anticipation of outdoor activities, beautiful spring flowers, the opportunity to garden and enjoy the fresh produce from their backyard. Some, however, dread this time of the year because they merely look forward to feeling miserable and sick until the leaves fall and winter has once again arrived. These people are said to be "allergic." They are sensitive to pollens, weeds, grasses, trees, dust, insects and assorted other things in our normal environment.

Typical symptoms include sneezing, wheezing, watery eyes, itchy eyelids and the like. Other symptoms may include redness and inflammation of the skin with itching and draining of fluid.

### 2.1 Disease Is Abnormal

All disease, whether it is a cold, flu, asthma or allergies, is abnormal. The body always strives to maintain a state of health which is normal. If the need arises, the body is capable of taking measures to maintain this state through the extraordinary elimination. To effect this, the body institutes a healing crisis which we call illness or disease.

When toxic waste products and toxic *ingesta* accumulate in the tissues beyond the body's toleration point, an effort will be made to expel them through various channels. These channels are the skin, lungs, mucous membranes, bowels; kidneys; etc. Individuals who are said to be "allergic" are experiencing a perpetual "healing crisis" by way of the mucous membranes of the nose, throat, bronchi or through the skin. The toxins being voided via this route sensitize these organs so that pollens, dust, hairs, etc.,

initiate a defensive reaction such as sneezing, runny nose, etc. The pollen is thus not a primary cause but an exacerbating factor.

## **2.2 Only Some People Are Sensitive**

Does it make sense that people should be "allergic" to things in their normal environment? If pollen, trees, flowers, ragweed, grasses, etc., are poisonous, should not everyone be affected? These items are part of our environment, and we live symbiotically with all plant life and its effluvia. Plants are not something for us to avoid and dread but to enjoy and appreciate for their beauty and usefulness. We also live in harmony with animal life.

During the summer months, the "allergic" individual often seals himself indoors and attempts to remove himself from the substances to which he is sensitive. However, instead of searching out the items to which a person may be sensitive, attempts should be made to discover the reason for this abnormal sensitivity.

## **2.3 Antibody-Antigen Theory**

The development of the antibody-antigen theory was presumed primarily on the idea that bacteria and "viruses" cause disease and that we must somehow create "immunity" from the "invasion" of these agents. The antibody-antigen theory also gave the scientists a basis for the practice of vaccination.

According to the generally accepted medical theory, the "immune" response resists invasion by infectious microorganisms. Two "immune" systems are distinguished; in each a different population of lymphocytes is activated and a different agent combats the invasion. In one, the B-cell system, the response is mediated by proteins, called antibodies. In the other, the T-cell system, the response is mediated by specialized cells sensitized to foreign substances. The B-cell system is said to be most effective against acute bacterial "infections," such as those caused by streptococci, pneumococci, and some "influenza" bacilli and meningococci, and against "viral reinfections." The T-cell system is most active in combating "viruses," fungi and bacteria causing chronic "infections." This theory is misleading.

Disease is the consequence of an accumulation of toxic materials in the tissues due to unhealthful living. We cannot make ourselves immune to such consequences while we still persist in unhealthful living habits. The body initiates the disease (healing) process to eliminate toxins in order to preserve health. There is no "immunity" against this healing process. Also, bacteria and viruses do not cause disease. As explained, disease is a vital process of healing and bacteria have a role to perform in this process. They act as scavengers cleaning up toxic debris and as soon as their role is completed, their numbers will decline. For this reason, they are associated with disease processes, but are not its cause. They no more cause disease than flies cause garbage. "Viruses" are cellular debris—they are the genetic material from dead cells. As dead material, viruses are toxic and pathogenic but not malevolent.

The entire theory of antibody-antigen is based on false ideas concerning the nature of disease. It is said that both B- and T-cells are lymphocytes and are produced in the red bone marrow and thymus gland. These cells are said to be found in the lymph, the bloodstream, and lymphoid tissue, which constitute the bulk of lymphoid organs. Lymphocytes are white blood cells which are present in the blood of all healthy individuals. Like all white blood cells, they perform important defensive functions, however, creating "immunity" to body-initiated disease is not one of their functions.

The triggering agents of the so-called immune response are called antigens. Antigens are said to provoke rapid cell division, with the formation of distinct clones (colonies of cells arising from a single parent cell) in lymphoid tissue. The cells thus produced by successive cell division are said to become more and more specialized. The end result of B-cell proliferation is the formation of cells, called plasma cells, that manufacture identical antibodies constructed to combine selectively with the triggering antigen.

It is thought that if a person was inoculated with a specific antigen, production of antibodies would

occur to build up "immunity" against that particular antigen. This is the theory behind vaccinations. However, there is a wealth of documented evidence that many more deaths resulted from the vaccines themselves than from the diseases they were supposed to prevent. Vaccines are composed of poisonous materials and are always harmful when injected into the bloodstream. Also, with the knowledge of the true nature of disease and the need for this healing process, it makes the vaccination theory even more invalid.

Since antibodies are proteins classified as globulins and are said to have immunological properties, they are called immunoglobulins. There are supposed to be five classes of immunoglobulins but the so-called IgE is the most common. IgE antibodies are called reagins; antigens that react with IgE are called allergens. When allergens enter the body and react with reagins which are affixed to mast cells, the mast cells rupture and release massive amounts of histamine and other substances. This reaction is said to be the cause of the symptoms of allergic reactions such as the swelling in the nasal passages with hay fever and in the skin with hives.

Histamine is a substance secreted as a normal part of the inflammatory reaction which is part of a healing process. This substance is kept in proper balance by the body's homeostatic controls. When too much histamine is present (in the body, a substance called histaminase will be released to reduce the amount of histamine in the blood or tissues.

The entire concept of the antibody-antigen reaction was created on erroneous concepts of the germ theory, immunity and vaccinations. It is not valid as you'll see.

## **2.4 Underlying Cause of Allergies**

It is more important to know what makes one sensitive than to know what he is sensitive to. Most allergy sufferers have chronic catarrh and have had it for many years, even before manifesting signs of sensitivity. Even after the "allergy season" has past they still suffer from catarrh and experience frequent colds during the winter.

What caused the chronic need for the body to eliminate its toxins in this manner? The causes may be many but basically it is unhealthful living that creates the problem. Overeating or eating in unsuitable combinations, lack of exercise, impure drinking water, living in unventilated houses or working and living in smoke-filled rooms, lack of sleep and rest or stress and emotional upsets may be the underlying factors in the development of catarrh in the mucous membranes, resulting in sensitivity to certain irritants. The lining of the membranes become inflamed and very sensitive to irritation. Inflammation that renders the membrane abnormally sensitive to the normal elements of man's environment.

Inflammation is a symptom of healing and if causes are removed, healing will be swiftly completed. If a person continues to live healthfully thereafter, there will be no further need for the disease (healing) process.

## **2.5 What Not To Do**

Many allergy sufferers are given anti-inflammatory drugs to suppress the uncomfortable symptoms that they are experiencing. Cortisone is one drug often prescribed and most often given, through injection, by the physician. At best, cortisone only reduces the symptoms for a brief length of time after which symptoms reappear and another injection is given. Much harm is done through this poisonous practice.

When hormones are injected into the body from without, the body's delicate balance of action and reaction to maintain homeostasis is disrupted. Anti-inflammatory corticoids include cortisol and cortisone which are secreted by the adrenal glands that are located on top of each kidney. Normally these hormones are secreted when a messenger lets them know that they are needed. This messenger is called ACTH (adrenocorticotrophic hormone) which is secreted by the pituitary gland. The adrenals can also produce pro-inflammatory corticoids; but this is regulated by a variety of complex factors, among which

ACTH plays only a minor role compared to renal blood pressure regulators and electrolytes.

By changing the proportion between pro- and anti-inflammatory stimuli, the body can regulate inflammation in response to local injury.

All other outside agents such as antihistamines, decongestants, etc., are harmful and suppress (depress) the healing ability of the body. Inasmuch as they do not remove the causes of allergy, there can be no correction.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 3. Bronchial Asthma

### **3. Bronchial Asthma**

Bronchial asthma is defined as "a disease marked by difficulty in breathing, coughing, and a sense of constriction, due to bronchial spasm and a swelling of the bronchial mucous membrane." Asthma can occur secondarily to a variety of stimuli. Mechanisms responsible for attacks of wheezing may be an imbalance of adrenal hormones or poor nerve control of airway diameter. These imbalances do not occur in a healthy individual but usually occur after drug therapy or other unhealthful practices.

Persons whose asthma is preceded by exposure to airborne pollens and molds, house dust or animal danders are said to have allergic asthma.

#### **3.1 Symptoms**

Individuals with asthma differ greatly in the frequency and degree of their symptoms. Some have only an occasional episode, mild in degree and of brief duration. Others have mild coughing and wheezing much of the time punctuated by severe increase of symptoms following exposure to known allergens, exercise or other irritants.

An asthma attack may begin suddenly with episodes of wheezing, coughing, and shortness of breath, or slowly with increasing symptoms and signs of respiratory distress. In either case, the patient usually first notices the onset of lack of breath, rapid breathing, coughing, and tightness or pressure in the chest, and may even notice audible wheezes. All of this may subside quickly or persist for hours to days.

#### **3.2 Treatment**

The usual medical approach for the treatment of bronchial asthma is to attempt to identify and control the environmental irritants. This is followed by drug therapy. Frequently used drugs include epinephrine, isoproterenol, ephedrine and corticosteroids, among others.

These drugs should never be used; they result in enervation and poisoning of all the organs, especially the central nervous system, and result in some measure of damage and disorder to every organ of the body. Among all the deadly drugs, some of the worst include the above named hormone-derived drugs. The notion of "cures" is an illusion. The only healing that can be experienced comes from within. Only the body possesses this capability. To realize healing the body merely has to be given a chance to perform its normal functions without interference.

Little good will be achieved by searching for the various irritating environmental agents if the source of the sensitivity is not eliminated. If we continue to build a state of toxicosis, the need for disease will always remain with us.

### 3.3 Cause of Asthma

According to medical writers, the cause of asthma is "hypersensitivity," and they divide this sensitivity into two classes: (1) Those sensitive to ingested substances such as oysters, meat, eggs, etc., and (2) Those sensitive to air-carried irritants—pollens, emanations from horses, cats, dogs, feathers, dust, etc.

According to Dr. Shelton, this protein hypersensitivity or allergy is merely another name for protein poisoning, that is, overconsumption of protein foods in those of a neurotic diathesis.

The immediate cause of the bronchial spasm, according to Dr. Shelton, is an irritation of the nerve endings of the vagus nerve which supplies the bronchi. Drugs, some foods, gas and indigestion, occasion reflex irritation of the nerve endings in the bronchi and bring on a paroxysm of asthma.

Breathing cold air, dust, pollens, gasses, foul odors, and other such things, produces a direct irritation of nerve endings in the lungs and brings on the symptoms.

If water, irritating foods, drugs, pollens and other things which are in our normal environment were the primary or direct causes of asthma, everyone would be afflicted with this condition. The underlying cause of asthma is that which sensitizes the nerves and the bronchial membranes.

The underlying cause of bronchial asthma is a state of toxicosis. If asthmatics were not enervated and their tissues were not saturated with toxins, there would be no hypersensitivity. All asthmatics have a chronic catarrhal condition. Those individuals with a neurotic diathesis will have asthma, while other individuals may develop colds or flu or other eliminative symptoms.

Asthma is brought on by overeating wrong foods or wrong combinations of foods or by other enervating indulgences which are wrong. The body's eliminative abilities are taxed beyond its capacities, and toxins build up in the blood and tissues.

In asthmatics, the finer bronchial tubes and the air cells of the lungs contract, and air entry into the lungs is severely reduced. The entire volume of blood cannot be sufficiently oxygenated and purified. Palliative treatment in the form of drugs only adds to the enervation and toxicosis while the underlying cause is not corrected.

When the underlying toxic condition is eliminated, all forms of sensitization disappear. When the asthmatic gets rid of toxemia, he automatically rids himself of all sensitivity to dogs, cats, horses, pollen, dust, etc.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 4. Eczema

### 4. Eczema

Eczema is a chronic form of dermatitis (inflammation of the skin). The skin becomes red, and fluid-filled pimples, called vesicles, may form, or crusts and scales may develop on the skin surface. Usually the area itches. Scratching the skin destroys the pimples or removes the crusts and scales. For this reason, the appearance of the area changes.

Doctors believe eczema is usually a form of allergy that results from extreme sensitivity to some substance. The substance may be in something the person eats, or it may be found in his surroundings.

Some of the more common substances which are said to cause eczema are plants and trees, citrus fruits and onions, chemicals, medications, cosmetics, household detergents and polishes; and a number of fabrics including wool, silk, synthetic fibers, leather, fur, and dyed goods.

Contact dermatitis may be caused by a primary chemical irritant or may be what the physicians describe

as "delayed hypersensitivity reaction."

Direct irritants may damage normal skin or irritate an existing dermatitis. Weak or marginal irritants, such as soap, may take several days of exposure to cause visually recognizable changes. Many soaps, deodorants, detergents, etc., contain harsh chemicals which are poisonous and may be absorbed through the skin. The body recognizes these poisons and tries to stop them from entering the system by initiating an inflammation response to local and "encapsulate" these poisons. Strong irritants, such as acids and alkalis, cause observable changes within a few minutes. These actually cause direct damage to the skin and the inflammatory response is immediate.

Medications, cosmetics, household cleaners, etc., all contain poisonous substances which are rejected and eliminated by the body. In certain individuals, this elimination occurs through the skin in the form of eczema. The wisest thing to do is simply not to use these toxic chemicals. Cosmetics are not needed as the skin of the healthy individual has a beautiful color which cannot be enhanced by cosmetics. Care should be taken in choosing household cleaners. Use only those which do not have harmful ingredients. Shakley's Basic H is quite good.

Allergic contact dermatitis is also said to be due to delayed hypersensitivity and requires a latent period ranging from five to six days to years between the time of first exposure and re-exposure that preceded that dermatitis.

Topical medications most often used include antibiotics, antihistamines, anesthetics, antiseptics and stabilizers. These are poisons and result in toxicosis. The reason that the symptoms of eczema do not appear immediately is that these toxins are often stored in the tissues and accumulate there until a saturation point is reached. At this point, the body initiates a "housecleaning" and begins to eliminate these toxins, and the skin is one route taken. At this time, eczema appears. It has really nothing to do with being "allergic." These toxins are eliminated through the skin in some individuals; in others the route would be elsewhere and termed a different disease.

Avoid toxin-building practices, and the need for eczema will not exist. It has been contended that eczema is also due to allergic reactions to normal elements in our environment, and is associated with the presence of IgE antibodies and peripheral eosinophilia. First of all, the underlying cause of eczema is the same—toxicosis. Secondly, the presence of numerous white blood cells including lymphocytes and eosinophils indicates that an inflammatory response is in progress and healing is taking place. All we must do is to allow the healing to take place and not add any further toxins to impair the body.

Hypersensitivity to wholesome foods, such as citrus fruits, is always due to a state of toxicosis and steps should be made to remove the need for eczema through a more healthful lifestyle.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 5. Hives

## 5. Hives

Acute hives is generally recognized among the medical community as an antibody-antigen reaction limited to the skin and subcutaneous tissue. It is often due to drug allergy, insect stings or bites, desensitization injections, or ingestion of certain foods, especially eggs and shellfish, some food reactions occur explosively following ingestion of only minute amounts. Others may occur only after over-indulgences.

It is thought by many physicians that hives may accompany, or even be the first symptom of, several "viral infections," including hepatitis, "infectious" mononucleosis and rubella. However, such diseases only follow hives after, they have been suppressed by drugs and the body finds other outlets for its toxin

load. The secondary diseases are worse, as more toxins have accumulated and vital energy has been lowered through treatments. Chronic hives is due to the use of drugs, preservatives, dyes or other food additives which have overtaxed the body and resulted in chronic toxicosis.

## **5.1 Symptoms**

In hives, severe itching is followed shortly by the appearance of wheals that may remain small or may enlarge. The larger ones tend to clear in the center and may be noticed first as large rings of redness and edema. Ordinarily, crops of hives come and go. A lesion may remain in one site for several hours, then may disappear, only to reappear elsewhere.

Hives may occur following drug treatment or after ingesting unwholesome foods such as eggs or shellfish. These agents possess toxic substances which the body must eliminate in order to preserve life. In some individuals, this elimination occurs through the skin in the manner called hives. This again, is a healing crisis—one which we should cooperate with and never meddle with. In a more chronic form, this skin "disease" is due to toxicosis which has built up over a period of time due to unhealthful living habits.

Often the symptoms may occur after an emotional upset, but this is not the primary cause. An emotional disturbance will not elicit hives in a healthy individual. Toxicosis must be present in order for this skin reaction to occur.

This inflammatory reaction is associated with a number of white blood cells which are a part of all inflammatory processes. They are a part of healing and not "turning against the body" as is said. This is a false idea—the body does not turn against itself but always strives toward what is best for the body as a whole.

## **5.2 Chemicals and Processed Foods**

Many people demonstrate symptoms of hives after ingesting foods containing chemical additives. This is especially true of people who have hives nearly all the time. In a study at the University of Uppsala, Sweden, persons who had frequent cases of hives were tested with various substances. Half of them had adverse reactions to food dyes and preservatives in amounts that could easily be present in the conventional daily diet. Most of those who were hypersensitive to dyes and preservatives also reacted to aspirin.

The chemicals which are added to processed foods are poisons. Those people who showed symptoms of hives were eliminating these poisons through the skin. Others will eliminate these poisons through other means and a healing crisis will be in the form of a cold or flu or something else. Processed foods, whether they have chemical additives or not, will result in toxicosis when ingested.

They are unbalanced and most, if not all, of their valuable nutrients have been destroyed. You should certainly not partake of processed foods.

The symptoms of hives should not be suppressed through ointments or by any other means. We should, instead, remove the need for this disease by avoiding all processed foods and drugs and by obeying the laws of health.

## 6. Gastrointestinal Allergy (Food Allergy)

Food allergy is defined in the medical textbooks as "an uncommon symptom complex due to ingestion of specific food or drug allergens, manifested by nausea, vomiting, crampy abdominal pain, and diarrhea." According to *The Merck Manual*, gastrointestinal symptoms from food are often secondary to digestive enzyme defects as in celiac disease and disaccharidase deficiency.

Celiac disease is intestinal malabsorption characterized by diarrhea, malnutrition, a bleeding tendency and low calcium in the blood. The presence of this disease is just another symptom of toxicosis and an enervated state of the body. When the need for this "disease" is eliminated by the body, this condition will be corrected along with allergy symptoms.

Disaccharides are complex carbohydrates which must be broken down into two monosaccharides in order to be absorbed. This is accomplished by certain enzymes which are always present in healthy individuals. If a person is enervated and toxic, bodily functions are impaired and malabsorption may occur. If we remove the causes, the body will heal.

### 6.1 Symptoms

The severe but rare acute reactions to food are characterized by nausea, vomiting, diarrhea and violent abdominal pains. Less severe reactions—chronic crampy pain, diarrhea and, Often, skin rash—are more common.

These are typical signs of not only food poisoning but any kind of poisoning where the body rejects this substance to protect its integrity.

### 6.2 Normal Digestion Entails Neither Indigestion Nor Allergy

Such affections as hay fever, asthma, eczema, certain cases of sinusitis, headache and other troubles are often attributed to food allergy. These symptoms indicate acute eliminative response involving a great tax upon the body and requiring the cooperative efforts of several organs. The chief concern is not with the character of the reaction but with the causes of the need for the reaction.

Dr. Shelton points out that if undigested proteins are injected into the body, they produce disease, while the same protein taken into the bloodstream after thorough digestion produces no trouble. He concludes that food allergy is due to failure of the digestive system to properly prepare the food for introduction into the blood. This failure may be due to the following reasons:

1. Weakness of the digestive function. Putrefactive bacteria in the intestinal tract decompose proteins and form toxic substances which may be absorbed. Toxicosis is present in all cases of allergy.
2. Unfitness of certain types of protein food for assimilative purposes. Many of the proteins of our conventional diet require a large amount of breaking down by the digestive juices, a task often beyond their powers. It taxes the strongest powers of digestion to deal, with the highly-complex animal albumens—the more complex these are, the more tax they place upon the organism. Allergy has never been observed as the result of a fruitarian diet.
3. Food taken in excess of the normal capacity of the digestive enzymes. All allergies result from a long-standing poisoning of the body by protein excess.
4. Foods taken under physical or psychological stress will not be digested properly. Wrong combinations of food, work, fatigue, fever, pain, fear, worry, anxiety and other emotional factors inhibit the digestive functions.
5. Proteins, if cooked, coagulate and do not digest. Their subsequent putrefaction results in many

toxic byproducts.

Hygienists know that protein allergy is the outgrowth of toxicosis. An impairment of the nervous system due to toxicosis results in impaired digestion, checked elimination and a derangement of all of the nutritive and defensive faculties of the body.

Many of the organs of the body produce a substance called histaminase, which serves to neutralize histamine, thus defending the body against its influence. Any derangement of the nervous system and any general toxic state will result in the inability of the various organs and tissues to produce the neutralizing substances necessary to counteract the poisons entering the body from the digestive tract. Allergy is impossible in the healthy individual.

### **6.3 How Not to Create Food Allergies**

In order not to have food allergies, you should take these simple measures:

1. Restore and maintain the efficiency of the digestive system. This can best be done by giving the digestive tract a thorough rest through a fast. After that, healthful living will maintain efficiency.
2. Eat only such protein foods to which we are biologically adapted. This would consist of the proteins found in fruits, vegetables, nuts and seeds.
3. Do not consume proteins in excess of digestive capacity. When nuts or seeds are eaten, they should be limited to a maximum of 4 ounces per day. We can do very well on less than this, however.
4. Eat all foods in proper combinations and under such physical and emotional conditions that will not inhibit digestion.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 7. Allergy And Hyperactivity In Children

## **7. Allergy And Hyperactivity In Children**

### **7.1 History**

As early as 1908, reports were published in medical literature stating that some children were noted to be fretful, irritable, restless and unable to sleep if they ate certain foods. It was wondered if some children had an allergy that affected their brain or nervous system rather than the lungs as in asthma or the nose as in hay fever. Early investigators often described some children as being extremely tired or fatigued rather than overactive. Sometimes the same child was too tired at certain times and too hyperactive at other times. Others noted that foods seemed to change some children's behavior so that they acted depressed, hostile or irritable. As the years passed, it was observed that pollens, dust, molds and certain odors such as perfumes could cause similar reactions in some patients.

In 1930, Albert Rowe described a condition which he called "food toxemia." In a book entitled *Food Allergy*, he and his son recounted numerous patients who had drowsiness, irritability, fatigue, weakness, slowness and inability to behave. He devised very strict diets that appeared to help many patients who had typical forms of allergy, as well as nervous-system problems. Dr. Rowe firmly believed that foods, as well as pollens and dust, could contribute to psychological and nervous-system problems in some patients.

During the 1940s and 1950s more and more reports described similar patients. Dr. Theron Randolph

described "allergic fatigue." He stressed that, at times, affected children and adults acted normal, but after eating certain foods or being exposed to offending odors or chemical substances, their behavior became distinctly abnormal. Some became very tired, others hyperactive. He noted affected individuals often had a rather pale face but were not anemic, and had swelling and black circles under their eyes.

In 1975, Dr. Ben F. Feingold of San Francisco wrote a book entitled *Why Your Child Is Hyperactive*, which was publicized quickly throughout the nation. In this book, he states that he believes hyperactivity is mainly due to artificial food coloring, artificial flavors, and salicylates.

Hygienists know that foods do not have the property to act upon the body. However, unwholesome foods such as those which are highly processed and contaminated with chemicals can intoxicate the body. In certain individuals who are prone to nervous conditions, the accumulation of these toxins could result in hyperactivity and other abnormal behavior. In these individuals, the brain and nervous systems demonstrate the effects of unhealthful living.

## 7.2 Symptoms

In her book, *Allergies and the Hyperactive Child*, Dr. Doris J. Rapp describes the symptoms of children who are considered to be allergic and have a central nervous system diathesis.

### Nervous System Symptoms

1. Hyperactive, wild, unrestrained
2. Talkative (explosive, stuttering, constant)
3. Inattentive, disruptive, impulsive
4. Short attention span
5. Restless legs, finger tapping
6. Clumsiness, incoordination, tremor
7. Insomnia, nightmares, inability to fall asleep
8. Nervous, irritable, upset, short-tempered
9. High-strung, excitable, agitated
10. Moody, tired, weak, weary, exhausted, listless, depressed
11. Easily moved to tears, easily hurt
12. Highly sensitive to odor, light, sound, pain, and cold

### Other Physiological Symptoms

1. Nose: year-round stuffiness, watery nose, sneezing, nose rubbing
2. Aches: head, back, neck, muscles, or joints, or aches unrelated to exercise
3. Stomach problems: stomach aches, nausea, upset stomach, bloating, bad breath, gassy stomach, belching, vomiting, diarrhea, constipation
4. Bladder problems: wetting pants in daytime or in bed, need to rush to urinate, burning or pain with urination
5. Face: pale, dark eye circles, puffiness below eyes
6. Glands: swelling of lymph nodes of neck
7. Ear problems: repeated formation of fluid behind eardrums, ringing ears, dizziness
8. Excessive perspiration
9. Low-grade fever

The above symptoms are all indications of toxicosis. Clearly, the body is attempting to eliminate toxins through the many and varied channels that it has for this purpose. Toxins are thus eliminated through the mucous membranes of the nose, through the urine via the kidneys, through the glands, etc. Indigestion from eating wrong foods results in pain, nausea, and other symptoms listed.

### 7.3 Determining the Cause

Great effort is made to determine what foods these children are allergic to. Finding these individual foods does not remedy the problem if the underlying cause still persists.

Dr. Rapp suggests going through a certain procedure to determine which foods are causing the adverse reactions. Once this is determined, this food is diluted into homeopathic doses, and given back to the child with an eye-dropper under his tongue. One drop is usually given. The child is then allowed to eat the food he was allergic to without restriction. This procedure cannot restore health.

All children who demonstrate food "allergies" have a history of consuming large amounts of junk foods: highly-processed food such as potato chips, salty french fries, candy, cakes, soda pop, etc. These foods quickly contribute to a toxic condition and the body must eliminate them in order to maintain balance.

The foods to which Dr. Rapp found most children "allergic" include milk, wheat, sugar, eggs, chocolate and food dyes. All of these foods contain toxic properties and will result in toxicosis in everyone who consumes them. Some children with neurotic diathesis become hyperactive, others may develop colds, others may develop asthma or tonsilitis or something else.

Mother's breast milk is the perfect food for babies, but after weaning they don't need it, *especially* not cow's milk. We lose the ability to properly digest milk because of the lack of the enzyme lactase to convert the lactose in milk to glucose and galactose. Improperly-digested milk ferments in the stomach and contributes to toxicosis.

Wheat is a highly acid-forming product. It is almost always ground into flour, made into bread and pastries and combined with other unwholesome and incompatible substances.

We all know sugar is bad for us. It is a highly-refined product totally without nutrients and therefore *depletes* needed minerals from our bones and tissues. It is one of the main causes of many degenerative diseases such as osteoporosis, arthritis, heart disease, diabetes, hypoglycemia and others.

Eggs are hard to digest, have a high-cholesterol level, and contain many toxic elements including avidin which binds biotin, (a B-vitamin) and makes it unavailable for use within the body.

Chocolate and cocoa interfere with calcium assimilation in the body and contain theobromine which has the same bad effects as caffeine. Food dyes are poisons and should never be consumed. All of the aforementioned foods are harmful to everyone and should never be eaten. It is therefore useless to try to determine which is the worst offender. They are all bad.

### 7.4 Finding the Cause Behind the Cause

While living near Buffalo, New York, I attended a lecture given by Dr. Doris Rapp on "Hyperactivity in Children." During the lecture, she showed movies of children who were under her care and who demonstrated severe reactions to certain foods. One child was shown calmly playing with some toys in her office. He was then given a slice of "Wonder Bread" and was instructed to eat the entire slice. Before the child had it half eaten, he started throwing "temper tantrums"—crying, whining, etc. He would throw things across the room and, at one point, he tried to hit his mother and was apparently almost entirely out of control.

What would cause such a sudden change in behavior. The food had not even had time to begin digestion and enter into the bloodstream. Why would the child exhibit such behavior, when another child would not, after eating the same food?

This child's body was in such a toxic condition and his nervous system and brain had become so sensitized, that an immediate severe reaction took place as soon as the exciting agent entered the body. What caused this toxic condition? This is where we get to the underlying reason for this child's "allergy." The primary cause is unhealthful living—wrong food is usually a major consideration. No child who eats only fresh fruits, vegetables, nuts and seeds in their raw and unadulterated form will demonstrate

such abnormal behavior. In addition to this, it is important that all of the other conditions for health are met. These are proper rest and sleep, exercise, sunshine, fresh air and pure water. When these conditions are met, the body will heal and maintain a healthy state.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 8. Hay Fever

## 8. Hay Fever

Hay fever is a chronic catarrhal inflammation of the mucous membrane (Schneiderian membrane) of the nose often involving the lining membrane of the eyes, throat, pharynx, larynx and bronchial tubes. The catarrh is continuous but is particularly subject to increase in severity of symptoms in the months of May, June, July and August.

According to *The Merck Manual*, hay fever is generally induced by wind-borne pollens. The spring type is said to be due to tree pollens (e.g., oak, elm, maple, alder, birch, cotton wood); the summer type is due to grass pollens (e.g., sheep sorrel, English plantain); the fall type is due to weed pollens (e.g., ragweed). Occasionally, hay fever is said to be due to airborne fungus spores. Geographic differences are said to have an effect.

These agents are only exciting causes which, when they come in contact with overly-sensitive mucous membranes of the nose, occasion irritation with profuse drainage, runny nose, etc. Changing location and climate will not eliminate the sensitivity even though the exciting cause has been avoided. Health has not been restored since the underlying cause of the sensitivity has not been dealt with.

### 8.1 Symptoms

The nose, roof of the mouth, pharynx and eyes begin to itch gradually or abruptly after the onset of pollen season. Secretion of tears, sneezing and clear, watery nasal discharge accompany or soon follow the severe itching. Frontal headaches, irritability, loss of appetite, depression and insomnia may appear. The mucous membrane which lines the eyelid is involved, and the nasal mucous membranes are swollen and bluish red. Coughing and asthmatic wheezing may develop as the season progresses. Many eosinophils are present in the nasal mucus during the season.

### 8.2 Eosinophil Cells

Eosinophil cells are somewhat larger white blood cells, and have received their name because they stain very easily with a dye called eosin. This coloring agent is frequently used for histologic studies to make cells more visible under the microscope. The function of the eosinophils is also still debated, but they seem to be related to inflammatory reactions, as seen in allergy, because their number increases remarkably when a person suffers from asthma, hay fever or similar conditions.

Scientists have found that the presence of pro-inflammatory corticoid hormones in the blood is accompanied by increase in eosinophil cells, and the presence of anti-inflammatory corticoides are associated with relative absence of eosinophils. These cells play an important part in this inflammatory process, which is a healing process. Increase of these cells during "disease" is a positive sign that healing is taking place.

### 8.3 Treatment

The usual treatment which is given by most physicians involves the employment of various drugs. The

most widely-used ones include antihistamines, decongestants, epinephrine and corticosteroid treatments.

All of these drugs are poisonous. They contribute to enervation and add toxins to the body. They also interfere with many physiologic homeostatic mechanisms which result in impaired health of all bodily organs. They never have any beneficial effects and cannot play any role in healing.

The ideal treatment is no treatment at all. If the body is given the proper conditions, healing will be carried on uninterrupted and health will be restored. When the underlying cause of hay fever is removed, these symptoms will not reoccur.

## 8.4 Causes

Although it is true that dust, pollen, emanations from horses, cats, dogs, birds, etc., and even cold air, will occasion more suffering, this does not prove them to be causes of hay fever. Anything that irritates a sensitive mucous membrane occasions a rush of blood to the point of irritation and the pouring out of an exudation to flush way the irritant.

The mistake is made to consider normal elements in our environment such as pollen or dust as *causes* of hay fever. If this were true, we would all exhibit these symptoms. The basic cause is that which gave rise to the sensitization of the membranes that are not normally sensitive to these triggering factors.

Two people may have catarrh and one develops hay fever and one does not. Both of the individuals are highly toxic, but the one who develops hay fever is subject to nervous problems.

Hay fever rests on a basis of enervation and toxemia. Enervating habits render the individual highly toxic due to inhibition of full and normal elimination within the body of normal body wastes. When the toxic accumulation reaches the saturation point, certain areas of mucous membranes are called upon to do various duties in excreting these toxins. When this condition becomes chronic, symptoms of hay fever become evident.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > 9. What To Do If You Have Symptoms Of Allergies

## 9. What To Do If You Have Symptoms Of Allergies

We know that the underlying cause of allergies is toxicosis. If the body did not need to eliminate this toxic material, there would be no allergic symptoms. It is the body's way of preserving health and healing.

The most efficient and quickest way to eliminate these toxins is through the fast. This means a total fast where no food is taken and only water is drunk according to thirst. The length of the fast depends upon the individual and his or her state of ill health. It is wise to consult with a Hygienic professional if it is your first fast. He will advise you how long to fast, how to conduct the fast, how to break the fast, etc.

After you have fasted and eliminated much toxic matter, you must then live in such a way so as to not create the need for "disease" again. This can simply be achieved by following all of the conditions for health outlined in the previous lessons.

## 10. Questions & Answers

**I suffer from eczema, and my hands and arms are very itchy and red with fluid oozing from certain places. Is there anything I can do for this discomfort while I am changing to a more healthful lifestyle?**

The fluid coming from the skin eruption is of an acid nature which results in itching and burning on the skin. You could wash those areas with distilled water to remove some of the fluid. Until these toxins are eliminated, this condition will persist; but do not suppress these symptoms. The body will heal, and soon the skin will again be smooth. A few days fast should speed up this healing crisis.

**I began a more healthful program and changed my diet to all raw fruits, vegetables, nuts, and seeds. In a few days, my allergy symptoms got worse. What am I doing wrong?**

You are not doing anything wrong. This may sound strange but it is a good sign for the symptoms to intensify. This indicates increased vitality and a more aggressive effort to *eliminate* accumulated toxins. This is a healing process. Do not worry, but be patient. Your symptoms will soon subside if you persist with your healthier regime, and you will feel much better than before the symptoms began.

**I have a child who is hyperactive and it was determined that he is allergic to all citrus fruits. Why would he be allergic to such natural foods as oranges or grapefruit?**

He has a very toxic condition, but his body will normalize when given a chance. Meanwhile, there are plenty of other fruits and vegetables he can eat. Keep him on an all-raw diet of fruits, vegetables, nuts and seeds; but for the time being, eliminate the citrus fruits. After a few months, you can gradually add some fruits to his diet as long as they are fully ripe. I believe that he will react favorably.

**I have asthma, and every time I try to do any vigorous exercises I have an "attack" and have to stop. Since exercise is a part of the healthful living regime, how can I attain health without this important aspect of the program?**

You must take first things first. My advice would be to go on a fast in order to eliminate some of the toxic buildup in your body. After the fast, adhere strictly to an all-raw Hygienic diet, and then gradually build up to a vigorous exercise program. This must be done slowly, so you must be patient. Do not exercise to the point of exhaustion as this will do more harm than good. You should feel invigorated and energetic after exercising. Just take it easy, and the rewards will come in increased vigor and health.

### Article #1: Hay Fever and Asthma by Dr. Robert Gross

The term "allergy" denotes that the allergic person reacts to contact—either through the mouth, nose or skin—with certain substances in a way that is different from the response of normal people. It is said

that his body tissues have greater sensitivity than those of nonallergics. When he is exposed to offending allergens, his "changed reaction" reveals itself in characteristic symptoms—red eyes, running nose, rashes, headaches, of abdominal distress. To most people, a plate of strawberries or tomatoes is an innocent and delicious repast. Yet in certain men, women and even small babies, these foods cause a severe rash, swollen eyes or an asthmatic attack. It is considered that these people are otherwise healthy, energetic folk, but in the language of the day, "allergic to strawberries or tomatoes." The term "allergy" is a catch-all term which is now generally used to describe the cause of all symptoms whose existence otherwise baffles the practitioners. It has been said that many individuals are "allergic" to their own bodies and hence get sick because of this.

There are no essential differences between hay fever and asthma; in the one, hay fever, the nasal portion of the respiratory tract is affected; in the other, the bronchi (air tubes) are affected. In many instances, both are affected. Hay fever is inaccurately named, for the condition is not caused by hay and there is no fever. Its well-known symptoms—itching eyes, nose and roof of mouth; nasal obstruction; paroxysms of sneezing; inflamed eyes; and a watery discharge are "triggered" by the airborne pollens of various plants, especially ragweed and grasses. Molds, dust, particularly house dust; hair of dogs, cats, horses and cows; feathers of chickens, ducks, and geese: and orris root, the base of almost all cosmetic powders, are other triggering agents.

Asthma is labored breathing occurring in paroxysms upon expiration and is accompanied by wheezing, coughing, slow respiration, sweating, blueness of skin (cyanosis) and coldness of extremities. The muscular coats of the bronchi become spastic (tightened and contracted) and occlude the lumen (bore) or the air tubes thus causing difficulty in expiration. These acute paroxysms occur at varying intervals and degrees of severity. Night "attacks" are common. The "attack" may last only for minutes, or it may continue for many hours or days. Between "attacks" the patient is seemingly quite well.

The medical profession believes that the fundamental cause of allergy is the powerful body chemical, histamine; this is the trigger that supposedly touches off the allergic attack. Irritated by offending pollen or food, histamine, it is said, lights the fuse for an explosion of sneezing, wheezing, coughing or itching. The profession has not yet found an explanation of why certain people become hypersensitive to certain irritants. It is believed that this reaction is due to some defect in the allergic person's tissues which cause the production of too much histamine when in contact with allergenic substances.

Despite the use of anti-histamines, adrenalin, nasal sprays, injections and drops, ephedrine, A.C.T.H., cortisone, inoculations and "patch tests," "allergies" are growing increasingly wider in scope and more aggravating symptomatically.

These drugs are complicating the symptoms, causing chronicity and precipitating the appearance of so-called "side effects": heart palpitation, nausea, nervousness, skin rashes, dizziness, sleepiness, stupor, chills, and headaches. Their poison effects are more devastating than the "disease" they are supposed to "cure."

Throughout the entire body—in the skin, mucous membrane of the nose, mouth and eyes; joints, muscles, tendons and ligaments, and most organs and glands—there exist tiny, microscopic nerve-end receptors. These infinitesimal nerve receptors mediate, variably, sensations of pain, touch, pressure, heat and cold to the deeper-lying nerves and spinal cord of the body. Some of these sensations are transmitted to the brain for conscious perception. When we live incorrectly by indulging in wrong food habits, wrong thinking and getting insufficient sleep, fresh air and exercise, our bodies become depleted of nerve energy. This state of enervation leads to lowered metabolism and elimination of the wastes, and the tissues, bloodstream, organs and nerve-end receptors become toxic. The latter may be "weak links" (susceptibility) in the body due to many factors. If this is so, the individual will become hypersensitive to all the triggering elements mentioned above and hay fever and asthma will be manifested. Thus, the basic cause of these derangements, as in all other disease states, is the mode of life pursued which leads to vital energy depletion with consequent toxemia formation. So-called heredity plays some part in these processes, where hay fever and asthma come down on one side of the family.

These families are likely to violate natural laws in the same manner from generation to generation. If the unhygienic living habits of the family were changed, the hypersensitivity or "allergy" would cease.

Most of these who have acquired this shortcoming began gathering these undesirable conditions unto themselves as children by their manner of living. This is not their fault but the fault of parents who stuff them with milk and devitalized products until they become catarrhal and "diseased" in other ways. They become so acidic that health is impossible; hypersensitivity is produced and causes hay fever and asthma.

When we live correctly, our bodies maintain a normal alkaline balance and we are free from all sickness. Wrong eating, wrong drinking and wrong living in all areas produce subnormal health.

Health is the characteristic of people who live according to nature's principles and who eat "good foods." The latter are foods which are very close to their natural state and not, as is the case with most of the food of civilized peoples today, the end products of a whole series of disruptive processes of refining and preserving. All these meddlings break up the foods and divorce them from their natural state and composition.

Abstention from all food (fasting) for several days has marked beneficial results with these "allergies." Improvement might be said to be extremely dramatic. Only ingestion of distilled water is permitted during this time. Following the fast, freshly-expressed fruit and vegetable juices are given in minimal quantities for a few days, followed by a fresh, raw fruit, vegetable, nut and seed regimen. Fresh air is a necessary factor in returning vibrant health as well as is a correct mental attitude. By taking the mental attitude of healthfulness, one can often ward things off. But if one takes the attitude that a certain calamity is to befall, one mentally cooperates to bring it about. We have seen people apparently sick due to fear, worry and depression, and yet when the mind was diverted into constructive channels, they become happy and hopeful within a few minutes. The conditions were not changed; the thoughts of the sick person were re-routed.

If you or a loved one or a friend are victims of your transgressions and have developed hay fever or asthma, you can surely become free of these annoying and debilitating manifestations by ceasing your faulty living habits and adopting the principles of nature. Only in this manner will you gain efficiency, effectiveness and true happiness.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > Article #2: Allergy by Dr. Herbert M. Shelton

### **Article #2: Allergy by Dr. Herbert M. Shelton**

The press of the country has recently been full of items and articles about what is called *allergy*, which is defined as an abnormal sensitivity to substances which are harmless to most people. Hay fever, asthma and hives are among the most common forms of suffering that are said to be due to allergy. Migraine headache is also classed as an allergic phenomenon.

The *American Weekly*, a Sunday magazine supplement of the Hearst papers, once carried a lengthy article on allergy.

We learn from this article that most microscopic fragments of a woman's hair, specks of skin, or powder and dandruff scales may cause cold symptoms, sneezing and other discomforts, and are told that cold water (as in cold bathing) can bring on allergic reactions.

The author of the article informs us that approximately one in ten of our population in the United States have hay fever or other allergic symptoms. Many of these people "have been suffering since early spring

from the pollen of successive plants which have come into bloom, such as the grasses, trees, and weeds. The peak of misery has come to them since the middle of August." In August, ragweed and cedar trees begin to shed their pollens.

The writer tells us that while the rich can get away to less pollen-infested regions, or install air-conditioning units with pollen filters in their homes and go "into virtual retirement during the annual hay fever season, most of the victims of hay fever have been tied to their jobs and to their everyday way of life and have sneezed and suffered and cursed their fate." Others, he reminds us "have tried the nose filters which cut down the amount of offending pollen inhaled at each living breath."

The article contains a brief outline of a fantastic and chimerical theory of the cast of allergy, which seems to be taken from a book, *Your Allergy and What To Do About It*, by Dr. Milion B. Cohen and his daughter, June Cohen.

Briefly stated, this theory is that the body manufactures antibodies to destroy germs and the toxins these produce, so once the body has discovered the ability to produce antibodies, it will supposedly react to any foreign substance—whether "dangerous living disease germs," or "substances that are inanimate and of themselves harmless"—by the production of antibodies, and thus make us sick. The article says:

*Whatever the reason, it is unfortunate that in certain people some nonliving harmless things cause the cells of the body to release a substance which is poisonous. This kind of poisoning, resulting from the action of antibodies on harmless nonliving things, is called an allergic reaction*

*In hay fever, the harmless thing attacked with ferocity by the body is the pollen of various plants, particularly ragweed*

*What has been said about the development of immunity from a disease like typhoid fever applies in the development of an allergy, except that it is the second—rather than the first—exposure to the allergic material which creates the symptoms*

*Let us go back to Mr. Smith again—or to you—and see what happens if it develops that you are allergic to eggs. You eat some eggs and absorb some of the protein called albumen into your bloodstream. This is a foreign protein. Ordinarily it would do nothing, for it is nonliving and will not grow and propagate itself*

*However, the antibodies of the body against this foreign protein begin to be created. But, by the time they have been created, the albumen has disappeared and they have nothing to contend with. They are ready to fight but have no opponent*

*When a dose of egg albumen is absorbed a second time, however, your cells are ready to act for they have attached to them the antibodies that attack egg albumen. Pouncing on their harmless foes, they produce poisons which cause the well-known allergic shock. This type of reaction can occur in anyone.*

In one of his syndicated articles, Dr. Irving S. Cutter says: "almost any plant along the roadside or in the woods may affect you or me." It seems man does not belong on earth. His whole environment seems to be opposed to him.

Now, "for the first time," says the article in the *American Weekly*, "science really knows what happens when you have 'allergies'." We are to understand that the above absurdities constitute this knowledge possessed by "science." There is no science about it—it is a mass of baseless speculation. No doubt this theory will stimulate the production of "cures" that do not cure, and the so-called victims of allergy will not be helped.

No plan of care based on the theory that hay fever, asthma, hives, migraine, eczema, etc., are allergic manifestations has ever provided more than a temporary and questionable palliation. Dr. Cohen is "barking up the wrong tree" if he imagines he has tracked down the cause of allergy (sensitivity). His speculations follow the well-known medical pattern and this pattern has always been barren of worthy results.

Sensitivity is not cause. It is but a link in a chain. Even assuming that his fanciful theory is correct, it must be recognized that the production of antibodies to fight harmless things is abnormal, and this abnormality is not causeless.

Let us quote again from the article in the American Weekly:

*There is a famous case reported to the American Medical Association in which a husband went into a severe and real fit of coughing from asthma whenever his wife came near him. His physician reported: "His attacks are of the severe asthmatic type, which require epinephrine for relief, and this he must take nightly if his wife is at home. For a few years, it has been impossible for them to sleep in the same bed at night. It has been suggested that the wife's hair might be the offending cause. Is this likely?"*

*The A.M.A. suggested a continuation of skin tests for allergic and offending materials and said that several hundred materials ought to be studied as the possible cause. That was over a year ago. No report on the case has been brought to public attention since that time.*

How futile is this study of "several hundred materials" to find what the "offending" materials are. It has been repeated in thousands of cases and nothing more than evanescent and more often than otherwise, harmful palliation, has come from it.

It is more important to know what makes one sensitive than to know what he is sensitive to. Let us dismiss the nonsense with which Dr. and June Cohen have filled a book, and look for a minute at a case of hay fever.

Examining the case, we discover that the lining membrane of the nose is inflamed, hence very sensitive to irritation. It is inflammation that renders the membrane abnormally sensitive—that is, sensitive to the normal elements of man's environment.

Continuing with our investigation, we learn that the sufferer has chronic catarrh and had it, in fact, for several years before hay fever symptoms developed. We find that when the hay fever season is over and the symptoms characteristic of this trouble are no longer present, the sufferer *still* has catarrh. Frequent colds are suffered through the winter.

Carrying our investigation still deeper we find indigestion (gastritis) with constant fermentation and putrefaction in the digestive tract. The first development of acute gastritis came in infancy following a period of overeating, or following upon the heels of too much excitement or other enervating influences. Due to wrong care and imprudent feeding, gastritis became chronic, and frequent nose colds were followed by chronic nasal catarrh and, finally, hay fever.

The sufferer from asthma has followed practically the same line of pathological evolution except that frequent chest colds and bronchitis have finally developed into chronic bronchitis with the same inflammatory sensitization of the bronchial membranes that is seen in the nasal membrane in hay fever.

To get rid of asthma and hay fever, get rid of the chronic catarrh that forms their foundation. To get rid of the catarrh, remove its cause. Toxemia is its cause and toxemia has many causes.

Six years ago a resident of Brooklyn, New York, who had spent five years in Arizona in a vain effort to cure asthma with the magic of climate, came to the Health School. After he had been here less than three weeks, his boy entered the solarium, where the man was having a sunbath. The boy was carrying a cat. The man took the cat in his hands and stroked it a few times then handed it back to the boy. He took a

deep breath and then, with a sigh of relief said, "Before I came here, if that cat had merely entered the room where I was, I would have had an attack of asthma."

How much better to get rid of the cause of sensitivity than to spend your whole life running from cats, dogs, horses, flowers and trees! Even if you can afford to air condition your home and put in special pollen filters, do you want to spend the rest of your life in the house? Or, do you want to wear a filter on your nose for the next ten to sixty years? Can you afford to leave your work or your business each "hay fever season" and go away to the mountains or to the sea.

Only the rich can afford most of these programs, and these, by palliating their symptoms and ignoring their causes, allow their whole bodies to give down before these causes. While the writer in the American Weekly assures us that "it is sheer fate which makes them (hay fever sufferers) suffer their tortures where normal people are completely well and untouched," we assert that abnormality has definite and ascertainable causes.

In 1918, I cared for my first patient with hay fever. It was summer in San Antonio and she was suffering with a severe form of hay fever. She had so suffered for several years prior thereto.

She made a speedy recovery right in her own home, with no attention given to pollens, cats, dogs," feather pillows, face powders or her husband's dandruff. She has remained free of hay fever to this day and has spent all these intervening years in San Antonio. All cases of bronchial asthma and hay fever may recover in the same permanent manner by overcoming their chronic toxemia. How do we know this? We know because we have seen it done in hundreds of cases, even in cases of asthma that had persisted for twenty years.

What about "egg allergy?" It is due to impaired digestion, or to eating beyond digestive capacity. The normal digestive tract, if not overloaded, will not permit any undigested egg protein to enter the bloodstream.

All proteins must be digested before they can be used by the body. After they are digested, they are transformed during their passage through the intestinal wall into human (therefore no longer foreign) proteins. All proteins are foreign proteins and are poisonous if they get into the body without undergoing these digestive and transforming processes.

All serums are foreign proteins, and they can produce anaphylactic shock, which is just another name for serum poisoning or protein poisoning. The "allergic" symptoms produced by serums are worse than any ever produced by eggs that are eaten.

We do not consider eggs good human food and do not advocate their use, but we know that when toxemia is eliminated and nerve energy restored, so that digestion and metabolism are normal, former sensitivity to eggs ceases to annoy. To restore good health ends all the annoying symptoms and reactions that are based on impaired health.

The normal man is adjusted to his natural environment. The normal elements in man's natural environment become sources of discomfort only after resistance has been broken down. When resistance is restored to normal, the former discomforts come to an immediate end.

[Home](#) > [Lesson 71 - Allergies, Hay Fever, And Other Chronic Diseases](#) > Article #3: Why Suffer With Hay Fever? by Dr. Herbert M. Shelton

### **Article #3: Why Suffer With Hay Fever? by Dr. Herbert M. Shelton**

What we now call hay fever got its name, rose cold, nearly four centuries ago. In his commentary on

medical practice, Botallus, who was royal physician to the city of Asta, wrote:

"I know for a certainty of men, who at the smell of roses were seized with a loathing as against their chief enemy and that to such an extent to be subject to headaches or a sneezing fit or a running at the nostrils so that for two days it could not be stopped by rubbing."

In 1691, in Dr. J. Constantino de Rebecque's *Storehouse of Medicine of the Swiss or Treasury of Drugs and Most Choice and Rare Medical Observations* (Geneva), are these words:

"I have thought it useful to relate the effects which roses have, on me. From my thirteenth year, at the rose-blooming time, each year, I am attacked by a running catarrh in which for many days a thin and sharp fluid flows from the nostrils, and the eyes are also affected so that tears are caused to flow. This state lasts as long as the rose season. When the rose season is over, this condition stops of itself. In the first year, I thought this was due not to roses but to the warm summer, but after more careful consideration of the affair I have found out that it is due solely to the roses."

"Rose cold" and "rose fever" are still used with reference to hay fever that develops in the spring, though it is now well-known that roses have nothing to do with the production of hay fever. Rose pollen is not an airborne pollen.

The strong and pleasant perfume of roses and related flowers suggests their attractiveness to insects and their dependence upon these, rather than upon the wind, to transport their pollens for purposes of cross-fertilization. In no part of the United States and other countries where such studies have been made, has the pollen of roses ever been found in the air. On the other hand, many of our cultivated varieties of roses are almost entirely devoid of pollen-bearing organs.

The pollens that irritate sensitive membranes in April, May, June and early July come from other flowers and from grasses that are abundant at this season. Blue grass (June grass), timothy and other such cultivated grasses shed their pollens at this time. Indeed, in most parts of the north temperate region, pollens from many plants are abundantly present in the air during rose-blossom time.

We have no intention of attempting to list all of the flowers, weeds, grasses and trees, the pollens of which are held responsible for hay fever. Ragweed, one of the most widely distributed of these, is, perhaps, best known to the average reader. Cedar trees in the fall and hundreds of other plants are held responsible for the development of hay fever.

These pollens are present in the air of all who breathe— non-hay fever sufferers among mankind and the lower animals, as well as hay fever sufferers all around us. If they are the real cause of hay fever all who come in contact with them, including the animal world, should develop hay fever. The fact is that less than 10% of men and women have hay fever and no lower animals have it at all.

The systemic condition back of sensitized membranes and the sensitive membranes are present before the plants shed their pollens. With most hay fever sufferers, these conditions are present all the year round. They do not become conscious of the sensitivity of their membranes until these are brought into contact with outside irritants.

Pollens irritate sensitive membranes; they do not make the membranes sensitive. The real cause of hay fever is the cause that sensitizes the membranes. Until this cause is recognized, understood and dealt with intelligently, no permanent relief from hay fever is possible.

When this cause is understood, it may be removed and when it is removed, the hay fever ceases without attention being given to the theoretically-offending pollens. There is then no need to run away from pollens, to live in air-conditioned houses, to wear air filters on the nose, to seek to "immunize" sufferers with allergens, to destroy pollen-bearing plants or to do any of the other things the mad "scientists" have done and are doing.

Restore the hay fever sufferer to health, and he will live in the same environment with the rest of us and

react to its normal elements in a perfectly normal way. Healthy men and women do not suffer with hay fever. It should be known that when health is restored, previously sensitive membranes soon lose their sensitiveness. The problems presented by hay fever are simple and easily solved once the subject has been stripped of the mystery thrown around it by the mystery-mongering professionals. At the Health School hay fever does not last long.

### 1. Introduction

"Rheumatism" is derived from the Greek word rheumatismos, that designated mucus (catarrh) as an evil humor that was thought to flow from the brain to the joints and other portions of the body, producing pain. Studies have shown that an alteration of an important constituent of the joint mucin (the mucopolysaccharide: hyaluronic acid) occurs in some of the "rheumatic diseases." The rheumatic diseases are those conditions where pain and stiffness of some portion of the musculoskeletal system are prominent. These include diseases of connective tissue. The connective tissue diseases exist because of unhealthful living habits. Toxic matter that was not eliminated by the body is often stored in these tissues.

Arthritis is the general term used when the joints themselves become inflamed. Sufferers of arthritis experience pain, stiffness, and swelling in their joints. Many people become crippled. In the United States, more than 31 million persons of all ages and backgrounds suffer from this disease.

Many, different forms of joint diseases are distinguished. Physicians say that some forms of arthritis are caused by known agents, others from unknown factors. All disease is abnormal. A healthy person does not suddenly become stricken with arthritis or any other disease. The factors behind all forms of rheumatic diseases are known. That is, there must be an underlying toxicosis before the symptoms of arthritis appear. Many forms of acute arthritis pass into a subacute or chronic state because of drug therapy and continued unhealthful lifestyle.

Most physicians categorize arthritis into one of five major groups:

1. Infections caused by a specific microorganism.
2. Cases that are possibly infectious but of unproved etiology.
3. Cases representing degenerative forms of joint disease (sometimes termed arthroses).
4. Cases in which the arthritis results from direct trauma to the joint (chondromalacia).
5. Cases of metabolic arthritis (e.g., gout).

The above five groups will be discussed in this lesson and refuted. They are all based on erroneous concepts concerning the nature of disease.

## 2. Structure And Function Of Joints

The joints allow controlled and almost frictionless movement. The human skeletal system (the bones and joints) provide structural support and protection to vital parts, yet allow sufficient directed movement for the functions of locomotion and the ability to grasp or seize objects.

The joint space, articular cartilage, and synovial membrane allow the wide ranges of motion necessary for these functions. The synovial joints comprise the majority of the body's moveable joints. On each end of the bones near a joint there is a thin plate of dense bone. Tightly attached to these bony plates are the hyaline articular cartilages. These are specialized structures made up of connective tissue that acts as the bearing and gliding surfaces of the joints. In the joint cavity there is a space that contains the synovial fluid. The ligaments and muscles around the joint offer support for the joint. Normal synovial fluid is clear, pale yellow, and viscous. It is normally present in very small amounts. One to four milliliters is found in the human knee, and less in smaller joints. Its purpose is lubrication of the joint. The synovial membrane surrounds the weight-bearing cartilage and secretes the synovial fluid. The synovial tissue does not have a structural barrier between its blood vessel space. Therefore, substances from the blood are easily carried directly into the joint fluid. All of the many impurities that circulate in the blood at various times due to toxins arising from fermentation or putrefaction of food in the stomach due to improper food or combinations of food; food additives and chemicals; or uneliminated metabolic wastes, may pass directly into the joints from the blood. Once inside the joints, these substances may precipitate arthritis by irritating the inner lining of the joints.

Proper lubrication is vital to the function of the joints since it serves to keep the opposing cartilage surfaces from touching each other. If the cartilage surfaces touch, immediate destruction begins.

The lubrication fluid must also have the right chemical makeup. The fluid consists of large and small molecules which change constantly in their concentrations. As weight is put on the joint, the smaller molecules are pushed into the cartilage leaving behind the larger molecules of hyaluronic acid to bear the weight and to keep the cartilage surfaces from touching.

A molecule consisting of carbohydrate and protein is responsible primarily for joint lubrication. In the cartilage, the protein structure is the critical component of these molecules since its digestion by enzymes called proteases results in an "uncoupling" of the proteoglycan (combination of protein and carbohydrate) from the cartilage and its subsequent loss. This loss from the cartilage results in a stiffer material and is more easily damaged by wear and tear. These proteases are activated at acid pH.

Anything that tends to make the joints more acid will cause an increased rate of destruction by speeding the removal of the proteoglycans from the cartilage. Lack of exercise, eating refined foods or sugar and meats tend to make the joints more acid.

## 3. Types Of Arthritis

### 3.1 Osteoarthritis

Osteoarthritis is a noninflammatory disorder of the moveable joints. Those joints most frequently affected are the hands, hips, knees, lower back, and neck. This disease is characterized by deterioration

and abrasion of articular cartilage (that cartilage which covers the ends of the bones forming the joint) and also by formation of new bone at the joint surfaces. Severe disability may result, especially if the conditions have progressed far.

People with osteoarthritis suffer pain in the afflicted area and may feel a grating sensation when they move. Knobs of bone and of hardening bits of cartilage may develop in the joint, causing swelling and deformity.

### **3.2 Rheumatoid Arthritis**

Rheumatoid arthritis is a systemic inflammatory disease. Being systemic, all the organs of the body are affected (as they are in all diseases), but the outstanding feature is the progressive deformity of the involved joints. Usually more than one joint is diseased and it is symmetrical; that is, if one hip is involved, the other usually is also. It usually begins in the small joints of the hands and feet, but it commonly affects the wrists, elbows, ankles, hips, knees, and spine. The synovial membrane becomes inflamed and develops into a mass of swollen and inflamed tissue. It becomes what is known as a pannus and it is thought that this is what eventually destroys the articular cartilage. It also extends to the joint capsule that surrounds the joint and the supporting ligaments and weakens the entire joint. It eventually destroys the articular cartilage, then the bone. In the later stages of the disease, the articular surface is eroded and the joint space is obliterated. In the final stages of rheumatoid arthritis, adhesions of fibrous tissue or bony ankylosis prevent the joint from moving.

### **3.3 Bursitis**

Bursae are closed sacs, lined with a cellular membrane resembling synovium. They serve to facilitate motion of tendons and muscles over bony prominences. Inflammation of a bursa, or bursitis may occur in any part of the body where bursae exist (there are approximately 78 bursae on each side of the body), but most frequently occurs in the shoulder. Bursitis does not necessarily always involve a joint but because it often does, it is considered here.

Repeated irritation of certain areas where bursae already exist are contributing factors in what is called "traumatic bursitis." The predominant cause is toxicosis. "Tennis elbow" is a common example of overuse and stress contributing to this condition. Couple this with enervation from poor living habits and the foundation is laid for the development of bursitis.

### **3.4 Gout**

Gout sufferers experience repeated flare-ups of painful swelling. The bunion joint, which connects the big toe and the foot, is affected first in most cases. Gout is associated with the presence of too much uric acid in the blood due to improper diet such as meat eating. Sugar and sugar-starch combinations are also contributing factors. Uric acid takes the form of needle-shaped crystals in the joints. These crystals irritate the surrounding areas and cause severe pain.

### **3.5 Chondromalacia of the Knee**

Chondromalacia is a softening of a cartilage. It most often occurs in athletes and is frequently seen in runners and competitive cyclists. It is a softening, fissuring, and degenerative process of the articular surface of the knee cap. It is thought to be due primarily to overuse and stress to the joint. While this is a contributing factor, the predominant cause is toxicosis.

There are many other forms of arthritis, but the above-named ones are those most often experienced by the majority of arthritis sufferers.

## 4. Why You Have Arthritis

Despite the many forms that arthritis may have, the underlying cause remains the same for all types. A joint may be injured and the development of arthritis follows. The joint didn't heal perfectly but remained stiff and painful with the end result being a weakened, or even crippled, limb.

The reason for the failure of the injured joint to heal is that the individual is already toxemic and the stage is set for the development of arthritis. Chondromalacia develops in athletes whose activities place a great strain on their joints, although it is not likely that these strains do more than determine the location of the development. The excesses in eating, especially wrong combinations and refined foods, for which athletes are noted, are the more likely causes.

Arthritis may develop at any season of the year in any climate. In many people, the cold weather seems to make the symptoms worse but this does not indicate that the cold, damp weather is the cause of the arthritis. This may be a secondary factor but often during the winter months, people tend to stay indoors, depriving themselves of fresh air and eating larger amounts of richer foods. These influences produce enervation and check excretion, resulting in toxicosis.

### 4.1 Poor Eating Habits

#### 4.1.1 Uric Acid in Flesh Foods

Arthritis is often associated with uric acid poisoning. Flesh-eating animals secrete hydrochloric acid about twelve times as strong as that of humans. Carnivores also have an enzyme called uncage, that breaks down uric acid into allantoin. Man does not possess this enzyme. Vegetable proteins, including fruits and nuts, contain enough carbohydrates to make this enzyme unnecessary. Beef contains about fourteen grains of uric acid per pound. If you are eating meat, you are consuming a lot of this poisonous end product without having the means of breaking it down and disposing of it. It is therefore deposited in tissues and can readily be carried into the tissues of the joints where they accumulate along with other toxins.

#### 4.1.2 Purines in Food

Purines are catabolized to uric acid in the body. Besides flesh foods, other foods that contain a significant amount of purine include dry beans, dry peas, lentils, spinach, sugar, cereals, bread, eggs, cheese, and milk. Below is a table that indicates the amount of purines in certain foods.

#### Group A: High concentrations (150-1000 mg per 100 grams)

Liver	Sardines
Kidney	Meat extracts
Sweetbreads	Consomme
Brains	Gravies

Heart	Fish roes
Anchovies	Herring

**Group B: Moderate amounts (50-150 mg. per 100 grams)**

Meat, game, and fish other than those in Group A	
Fowl	Asparagus
Lentils	Mushrooms
Whole grain cereals	Spinach
Beans, dry	Peas, dry

**Group C: Very small amounts**

Milk	Coffee
Cheese	Tea
Eggs	Chocolate
Fats*	Carbonated beverages

Refined cereals, spaghetti and macaroni, sugars and sweets, tapioca, yeast

\*Fats interfere with the urinary excretion of urates and thus should be limited so as not to interfere with excretion of uric acid.

**4.1.3 Sugar-Starch and Starch-Protein Combinations**

Members of the legume family consist of a protein-starch combination. This combination is handled poorly by the body resulting in putrefaction. The end result is the formation of many toxins that contribute to toxicosis (the underlying factor in all arthritis). This is in addition to the formation of uric acid.

All refined sugars including white sugar, honey, molasses, maple syrup should not be included in the diet. They are unbalanced and "borrow" needed minerals from the bones and tissues. This is a contributing factor in osteo-arthritis where a degeneration of bone is evident. In addition to this, many toxic byproducts from the refinement process are found in these products that also contribute to toxicosis.

All cereals, including grains and bread, are not digested efficiently since humans are not biologically equipped to deal with large amounts of starches. We do possess the enzyme ptyalin in the saliva and starch digestion will begin if food is chewed proper. However, this enzyme will not be secreted if the starch food is combined with protein foods such as bread and peanut butter or cereal and milk. The starch is not digested at all and *fermentation* occurs in the digestive tract.

Sugar-starch combinations will also result in fermentation. As in protein-starch combinations, when sugar is eaten with starches such as bread and jelly or fruit with cereal, no ptyalin is secreted for starch digestion. Monosaccharides and disaccharides ferment more quickly than the polysaccharides (in starches). No digestion of sugars takes place in the mouth or stomach. The sugars are delayed in the stomach awaiting the digestion of starch and fermentation is the inevitable result.

Toxins resulting from fermentation of starches and sugars, and putrefaction of proteins, enter the bloodstream. Some are eliminated by the body in the urine or through other channels and some toxins are deposited in the tissues such as the connective tissues of joints and muscles. The stage is now set for arthritic diseases.

## **4.2 Enervating Habits**

Any enervating habit such as smoking, alcohol, coffee drinking, etc. contributes to toxicosis and may result in arthritis.

It is known that cigarette smoke contains approximately one to five percent carbon monoxide (a poisonous gas) and the concentration of this gas increases as the cigarette burns down. The carbon monoxide combines with hemoglobin in the blood to form a union called carboxy-hemoglobin (COHb). Heavy cigarette smokers reach levels of five to fifteen percent COHb concentrations. The nicotine in the tobacco is also a deadly poison. These agents, together with many other poisonous products found in tobacco, contribute to overall toxicosis. Some of these toxins are inevitably deposited in the joints.

Alcohol results in damage to all tissues where it comes in contact. The presence of this substance in the blood results in enervation and toxicosis of all organs and tissues in the entire body. The ability of the body to heal and eliminate normal metabolic waste products is greatly reduced and degenerative diseases result when such habits are continued.

Caffeine in coffee, cocoa, and soft drinks results in stimulation of the central nervous system and impairment of all bodily functions. It has a detrimental effect on the entire endocrine system and has been proven to alter release of certain hormones which are associated with arthritic conditions.

## **4.3 Lack of Exercise**

While arthritis is frequently observed among athletes, a lack of exercise may also contribute to its causation. It is impossible to obtain optimum health without adequately meeting the normal needs of life. A sedentary lifestyle lowers the tone and functioning vigor of the body. If you are inactive, your circulation will be sluggish. This prevents normal tissue renewal and nutrition. The ground is thus prepared for the development of disease (a healing crisis).

## **4.4 Insufficient Sleep**

Only a vital organism can perform all physiological functions with the utmost efficiency. If you get insufficient rest and sleep, all bodily functions become sluggish. This enervated condition always leads to toxicosis. Sleep is a great restorer of vitality and is essential for our general well-being. Rest is the means of restoring normal nerve energy—rest of the body and mind. Physiological rest (fasting) is the surest, best, and most satisfactory means of promoting the excretion of accumulated toxins.

## 4.5 Fresh Air and Sunshine

Respiration involves the exchange of oxygen and carbon dioxide. The body rids itself of a poisonous waste product (carbon dioxide) and takes in oxygen. Oxygen is required for all cellular functions and if this air is impure, our cells will be correspondingly contaminated. It is important that our homes are well-ventilated so there is a constant flow of fresh air from outdoors. Stay away from smoke-filled rooms as much as possible. This is also harmful, even if you yourself don't smoke.

A daily walk in the fresh air and sunshine is a healthful activity. Besides the vitamin D that is synthesized in the skin from the sunlight, being outdoors in the sun (even for short intervals) is very beneficial. Research is still being done on this subject and details concerning all the benefits of sunlight still need to be discovered. However, this is one component of healthful living that should not be neglected.

## 4.6 Emotions and Stress

Emotions and stress are physiological occurrences. Under a stressful situation, the body responds by initiating a series of hormones to maintain stability. Repeated stress could exhaust this homeostatic mechanism and the entire endocrine system may be affected. The adrenals secrete anti-inflammatory hormones. If the adrenals were not performing normally, there would be a lack of this and other hormones in the body. This could lead to many abnormal conditions throughout the body and arthritis is one possible outcome.

[Home](#) > [Lesson 72 - Rheumatic Diseases](#) > 5. Treatments

## 5. Treatments

There are many different treatments given to arthritis sufferers. Most involve drug therapy, some involve massage, whirlpool baths, herbs, or superstitious practices which have no beneficial effects.

### 5.1 Aspirin and Nonsteroidal Drugs

The nonsteroidal anti-inflammatory drugs are agents that suppress the signs and symptoms of inflammation. Examples include aspirin, phenylbutazone, indomethacin, ibuprofen, fenoprofen, anprofen, and toletin. These drugs are totally ineffective for arthritis. While the pain may be somewhat lessened during their use, the symptoms return as soon as they are discontinued. Meanwhile, damage to the joints continues to occur while these drugs are being administered and no good has been accomplished.

While these drugs have no ability to heal, their use can result in general adverse effects throughout the entire body. This accounts for their so-called "side effects" which are really general effects. They are poisons that contribute to arthritis and their use makes the disease worse.

### 5.2 Corticosteroids

Glucocorticoids are a class of naturally-occurring adrenal corticosteroid hormones which are so named because of characteristic effects on the intermediary metabolism of glucose. These steroids are often manufactured in the laboratory or extracted from animals and injected into the joints of arthritis sufferers for their anti-inflammatory properties.

Inflammation is associated with most arthritic conditions. But do we want to suppress or halt inflammation? When you suppress inflammation, you are also stopping a healing process. Physicians will tell you that there is no "cure" for arthritis and they are correct. However, if the arthritis has not progressed to the point where bones become fused, the body can and does heal when the correct conditions are provided.

Administration of glucorticoids produces systemic effects. Mechanisms throughout the entire body are adversely affected and no good ever comes from this practice.

Mark Bricklin, author of *The Practical Encyclopedia of Natural Healing*, cites a case of a lady who had been on corticosteroid medication for a number of years. She bumped her arm against a table and discovered a few days later that she had broken a bone. At this point, her doctor informed her, "Well, that's what happens when you take corticosteroids for a long time. Your bones go." This is a common effect of this drug which results in calcium wasting from the bones.

There have also been cases of diabetes-like increases in blood sugar, of hairy growths on the faces of women, and rounding of the face and watery accumulations in children and adults, of high blood pressure, skin eruptions, emotional upsets, even giddy gaiety or depression of manic mental illness. These effects disappear when the hormone is stopped.

### 5.3 Other Therapies

Other treatments have been used for arthritis including massage, orthopedic shoes, megavitamins, mineral supplements, hypnosis, acupuncture, alfalfa, and many more. Not one of these therapies are beneficial. The underlying cause of this abnormal condition has not been corrected. The unhealthful diet and other contributing factors in toxicosis should be corrected so that the body can proceed in healing. Only then can a healthy state be restored.

[Home](#) > [Lesson 72 - Rheumatic Diseases](#) > 6. Erroneuous Theories

## 6. Erroneuous Theories

As stated earlier, most physicians categorize arthritis into one of five major groups:

1. Infectious cases caused by a specific microorganism.
2. Cases that are possibly infectious but of unproved etiology.
3. Cases representing degenerative forms of joint disease (sometimes termed arthroses).
4. Cases in which the arthritis results from direct trauma to the joint (e.g., chondromalacia).
5. Cases of metabolic arthritis (e.g., gout).

The first two groups are based on the germ theory of disease. Although bacteria is associated with different diseases, they do not cause that disease. All disease is a vital effort on the part of the organism to heal. It is a bodily response undertaken in order to correct conditions that are harmful. When toxicosis exists and threatens the well-being of the organism, the body responds by eliminating those toxins and the symptoms of disease are felt. Bacteria are present to "clean up" decaying tissues, cells, toxins, etc., and are a useful part of this healing process. Arthritis is not a condition that is inflicted upon people in an indiscriminate manner by bacteria or viruses. It is a condition that has developed within the body due to unhealthful living practices.

The third group consists of degenerative forms of joint diseases that would include osteoarthritis and rheumatoid arthritis. When you persist in unhealthful living habits and suppress symptoms of disease with drugs or other means, degenerative diseases result. According to your particular diathesis, you may

develop arthritis, heart disease, kidney disease, etc. Even though the various types of arthritis are different, the cause remains the same for all forms. Accumulation of toxins irritates and weakens the membranes and tissues in the joint. Irritants or toxic substances degenerate cartilage. Then the body deposits, through a process of ossification, mineral salts in the joints. These salts are mostly calcium urates, created by the body's neutralization of uric acid with its own calcium. Calcium is thus depleted from the bones and wasting is seen. Mineral deposits in these joints harden and the final result would be fusion of the entire joint.

The fourth group consists of arthritis resulting from direct trauma to a joint. In a healthy individual, arthritis would most likely not occur due to use, such as in running. The joints must first be weakened by toxic accumulations and mineral deposits. The trauma then initiates the onset of the disease. If a joint would be greatly overworked, as in a series of marathons, inflammation may occur. However, if the individual were healthy, healing would occur after resting the joint involved, and there would be no lasting adverse effects.

The fifth group consists of metabolic disorders. Gout is a disease that is associated with high amounts of uric acid in the blood. It is also associated with high amounts of uric acid in the urine. The physiology books will tell you that this is common and quite innocuous. This may be true, but it is not normal. The body rids itself of this poisonous material through the kidneys, but the fact that it exists in high amounts in the urine indicates errors in diet. The presence of uric acid in the blood of gouty individuals is considered by many physicians as a primary disease that arises without extrinsic cause. However, this condition would not occur in anyone who lived healthfully. The extrinsic cause that results in high levels of uric acid lies in eating foods that are unsuitable. Flesh foods are main contributors but also consumption of alcohol is a major factor. These conditions must be corrected if health is to be restored.

## **6.1 The "Immune" Theory**

Our system normally comprises various types of white blood cells and molecules made by those cells. These cells and molecules normally reside in the lymph tissues and bloodstream and migrate to certain areas when needed to perform their specialized duties (such as in inflammation as the result of an injury).

Most of these cells and compounds have now been identified in human joints actively afflicted with rheumatoid arthritis. They include monocytes, macrophages, neutrophils, etc. The scientists do not know why these cells congregate in the rheumatoid-diseased joint. The reason, however, is not so baffling when you realize that the body initiated an inflammatory process in its attempts to heal. All inflammatory processes are associated with the above-named white blood cells. It is their duty to engulf and destroy all foreign matter and "clean up" the area along with other important functions. The scientists speculate that it is these white blood cells that inflict disease but they admit that they do not know why or how they accomplish this matter. The truth is that these white blood cells do not inflict disease even though they are identified with this disease process. In fact, they are "helpers" in the healing process.

It is generally believed that neutrophils (white blood cells) produce proteases that destroy cartilage in the joint. This enzyme may destroy the cartilage eventually, but it is not the cause of the disease. This situation would not occur if the pH of the area were not too acid from excessive meat eating and sugar eating. About 1/6th of meat is composed of uric acid. The body cannot digest and utilize animal wastes. So it neutralizes these harmful acids with base materials, such as calcium. Calcium urates form and are deposited in joints or muscular tissue around the joints. Meanwhile, the joints are being destroyed by the leaching of minerals from the bones and calcium deposits form in the joints irritating the tissues resulting in inflammation, pain, and swelling.

Based on these erroneous conceptions of the immune system working against the body, various drugs are given to suppress the activities of these cells. Aspirin is given to suppress the inflammation but it also suppresses healing, the formation of prostaglandins that also play a role in healing, and many other

physiological functions.

Injectable gold is given to arthritis sufferers, but patients suffer itching, stomach discomfort, anemia, and platelet disorders. A drug called D-penicillamine results in bone marrow suppression or kidney disease in many people. Benoxaprofen was given to inhibit the migration of monocytes (a normal occurrence). This drug did not only offer no benefits but had to be removed from the market by Eli Lilly Company for an indefinite period of time because it had been linked with 61 deaths among elderly patients in Great Britain.

You cannot be poisoned into health nor can health be achieved through interference with normal, cellular activities. Once underlying causes are removed and corrected, the body will heal. If the disease has progressed to the point where the joints have become fused, complete recovery may not be achieved, but improvement will be made. Further joint destruction will be halted and general health will greatly improve.

[Home](#) > [Lesson 72 - Rheumatic Diseases](#) > 7. What To Do If You Have Arthritis

## **7. What To Do If You Have Arthritis**

### **7.1 The Fast**

Dr. Shelton describes a case where a lady with arthritis, recovered completely after a fast: "Mrs. G. was forty-four years old. Her arthritis was of but a few months standing, but it was painful and crippled her movements. Mrs. G's physician could promise her nothing but temporary relief which was aspirin or cortisone for the rest of her life. He told her there would be a probable spreading and increase of pain. She journeyed to the United States from Canada and underwent a fast. The fast lasted only three weeks, but it freed her of all pain and inflammation and restored normal movement to her joints." After the fast she remained free of the pain and inflammation of arthritis.

The body has remarkable recuperative powers. The body's ability to heal can be enhanced if the remedies and the causes that have built the disease are removed. The body must be given an opportunity to eliminate its toxic accumulation by means of a fast and then given an opportunity to alter its blood chemistry by means of a change in the plan of eating.

During a fast, the chemistry of the body (especially its fluids and secretions) undergoes a rapid change and returns to a normal healthy state. Fasting relieves the pains of arthritis more effectively than drugs and does it without risk or harm. It is not because the fast itself did anything. Fasting did nothing. But it provided the best condition for the body to heal and repair itself. This is why you fast.

The duration of the fast in arthritis depends on individual circumstances and should only be undertaken under the personal supervision of one who is thoroughly familiar with the techniques of fasting.

Recovery from chronic arthritis is a slow process out of a state of ill health and into a state of biochemical normalcy and health. According to Dr. Shelton, recovery depends on many factors—age, weight, extent of the disease, its duration, degrees of joint destruction, the amount of ankylosis, previous habits of living and eating, the amount of nerve energy in reserve, the character of complications that exist (such as heart disease), the occupation, disposition and environment of the patient. All of these factors determine the extent of recovery possible and the rapidity with which recovery can take place.

While some joints may be permanently ankylosed, the fast can still result in improved health in all cases. A higher state of health will result overall.

## 7.2 After the Fast

After the fast you should try to implement a more healthful diet into your daily life. The best diet for all humans is one that consists of all raw fruits, vegetables, nuts and seeds, organically grown. On this diet, arthritis sufferers have had the most success in recovery and maintaining health thereafter. This is a diet that contains no harmful toxins that would create the conditions for any disease to exist. When eaten in correct combinations, there will be no fermentation or putrefaction that results in the presence of toxins in the body. These foods are easily digested, supply us with all nutrient needs, and will provide, the correct conditions for health.

You must keep in mind that the body always strives toward health and will always heal and repair itself even in seemingly hopeless cases when the proper conditions are provided.

Besides fasting, and proper diet, all of the other conditions must also be provided (proper rest and sleep, exercise, etc.).

[Home](#) > [Lesson 72 - Rheumatic Diseases](#) > 8. Questions & Answers

## 8. Questions & Answers

### **Will elimination of nightshade fruits cure arthritis?**

The nightshade fruits (tomatoes, eggplants, peppers, and potatoes) will not cause arthritis and their elimination will not "cure" it. There are no cures. Adhering to a healthful lifestyle will enable the body to heal and this is the only road to health.

### **I read that vibrators are good for the relief of arthritis. Is this true?**

The federal government ruled that it is illegal to offer vibrators for the relief or prevention of arthritis or rheumatism. In spite of this fact, 14 out of 100 arthritics use a device of this kind. The machines have been proven ineffective. In some instances, where rest of the affected parts is desirable, use of a device may have harmful effects. Nevertheless, thousands are being sold annually to arthritics eager to grasp at any offer of relief. Do not be fooled into believing that any device will relieve arthritis.

### **Are liniments effective in treating arthritis?**

Liniments, ointments, and lotions are entirely ineffective in relieving arthritis. Anything outside of the human body has no ability to heal. These agents may be harmful if they are absorbed through the skin and they may aggravate the condition rather than help it.

### **I have rheumatoid arthritis in my hands and all the joints are very swollen and painful. My doctor told me to melt parafin wax with mineral oil and coat my hands with this mixture twice a day. Will this help my condition?**

No, this treatment is ineffective in relieving pain. Furthermore, it is very stressful for the arthritis sufferer and results in further enervation. Your hands are already extremely sensitive due to the inflammation in the joints. Placing them in hot wax will result in even more discomfort. Disregard this practice and try a more healthful lifestyle beginning with a fast. The results will be positive with no adverse effects.

### **Years ago I heard about "immune milk" as a remedy for arthritis. Can I still purchase this**

## product?

Several years ago "immune milk" was widely advertised as a remedy for arthritis. According to Dr. Ronald W. Lamond-Havers, medical director of the Arthritis and Rheumatism Foundation, "scientifically-controlled studies of the product show it has absolutely no effect on the disease." The so-called "immune milk" allegedly gets its "immunity" to rheumatoid arthritis from antibodies produced in the udders of cows injected with streptococcus and staphylococcus vaccines. The victim of the disease, according to the theory, then gets his "immunity" or "cure" by drinking a quart of the "milk" a day

Dr. Lamont-Havers points out there there is no evidence that streptococci or any other agent directly causes rheumatoid arthritis, and that treating patients by injecting such vaccines was tried and discarded

Any product which promises "immunity" to arthritis or any disease is fooling the public into purchasing the product under false theories. Stay away from all such products and vaccines.

## Will fasting "cure" arthritis?

This question is best answered by quoting Dr. Shelton from *The Science and Fine Art of Fasting*, he says:

"We do not-claim that fasting "cures" disease, but simply that it enables the organism to heal itself. What, then, does fasting do?

1. It gives the vital organs a complete rest.
2. It stops the intake of foods that decompose in the intestines and further poison the body.
3. It empties the digestive tract and disposes of putrefactive bacteria.
4. It gives the organs of elimination an opportunity to catch up with their work and promotes elimination.
5. It reestablishes normal physiological chemistry and normal secretions.
6. It promotes the breaking down and absorption of exudates, effusions, deposits, "diseased" tissues, and abnormal growths.
7. It restores a youthful condition of the cells and tissues and rejuvenates the body.
8. It permits the conservation and recanalization of energy.
9. It increases the powers of digestion and assimilation.
10. It clears and strengthens the mind.
11. It improves function throughout the body

[Home](#) > [Lesson 72 - Rheumatic Diseases](#) > Article #1: Why You Have Arthritis by Dr. Herbert M. Shelton

## Article #1: Why You Have Arthritis by Dr. Herbert M. Shelton

Years ago when a man or woman had pains and inflammation in the muscles and/or joints, the diagnosis was likely to have been rheumatism.

Rheumatism took many forms, such as inflammatory, muscular and joint rheumatism. In the lower back it may have been called lumbago. Rheumatism of the chest muscles received the name pleurodynia. Sometimes this was mistaken for pleurisy. Then there was the acute form that was known as rheumatic fever.

Today, the term rheumatic is not used so much. The "old disease" has been fragmented into arthritis, of which several varieties are listed: lumbago, bursitis, sciatica and other so-called diseases. Chronic rheumatism of the joints (rheumatoid arthritis) is said to sometimes follow a cold, acute rheumatism, tonsillitis, and to sometimes develop independently of these "diseases." It may develop in any joint in the body and slowly extend to other joints, but has a tendency to develop first in joints that have been injured.

In persons past forty, sprains and other injuries are sometimes followed by the development of arthritis. The joints don't heal perfectly but remain stiff and even painful, with the result that the limb is weakened or even crippled.

The reason for the failure of the injured joint to heal is that the individual is already toxemic and ripe for the development of arthritis. Such a development may receive the name *traumatic arthritis*. Arthritis is a frequent development in athletes whose activities place a great strain on their joints, although it is not likely that these strains do more than determine the location of the development. The eating excesses and indulgences for which some athletes are known are the more likely causes.

Arthritis may develop at any season of the year but is more often developed in the winter season, and cold seems to make the symptoms worse. The disease is much more prevalent in cold climates than in warm ones. However, there is no reason to think that climate, per se, is a cause of the disease. It is more probable that the inactivity of the indoor life, the lack of fresh air and the overeating of the richer foods that characterize winter living are the chief causes. It should not have to be repeated that any influence that produces enervation and checks excretion will contribute to cause.

All so-called rheumatic conditions were once attributed to the accumulation of uric acid within the body. There are those who still hold to this older theory. This acid is one of the end products of protein metabolism, but is unlikely that any one of the end products of metabolism (this is to say, any one of the wastes of the body) is solely responsible for the disease. There may be some deposit of uric acid crystals in the capillaries but this does not seem to be the cause of arthritic diseases.

The idea that arthritis and other "rheumatic" diseases are caused by the accumulation in the body of uric acid led to the idea that flesh eating causes or helps to cause such affections. The fact is that excessive starch and sugar eating seems to have more to do with the evolution of arthritis than does flesh eating. But we cannot lay such developments to any one habit of life or to any one article or one class of food. The total enervating mode of living and the total toxic load carried by the individual must be regarded as cause.

Fermentation in the stomach and intestines (indigestion) resulting from wrong combinations is perhaps more important as a factor in causing this condition than the food itself. In most, if not all, cases of arthritis there is a long history of indigestion preceding the development of the joint inflammation. (Inflammation of a joint is the meaning of the term arthritis.)

Food combinations that do not digest readily favor fermentation and putrefaction. If elimination is also checked as a result of an enervating mode of living, the toxins absorbed from the digestive tract tend to accumulate in the body. This results in the evolution of disease in line with the individual diathesis.

Indigestion, whether resulting from wrong combining or from any other cause, favors the evolution of serious disease. The liver and kidneys are constantly taxed beyond their limit in excreting the poisons that come from indigestion. It becomes impossible for them to keep the blood and tissues free of waste and the absorbed poisons. The resulting accumulation of toxins from the tissues and from the digestive tract cause disease.

While arthritis is frequent among athletes and physical laborers, a *lack* of exercise may also contribute to its causation. It is impossible to have normal health without adequately meeting the normal needs of life. A sedentary existence is itself a cause of a general lowering of the tone and functioning vigor of the body. The inactive person has sluggish circulation. This prevents normal tissue renewal. The ground is thus prepared for the development of disease.

Among the most common causes of indigestion are overeating, drinking with meals, eating when fatigued, eating immediately before engaging in heavy work, eating when emotionally stressed, eating between meals, lack of sleep and taking drugs. Among the common causes of enervation, a state that both checks excretion and impairs digestion are all drug habits—the coffee, tea, chocolate, alcohol, tobacco, antacid tablets, headache pills, sleeping pills, etc., and poor physical habits—overworking, excesses, oversunning, overbathing and all other indulgences. Overworked emotions are one of the main causes of enervation.

It is said that "rheumatism" almost always weakens the heart. Great numbers of cases of so-called "rheumatic heart" are credited to "rheumatic fever" in infancy and early childhood. It has been known for over eighty years that the salicylates (aspirin) damage the heart. Yet when this drug is freely given in so-called rheumatic fever and in arthritis and the heart is damaged, the effects of the drug are ignored. It is doubtful if heart damage will occur in cases not treated with drugs.

Many years ago Sir William Osier said in his *Principles and Practices of Medicine*, "The salicylates (a class of drugs which we have previously pointed out is employed in almost all treatment of the so-called rheumatic diseases) are useless." They are employed to relieve pain and for no other purpose. The patient pays a fearful price for a brief respite from pain, for it is necessary to repeat the dose at intervals and to increase both the frequency and the size of dose as the use of the drug discontinued.

It is freely admitted by the profession (an admission that even the vendors of patent medicines keep echoing) that there is no *cure* for arthritis. All the drugs employed in the treatment of arthritic sufferers are employed as palliatives. Cortisone has replaced the old standby of yesteryear—potassium iodide. It may be less damaging than the older drug but is no longer thought of as anything more than palliative. It has very harmful "side effects" and will sooner or later be abandoned.

The climate cure, the Turkish bath *cure*, the hot springs and mineral springs *cure*, massage, etc., have been and are popular in treating arthritis. They have no other apparent benefits than that of temporarily palliating symptoms. As palliatives they are less damaging than drugs. This is the best that can be said of them. The sweat baths, hot baths, prolonged baths, massage and similar treatments add to the enervation of the patient and help to prolong the disease.

Nothing short of *the removal and correction of the causes of enervation* assures a re-establishment of health. Rest is the means of restoring normal nerve energy—rest of body and mind. Physiological rest (fasting) is the surest, best and most satisfactory means of promoting the excretion of accumulated toxins. A corrected mode of living after the fast will prevent a return of the toxemic state and promote the evolution of good health. The arthritic who as a remedy mentality will search in vain for a remedy that will restore him to health; the intelligent individual may easily live himself into good health. Health is an evolution of healthful living; it is not the product of "cures."

Chronic rheumatoid arthritis is a state from which recovery (full and lasting recovery) is easily possible if a Hygienic program is fitted to the individual's needs before irreparable damages have occurred in the joint tissues. Even apparently hopeless cases make full recovery. There are, in many advanced cases, tissue changes that cannot be undone. This makes it all the more important that Hygiene be adopted early.

## Article #2: Arthritis by Dr. Robert R. Gross

Arthritis is a "disease" caused principally by impaired metabolism and toxemia (poisons in the blood and tissues), acid pattern is eventually developed in the joints by the type of food eaten and the faulty habits experienced. A fibrositis (fiber inflammation) followed by a hardening of tissues surrounding the joint occurs. All the structures composing a joint-articular cartilage, synovial membrane, synovial fluid, articular capsule, ligaments, tendons, and muscle endings may become involved. Blood circulation to the parts is obstructed and calcium tends to infiltrate and precipitate in any of the areas. Mobility is reduced, and, ultimately, the joints may become locked (ankylosis) and deformed.

Arthritis is classified by physicians into different forms: osteoarthritis, rheumatoid arthritis, gouty arthritis and rheumatic fever arthritis. All these afflictions are basically the same type in the joint. The cause is the same (toxemia) and the care is the same. This abnormal state exemplifies typically the Natural Hygienic axiom of the unity of disease.

Pathology texts describe osteoarthritis as the hypertrophic form (joint enlargement) and rheumatoid arthritis as the atrophic form (wasting). I have seen innumerable cases wherein both forms were combined in the same joint. As a matter of fact, it is impossible that one form exist as an entity unto itself without involving some joint disturbance attributed to the other.

Medicine likes to classify health deviations down to impractical differences whereas all derangements are practically the same. The use of "medical jargon," descriptive Latin and Greek names, and utilization of imposing-looking diagnostic instruments and laboratory procedures lend an aura of "science" to the practice of drugging. These adornments and embellishments are so much "eyewash" and serve to detract from the actual cause-and-effect relationship of all disease processes and their care.

### Cause of Arthritis

The inflammation, pain and stiffness, lime deposits, deformity, ultimate destruction of the normal joint structures, and "locking" of the joint all stem from a form of life destructive to general health. Poor eating habits; smoking; consumption of alcohol and coffee; insufficient sleep, sunshine, fresh air and exercise; emotional intemperance; use of medicine and pills and other factors cause nutritional impairment, intestinal poisoning and chronic toxemia with arthritis.

The results of drugging and therapeutic abuses have made arthritis a hopeless condition. There is tremendously more harm, suffering, inconvenience and abuse caused by the treatment employed than by the arthritis itself. The evils of cortisone: ACTH, phenylbutazone, aspirin, gold salts and x-ray radiation have made hopeless cripples of mild arthritic sufferers. *Persistence in ignoring causes of disease and refusal to remove them is the greatest evil of medical treatment.*

### Hygienic Care of Arthritis

Arthritis is not the hopeless condition that medical men make of it. It must not be permitted to advance beyond the possibility of vital redemption before Natural Hygienic care be instituted. In all cases that have not advanced to joint destruction and ankylosis, recovery may be experienced to varied degrees if the sufferer will forego the destructive way of life causing the derangement. He must be willing to adopt, and persist in, a regime from which normal health will evolve.

I have had innumerable arthritics recover normal joint function through fasting followed by a vegetable, fruit and raw nut regime. The fast promotes detoxification of the body, and marked improvement, both in general and local conditions, follows. Relief from excruciating pain is gained within only a few days after the fast is instituted. Marked reduction of the swelling and enlargement of the joints, restoration of motion in the stiffened parts and great comfort and ease are immediately enjoyed.

Some cases require two or more fasts before accumulated poisons are ejected and full recovery is accomplished. In advanced cases one or two years may be required before normal joint movement is obtained. The patient must be persistent and cooperative with nature's infinite wisdom in the self-healing powers of the body. If he will do this, he will not only recover health but he will retain good health.

Faulty habits of living dangerously reduce nerve functioning power and maintain it at a level inconsistent with high-grade health. This substandard functioning power is the antecedent of all disease irrespective of by what name it goes and no matter what complicating causes may be superadded to them. The body does not possess unlimited power of recuperation, thus, diseased states in any degree should be immediately subjected to Natural Hygienic care.

### **Article #3: Well! You Wanted to Know! by V. V. Vetrano, B.S., D.C., M.D.**

#### **How does rheumatoid arthritis differ from other arthritis and what can be done about it?**

Arthritis is a general term referring to any inflammatory disease involving a joint. There are many different types of arthritis, their names being based upon different things, such as whether or not it is acute or chronic, its cause, or etiology, the specific joints involved, etc.

Suppurative arthritis is a condition where the inflammation is associated with the formation of pus. It is thought that this type of arthritis is due to direct bacterial invasion, sometimes causing the white blood cell count to reach 200,000 mm<sup>3</sup>. It is usually limited to one joint. As the process advances, this type of arthritis can destroy the structures of the joint just as badly as does rheumatoid arthritis. The only difference is that in rheumatoid arthritis multiple joints are involved and pus does not form.

Tuberculous arthritis sometimes develops as a complication of pulmonary tuberculosis. This type of arthritis is even more destructive than suppurative arthritis and frequently normal tissues of the joint are replaced with scar (fibrous) tissue. Calcification (ankylosis) of the joint also takes place.

Rheumatic fever is always associated with a type of migratory arthritis. This type of arthritis usually subsides without injury to the joint. It is well known, however, that the heart is often damaged. It is the belief of Hygienists, however, that the heart damage is probably due to the drugs used to treat the problem rather than bacteria or the disease.

In arthritis associated with gout, which is a systemic disorder of uric acid metabolism, urates will be deposited in and about the joints. This kind of arthritis leads to extensive destruction of the articular surfaces. It is very chronic and extremely painful. It is so severe in some people that the least movement or just the touch, of a sheet will send the sick one into agonizing pains.

Rheumatoid arthritis is a systemic inflammatory disease of *unknown* etiology according to physicians. However, the etiology is not unknown to Hygienists. Being systemic, all the organs of the body are affected, but the outstanding feature is the progressive deformity of the involved joints. Usually more than one joint is diseased and it is symmetrical; that is, if

one hip is involved, the other usually is also. It usually begins in the small joints of the hands and feet, but it commonly affects the wrists, elbows, ankles, hips, knees and spine. The synovial membrane (the membrane which secretes the joint fluid) becomes inflamed and develops into a mass of swollen and inflamed tissue with tags protruding out into the joint itself. It becomes what is known as a pannus and it is thought that this is what eventually destroys the articular cartilage. It also extends to the joint capsule which surrounds the joint and the supporting ligaments and weakens the entire joint. It eventually destroys the articular cartilage, then the bone. In the latter stages of the disease, the articular surface is eroded and the joint space is obliterated. In the final stages of rheumatoid arthritis, adhesions of fibrous tissue or bony ankylosis prevent the joint from moving. Complete confinement to the wheel chair is the final outcome of those who do not learn about Hygiene before this destruction takes place.

Osteoporosis is different in that it occurs principally in weight bearing joints, and is very slowly progressive. The current thought is that the condition is essentially a "wear and tear" or aging phenomenon and should not be called arthritis because it is not basically an inflammation. Pathologists who desire to be technically correct call the problem degenerative joint disease. Degenerative joint disease may appear in younger people when the joint has been injured.

All types of arthritis develop from chronic toxemia. Even with an arthritic tendency one does not necessarily have to develop the disease. A correct mode of living will prevent the development of the disease even in those predisposed to it. Physicians are still ignorant of the cause as is stressed in the following quotation: "It is depressing to relate again, as with so many diseases, that the cause of osteoarthritis is unknown." It is thought that laxity or instability of the supporting tissues of a joint, whether because of previous injury or aging, predisposes one to osteoarthritis. Trauma, slowing of the body's ability to repair as one ages, and anatomical and biochemical changes are all given as possible causes when the real cause is a biochemical perversion from wrong ways of living. As long as the tissues of the joint are normal and all the metabolic wastes are carried away as fast as they are formed, the joint will repair itself even of gross and microtraumas of long years standing.

The primary difference between the two great types of arthritis, rheumatoid and osteo, is that the joints most commonly affected in osteoarthritis are those most active, such as the articulations of the vertebrae, hips, knees, and the distal interphalangeal joints of the fingers. The wrists, elbows, and shoulders and the proximal interphalangeal joints are seldom involved.

Actually, osteoarthritis differs greatly from rheumatoid arthritis in almost every way. It is equally common in both sexes, however, and it develops most often later in life. In osteoarthritis, "there is no evidence of a toxic factor; the large joints are commonly involved, often only one joint; there is no true ankylosis." In osteoarthritis, movement is limited by bony outgrowths, but the two bones never become joined together (ankylosis) as in rheumatoid arthritis. Women especially are prone to the development of Heberden's nodes. I'm sure you have all seen the knobby hands of some older women, especially the bumps on the last joint of the fingers. These are known as Heberden's nodes and they arise because of degeneration of the tissues around the joint after which they are subsequently ossified.

## Article #4: How to Deal With Bursitis by Dr. Herbert M. Shelton

At intervals, *U.S. News and World Report*, which conceives it a duty to the public to keep them informed on the "progress" of medical mischievousness, has one of its reporters interview some little *gutta percha* god of medicine on some subject and give the results to its readers. In its issue of January 11, 1960, it published an interview with Joseph J. Bunim, M.D., of the National Institute of Health, under the misleading title: "Bursitis: Latest on its Cause and Cure." It declares Bunim to be one of the "nation's top notch authorities on rheumatic diseases," a distinction he seems to have acquired by being ignorant of the "diseases" in which he has specialized. His "latest" is old stuff that has been to the cleaners.

Our grandfathers used to suffer with what was called rheumatism. Rheumatism was a blanket term that covered a wide variety of pains and inflammations in various parts of the body. They had "muscular rheumatism," "articular rheumatism," "sciatica," "lumbago," "pleurodynia," and other "forms" of rheumatism. Nobody has rheumatism today, for the old "disease" has been run through a food chopper and so fragmentized that today we have a whole variety of "diseases" as substitutes for rheumatism. We have "neuralgia," "neuritis," "sciatica" (which is a neuritis), "fibrosis," "arthritis," "myositis" "bursitis," etc. Just as *arthritis* may develop in any movable joint and *neuritis* may develop along the course of any nerve, so *fibrositis* may develop in any fibrous tissue, *myositis* may develop in any muscular tissue and *bursitis* may develop in any bursa. "Itis" is a little Greek word meaning inflammation, which is used as-a suffix. When added to the name of an organ or part, it indicates inflammation in that organ or part. Thus, all of these separate *diseases*, in many different locations are but local inflammations. Their names do not seem to be important.

I quote the following words from a standard textbook on the practice of medicine: "The etiology (cause) is unknown." This is the gist of the statements concerning cause that one finds in all of the standard texts and reference works dealing with these so-called diseases. Sometimes we get such stupidities as "many patients notice a direct relation between exacerbations of muscular symptoms and infections of the upper respiratory tract, influenza, exposure to damp and cold weather, fatigue and overexertion." The authors of these ponderous works devote much attention to "diagnosis" and "differential diagnosis" and recommend measures of treatment that, at their best, are merely palliative; at their worst, are more harmful than the cause of the disease for which they are administered. Never do they suggest removing cause—how could they, when they confess ignorance of cause? They advise protecting these patients against respiratory *infections*, but neglect to explain how this is to be done.

*Bursitis* is one of these "rheumatic diseases" that have taken the place of the rheumatism of our grandfathers. It is inflammation of a bursa. A bursa is a small sac interposed between movable parts for purposes of lubrication. Bunim explains that a bursa is "a small sac containing fluid, which is usually situated between a tendon and the bone over which the tendon glides." He says that "tennis elbow" and "housemaid's knee" are good examples of bursitis. He differentiates bursitis from arthritis by saying that arthritis is inflammation of the intrinsic structure of a joint, such as the lining of the joint, or the cartilage or the capsule, whereas, the bursa lies outside of the joint and is not part of the joint. This means that, while bursitis is contiguous to the joint, and often seems to be in the joint, it is only close to the joint.

When asked if "we" are getting closer to an answer to bursitis, Bunim declared that "we" know much more about bursitis as a result of research which has been done on changes in the body's tissues in the areas of bursitis. This only means that they have made more extensive studies of local pathology, not that they know any more about inflammation now than they did ten years ago. He says that they hope to learn more about the process which results in bursitis and adds that during the past ten years more research has been done on this subject than during the previous century. What he failed to add is that, with all' this research, they are still ignorant of the cause of bursitis. Injury and overstrain and aging are about' the only "causes" they recognize.

"There is no cure, as yet," he says, but he states that there are several measures that can be utilized for relief of pain. Every time we read a medical treatise on any so-called disease, we run up against the same state of affairs. "There is no cure," but we can provide evanescent "relief." Medicine is a system of spectacular palliation. When asked if he thought that medical research will find "an answer to bursitis," Dr. Bunim stated that he is not sure that they will find an immediate answer, but "we certainly hope to learn more about the process which results in bursitis from a greater knowledge of the chemistry and metabolism of connective tissue, because the basic trouble is degeneration of connective tissue." There seems to me to be a note of pessimism and doubt in that answer. There is also the fallacy that the "basic trouble" is the end point of the process. Tissue degeneration is not cause. It is effect—long-range effect.

Dr. Bunim says that "since we do not yet have means for eliminating the cause" they cannot *cure* bursitis. So they treat the local area with X rays, with surgery, apply heat, administer aspirin or other analgesic (pain killer or patient-killer, depending on the point of view), but they cannot provide more than temporary relief by such measures. There is a lot of guess work, as he frankly admits, connected with the physician's care of the patient with bursitis and they guess about how the "relief" they afford is accomplished. He is sure that the steroids (probably ACTH and cortisone) that have been recently employed in the treatment of arthritis may be used in bursitis, but they are not to be given orally. They must be injected at the site of the inflammation. If they are no more successful in bursitis than in arthritis, one can only wonder why they should be used.

When asked: "Is there research aimed at developing drugs specifically for bursitis?" he replied: "There is. Research for new drugs is continuing all the time in hopes of finding a drug which would be as effective or as potent an agent as the steroids which are now in use, but would have less toxic effects or would not have the potential hazards and the undesirable side effects that the current steroids have."

That about sums it up. They are searching for a drug. The medical mind can think only in terms of drugs. They must have a drug; they hope to find one that will be effective as a means of "relief" or *cure* and will not have side effects, will not be poisonous. They are forever engaged in searching for that which does not exist. Whether it is bursitis, arthritis, the common cold, pneumonia or any other so-called disease, they are searching for a drug. For twenty-five hundred years they have been searching for drug;. They have found and used hundreds of thousands of thorn. They have all proved to be toxic. They have been hazards. They have all produced undesirable side effects. But they have never lost hope. They are still searching for a poison that is not a poison.

The remedy for bursitis is so simple that a child may apply it with far greater success than the learned medical profession and all of its "top-notch authorities" now apply their doubtful means of palliation. When once it is learned that toxemia is the basic cause of tissue inflammation, that injuries heal quickly in the nontoxemic, that recovery from overexertion is rapid when the individual is not toxic, that fatigue is speedily recovered from by the man or woman of pure blood, and that no inflammatory condition lasts beyond the removal of its cause, it will be readily seen that the remedy for bursitis is the simple one of detoxification. Rest of the injured and inflamed part is essential; often rest of the whole body is important. Certainly, if one is suffering from fatigue, the only means of recuperation is rest. If one has overexerted a part, it needs rest. If there is inflammation in a part of the body, it should be set at rest. This is often all that is required for recovery from slight cases of bursitis. A fast will be needed in the more severe cases. If the pain is great, heat to the painful area will provide relief. No drugs should ever be employed for relief of pain.

Bursitis develops in the toxemic; it does not evolve in the man of pure blood. An injury will result in inflammation in both the toxemic and the nontoxemic, but in the nontoxemic healing is rapid; in the toxemic it is slow and often drawn out. Indeed, if the toxemia is not eliminated, it may not occur at all. Bunim says that the physician knows that sooner or later the bursitis will come to a natural termination, that it is a self-limited condition. This simply means that recovery is spontaneous and that the treatments of the physician have no office in producing the recovery, What he fails to say is that the meddling of the physician-often prolongs the trouble for weeks and months. All systems of cure ride to glory on the self-healing powers of the body, which is all that is inferred in the statement that a *disease* is self-limited.

Bunim discusses calcium deposits in bursitis and also abscess formation in some cases. He also describes adhesions and more or less permanent limitation of movement of the joint. None of this need occur even in the most severe cases if fasting is immediately instituted. If the fast is resorted to at a later date, this is to say, after calcium deposits have occurred, the fast will result in the absorption and removal of the calcium. Bunim teaches at Johns Hopkins and Georgetown Universities, is on the staff of the Walter Reed Hospital, edits the *Bulletin on Rheumatic Diseases*, "pioneered" the use of synthetic cortisone-like drugs, is clinical director of the Government's National Institute of Arthritis and Metabolic Diseases, "where he directs research and evaluates treatments in arthritis," but he has not and he will not evaluate any common sense methods of care of arthritis or bursitis. He is wedded to drugs and is incapable of conceiving of any care that does not involve poisoning the patient. He will not do any research into the subject of fasting and he will not evaluate it. Intelligent readers will not be misled by his self-imposed blindness.

### 1. Introduction

The word diabetes is from the Greek word meaning to siphon and refers to the marked loss of water by urination, polyuria. The word mellitus is derived from the Latin word for sweet and thus diabetes mellitus—sweet urine disease.

Diabetes mellitus ranks among the leading factors of death in the United States. It is estimated that approximately 10 million Americans have diabetes. It is regarded as a metabolic disease of unknown

cause resulting from a deficiency of the pancreatic hormone insulin and an irregularity in the release of glucagon, a polypeptide hormone, and other hormones.

When you become enervated due to unhealthful living habits, a state of toxicosis develops. This situation will result in a lowered function of all cells and organs of the body. Certain tissues or organs may be more noticeably affected than others if they are inherently weaker, but the fact still remains that the entire system is affected.

Diabetes is a symptom of toxicosis. Often, the sufferer of this "disease" has been consuming large amounts of refined sweets such as cakes, pies, ice cream, candies, pastries, refined wheat products, etc. Under these conditions, the pancreas is continually stressed to secrete its hormone in order to eliminate the excess glucose from the blood. This results in enervation of the gland and exhaustion leads to decreased insulin output. The fact still remains that all organs are involved and this is seen in the many other symptoms manifested by the diabetic such as arteriosclerosis, blindness, etc. One problem with refined sugar is that it goes immediately into the blood without digestion. This flood of sugar is very enervating to the pancreas.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 2. History

## **2. History**

Diabetes mellitus was first described in an ancient Egyptian papyrus dating from the second millennium B.C. An Egyptian priest had observed that the urine of people afflicted by a disease of weight loss and excessive urination attracted insects, particularly bees and ants. Over the centuries, various other authors described a similar phenomenon without completely characterizing the disease or naming it.

It was the Greeks who characterized the excessive urination and the siphoning effect, or "the melting of the body through the loins" (weight loss and polyuria). A few centuries later, the Romans added the name mellitus, presumably because some enterprising physician gave the urine the taste test, discovering for sure its sugar content.

There were few developments that advanced our understanding of diabetes over the next millennium and a half. In more modern times, various diets were tried, some of them quite horrible. The rancid fat diet, popular in France in the 18th and 19th centuries, is one such example.

Scientific progress in our knowledge of diabetes began in the 18th century with the development of the microscope and Langerhan's description of the beta cell containing islets in the pancreas. Subsequent pathologists such as Virchow (1821-1902) and others then described the lesions of the pancreas, leading Minkowsky (1858-1931) to hypothesize that the pancreas was somehow involved in diabetes. Minkowsky then performed pancreatectomy in animals and produced diabetes. This experiment led to the speculation that the pancreas continued an internal secretion whose deficiency was responsible for the disease. Many experienced investigators searched in vain for the internal secretion of the pancreas. All efforts were thwarted because the enzymes of the exocrine pancreas digested the beta cells.

In the summer of 1921, Dr. Fredrick Banting devised a way of ridding the body of the exocrine pancreas while preserving functioning beta cells. Charles Best, a young graduate student working with Dr. Banting that summer, developed the alcohol techniques for extracting the hormone from the remaining pancreatic tissue and for measuring blood glucose. In August 1921, after several failures, an extract of pancreas produced a dramatic drop in blood glucose in a diabetic dog, thus the internal secretion of the pancreas had been isolated.

### 3. Classification

The National Diabetes Data Group from the National Institutes of Health distinguishes five subclasses of diabetes mellitus:

1. *Insulin-dependent diabetes mellitus or Type I*

Persons with this type of diabetes are supposed to be more prone to ketosis. This type is associated with an incompatibility of certain antigens with islet cell antibodies

This is the usual medical approach and is based on an erroneous "immunity" theory. Diabetes (like all other "diseases") is developed over a certain period of time due to unhealthful habits resulting in enervation and toxicosis. We cannot create "immunity" from the effects of eating wrong foods or procuring insufficient sleep. Ketosis is a symptom of general bodily enervation and toxicosis.

2. *Noninsulin-dependent diabetes mellitus or Type II*

This is a type of diabetes that is said not to be associated with ketosis or any other disease. However, people are not suddenly stricken down by diabetes. It is not an affliction that involves only the pancreas and no other tissues, glands or organs. An individual who is ill and shows symptoms of diabetes has a systemic toxicosis but the major sign of this toxicosis has demonstrated itself outwardly in the malfunction of the pancreas. In these cases, the pancreas is still secreting insulin but not in normal amounts. Physicians, therefore, do not necessarily prescribe insulin but usually control the diabetes through specially devised diets or with oral drugs. In so doing, they are still not removing the cause for the diabetes. (More about diet later.)

3. *Diabetes associated with certain conditions and symptoms such as pancreatic disease, changes in other hormones besides insulin, the administration of various drugs and chemical agents, insulin receptor abnormalities, genetic syndromes, and malnourished populations.*

In this type of diabetes, other symptoms of toxicosis are recognized. It becomes especially clear that many bodily functions are also deranged when severe symptoms of diabetes are diagnosed. The body is a unit and works as a unit. If one organ is deranged, all are more or less functionally below par. The body will heal once the cause for toxic accumulation has been removed. In other words, if the cause of enervation and toxicosis is removed and the body is given a rest, healing will commence.

4. *Gastrointestinal diabetes, where glucose intolerance develops or is discovered during pregnancy and disappears afterwards.*

This is not a common type of diabetes. During pregnancy, the body makes a number of adaptations. More research should be done in this area but it may be incorrect to diagnose diabetes in this incidence.

5. *Impaired glucose tolerance is present when individuals have plasma glucose levels intermediate between normal and those considered diabetic.*

Blood glucose levels fluctuate and many factors may affect the outcome of glucose tolerance tests. A stressful situation may elevate blood glucose levels, plus diet, exercise and a number of other factors even though a person fasted 10 to 16 hours before the tests. Just because a person's glucose levels are a little higher than normal does not necessarily mean that his insulin secretions are not normal.

## 4. Derangement Of Function

There are several major areas where functional derangement is especially evident in diabetes.

### 4.1 Hyperglycemia

A partial or absolute lack of insulin secretion results in excess glucose in the blood. Glucose is the primary fuel for all body tissues. The brain utilizes 25% of the total body glucose. Because brain energy stores are very small, a constant supply of glucose must always be available to maintain adequate brain function. It is, therefore, imperative that the blood glucose level be maintained in the 60 to 120 mg/dl (deciliter) range to prevent central nervous system impairment. The body has special homeostatic devices to maintain this required range.

#### 4.1.1 Insulin

Insulin is the primary hormone for regulating blood glucose levels and does so by controlling the rate that blood glucose is taken in by muscle, fat and liver cells. Each of these three types of cells utilizes glucose in a different way, as determined by specific enzyme systems.

##### Fat Cell

The primary function of the fat cell is providing storage. It contains unique enzymes that convert glucose into triglycerides as well as enzymes that convert triglycerides to fatty acids. These fatty acids are released and converted to ketones in the liver, when needed.

The conversion of glucose to triglycerides and the breakdown of triglycerides to free fatty acids take place continuously and simultaneously within the same fat cell, and both processes are regulated by insulin. High blood insulin levels stimulate the uptake of glucose by fat cells to form triglycerides; thus there is a net gain of storage fat. During low blood insulin levels, glucose uptake into the fat cell is poor; thus less triglyceride is formed. Triglyceride breakdown then exceeds formation, resulting in a net loss of the storage fat. Thus, by regulating glucose uptake into fat cells, insulin can influence net fat metabolism.

Insulin also inhibits the enzyme lipase, which breaks down storage fat into fatty acids and glycerol. When insulin is high and lipase is inhibited, there is also a net increase in storage fat. There is a net decrease in storage fat when insulin is low, because lipase becomes activated and a fat is then broken down.

##### Muscle Cell

The muscle cell has two primary functions: it converts glucose into energy needed for muscle function, and it serves as a reservoir for protein and glycogen. During starvation, the protein of the muscle itself can be made available in the form of amino acids. These amino acids can then be converted in the liver into glucose in order to maintain blood glucose at an adequate concentration for brain function.

In the muscle cell, as in the fat cell, insulin promotes the uptake of glucose. The muscle cell, however, has different enzymes that control two metabolic pathways for glucose. First, glucose can be converted into "contractile energy." Second, glucose can be converted to glycogen, a storage form of glucose that is more readily available than triglycerides in times of glucose insufficiency.

When blood glucose levels are normal, insulin also affects the enzymes of the muscle cell to maintain muscle mass by promoting the uptake of amino acids and preventing the breakdown of protein.

##### Liver Cell

Liver glycogen is another storage form of glucose. Glycogen is more readily available for use than are

triglycerides, which first have to be converted to free fatty acids and then converted to ketones. The liver monitors these conversions and also converts amino acids to glucose when necessary. The conversion of amino acids to glucose is called gluconeogenesis.

Although insulin is not required for the transport of glucose into the liver, insulin directly affects the liver to promote the uptake of glucose by reducing the rate of glycogen breakdown, increasing glycogen synthesis, and decreasing the rate of gluconeogenesis.

#### **4.1.2 Beta Cell**

Insulin is secreted by the beta cells of the pancreas. The beta cells function first as a sensor of blood glucose levels. The beta cells then secrete enough insulin to regulate the carbohydrate load, maintaining the blood glucose level within a very narrow range. A feedback system exists whereby a small amount of carbohydrate stimulates a small amount of insulin release. The liver responds to increased insulin secretion by suppressing glycogen release (glycogenolysis). The formation of new glucose is likewise suppressed. A large carbohydrate intake stimulates a greater insulin response, and the peripheral and liver cells take up glucose. When glucose levels are low, insulin release is suppressed and glycogenolysis and gluconeogenesis occur in order to feed glucose into the system and maintain the blood glucose levels.

When the body is enervated and a state of toxicosis exists, all bodily functions will be impaired. This may effect the pancreas and its secretion of insulin. When insulin secretion is abnormally diminished, glucose will not be utilized by the fat and muscle cells and the liver will continue to break down glycogen to glucose to further add to the blood glucose levels. Hyperglycemia is then present.

Other hormones contribute to the release of glucose in the blood and further complicate the situation when insulin secretion is diminished. Stress stimulates epinephrine release and the hormone then serves to mobilize glycogen to yield a higher blood glucose level. Epinephrine also suppresses insulin release to further enhance blood glucose levels. Glucagon and cortisol also increase levels of blood glucose.

## **4.2 Large Vessel Disease**

Diabetics have an increased incidence, earlier onset and increased severity of atherosclerosis and calcification of the arterial wall. Peripheral vascular disease is 50 to 100 times more common in diabetics than in healthy individuals. More fat is broken down when insulin is low and enters the bloodstream. Excess fat in the blood may then accumulate in the large vessels of the heart or elsewhere.

It is likely, however, that there is already some arteriosclerosis in diabetic patients, not because of the diabetes, but it is due to the same conditions that resulted in the diabetes in the first place. That is, a diet too high in fats and sugars, lack of exercise, and a generally unhealthful lifestyle.

## **4.3 Microvascular Disease**

Many diabetics demonstrate a thickening of the capillary membrane in major areas of skin and skeletal muscles. This is most obvious in the retina of the eye and the renal glomeruli of the kidney and this situation may eventually lead to blindness or kidney failure. It becomes clear that diabetes is not a "one-organ disease" but does indeed involve the entire system. Suppressing one symptom, such as hyperglycemia, certainly does not produce health.

## **4.4 Neuropathy**

Neuropathy involves injury to nerves, associated with destruction of the myelin sheath of nerve tissue and nerve cell degeneration. This involves sensory and motor nerves, nerve roots, the spinal cord, and the autonomic nervous system. Affected nerves show basal membrane thickening similar to the capillary

abnormalities.

Did the diabetes cause this nerve degeneration? No, diabetes is merely a symptom of a systemic disorder. Again, this "disease" that is associated with diabetes is another indication of systemic involvement.

## 4.5 Ketoacidosis

The fat cell attempts to provide fuel in the absence of insulin by mobilizing fat stores. The free fatty acids are initially utilized for energy production, but the majority reach the liver where three strong acids are found: acetoacetic acid, beta-hydroxybutyric acid and acetone. The keto-acids are ultimately excreted by the kidneys along with sodium bicarbonate. The combination ketoacid accumulation and bicarbonate excretion causes a fall in plasma pH, resulting in acidosis.

A diet high in acid-forming foods further complicates this problem. This would include such foods as meat, dairy products, dry beans, most cereals (especially wheat) and all refined sugars.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 5. Symptoms

## 5. Symptoms

Early symptoms are polyuria (excessive elimination of urine), polydipsia (excessive drinking of water), polyphagia (excessive eating), loss of weight and a lack of energy. The extremely high extracellular osmotic pressure, caused by the excessive amount of sugar in the bloodstream, causes dehydration of the body cells. As the sugar is then eliminated by the kidneys, it carries water with it, thereby dehydrating the bloodstream and other extracellular fluids. Both the extracellular and intracellular dehydration cause excessive thirst and water drinking.

Since the diabetic cannot store glucose or glycogen, nor use it for fuel and energy, he has a tendency to lose weight. He is lacking in energy, despite the inordinate eating. The lack of energy may also be due to the fact that muscles respond better when using carbohydrate for energy than when using fat, which the diabetic must do. It is thought that the loss of proteins from muscles also causes part of the energy lack. Much of the energy lack is also due directly to the lack of insulin, for it is necessary for regulation of the oxidative reactions in the cell.

In children the classical symptoms may come on very quickly, as if the disease develops overnight. Of course, we know that it doesn't. In most cases, even in children, there is a slow development of the symptoms, lasting months or years. It takes a period of unhealthful living to accumulate the toxins that result in these symptoms. Sugar may be present in the urine occasionally or even continuously for years and never produce symptoms enough to cause alarm. In so-called latent diabetes, there is usually a slight hyperglycemia, discoverable only by special tests.

Other early symptoms are generalized itching, or itching of the female genital organs, boils, carbuncles, eczema, sometimes steatorrhea due to inflammation of the pancreas, and neutritis. Retinitis, acidosis, coma and gangrene are symptoms that usually belong to the later stages of the disease, but occasionally the disease is not realized until these dire consequences arise. Symptoms and clinical manifestations occurring that arise from a condition of acidosis are air hunger, coma, ketone bodies in the urine and lipemia.

Diabetes is thought to be hereditary. If any disease were truly hereditary, it would manifest itself early. If not, and it takes years to develop it, then we must assume that something else must be responsible for its development. You may inherit a tendency to diabetes, but whether or not you develop it depends upon

your mode of living.

Most cases of diabetes occur in people over 40. It often takes many years of unhealthful living to develop the conditions for diabetes to exist. It takes a lot of abuse to bodily organs and systems to result in the degeneration of the pancreas and other organs intimately involved in this abnormal condition. There are no "miracle cures" that will eliminate all those years of abuse. However, if all of these errors are corrected, the body will heal as long as there is not permanent damage. At any rate, a change to a more healthful lifestyle will result in better, if not perfect, health.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 6. Medical Diagnosis

## 6. Medical Diagnosis

The physician has several diagnostic methods for diabetes and none are foolproof. The most widely-used methods are the serum blood glucose test and the urine test. The presence of glucose in the urine indicates that the body is attempting to maintain balance. When glucose levels reach a certain point in the blood, excess will be eliminated by the body through the urine. This is a bodily mechanism to keep itself in a stable condition and is a positive sign of self repair. However, this homeostatic mechanism can be exhausted if causes are not removed.

Testing of the urine for levels of glucose is one of the most common but least effective methods of screening for diabetes. The urine test will be positive for glucose only after the blood glucose values have become sufficiently elevated to allow glucose to spill into the urine, usually a blood glucose value of 180 mg/dl or more. Thus the urine test will be positive in advanced states of disease. However, there is also the possibility of obtaining a *false* positive indication. If an individual has recently eaten a breakfast of sugar-coated cereal, this would be enough sugar to cause a false positive test. A false negative can also result and does not outrule diabetes.

The fasting blood glucose test is probably the most frequently-used laboratory test for diabetes. It is still not totally reliable. A patient is given a sugar-type drink after fasting 10 to 16 hours and his blood is tested after 1, 1 1/2, 2 and 3 hours. If the glucose level rises and remains high, diabetes is suspected.

There are other tests utilized but they are meaningless here. Diabetes or any disease cannot be corrected by suppressing one symptom. The total person must be considered since the total organism is involved. Insulin will get rid of the glucose in the blood but it does not correct the condition and does not remove the underlying cause (toxicosis).

Diagnosis is a useful tool if diabetes is detected early and the person becomes aware of the results of his wrongdoing, and can then remove the need for disease and regain health without using insulin or any other drugs. The diabetic can then completely regain health. If nothing is done and the unhealthful lifestyle is persisted in, diabetes may progress and ketoacidosis may result. The possibility of ketoacidosis is suggested by

1. confusion or coma, the person becoming extremely ill with changes in sensory mechanisms;
2. air hunger (this is an attempt to compensate for metabolic acidosis through rapid breathing in order to eliminate as much carbon dioxide as possible to increase alkalinity);
3. fruity acetone odor on the breath (acetone is produced in excess in diabetics when the fats are not properly oxidized, due to inability to oxidize glucose in the blood);
4. nausea and vomiting;
5. abdominal tenderness;
6. extreme thirst and dry mucous membranes, reflecting water depletion due to loss of sodium and

potassium as the body tries to buffer the acid condition with these base minerals;  
7. weight loss.

Do the above symptoms indicate anything other than systemic involvement? No. Then we should consider the body as a whole and not as separate units.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 7. Medical Treatment Of Diabetes Mellitus

## 7. Medical Treatment Of Diabetes Mellitus

According to the *Merck Manual*, "The primary objective is to achieve the patient's optimal health and nutrition." If this truly were their primary objective, physicians would discontinue looking to drugs for palliatives and begin to search for the underlying cause behind this "disease." If they were to discover that depressed function of the pancreas of insulin secretion is really only a symptom of general toxicosis, they would begin to teach their patients how to live so as not to create these conditions that result in ill health.

*Merck Manual* further states, "Whether treatment of asymptomatic hyperglycemia decreases morbidity and mortality is unknown, and there is significant risk of hypoglycemia in elderly patients given oral hypoglycemic agents or insulin therapy." It is known that drugs and insulin can harm and whether they do any good is questioned even by the physician. People with improperly-diagnosed diabetes have been placed on insulin. Because of the presence of this insulin in the blood, the pancreas ceased to secrete normal insulin, atrophied and eventually ceased to work even when needed. Thus, diabetes was *created* where it was not formerly present.

Scientists have come up with a new form of insulin that is supposed to simulate functions of the pancreas in that it supplies insulin constantly at low doses. It is called an insulin pump and is worn on the belt. It constantly infuses a low dose of rapid-acting insulin subcutaneously or intravenously with additional boluses of insulin pumped in immediately prior to meals.

It is hoped that these attempts to emulate normal pancreatic function may be associated with a clearly demonstrable improvement in the morbidity and mortality from the vascular and neural manifestations of diabetes. However, this cannot be possible with this approach. The physicians are looking at the situation too narrowly. The entire person must be considered and not only the pancreas. Palliating one symptom of ill health does not procure overall health.

According to the physician, the objectives of symptom control are twofold: (1) to avoid ketoacidosis, and (2) to control symptoms resulting from hyperglycemia and glucosuria. Symptom control involves constant monitoring of urine glucose levels and plasma glucose levels by laboratory determination. As stated, symptom control does not procure health.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 8. Effects Of Insulin

## 8. Effects Of Insulin

There are seven forms of insulin currently in use and they are grouped into three classifications

according to their duration of action. They are fast-, intermediate-, and long-acting. Most insulin is made from beef or beef/pork pancreas. Some is now being made from only pork. All of these insulins contain pancreatic impurities including glucagon, somatostatin, pancreatic polypeptide, and proinsulin. Experiments with purer strains are now being tested since many patients have had adverse reactions from the impure type of insulin. The body rejects what is not normal and foreign protein injected into an organism is treated as a poison and eliminated as quickly as possible. Other complications may arise from insulin treatment.

Insulin shock (hypoglycemia) may occur if too much insulin is taken. Local reactions to insulin injections, often occurring during the first few weeks of insulin therapy, most commonly consist of stinging or itching at the injection site followed by heat, induration, erythema, and an urticarial reaction. Systemic reactions may include hives, urticaria, cardiopulmonary or gastrointestinal symptoms, and rarely, anaphylactic reactions. In this case, higher doses of insulin are given or more purified types are given.

All of these symptoms are indications of a bodily response to unwanted agents outside of the normal constituents. Concerning this palliation, Dr. Vetrano writes, "Medical treatment for diabetes is insulin. Symptoms only are treated with no effort to eliminate the cause. This does not help the patient to regain health. On the contrary, besides the side effects of foreign protein, it perpetuates the disease. If normal functioning cells were left before beginning insulin treatment, these soon atrophy from lack of function. The diabetic of today may live longer than diabetics of the past; but nothing constructive has been done to eliminate toxemia, so he is doomed to live the life of a vampire, because the death of other animals is necessary for his life. The toxemia which caused his first disease is not eliminated and he lives only to suffer from the effects of his drugs and toxemia."

It has been said that the rise in the death rate in diabetes is "in spite of insulin." Dr. Shelton says that it is because of insulin. He states that insulin is, both directly and indirectly, the cause of a large part of an increased death rate and is a big factor in preventing thousands of diabetics from recovering.

It has been proven that insulin does not "cure" diabetes and that it does not even improve the condition. According to Dr. Shelton, insulin is presented to us as a crutch. He explains that insulin is something the diabetic can lean upon and it will enable him to "live a normal life" in spite of diabetes but it is still employed as a crutch. But by "living a normal life" is meant eating and drinking and living in a conventional manner—in the manner that produced the diabetes and other troubles in the first place. The employment of a crutch always leads to ignoring causes. The use of insulin encourages patients to continue doing things that are known to make diabetes worse. If more enervation, or added toxemia, or continued overeating results in an increase of symptoms, the physician quickly sets matters right by increasing the dose of insulin.

Insulin reduces the sugar in the urine and blood but it has no effect on the causes of diabetes. While it aids in controlling one symptom, it constitutes an added cause.

Dr. Shelton says, "Insulin is a powerful drug. A slight overdose causes a light insulin shock; a little more produces coma; a little more results in death. The continued use of this drug produces damage of its own, not the least of which is the added impairment of the function of the pancreas."

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 9. Oral Hypoglycemic Agents

## **9. Oral Hypoglycemic Agents**

Often, oral medication is given to diabetics instead of insulin to control the symptoms. It is said that

some sulfonylureas lower the blood glucose levels when given orally. These include tolbutamide, chloropropamide, acetohexamide and tolazamide. The University Group Diabetes Program attempted to evaluate various types of therapy, in noninsulin-dependent diabetic patients, comparing tolbutamide or phenformin treatment with diet alone. They concluded that these two drugs were no more effective in controlling diabetes than diet alone.

There has been some evidence that the use of these drugs increases cardiovascular mortality but this has not been proven conclusively and more research needs to be done. However, acute toxic effects have been known to follow the use of these oral hypoglycemic agents. There is no doubt that these agents are poisons and should not be employed.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 10. The Diabetic Diet

## **10. The Diabetic Diet**

The conventional diabetic diet is calculated in terms of the total requirement for calories and a ratio of these calories in grams of carbohydrates, proteins and fats.

### **10.1 Calories**

Calorie specifications are based on "ideal weight," with allowances for physical activity or added stress, such as growth. If the patient is obese, as many adult diabetics are, then the diet prescription would indicate a sufficient reduction in calories to effect a gradual weight loss—no more than 1,200 to 1,500 calories per day. If the patient is a fast-growing, lean, adolescent boy, the calories may be as high as 4,000.

Weight will normalize on a diet that is compatible with our biological requirements. That is a diet of raw fruits, vegetables, nuts and seeds. "Ideal weight" charts are invariably too high and not accurate guides. Calculating diets based on preconceived numbers of calories per day is tedious and unnecessary. Furthermore, few diabetics will adhere to such a diet.

### **10.2 Protein**

It is generally recommended that 5% of total calories of the diabetic be protein. In a 1,500-calorie diet that would mean 75 grams of protein. This amount of protein greatly exceeds the needs of even the most active man. The average person cannot utilize more than about 20 to 25 grams of protein daily.

Any protein in excess of this is either stored in fat or muscle or eliminated from the body. This is an expenditure of vital energy that should be used for healing and repair—a situation that will result in enervation. Such excess protein accumulated in the tissues eventually results in impaired function. The body periodically makes great efforts to eliminate these excesses through such eliminative endeavors as colds, flu, skin eruptions, etc. If the body is greatly enervated, such vital eliminations may not occur and degenerative diseases will begin to develop.

Every item of food that we eat has some protein when it is consumed in its natural state. Even fruits and vegetables contain some protein. In fact, it is in this form that protein is most easily utilized and requires the least amount of vital energy to digest and assimilate. Also, we do not clog our system with excess toxins as we do when we consume the protein of flesh, dairy products or eggs. It is important that the diabetic consume foods that require little vital energy to digest and also contain little or no toxins. Energy is needed for healing and further toxins will impair this process.

### **10.3 Carbohydrate**

There is less emphasis now upon strict carbohydrate control than in past years for the diabetic. As a general rule, the carbohydrate grams recommended are 10% of the total number of calories. Refined carbohydrates certainly should never be consumed such as cookies, pies, cakes, candy, etc. However, the simple carbohydrates as found in ripe fruits and vegetables should form the bulk of the diet. The carbohydrates of fruits are easily assimilated and also contain many of the base minerals that are so important in the diabetic's (and in everyone's) diet. You can be assured that all your needs will be met.

### **10.4 Fat**

As a general rule, the grams of fat in the diabetic diet are recommended to be 5% of the number of total calories. (In a 1,500-calorie diet, there would be 75 grams of fat.) This is entirely too high. You cannot utilize that amount of fat and the excess adds to toxicosis. All the fat that you require is found in nuts and avocados. If these items are eaten moderately a few times a week, your fat requirements will be met. Remember that your fruits and vegetables also contain small amounts of fat.

While it may be necessary to continue insulin therapy to a certain extent, a diet of fruits, vegetables, nuts and seeds will provide the body with the proper conditions to heal and repair. The pancreas will no longer be stressed with large amounts of glucose in the blood due to refined sugars in the diet and healing will take place.

### **10.5 Food Exchange Groups**

The conventional program for diabetic diets utilizes a food-exchange system where foods of like proteins, fats and carbohydrates are grouped together. The patient is assigned a certain number of units that he may have per day from each group and he may exchange them for certain foods within that group. This is a tedious procedure that is slowly being abandoned even by the physicians and most dietitians. It is unnecessary if the general dietary program is correct. As stated earlier, a diet of ripe fruits, vegetables, nuts and seeds, all in a raw state, provides us with all our dietary requirements without excesses or deficits.

### **10.6 "Anything Goes Diet"**

Another approach that is now being taken is to let the diabetic eat anything that he wants. Sometimes refined sugar is eliminated but not always. S/he is then closely monitored and insulin doses adjusted accordingly, as needed. This is certainly unwise and cannot produce health. People need to be educated in regard to the proper diet and not let them grope on their own. If a person stays on his conventional meat, potatoes, bread and sweets diet, more ill health will result. Causes must be removed in order to regain health and an improper diet is a major cause of diabetes and other chronic disorders. That is, the toxicosis that resulted from the improper diet.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 11. Why You Have Diabetes

## **11. Why You Have Diabetes**

It is your total way of living that causes you to develop diabetes—your excesses, deficiencies and poison habits. Excesses include: overeating, overworking, wrong emotions, worry, anxiety, tension, etc. Deficiencies are: lack of sleep, lack of rest, lack of exercise, demineralized foods, lack of fresh air, lack

of sunshine, and lack of emotional poise. Finally, by your poisonous habits, you add to the total toxic load of the body. You poison your body with alcohol, coffee, tea, soft drinks, cigarettes, poisoned articles passing for food, the many drugs thrown into your system daily to suppress the discomforts arising from a way of life that is destructive to health. The real cause of diabetes came before the deficiency of insulin.

Dr. Vetrano says that most writers on the subject think that there is a definite link between diabetes and civilization. In more primitive atmosphere it would naturally follow that there would be fewer cases of all varieties of diseases, including diabetes. In primitive conditions food is more natural, working hours fewer, more sleep and rest can be obtained, air and water are purer, there is less tension and worry, and the way of life more simple in general. More sunshine and exercise are incorporated into each day. Primitive living is more healthful, hence, fewer diseases develop.

Dr. Shelton says, "Diet and drink, sleep, work and play, and many other factors enter the cause of every so-called disease. Any form of overstimulation—mental, emotional, sensory, physical, chemical, thermal, electrical—may give rise, first to functional, and, finally, to organic disease. Diabetes is a functional disturbance at its beginning."

Diabetes is more prevalent in those countries where sugar consumption is highest—United States, France, Germany and Great Britain. Every fat person is a potential diabetic. Overeating results in overwork of the pancreas and as overwork of any organ results in impairment of the function of the organ, pancreatic failure results. If its causes are not corrected, functional impairment gradually passes into organic disease.

Carbohydrate excess (in refined form) places a strong stress on the pancreas and when this gland is overworked by too great an intake of starches and sugars, there will be first, irritation and inflammation, then enlargement, followed by degeneration. The body then loses control of sugar metabolism.

However, overeating of refined carbohydrates is not the sole contributor to pancreas impairment. Anything that produces enervation—tobacco, tea, coffee, chocolate, cocoa, alcohol, cola, loss of sleep, overwork, general overeating, emotionalism, etc., impairs organic function in general, including pancreatic function.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 12. How You Can Improve Your Overall Health

## **12. How You Can Improve Your Overall Health**

Many people think that once they are diagnosed as a diabetic they are doomed to a life of dependency upon drugs, and forced into a life of suffering from the general toxic effects of those drugs. However, this is not the case. The adoption of a healthier way of life would permit them to live to a ripe old age without drugs and their poisons. But the choice rests with the individual.

A fast is important to allow the body to rid itself of toxins. If you have been on insulin for more than two years, however, great care must be taken. The insulin dosage must be cut down very gradually. If there is a complete degeneration of the islets of Langerhans, you may be compelled to take minute doses of insulin for the rest of your life, but living healthier will keep you in better condition than the average diabetic. You will be able to escape the degenerative diseases that usually complicate diabetes.

Dr. Vetrano states, "For those who still have good functioning tissue, health can be regained and maintained. It is amazing what the human organism can do for itself in the way of rejuvenation of sick cells when poisoning is discontinued and toxemia is eliminated and a plan of care is instituted that

provides the body with the primordial requisites of life."

Dr. Shelton explains that once a person has become enervated, recovery of nerve energy needed for healing requires conservation of energy and removal of all enervating influences. He further says that improper eating is undoubtedly an important factor in the causation of diabetes, but most diabetics have many other unhealthful habits besides wrong eating, and all these habits must be corrected.

For those who cannot fast, recovery is still possible. While fasting is of great value in diabetes, it is more important that the diabetic learn how to live, learn what foods he can take, learn his limitations and learn to live within these, and that he fast. Recovery can occur only after cause has been removed and fasting is but one part of the process of removing cause.

The diet of the diabetic should be the same as for a healthy person. That is, raw ripe fruits, vegetables, nuts and seeds. At first, it may be necessary to eliminate dried fruits and some of the sweeter fresh fruits until a higher degree of health is achieved. On this diet, physiological functions will normalize and health will be restored as long as there is not any permanent destruction of tissues. In any case, a much healthier overall condition will be attained.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 1. Introduction

## **1. Introduction**

Diabetes insipidus is much less common than diabetes mellitus. It is a disorder where there is either a deficiency of vasopressin (ADH) or an insensitivity of the kidney tubules to the presence of this hormone.

The hypothalamic nuclei of the pituitary gland secretes the antidiuretic hormone. This hormone acts mainly in the distal-collecting tubules of the kidney and stimulates the reabsorption of water according to bodily need. Onset of this "disease" is said to be insidious or abrupt and may occur at any age. However, we know that no disease occurs abruptly but it develops only after a period of time due to unhealthful practices.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 2. Symptoms

## **2. Symptoms**

Enormous quantities of fluid may be ingested and excreted (3 to 30 liters per day). Urination is especially excessive during the night. Dehydration develops rapidly if urinary losses are not continually replaced.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 3. Medical Treatment

### **3. Medical Treatment**

The usual treatment is hormonal therapy. ADH is administered either via a nasal spray or intramuscular injection. Nonhormonal therapy involves the use of certain diuretic drugs. This palliative treatment cannot result in health. It only treats the symptoms of this disease without considering causes. Other systemic disorders are present in this disease, such as chronic renal disorders and other systemic or metabolic impairment.

To treat one symptom is foolish. As in diabetes mellitus, the underlying cause of ill health must be corrected and only then will general health result.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 1. Introduction

#### **1. Introduction**

Hypoglycemia is abnormally low blood glucose level. This is a condition where the islets of Langerhans are too sensitive. In response to the metabolic demand, they secrete too much insulin. The liver converts too much sugar into starch, leaving too little in the circulating blood. The final result of eating a meal is a drop in blood sugar. The sufferer from this condition is always hungry and no amount of eating will keep the level of his blood sugar where it belongs.

Overindulgence in sweets tends to sensitize the islets of Langerhans by subjecting them to repeated stimulation and exercise. The body overcompensates, as it were, thus disorganizing and upsetting the internal hormone balance. Here then, is the connection between sugar and starch addiction and hyperinsulinism.

Another factor is the indulgence in any substance that contains caffeine. Caffeine (a drug found in many beverages like coffee, tea, coca cola and soft drinks, cocoa, chocolate, etc.) is a common cause of the upset of the delicate mechanism involved in sugar tolerance. Caffeine results in the stimulation of the adrenal cortex and more of its hormones are produced. These hormones, in turn, induce the liver to break down glycogen into glucose that flows into the bloodstream. The islets of Langerhans go to work to secrete insulin to force blood sugar to its normal levels.

In the course of time, because of their repeated stimulation, the islets become so sensitive, due to enervation, that the delicate control is lost and they overrespond to a normal stimulus.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 2. Other Factors

#### **2. Other Factors**

Other factors may produce hypoglycemia. An overdose of insulin by the diabetic patient often results in hypoglycemia. Depending on the amount, this can result in coma or even death. Certain oral hypoglycemic drugs such as the sulfonylureas often result in low blood sugar. Hypoglycemia can be induced by alcohol, salicylates (in aspirin, etc.), and other drugs such as aminobenzoic acid, haloperidol, propoxyphene and chlorpromazine.

Deficiency of contrainsulin hormones such as glucagon, cortisol, growth hormone, epinephrine or thyroid hormones can result in low blood sugar. In fact, any excess or deficit in any gland or organ may

have some effect. This is so because the body works as a unit and never as separate parts or units.

As in diabetes mellitus, not any one factor results in hypoglycemia but it is the total effect of our general lifestyle that affects our health. For example, our diet may be perfect but if our sleep is insufficient, all vital organs will be affected.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 3. General Symptoms

### 3. General Symptoms

Most physicians group the symptoms of hypoglycemia into two categories:

1. Faintness, weakness, tremulousness, palpitation, diaphoresis, hunger and nervousness, such as may result from epinephrine administration

Epinephrine is a hormone that has multiple effects to prepare the body for many different kinds of stress. Its effect on glucose is very rapid and can produce minute-to-minute changes in blood glucose levels. Stress stimulates epinephrine release, and the hormone then serves to mobilize glycogen to yield a higher blood glucose level. Epinephrine also suppresses insulin release to further enhance blood glucose levels. Acute hypoglycemia with epinephrine-like symptoms indicates that endogenous epinephrine-induced glycogen mobilization has already started.

2. A pattern of central nervous system symptoms including headache, confusion, visual disturbances, motor weakness, palsy, ataxia, and marked personal changes. These CNS disturbances may progress to loss of consciousness, convulsion and coma. With recurring episodes of hypoglycemia in the same patient, the symptoms may be repetitive, although the tempo and severity of an attack may vary

Symptoms of anxiety, including sweating, headaches, hunger, tachycardia, weakness, and occasionally seizures and coma may suggest hypoglycemia but not necessarily. At any rate, the underlying cause is the same and that is enervation leading to toxicosis and eventual impairment of all (not just one) bodily functions. The various symptoms demonstrate systemic involvement.

#### 3.1 Mind/Body Symptoms

If the blood sugar drops too low, the nervous system is in jeopardy. The brain relies on blood sugar for its functioning, and if it is deprived of it, it cannot continue. This is what happens when a diabetic gets an overdose of insulin. All the sugar enters the cells. There is none readily available for the brain, so the person lapses into a coma. Though such a drastic drop in blood sugar is not usually experienced by the hypoglycemic, the decrease is still interpreted as a danger signal, and the adrenal glands usually respond by secreting adrenalin. This helps mobilize stored glucose from the liver, but it also sets off a general alarm, alerting the whole body as for emergency action. One may feel apprehensive, tremulous and find that his/her heart is beating rapidly, his/her hands are becoming cold and clammy and s/he is breathing in a rapid and shallow way. How severe these symptoms are depends on how low the blood sugar drops and how drastically the adrenal glands respond.

It has been demonstrated that those who experience drastic dips in their blood sugar levels excrete more of the breakdown products of adrenalin in their urine. They are repeatedly responding as though to danger. The result can be an overall feeling similar to what we call "anxiety." It has been proposed that drops in blood sugar constitute a sort of "internal stress" and may create a great deal of wear and tear on the individual, both provoking mental problems, aggravating emotional crises, and increasing irritability and difficulty in working with others. Such chronic stress and the resulting chronic anxiety could be a

factor in the development of ulcers, headache or simply general enervation.

Though hypoglycemia may be one aspect of the development of any of a variety of disorders, it cannot itself be called the "cause" of anything. It is rather one symptom in a chain of events that may have begun with the improper selection of food, along with lack of rest or exercise, etc., and continues to worsen as these bad habits are continued.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 4. Medical Diagnosis

## **4. Medical Diagnosis**

The generally accepted method of diagnosis of this condition is the glucose tolerance test. This is usually carried out in the following manner. For three days, a high-carbohydrate diet is eaten. On the fourth day, the level of blood sugar is tested in a fasting state, and a drink containing a great amount of sugar is given. Then, on an hourly basis, blood samples are drawn and checked for sugar content. The test continues for five to six hours. Typically, in a hypoglycemic, the blood sugar level does not increase at the normal rate. The initial rise is followed by a steep fall to below-fasting levels.

In any person who is in an enervated condition, blood sugar levels may not rise to normal levels for a considerable time due to this enervation. It does not necessarily mean that the individual has hypoglycemia. It does indicate that the individual is in a generally poor state of health but a glucose tolerance test is really not needed to determine this.

In this case, diagnosis is really a useless tool. All the physician has to do is to instruct his patient how to live for total health and all symptoms of ill health will disappear when a healthier lifestyle is adhered to.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 5. Medical Treatment

## **5. Medical Treatment**

In acute or severe episodes of hypoglycemia with central nervous system symptoms, physicians usually recommend ingestion of oral glucose or sucrose. This relieves the symptoms by flooding the blood with glucose but it also stimulates the pancreas to secrete another dose of insulin and the blood sugar is reduced to even lower levels than before the glucose was ingested. No good is achieved by this treatment and the condition is only made worse.

Generally, the hypoglycemic patient is advised to adhere to a low-carbohydrate diet similar to that of the diabetic. Basically, this means eating from four to six small meals a day, each of them containing a generous amount of protein. Sugar in any form is completely forbidden. Besides no ice cream and cake, this means no processed foods of any kind to which sugar has been added. Coffee, tea and alcoholic beverages are also forbidden.

## 6. Concentrated Sugar

The body is really not set up to handle concentrated sugars. Although 'sugar' (not refined) is the fuel that runs our entire body, using concentrated forms of sugar found in pastries, pies, sugar-coated cereals, candy, etc., overloads the delicate control mechanism and the pancreas overreacts by producing too much insulin. There will then be a signal for food and too often a wrong choice is made when this need is acute. Thus a vicious circle is established with general effects upon our entire system and all the attendant symptoms resulting from it. Often, too little fruits and vegetables are used. Instead, the convenience-type foods take over a large percentage of the daily intake.

## 7. Conversion Mechanism

The sugar that the body cannot use as energy when it has been acted upon by insulin will be converted to glycogen, and is stored in the liver and muscles; or what cannot be stored as glycogen will be converted to fat.

In normal body function, there is a conversion mechanism that protects us against the rapid drop of blood sugar. The adrenal glands secrete a hormone (epinephrine) that begins the change process of glycogen back to glucose. This same response is brought into play when fear, anger or expenditure of energy requires lots of fuel, so glycogen from the liver and muscles is immediately turned into glucose.

If the glycogen conversion mechanism is not working well, the body has a backup mechanism. This consists of the conversion of amino acids and triglycerides into a fuel. Amino acids are capable of being converted to glucose but do so at the expense of tissue repair and making of enzymes, hormones and other essential processes which require amino acids. Since it is a kind of emergency assistance, you can easily imagine how the body suffers if this must take place on a continual basis.

Carbohydrates are converted to glucose in the gastrointestinal tract and absorbed into the bloodstream where they then pass on to the liver. If there is too much glucose, the liver will convert it to glycogen and store it until needed. When blood glucose levels drop, a hormone from the adrenals (epinephrine) facilitates the conversion back to glucose.

Many of these mechanisms are dependent upon hormones, and particularly upon adrenal hormones. Many physicians are convinced that the single most common cause of hypoglycemia is a poorly functioning adrenal system. However, we must also ask, "What caused the adrenal system to go amuck?" It is the same reason that caused the hypoglycemia and other symptoms. That is, general enervation and toxicosis. Underlying causes must be sought. You must stop treating symptoms and begin correcting the errors behind the symptoms.

## 8. Hormones That Maintain Balance

Several important hormones play significant roles in maintaining blood glucose balance:

1. *Cortisol (hydrocortisone) and cortisone*

Cortisol and cortisone belong to a class of steroid hormones synthesized in the cortex of the adrenal glands, known as glucocorticoids. They have a primary effect on carbohydrate, protein and lipid metabolism. They are in many ways antagonistic to insulin. They elevate blood glucose and increase production of glucose from protein.

2. *Adrenocorticotropin (ACTH)*

This Hormone is liberated by the anterior pituitary gland and stimulates the cortex of the adrenal glands. If too little of this hormone is secreted, the adrenal glands will secrete too little of their hormones and if ACTH is present in too large amounts, adrenal hormones will be secreted in too large amounts.

3. *Growth Hormone (Somatotropin)*

Growth hormone is the only hormone of the anterior pituitary gland that does not exert its effect on other endocrine glands. Growth hormone or somatotropin is a protein. It stimulates growth, increases protein synthesis, decreases carbohydrate utilization, and increases fat catabolism. Because somatotropin suppresses carbohydrate utilization, blood glucose increases, stimulating insulin secretion. Two factors from the hypothalamus control secretion: the growth hormone releasing factor and the growth hormone release inhibiting factor. During protein deficiency, growth hormone secretion increases as it does when the blood sugar level falls. Exercise increases secretion also.

4. *Epinephrine*

In times of stress, small amounts of epinephrine (adrenaline) are discharged from the adrenal glands into the bloodstream. Epinephrine ultimately causes the release of a flood of glucose molecules from the liver into the bloodstream for quick energy for the muscles. One epinephrine molecule is thought to cause the release of about 30,000 molecules of glucose.

5. *Thyroid Hormones*

Thyroxine and triiodothyronine are two chemically similar hormones secreted by the thyroid gland. Both have the same physiological effect on tissues. The most obvious effect they have is to increase the rate at which cells burn glucose. They also work in "partnership" with cortisol in defending the body against stress resulting from extreme cold. In general, thyroxine comes into play when there is an extra demand for energy.

As you can see, there is an intricate relationship between all bodily parts and the disfunction of one affects all. The more you study physiology, the more you realize the foolishness of treating symptoms. They are merely indications of systemic impairment.

## 9. Progression Of Hypoglycemia

A vicious cycle begins to emerge when repeated errors of diet are made. These errors do not always result in hypoglycemia, but they can. In some persons, severe symptoms will arise elsewhere.

However, in the person demonstrating symptoms of hypoglycemia, this is what happens:

A concentrated sugar-containing food is consumed. Blood sugar begins to rise rapidly. Because of the intense sugar concentration of the food resulting in an abrupt rise in blood sugar, the pancreas is stimulated to produce a large amount of insulin needed to dispense the sugar. If the adrenals do not quickly produce a counter-balancing hormone to signal the end of insulin production, it is possible that blood sugar levels will fall below an acceptable level.

At this point, blood sugar levels are below normal and the signs of hypoglycemia are present: fatigue, headaches, irritability, etc. This will often be "cured" by the consumption of either a concentrated sugar product or an adrenal stimulant such as coffee, cola or nicotine. The cycle is repeated over and over, thus resulting in enervation of bodily organs and glands and toxic accumulation from the refined sugar products and other wastes.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > 10. The Liver

## **10. The Liver**

An organ in the body that plays a great part in the blood sugar regulation is the liver. It is in the liver that sugar is converted to glycogen for storage, then stored in the liver as well as muscle tissue, and, as needed, converted back into sugar again. It is easy to see the importance of good liver function for proper blood sugar levels.

The liver can be damaged or have its functional capacity reduced by several factors: alcohol consumption, tobacco, smog and toxic drugs. Fortunately, the liver is one of the fastest regenerating organs in the body and, once these factors are overcome, it will restore itself and carry out the many body functions it performs. It is these same factors that also result in impaired function of all of the other vital organs in the body and it is imperative that these errors in living be corrected for health to be restored.

Actually, large quantities of sugar should never reach the bloodstream in the first place. Food absorbed from the intestines is taken up by the portal vein and goes directly to the liver. Here all blood is filtered and nutrients are sorted out, some put in storage (in the form of glycogen) and others released for immediate use, according to what is appropriate. If the liver is healthy and is able to store glucose, then excessive amounts of this sugar are not dumped wholesale into the blood.

Hypoglycemia then, is not necessarily due to only an inappropriate insulin response but to a weak or sluggish liver that is unable to perform its duties properly. This is illustrated by alcoholics where the liver is damaged from habitual drinking. They are often hypoglycemic. Consumption of large amounts of protein put further burden on the liver.

There is no real reason why a flood of sugar has to be delivered to the bloodstream or to the liver. Whether it is or not depends on what kind of carbohydrate was eaten. White sugar is rapidly absorbed from the intestine and immediately floods the blood with glucose. On the other hand, carbohydrates in the form of fruits are absorbed more slowly owing to their more complex nature, and are therefore taken into the blood more slowly and the pancreas is not unduly stressed.

## 11. Hyperinsulinism

Hyperinsulinism is another term that is often used synonymously with hypoglycemia. (However, hypoglycemia is not necessarily accompanied by hyperinsulinism.) This term simply means too much insulin in the blood. Another interesting tie-in of the adrenal glands and the pancreas is seen here. When the amount of insulin necessary to do the job on a given amount of sugar has been secreted, it is the job of an adrenal hormone to send a message to the pancreas to stop producing insulin. A sluggish adrenal will be late in this function, thus allowing an overproduction of insulin with a resultant excessive lowering of the blood sugar. Epinephrine and norepinephrine act directly on the pancreatic islets to inhibit insulin secretion.

## 12. What To Do If You Have Symptoms Of Hypoglycemia

Fasting is the best way to quickly eliminate the toxemia that resulted in your hypoglycemic symptoms. Through the fast you will give your body the rest that it needs to carry on its job of cleansing and repairing.

People with hypoglycemia are often fearful of fasting. They believe they will go into shock if they don't eat some protein every few hours. But professional Hygienists have seen these people regain their health after a fast. However, they do need expert supervision.

Dr. William Esser says, "Hypoglycemia can very definitely be benefited by a fast." He says that functional types of hypoglycemia can be corrected without too much difficulty through fasting and a change in habits.

Since hypoglycemia is a condition that arises out of factors of irritation, abuse and exhaustion, involving the entire body, the only "remedy" for this exhaustion is rest. The body must be allowed to slow down and the stress factors must be eliminated as much as possible. A period of fasting under proper supervision is important for the purpose of fostering metabolic housecleaning and a thorough physiological rest for the exhausted organs and glands. All draining of functioning power must cease. Emotional, sensory, and physical power is restored by physiological rest.

The fast should be continued long enough to marshal all the power and force of the organism to regenerate itself and to return to normal functioning. It is only through the return of this power that the organs involved in blood sugar metabolism can resume the work that they have been created to perform.

After fasting, all refined foods and other harmful substances should be eliminated, especially white flour products, refined white sugar, alcohol, caffeine, salt and nicotine. Any small amount of these poisons may overstimulate and exhaust the pancreatic-adrenal mechanism, thus reactivating the hypoglycemic pattern.

The natural diet of humans is one of raw ripe fruits, vegetables, nuts and seeds. Dr. Frank Sabatino suggests that for a period of time, the elimination of certain foods, such as sweet and dried fruits, may be necessary. Even such an excellent food as bananas may be on the prohibited list for a while. In the fruit family, the more desirable items during this period, according to Dr. Sabatino, should be citrus (oranges and grapefruit), and sub-acid fruits (such as peaches, pears, apples). He also suggests a three-meal-a-day plan of one fruit meal and two salad meals, with ample use of greens, sprouts and avocados. After,

health is restored, more fruit meals with sweet fruits included may be eaten.

In addition, you should not neglect the other conditions for health such as proper exercise, fresh air, sunshine, emotional poise, rest and sleep. This is the only way to regain health and correct this condition of disturbed physiology.

## Questions & Answers

### **Does the pancreas have any reserve capacity after it has been partially destroyed?**

The pancreas has an enormous reserve functioning capacity. This has been proven experimentally in animals where large amounts of pancreatic tissue have been removed. In these experimental animals, diabetes mellitus has been induced by different methods. The method most often employed is depancreatectomy. In order to attain significant diabetes, at least 90 to 95% of the pancreas usually must be removed, otherwise, the islets of Langerhans in the remaining pancreatic tissue will often be able to hypertrophy significantly to supply enough insulin for normal metabolic needs. This indicates that the islets of Langerhans normally have a tremendous reserve capacity.

### **I heard about a high-carbohydrate and high-fiber diet that is supposed to be a "miracle cure" for diabetics. Is this true?**

There are no "cures." The high-fiber diet may temporarily alleviate the symptoms because the glucose is entering the blood at a slower rate due to the types of complex carbohydrates that are eaten. However, no causes have been removed and the errors in living that resulted in diabetes have not been corrected. There is no other way to achieve health.

### **Why has the incidence of diabetes increased so dramatically in recent years?**

Statistics show that many more people are going out to eat now than ever before and they most frequently go to the fast food restaurants. Consumption of prepackaged dinners and other junk foods are increasing

Also, people are exercising less and indulging in other enervating habits such as cigarette smoking, coffee, alcohol, etc. All of these factors lead to toxicosis and the end result, in many people, is diabetes.

### **Is there any other clinical evidence that diabetics have had success on a raw foods program?**

According to Dr. John M. Douglass, of the Southern California Permanent Medical Group and Kaiser Foundation Hospital of Los Angeles, diabetics who make an effort to eat more raw foods may be able to decrease or eliminate their need for insulin

One of Dr. Douglass' patients, an elderly man, had been taking insulin twice a day. When he started eating more foods in their raw uncooked state, his insulin requirements began to fall. After four years, he was able to get by with just half his usual amount of insulin a day

A second patient, a young Mexican-American man, complained to Dr. Douglass that he would rather die than continue taking insulin "shots." By shifting to an 80% raw diet, he was

able to control his diabetes with oral drugs alone. (Perhaps if a 100% raw food diet were implemented, he would have been able to dispense with the oral drugs also)

What led Dr. Douglass to try the raw food regimen? "My rationale was that since early man lived entirely on raw food, perhaps such a diet would be less stressful to the human system in general and less diabetogenic than a cooked food diet." Raw vegetables, seeds, nuts, berries, melons and other fruits and part of Dr. Douglass program.

[Home](#) > [Lesson 73 - Sugar And Carbohydrate Metabolism Disease](#) > Article #1: Diabetes Mellitus by Dr. Herbert M. Shelton

### **Article #1: Diabetes Mellitus by Dr. Herbert M. Shelton**

This is the name given to a group of symptoms that center around an impairment of carbohydrate metabolism. Commonly we are told that it is a disease of the pancreas, but it is coming to be realized that it is a disturbance of the metabolic process involving the entire organism and not strictly localized in any one organ. It is, in other words, a manifestation of a systemic derangement and, however important the pathology in the pancreas may be, this is secondary to the systemic derangement which has resulted in the disease of the pancreas.

The Islands of Langerhans may be described as little organs within the pancreas or sweetbread. These structures produce an internal secretion commonly known as insulin which is essential to the oxidation of sugar. When they fail to secrete sufficient insulin an excess of sugar accumulates in the blood and is eliminated by the kidneys in the urine. Hence sugar in the urine (glycosuria) is the principal symptom of what the layman calls *sugar diabetes*. But it is a subordinate symptom and is valuable chiefly as a criterion of the progress of the condition.

The condition of the pancreas of diabetics has been thoroughly studied after death and the destructive changes therein found have been carefully described and catalogued. But the patient may have had diabetes ten or more years before death and the pathologist, studying the end-point of the pathological process after death, gives us false picture of the condition of the pancreas except the terminal stages of the disease. Thus the hopeless view of diabetes taken by medical men.

There is no destruction in the pancreas when the disease first begins and the destructive changes take place slowly against the weakened resistance of the body. Enervation (fatigue) of the Islands of Langerhans is the probable beginning of diabetes. It is toxemia that produces the pathology (the destruction) in the pancreas. Toxemia produces first a mild, chronic pancreatitis which may persist for a long time before marked damage to the pancreas occurs.

Under causes of diabetes, Dayton's *Practice of Medicine* gives "Heredity, male sex, adult life, Jewish race, obesity, cerebral or spinal disease or injury, infectious diseases, overwork and nervous strain predispose. Actual cause is unknown. Pancreatic disease is probably important."

Heredity! Male sex! Adult life! Jewish race! These are not causes of anything. If adult life predisposes to diabetes then it is certainly dangerous to grow up. If male sex and Jewish race predispose then it is dangerous to be a man and a Jew.

If adults have more diabetes than children it is because more years of wrong living have produced more pathology in them. If men have more diabetes than women, it is because their mode of living is worse. If Jews have more diabetes than others it would have to be something in their diet or mode of living that produces the diabetes.

Perhaps pancreatic disease is important, but it certainly is not self-originating and self-evolving. It must be the outgrowth of causes antecedent thereto; must be secondary to other causes and conditions. Healthy men and women, Jews or heathens, do not develop diabetes.

Heredity! Is there such a thing? It is true that there are many cases of diabetes in children and youth and it is quite possible that there is marked larval endocrine deficiency in all such children. It may even be a lesser degree of larval endocrine deficiency that establishes the tendency to diabetes in adults. The time of life at which carbohydrate tolerance breaks down may be considered an index to the larval endocrine imbalance in the individual. But we must not overlook the fact that of two individuals with the same degree of larval endocrine deficiency, the one that subjects his body to the most enervating influence and consumes the greatest amount of carbohydrates will break down his carbohydrate tolerance first.

In those cases developing after the thirty-fifth or fortieth year we think the larval deficiency may be considered negligible and think that the cause is a decidedly overcrowded general nutrition in which carbohydrate consumption has been excessive throughout life. The Islands of Langerhans have merely been overworked through the years.

Worry, anxiety, grief, shock-fright, accidents, surgical shock—will so impair the function of the pancreas that sugar shows up in the urine immediately. In many cases of diabetes, emotional stress is the chief cause, but it is never the sole cause. Every so-called disease is a complex effect of a number of correlated antecedents.

Diet and drink, sleep, work and play, and many other factors enter the cause of every so-called disease. *Any form of overstimulation—mental, emotional, sensory, physical, chemical, thermal, electrical—may give rise, first to functional, and, finally, to organic, disease:* Diabetes is a functional disturbance at its beginning.

Diabetes is more markedly on the increase in those countries in which sugar consumption has mounted to such high figures during the past fifty years—France, Germany, Britain and the United States. Every fat person is a potential diabetic. The overfeeding which is responsible for the fat overworks the pancreas and as overwork of any organ results in impairment of the function of the organ, pancreatic failure results. If its causes are not corrected, functional impairment gradually passes into organic disease.

Carbohydrate excess places a strong stress on the pancreas and when this gland is over-worked by too great an intake of starches and sugars, there will be first, irritation and inflammation, then enlargement, followed by degeneration (de-secretion); after which the body loses control of sugar metabolism and of the excess acidity caused by too much starch and sugar.

But it should not be thought that overeating of carbohydrates alone impairs the pancreas. Anything that produces *enervation*—tobacco, tea, coffee, chocolate, cocoa, alcohol, soda fountain sweets, loss of sleep, overwork, general overeating, emotionalism, etc.—impairs organic function in general including pancreatic function.

Sedentary habits added to overeating increase the tendency to diabetes, as they do to all other so-called "*degenerative diseases of later life.*"

Let us glance briefly at the symptoms of diabetes. The urine is frequently voided, is pale and of high specific gravity unless there is inflammation of the kidneys in which case specific gravity is not so high. The urine contains varying amounts of sugar and certain acids that are absent from the urine of healthy subjects.

There is great thirst and a ravenous appetite with, commonly, loss of weight. Headache, depression and constipation are common. The breath is sweet, though unlike that of the healthy person. The mouth and skin are dry, even parched, the tongue is red and glazed, and when the disease is advanced the teeth usually decay and become loosened. There is a tendency to pyorrhea and bleeding of the gums. Loss of sex power is common, while Bright's disease may develop as a "complication." Impairment or loss of

vision may occur. Boils and eczema are also frequent. The disease progresses more rapidly in young patients than in older ones and it is thought by some *Hygienists* that children rarely if ever make a complete recovery.

Recovery—the medical term is "once a diabetic, always a diabetic"—depends upon the amount of functioning tissue left in the pancreas. Fortunately, the pancreas, like all other organs of the body, possesses a great excess of functioning power over that needed for the ordinary activities of life, so that even after part of the Islands of Langerhans have been destroyed the remainder will be able to function sufficiently to meet the regular needs of life, provided the impairing causes are removed and they are given opportunity to return to a state of health.

When organs are not destroyed beyond repair, rest, poise, self-control, and a restricted, proper diet will restore normal functioning. In diabetes, rest and proper food, with diet restricted to the patient's digestive capacity, and full cooperation will result in dependable health in a few years. Failure is for all those who are not willing to live according to nature's principles.

All enervating influences and habits must be corrected or removed. Sufficient rest for restoration of nerve energy is imperative. A fast, not merely to give the pancreas a rest, but of sufficient duration to free the body of its load of toxins, must be followed by a diet that is designed to produce all possible regeneration in the pancreatic gland. Feeding that is designed merely to cause the disappearance of sugar from the urine may speedily kill the patient. After health is restored the patient must be taught to live within his compensating capacity.

## **Article #2: Diabetes**

In spite of the optimistic expectations with which Banting's discovery of insulin was heralded, this drug has proved to be nothing more than another palliative. It has contributed nothing towards the radical solution of the problem of diabetes. On the contrary, satisfaction with the palliation which insulin affords has tended to discourage further search for a genuine solution of the problems presented by this disease. Physicians and patients alike seem to be wholly satisfied to go on using insulin and ignoring all else.

Diabetes is on the increase in all the industrialized countries of the world and has steadily increased from the time of the discovery of insulin. The number of cases, world-wide, is estimated by medical authorities to run into many millions. *World Health News*, March, 1965, stated that "the incidence of diabetes is increasing all over the world and a WHO expert committee which has convened to discuss the problem considered that there is 'unassailable evidence that overweight predisposes people to diabetes ...' Some idea of the incidence of the condition can be gained from the figures for the United States, where there are estimated to be four million cases ..."

The dependence of the profession upon insulin is pathetic. It is no longer thought that insulin does any more than palliate symptoms. But there is the unfortunate fact that thousands of people have been given insulin who had nothing more than an evanescent appearance of sugar in the urine. Many of these have been kept on insulin until their pancreas underwent so much deterioration that they were unable to get off the drug. They did not have diabetes when they began the use of insulin, but they now have diabetes as a direct result of insulin dosage.

Insulin never restores health, hence its use is purely palliative. Before it came into use, physicians and patients made some effort to correct the mode of living. The diet of the diabetic was carefully regulated, even if not always well regulated, and physicians often sought for various causative factors in the life of

their patients. This is no longer so. Insulin enables them to live in spite of their indiscretions. This does not mean that insulin wipes out the effects of their indiscretions, but that it palliates one of the effects of these indiscretions. The result of the use of insulin has been a steady increase in the early death rate from diabetes from the year it was introduced. This is true because both physicians and patients rely upon the drug and ignore all causes of disease.

Calling diabetes a *disease of civilization*, while it stresses the fact that the less civilized, whose lives are more natural and whose diets are not processed and refined and not overabundant, have little or no diabetes, does not place its finger on the true cause of the deficiency of function. Until we are willing to recognize the genuine etiological factors and correct these, we are going to continue to watch the increase in the incidence of diabetes and depend on the processing of the pancreas of animals as a means of palliation. Today we do not even feel any shame for our illegitimate dependence on cattle and swine for such palliation.

The precarious condition in which the medical profession and their diabetic patients find themselves, growing out of their dependence on slaughter houses for insulin, has caused much concern. To date no means have been found to produce insulin, artificially, and the only available supply is from slaughtered animals. As the human population continues to increase and earth's animal population decreases, this could become serious from the standpoint of medicine. What would happen if the world became vegetarian, as it must in the future, and the slaughter of animals were discontinued? In his book, *The Genetic Code*, Prof. Isaac Asimov says: "Suppose though that increasing population pressure forces future generations more and more into a vegetable diet. This would mean a steady decrease in the potential supply of insulin." He implied that as far as he could see into the future, insulin production would continue to be dependent on animals.

This uncertainty about the future insulin supply underscores the urgent need for a discovery of the cause of diabetes and for finding a means for restoring health to the diabetic patient, instead of depending upon the palliation insulin provides. As no means of restoring health exists except those that constitute Natural Hygiene, the future diabetic will be forced to depend upon Hygiene rather than the animal product.

### **1. Introduction**

Heart disease is the end result of a lifetime of unhealthful living. It is not due to diet alone or lack of exercise alone but it is the cumulative effect of all our unhealthful habits. It will become clear, after completing this lesson, that the entire body is involved in the development of this condition. Systemic impairment begins long before the symptoms of heart disease become apparent.

The study of the physiology of the heart will demonstrate the unity of the body. The various heart diseases differ in certain respects but they are all indications of total bodily enervation and toxicosis. There are many factors that contribute to this enervated state including cigarette smoking, improper diet and exercise, alcohol, stress, obesity, etc., all to be discussed in this lesson.

### **2. General Physiology**

#### **2.1 The Circulatory System**

The circulatory system transports blood from the heart to the cells and back again to the heart in a never-ending stream. The red blood cells contain hemoglobin, a complex protein arranged around iron. They have the important role of taking up large quantities of oxygen as it passes through the lungs and then passing this oxygen to the body cells. As the blood in the lungs picks up oxygen, the hemoglobin becomes bright red (arterial blood). When the hemoglobin reaches its destination, the individual cell, it releases oxygen and picks up carbon dioxide, a waste product of metabolism. The color of the blood carrying carbon dioxide to the lungs for elimination from the body is a bluish red (venous blood).

Hemoglobin has another important function, that is, helping to maintain the acid balance of the blood. Each day the carbon dioxide resulting from cellular metabolism is equivalent to a little more than one-half gallon (2.6 liters) of concentrated hydrochloric acid. That high concentration of acid would injure the cells, so nature provides a neutralizing base, half of which comes from the food consumed each day and the remainder from the body's built-in buffering agents, one of which is hemoglobin.

## **2.2 Structure of the Heart**

The heart is completely enclosed by a thin sac called the pericardium. This tough tissue protects the heart from rubbing against the lungs and the wall of the chest. The inside of the pericardium has a smooth lining that secretes a lubricating fluid. The heart beats smoothly and with little friction against the moistened lining of the pericardium.

A muscular wall called the septum divides the heart lengthwise. Two chambers, one above the other, are on each side of the septum. The upper chamber on each side is called an atrium. The thin-walled atria collect the blood flowing into the heart from the veins. Below each atrium is another chamber called a ventricle. The two ventricles pump the blood into the arteries.

The walls of the ventricles are made of thick, strong muscles. The right ventricle pumps blood through the pulmonary artery into the lungs. The left ventricle pumps blood to the entire body through the aorta. The left ventricle has walls three times as thick as those of the right ventricle because it has to pump the blood so much farther. Valves control the flow of the blood through the heart. The tricuspid valve is between the right atrium and the right ventricle. The mitral valve is between the left atrium and the left ventricle. The semilunar valves control the flow of blood from the ventricles to the arteries. The semilunar valve that controls blood-flow from the left ventricle to the aorta is also called the aortic valve.

Arteries carry blood from the heart to other parts of the body, but the heart itself must also receive nourishment. Blood flows to the heart muscle through coronary arteries. The coronary arteries lie over the walls of the heart in a complicated network, and carry oxygen to all parts of the heart muscle.

The interior of the heart is lined with a smooth membrane, a single layer of cells called the endocardium. The same kind of membrane also lines the valves and the blood vessels. The lining prevents damage to the blood cells by reducing friction and by minimizing the danger of blood-clot formation either inside the heart or inside the blood vessels themselves. Between the endocardium and the outer layer of the heart (epicardium) is the muscular wall itself, the myocardium, consisting of muscle cells surrounded by connective tissue.

The many connections between muscle cells in the atria and the ventricles form the basis for the conduction of impulses from cell to cell. Near the entrance of the two veins that bring blood from the upper and lower parts of the body into the top of the right atrium (the superior and the inferior venae cavae) is a small bundle of highly-specialized muscle fibers that generate impulses necessary for the coordinated contraction of the heart. This bundle is called the sinoatrial node, or pacemaker. The impulses from the sinoatrial node are collected and conveyed to the ventricles by another group of cells in the connective tissue between the left and right sides of the heart. This group is called the atrioventricular node, and from it other specialized muscle fibers, called the bundle of His, after the German anatomist who discovered them, run from the upper to the lower chambers, splitting to left and right as they descend. The two main branches of the bundle of His connect with a network of smaller impulse-carrying fibers (Purkinje fibers), which run to all parts of the ventricles. It is by means of this intricate system of specialized fibers and cells that the heart receives the electrical impulses necessary to maintain a rhythmic, effective and concerted beat.

### **3. How The Heart Works**

Each side of the heart performs a different pumping job. The right side takes blood from the body and pumps it to the lungs. The left side collects blood from the lungs and pumps it to the body.

Blood entering the right side of the heart contains carbon dioxide, a waste product of the body. All blood entering the right side of the heart goes to the lungs before it reaches the left side of the heart. In the lungs, the carbon dioxide is removed, and oxygen is added to the blood, blood that flows to the body from the left side of the heart contains fresh oxygen. The oxygen is used in the body cells to produce energy.

Blood from the body flows into the right atrium through two large veins. One of these veins, the superior vena cava, carries blood from the head and arms. The other vein, the inferior vena cava, carries blood from the trunk and legs.

Blood from the body fills the right atrium. The atrium then contracts, squeezing blood through the tricuspid valve into the ventricle. The tricuspid valve is made of three little triangular flaps of thin, strong fibrous tissue. These flaps permit the blood to flow into the ventricle, but they prevent it from flowing back into the atrium. They are like doors that open only in one direction.

At first, the ventricle is relaxed, but it contracts when it is filled with blood. The resulting pressure closes the tricuspid valve and opens the semilunar valve between the ventricle and the pulmonary artery. Blood gushes through the valve into the artery, which leads to the lungs. The valve is called semilunar because it has three flaps that are shaped like half-moons. Blood squeezed from the ventricle pushes the flaps against the walls of the pulmonary artery.

From the lungs, the blood flows back to the heart through the four pulmonary veins. It flows out of the pulmonary veins into the left atrium. The left atrium, like its neighbor on the right, then contracts, squeezing blood through the mitral valve into the left ventricle. The mitral valve is similar to the tricuspid valve, except that it has only two flaps. The left ventricle contracts, forcing blood through another semilunar valve into the aorta. The aorta, with its numerous branches, carries blood throughout the body.

### **4. Control Centers**

Because the cardiovascular system is the major environmental control center in the body, it utilizes a battery of sensors and monitoring devices to trigger corrective action or relay information to other body systems. Thus monitors within the cardiovascular system measure blood pressure and send this data to the brain, which then determines necessary adjustments.

#### **4.1 Nervous System**

The primary regulator of blood pressure is the brain stem, where groups of specialized nerve cells control the activity of the heart (cardiac-activating and cardiac-inhibitory centers) and another nerve-cell group regulates the diameter of blood vessels (vasomotor center). Blood pressure is augmented when the

sympathetic nervous system carries commands from the cardiac-activating center to increase the heart's activity and from the vasomotor center to constrict arterioles and veins. Blood pressure is decreased when the vagus nerves convey commands from the cardiac-inhibitory center to the sinoatrial node, slowing heart activity.

When blood pressure rises, sensors in the aorta and carotid arteries send impulses to the brain which inhibit the cardiac-activating center and the vasomotor center and simultaneously stimulate the cardiac-inhibitory center.

Sensors in the heart and lungs monitor the volume of blood in the vascular system. Messages sent by these receptors lead to adjustments in the circulatory system via sympathetic nerves. Other sensors monitor the oxygen content of blood and lead to changes in the respiratory system. These various monitoring cells supply the brain with the essential data for adjusting the circulation so that it can respond to any stress.

## **4.2 Hormonal Control**

The action of the nervous system on the circulation is augmented when necessary by hormones secreted into the bloodstream from endocrine glands. Among the many hormones that can affect the function of the heart and blood vessels, the most important are adrenal catecholamines and angiotensin II.

### **4.2.1 Adrenal Catecholamines**

There is an adrenal gland located just above each kidney. These glands consist of a central group of cells, the medulla, surrounded by a layer of different cells, the cortex. The medulla produces two substances called catecholamines—norepinephrine and epinephrine. The norepinephrine secreted by the medulla increases the rate of the heartbeat and the strength of heart muscle contraction and at the same time causes constriction of the muscle cells in the blood vessel walls. The epinephrine causes relaxation of blood vessels in the skeletal muscles, which augments the blood flow to the muscles during exercise.

The cells of the adrenal medulla are controlled by the sympathetic nerves; each increase in the number of impulses from these nerves increases the secretion of the catecholamines.

### **4.2.2 Angiotensin II**

Cells located in the walls of kidney arterioles produce a chemical substance, renin, which is converted into angiotensin II. This very active product increases the formation of aldosterone (one of the hormones produced by the adrenal cortex), which in turn causes greater reabsorption of sodium and water from the kidneys and a subsequent increase in blood volume. Angiotensin II also acts more directly to cause muscle cells in the walls of the arterioles to contract; the result of all this activity is an increase in arteriolar resistance.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 5. Factors Contributing To Heart Impairment

## **5. Factors Contributing To Heart Impairment**

Heart impairment results after many years of unhealthful living. It is the cumulative effect of improper diet, poison habits, sedentary lifestyle, overwork, etc. All of this leads to enervation, impaired elimination and toxicosis. Major factors resulting in this toxicosis include cigarette smoking, improper

diet, lack of exercise, alcohol, coffee, stress, obesity and drugs. The combination of these factors eventually leads to impairment of one or several of the mechanisms described in the physiology of the heart. When any of these mechanisms are impaired, the heart is directly affected.

## **5.1 Cigarette Smoking**

The single most important effect on health due to cigarette smoking is the development of heart impairment. In 1975, approximately 25% of the 650,000 deaths from coronary heart disease were attributed to cigarette smoking. The 1979 Report of the Surgeon General On Smoking and Health identifies smoking as related to coronary heart disease for both men and women in the United States, and cigarette smoking as a major independent risk factor for the development of fatal and nonfatal myocardial infarction.

Smokers who quit reduce their risk of dying from coronary heart disease; the reduction approaches that for the nonsmoker following a total abstinence of ten years. Studies show that smoking low tar and nicotine cigarettes does not reduce one's risk significantly; some smokers merely inhale more deeply or smoke more often.

It has also been shown that cigarette smoking is associated with more severe atherosclerosis of the aorta and coronary arteries than has been found in nonsmokers. Smoking is also reported as being responsible for increased deaths from arteriosclerotic aneurysm of the aorta (a ballooning effect that can lead to its rupturing).

Recent research would indicate that carbon monoxide may be one of the factors in the cigarette smoke that leads to the development of atherosclerosis, resulting in angina pectoris and heart failure.

Carbon monoxide (CO), one of the most poisonous byproducts of cigarette smoking, is a colorless, odorless gas that makes up anywhere from about one to five percent of cigarette smoke. Because it has an extremely strong affinity for hemoglobin (which carries oxygen to the tissues), any inhaled CO quickly displaces the oxygen in the blood, forming carboxyhemoglobin. Carbon monoxide may cause damage by injuring the walls of the arteries, enhancing the development of atherosclerosis, which narrows the arteries, diminishing the supply of oxygen and other nutrients. In addition, carbon monoxide is the principal contributor to diseases of the respiratory system and sudden death from coronary heart disease.

Nicotine is generally understood to be the addictive element in tobacco that results in stimulation of the adrenal glands and certain heart tissues to release certain hormones called catecholamines. The catecholamines raise the blood pressure and the heart rate, causing the heart to work harder, thus requiring a greater amount of oxygen. But as smokers take in nicotine, they are also inhaling carbon monoxide, which decreases the amount of oxygen in their blood. Thus, nicotine in combination with carbon monoxide may be the predisposing factor in the development of heart disease and heart "attacks."

In addition to speeding up the heart rate and causing a rise in the blood pressure, nicotine also results in a constriction of the blood vessels. The constriction of blood vessels additionally leads to a decrease in blood flow to the fingers and toes and aggravates such peripheral vascular conditions as Buerger's disease and Raynaud's phenomenon.

You must realize that cigarette smoking is one of a series of factors that lead to heart impairment. Other factors are important also and together create the conditions (a state of toxicosis) that results in this degenerative disease.

## **5.2 Diet**

Habitual excesses in eating (especially in concentrated fats, protein and sugars); eating the wrong kinds of foods; eating improperly-combined foods; result in toxicosis and enervation of all bodily organs including the, heart.

### 5.2.1 Fats

In 1961, the American Heart Association began providing information to the public on the link between high levels of cholesterol in the blood and the development of atherosclerosis, the disease where fatty deposits or plaques accumulate in the walls of the arteries. Simultaneously there was encouragement of the public to decrease its intake of fat and cholesterol. Such advice has its origin in the research around 1913 by a Russian scientist, Nikolai Avitshev, showing a connection between a high-cholesterol diet and fatty deposits in the arteries (atherosclerosis) of rabbits. This discovery has led to extensive medical research on how blood fats and cholesterol contribute to disease of the human circulatory system.

Atherosclerosis develops gradually due to an unhealthful lifestyle, with no symptoms, for anywhere from twenty to forty years or even longer. Then serious clinical signs manifest themselves. These may be in the form of chest pain, heart "attack," stroke or sudden death.

Dietary substances and blood constituents other than cholesterol are also involved in the development of atherosclerosis. When you follow a more healthful lifestyle, including proper diet, the accumulation of these fatty substances do not occur.

In order for the body to transport and use fats, they must be combined with another molecule to make them soluble in the blood serum, the fluid portion of blood. This molecule is a protein, that combines with the fats to form lipoproteins, making possible the transport and utilization of fats. Lipoprotein molecules come in various sizes and weights and the amounts of cholesterol and other lipids they contain vary according to the size and weight.

The heaviest of these molecules is high-density lipoprotein (HDL). HDL contains the highest proportion of protein and has recently been shown to be possibly important in transporting fat away from body cells. Thus, cholesterol and other fats do not accumulate within the artery walls. There is also evidence that the higher the amount of HDL in the blood, the lower the subsequent risk of fatty artery disease, heart failure and strokes. Normal levels of HDL are found in people whose diet consists chiefly of raw fruits, vegetables, nuts and seeds.

Low-density lipoprotein (LDL) is lighter than HDL and contains the largest proportion of cholesterol of any of the lipoproteins. There is considerable evidence that a high amount of LDL is a factor in the accumulation of fatty materials in artery walls. High levels of LDL are found in those people whose diet is high in animal products—meat, eggs and dairy products.

Researchers have found that lower cholesterol levels are associated with lower incidence of heart disease. For example:

Monkeys fed a high-fat diet to increase their levels of blood cholesterol, after returning to their normal low-fat diet, do show evidence of reduction in fatty deposits in their arteries.

Wartime experiences in Switzerland, Scandinavia and other European countries during the 1940s suggest that changes in diet, which included reduced consumption of fats and increased consumption of vegetables, resulted in a lower incidence of heart impairment in a fairly short time.

Dietary changes in Europe after World War II, and increased consumption of fats and sugar among immigrants to Israel and the United States, coincided with an increase in blood cholesterol levels and a rapidly increasing frequency of heart attacks.

#### **Dietary Sources**

Many people use margarine because they are told that the unsaturated fat in margarine is much more desirable than the saturated fats found in butter. But margarine is an artificial product full of additives, emulsifiers and chemicals that aren't meant for human consumption. Flavor enhancers in the form of diacetyl and isopropyl and steryl citrates are added to margarine. Sodium benzoate, benzoic acid or citric acid are added as preservatives. (The benzoates are poisonous and have actually resulted in death.) Emulsifiers are also added, such as diglycerides, monoglycerides, etc. and these do not have to appear

on the label.

When margarine is hydrogenated, a chemical process is used where hydrogen is added to unsaturated bonds of carbon or oxygen of the oil. Under a controlled process, however, most of the essential fatty acid, linoleic acid, is changed to oleic acid. The hardening process may also produce a different spatial arrangement of the atoms of the molecule of an essential fatty acid (EFA). Because of this difference, the EFA are not utilized properly by our cells and can actually interfere with the utilization of normal fatty acids. This situation may accentuate a deficiency of EFA. Researchers report that cancer, arthritis, heart disease, skin disease, arteriosclerosis, and other degenerative conditions appear to be affected by a lack of EFA.

It becomes clear that margarine is something that we definitely should not consume. Butter does not contain as many artificial additives but it is a saturated fat known to play a role in the development of arteriosclerosis. It is also often heavily salted and dyed. Many physicians advocate the inclusion in our diet of such polyunsaturated oils as corn or safflower oil in the place of butter or margarine. However, consumption of polyunsaturated fats is known to result in the formation of free radicals.

When atoms combine to form molecules, their electrons usually group together in pairs. If one of the electrons is lost, the molecule becomes a free radical. In the presence of oxygen, free radicals form spontaneously in the tissues from certain substances, mainly polyunsaturated fat. According to Zane Kime, unpaired electrons are very unstable. They react abnormally with almost anything close by and can result in damage to nearly every system in the body. As the unsaturated and polyunsaturated fats increase in the diet, they also increase in the tissues. Metabolism can be altered because the cell walls are further weakened due to the abnormal fatty acid formation. This allows many impurities to enter the cells that would not ordinarily enter.

Where are we to obtain our dietary fats if not from margarine, butter or free oils? The best source is found in our natural foods—fruits, vegetables, nuts and seeds. We are not only receiving all the fats that we require from these foods but we are acquiring them in the correct proportions with the vitamins and minerals and other food constituents. The body makes use of this form of EFA easily and perfectly.

### **Research Studies**

In a study comparing the effects of substituting plant for animal fat in the diet, six subjects showed significant reductions in serum concentrations of free and esterified cholesterol and of phospholipids when plant fats were substituted for animal fats during a four-month period. The approximate change was a 20% decrease even though body weights and caloric intakes were kept constant during the experiment.

In another study, 58 vegetarians who eat no animal products and live on a farm commune were examined. The average lipoprotein-cholesterol level of this group were 60% of age-and-sex-specific normal levels compared to a control group. The conclusion of the study placed the vegetarians in a lower-risk category for the development of clinically manifest atherosclerosis.

### **5.2.2 Carbohydrates**

Consumption of refined carbohydrates results in enervation and impairment of all bodily cells, tissues, glands, organs and systems. This unhealthful habit often results in diabetes and/or arteriosclerosis. Overconsumption of refined sugar stresses the pancreas until it becomes so enervated that it ceases to function. The body then begins to break down stored glucose in the fat cells into triglycerides. This increases the fat in the blood to above normal levels and some of this fat remains in the arteries of the heart and elsewhere.

The results of incorrect diet are systemic and do not involve just one organ or gland. It takes many years of this unnecessary abuse to damage the heart so severely that it is incapable of performing.

As in all bodily organs, the heart is intimately involved with, and dependent upon, all other bodily systems. Any slight impairment in any of the systems—nervous, endocrine, digestive, etc.—will affect the heart.

Overconsumption of carbohydrates results in a toxicosis that ultimately affects total health.

### **5.2.3 Proteins**

The quantity and quality of the proteins are essential for optimum health. Many people overeat on protein foods. This results in enervation, since much more energy is needed for digestion and metabolism of protein. The body must either eliminate excess protein or store it for future use. This situation is enervating and, if continued, will result in impaired elimination with the increase of endogenous and exogenous poisons. The end result is degenerative disease. Dr. Robert Gross states, "The end products of protein digestion are acidic—urea, uric acids, adenine, etc. which, beyond a certain normal range, will cause degeneration of body tissue, producing gout, liver malfunctions, kidney disorders, digestive disturbances, arthritis and even hallucinations." Dr. D. J. Scott says: "Too much protein solidifies (like coffee) and has the same stimulating effect, and a high-protein diet will eventually destroy the glandular system, and damage the liver, adrenals and kidneys." When any of these organs are affected, the heart is also.

Not only the amount of protein, but the kind of protein is important. The best sources of concentrated protein for man are raw unsalted nuts and seeds. In their raw state, all the enzymes are intact and the amino acids are unchanged. Fruits and vegetables, though containing relatively smaller amounts of protein in their natural state, also provide amino acids for complete and optimal nutrition.

When proteins have been cooked or preserved, enzymes are coagulated, cleavage is inhibited and the amino acids may not be liberated for body use. Instead they become soil for bacteria and poisonous decomposition byproducts. Man cannot digest flesh protein properly and putrefaction invariably results. This adds poisons to the body in addition to the poisons that are already in the meat. All of this contributes to the development of disease.

### **5.3 Exercise**

Dr. Shelton says, "The heart is a muscular organ—it is almost all muscle—and like all other muscles of the body, is strengthened by use. A heart that is never called upon to do vigorous work does not grow vigorous and strong. If it always does light work it tends to become soft and flabby. It needs periods of vigorous work to build up and maintain its maximum strength and ability."

The response of heart muscle to exercise is similar to that of skeletal muscle. After such training, the heart can contract more strongly and in a better coordinated way so as to wring out more blood with each contraction. In endurance training, the heart muscle becomes larger, adding to the potential power of each stroke. The heart rate becomes slower at rest (intensive endurance training can slow the resting rate ten beats per minute). The coronary circulation increases as the result of exercise. This increase in coronary vessels appears in all active tissues, aiding in the delivery of supplies and the removal of waste.

Thus, with proper exercise, the heart becomes richer in oxygen, more massive and powerful, and more efficient. The reconditioned heart beats more slowly at rest and during work, and acquires a greater pumping capacity.

Exercise also provides the heart with a fantastic support system. Every muscle is like an auxiliary heart, helping to pump blood. When a muscle contracts, it squeezes blood toward the heart. When it relaxes, it allows the muscle to be filled with blood—exactly like the heart. The proper conditioning exercise is a rhythmic continuous one where the muscles pump repetitively. As blood pumps' from the muscles, it is always toward the heart.

When a sedentary person becomes fairly active by adding a mild exercise such as walking, many

changes take place in his body that are important in improving the general health. Blood pressure is lowered, resting heart rate decreases, muscles (including the heart muscle) become stronger and there is a vast increase in the number of active small blood vessels that carry blood to the cells of the muscular tissues. The blood itself is improved; it carries more oxygen; and the blood platelets become more efficient.

According to Dr. Fred Stutman, author of *The Doctor's Walking Book*, people with sedentary jobs run a higher risk of coronary artery disease. He says that walking between 45 minutes and one hour, three or four times a week, may decrease this risk. Walking increases the ability of the heart and lungs to take in and distribute oxygen in the body and this helps build physical endurance. It is claimed that this factor has been beneficial to patients with coronary heart disease. However, keep in mind that this is only one aspect of health and must be combined with all of the other conditions in order to result in health. Heart disease cannot be eliminated through exercise alone, but it helps when all of the other conditions for health are provided.

Dr. Stutman also points out that moderate exercise results in lowered circulating blood fats to the same extent as the more strenuous forms of exercise. We do not have to be marathon runners for optimum health but a moderate exercise program is recommended. Exercise results in the altering of the distribution of different forms of lipoproteins in the blood.

## **5.4 Caffeine**

Caffeine results in stimulation of the heart and rapid heart beat and arrhythmias are typical symptoms of this stimulation.

A substance found in almost all cells, including lymphocytes, is known as cyclic adenosine monophosphate (C-AMP). If high levels of cyclic AMP build up in the lymphocytes, they become unable to function properly. Coffee, tea and chocolate containing caffeine, theophylline, and theobromine increase the amount of C-AMP which would normally take place. Increased C-AMP depresses the ability of the lymphocytes to function, and is a stimulant to the nervous system.

Researchers have found that 158 mg. of caffeine results in a rise in cardiac index and stroke index in normal subjects. Caffeine also results in cerebral vascular resistance with a decrease in blood flow.

Sandord Bolton reported a 60% increase in acute heart attacks associated with consumption of one to five cups of coffee and a 120% increase with more than five cups. An epidemiological study involving Hawaiian males showed a significant correlation between coffee consumption and heart disease.

Caffeine also stimulates release of catecholamines from the adrenal medulla. Catecholamines have a marked effect on the central nervous system, metabolic rate, temperature and smooth muscle.

In one study, instant coffee (220 mg. of caffeine), was given to 18 young males with a resultant increase in epinephrine blood levels and urinary output. Blood lipids were also increased as a result of catecholamine stimulation. Epinephrine is a vasoconstrictor and cardiac stimulant.

Even in small doses, caffeine is a powerful poison that results in impairment of all parts of the body. These systemic effects often result in heart impairment as enervation of this organ becomes greater.

## **5.5 Alcohol**

Evidence linking alcohol consumption and heart disease includes the following:

1. Heavy alcohol consumption is associated with elevated blood pressure.
2. Distinctive forms of heart enlargement and heart failure occur in advanced alcoholics, who often tend to be malnourished.
3. Alcohol has been shown to result in impaired performance of heart muscle in humans.
4. Experimental evidence in animals shows structural and functional derangement of heart muscle

cells as an effect of chronic administration of alcohol.

Alcohol is a poison and its ingestion results in enervation of all bodily organs including the heart. The heart is at first stimulated while it attempts to rid the body of this poison but after a time becomes enervated and its function becomes impaired. Accumulation of the very toxic products of alcohol burden the liver and all other parts of the body including the nervous system and glands that directly affect the heart performance.

## 5.6 Stress

Various studies have shown coronary heart disease to be associated with such psychological tendencies as anxiety, neuroticism, depression, aggression, hostility, sense of time urgency and with such social factors as mobility, status, life events and dissatisfactions.

These factors may contribute to the development of heart impairment along with underlying conditions of enervation and toxicosis that result from improper diet and the rest of the factors which result in chronic disease.

Under stressful conditions, adrenal glands will secrete certain hormones that have a direct influence on the heart. Repeated stress will eventually result in enervation of the heart and the rest of the organs responding to that stress. This is just another factor in the total health package that should not be ignored.

## 5.7 Obesity

Evidence linking obesity and overweight to cardiovascular risk includes the following:

1. Insurance experience indicates that the death rate from all "diseases" including cardiovascular rises, as relative weight goes from low to above average.
2. Some follow-up studies of United States populations show similar relationships and risks.
3. Obesity and overweight are widely associated with other risk characteristics thought to have an influence in fatty artery disease (specifically, high blood pressure, glucose intolerance and diabetes and elevated blood uric acid). All of these factors can be resolved through a proper diet and weight reduction, as can cholesterol and triglyceride levels.

Obesity, obviously, is the result of improper diet together with lack of exercise. This condition is the direct result of a diet high in fats, meat, dairy products and sugar. All of these foods will not only result in obesity but the toxins invariably found in all of these foods will clog the body with poisons and contribute to the development of degenerative diseases of all kinds including heart impairment. Obesity may be corrected quickly through a fast followed by a diet of raw fruits, vegetables, nuts (unsalted) and seeds. Not only will weight normalize but general total health will greatly improve along with the lowered incidence of heart disease.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 6. A Look At Other Societies

## 6. A Look At Other Societies

Weston Price attributed degeneration of modern society to modern refined foods. To prove his theory, he visited several "primitive" tribes of people, during the 1930s, in many parts of the world. In every case, those people who lived exclusively on natural foods were free from dental caries and other signs of

physical degeneration and they lived long and healthy lives. However, when some members of their society adopted the "modern" dietary of refined white flour, sugar, pastries, jams, and canned goods, their health declined. This was evident in the first generation after the adoption of the modern diet.

More recently, Dan Georgakas conducted a study of longevous peoples throughout the world. It is well known that the people from Abkhasia in Russia are especially long-lived and healthy. Such degenerative diseases as heart disease are virtually unknown there. Commenting on the diet followed by these people, Georgakas says, "The traditional diet followed by most of those who became centenarians contained between 1,500 and 2,000 calories a day. Seventy percent of that intake was from vegetables and dairy products. Fruits, nuts, grains made up the rest of the diet."

In addition, Georgakas notes, there was no coffee, tea or sugar and little butter or salt. Whatever the food served, all leftovers were discarded, because they were considered harmful to good health. Such concerns for freshness guaranteed that a minimal loss of nutrients took place between garden and table. Most food was consumed raw or boiled, with nothing fried.

Georgakas says, if the 1970 census is accurate, Abkhasia would have a longevity rate 20 times that of the United States. Factors such as the nature of the traditional diet, strenuous physical activity throughout life, the hilly terrain, rhythmic patterns of work, a pollution-free environment and the unique psychological support enjoyed by the long-lived figure heavily in their longevity.

In Hunza, heart trouble is virtually unknown. The Hunzas live upon the produce of their land (mainly fruits and nuts); engage in strenuous physical exercise throughout their lives; and live in an unpolluted environment free from stress. This healthy regime results in longevity and a life free from all degenerative diseases.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 7. Hypertension

## **7. Hypertension**

Blood pressure is the force exerted by blood against the walls of the vessels that carry it. When the heart contracts, the pressure is increased. When the heart relaxes, the pressure is decreased. The blood pressure is determined not only by the power of the heart expelling the blood, but also by the resistance to the blood flow encountered in the arterioles acting under the influence of the nervous system and of the hormones.

When our regulatory devices become impaired in any way, the arteries may constrict and stay that way. The blood pressure rockets. Physicians label this condition "essential hypertension." To correct this condition, we must simply eliminate the cause of all disease by living according to the needs of the body and eliminating poisons and enervating influences.

High blood pressure is a symptom that is present in many diseases. It is one of many endings of a series of crises in toxicosis. Dr. Shelton says, "Perhaps the greatest single cause of high blood pressure is toxemia resulting from checked elimination. Secondary toxemia, such as that seen in nephritis, and intestinal autointoxication arising out of gastrointestinal fermentation and putrefaction, all produce enough nerve irritation to cause high blood pressure. A high-protein diet gives rise to a particularly virulent irritation when it putrefies in the digestive tract."

Dr. Shelton further explains that any form of excess taxes the nervous system and brings on enervation, checking secretion and excretion. Checked secretion produces indigestion with its consequent intestinal autointoxication; checked excretion produces toxemia.

Fasting, especially a long fast, tends to lower the blood pressure. The blood is less viscous when fasting,

and arterial obstructions are cleared out. The body is generally less congested and the blood flows more easily. The pulse goes down, the blood pressure drops, and energies are conserved. During the fast, the body removes its excess toxins and irritations. However, it is important that the person learn to live healthfully after the fast or the blood pressure will rise again. Dr. Shelton says, "To go to bed and fast and reduce blood pressure, and then return to the former mode of living—the former excesses and indulgences, to the poisonous vices and emotional habits, to the prior sexual excesses and to dishonesty, gambling, etc.—is to rapidly rebuild the pathological state that produced the high blood pressure."

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 8. Cardiovascular Drugs

## 8. Cardiovascular Drugs

To quote Dr. Shelton, "The broad and distinct difference between the Hygienic system and the drug system is this: Hygiene seeks to restore health by healthful means and conditions; drug systems seek to cure disease with agents that are known to produce disease in the well. Instead of filling our bodies with poisons, why not look to rest, sleep, better food, fasting, exercise, sunshine, emotional poise, cleanliness, and plain and simple wholesome food as the means of restoring us to health? Hygienic care consists in the use of such means as when applied to a man in health will keep him in health and will not tend to make him sick. Medical treatment of the sick consists almost wholly in the use of means which if given to a man in perfect health would unfit him for work or business or, perhaps, even kill him. The Hygienist rejects all poisons and employs only beneficial substances and conditions to aid the healing processes of the body."

So drugs are not recommended. They do not produce health but contribute to disease.

### 8.1 Digitalis

Digitalis is a highly-poisonous substance derived from the leaves of the foxglove, formerly used as an "herb remedy." It was first introduced to formal medicine in 1785 by the English physician William Withering, but its use in folk medicine preceded that date by many years.

Digitalis belongs to a group of drugs called the cardiac glycosides. The two most commonly-used glycosides are digoxin and digitoxin. This drug is known to result in many adverse effects. The most serious toxic effect is a dangerous irregularity of the heartbeat, but the patient may also suffer nausea, vomiting, and various symptoms of brain involvement, including drowsiness, headache, and blurred or strangely colored vision.

Stimulation from any drug is a very exhausting action and is always followed by a period of depression or exhaustion. Digitalis slows the heart action by stimulating the vagus nerve centers. The right vagus nerve is distributed predominantly to the sinoatrial node, and the left vagus affects principally the atrioventricular node. Stimulation of the right vagus decreases heart rate, whereas left vagal stimulation may induce ventricular slowing subsequent to the development of heart block. Large doses of digitalis or an accumulation of smaller doses can result in heart block. If a complete block of the heart's electrical conduction system occurs, the heart may be slowed to an extent that it cannot sustain life.

Digitalis also results in a disturbance of the normal rhythm of the heart (arrhythmia). The rhythmical projection of impulses from the sinus node are disturbed so that the heart rate shows regularly alternating short phases of slowing and acceleration.

A bundle of muscular fibers in the heart known as the auriculoventricular bundle or the bundle of His, conducts impulses from the auricle to the ventricle. These are conducted in a way to cause the

ventricular beat of the heart to follow the auricular beat in about one-fifth of a second. The administration of digitalis retards or prevents this conduction of impulses. Here again the effect is due to the stimulation of the vagus center. It is not uncommon for a prolongation of the interval between the auricular and ventricular beats from three-tenths to three-fifths of a second, when digitalis is given in so-called therapeutic doses.

The excretion of digitalis is slow so that continued administration of large doses of the drug easily gives rise to "accumulative poisoning." Poisoning resulting from an overwhelming dose results in death in a few minutes. This state of poisoning presents four well-defined states:

1. Vagus and vasoconstrictor stimulation with slowed heart, rapid rise in blood pressure, and diastolic relaxation indicating diminished tone of the heart muscle.
2. Predominance of vagus action, with greater loss of tone and heart block, or brief periods of vagus standstill, and sometimes premature beats from, muscular irritation.
3. Predominance of muscular action with abrupt changes to tachycardia, very rapid beating of the ventricle, usually not in unison with the auricle, high arterial pressure.
4. Weakness and excessive irritability of the heart muscle with auricular tremor, ventricular tremor and death.

## **8.2 Diuretics**

High blood pressure with excessive blood volume is often the result of excessive water and salt retention. The single greatest cause of salt and water retention is the dietary consumption of inorganic sodium chloride (table salt). Salt affects the vascular system in two ways: as an osmotic influence (attracting molecules of water) and as a chemical irritant that sensitizes the vascular smooth muscle to normally-occurring vasoconstrictor substances such as adrenalin. Direct interference with kidney function is another way that salt use contributes to high blood pressure.

Diuretics are given to prevent the reabsorption of salt and water by the kidneys and thus lessen the symptoms of congestive heart failure. There are many kinds of diuretics but all have the same objective to increase the output of salt and water in the urine. One of the major problems they present is an excessive loss of salt and other minerals, especially potassium. Potassium loss is most common with the widely-used thiazide class of diuretics (chlorothiazide and hydrochlorothiazide). Their use can result in feelings of weakness and if digitalis is being taken at the same time, can make toxicity even greater. This loss of potassium is often counteracted by adding a second diuretic—one that does not cause potassium loss—to the thiazide. However, the combination of diuretics induces another danger: diuretics that prevent potassium loss do so by interfering with the kidneys to excrete the mineral. This can lead to a dangerously high level of potassium in the body. Thiazides can also reduce the elimination of uric acid and thus aggravate an existing case of gout and redeposit this highly toxic by-product into the tissues.

## **8.3 Vasodilators**

Drugs that result in the dilation of blood vessels are often given to heart patients. The vasodilators longest in use (more than one hundred years) are the nitrates. Nitroglycerin is the most-frequently used and is usually taken in tablets that are placed under the tongue and allowed to dissolve.

The toxins of the nitrates result in fainting or dizziness, headaches, and palpitations resulting from the compensatory increase in heart rate and the speed of heart contraction. The presence of this poison in the system requires additional work of the already-exhausted heart to eliminate this harmful substance.

## **8.4 Propranolol**

Propranolol (Inderal) is a drug that results in a block of some of the sympathetic nerves to the heart. These nerves (the beta-sympathetic or beta-adrenergic nerves) carry messages from the brain that cause

the heart to increase its rate and the speed of its contraction. When these messages are blocked, the heart rate slows, the speed of contraction decrease and the heart's demand for oxygen decreases.

One of the possible dangers is the development of congestive heart failure because the speed and the force of the heart's contraction are reduced. However this poses two major problems: the congestive failure itself; and the consequent expanded volume of blood in the heart, which increases its size and may make the angina worse.

Another toxicity results from propranolol. This drug affects the beta-sympathetic nerves throughout the body, not just those of the heart. Since these nerves are responsible for dilating the blood vessels of the skin, propranolol use can result in constriction of these vessels, leading to pale, cold hands and feet. The same nerves also cause the body's air tubes to dilate, and when that dilation is blocked, the air tubes become constricted. A patient with asthma can find the condition aggravated.

Patients who are taking insulin for diabetes experience another problem with this drug. Beta-sympathetic nerves cause an increase in blood sugar when the level drops too low. In a diabetic person who is taking insulin, a low sugar level can be aggravated or prolonged when propranolol is also being taken. Propranolol can also result in depression, difficulty in sleeping, and sometimes, impotence.

A number of other drugs are also given to heart patients. They are all poisons. The result from taking any drug is enervation and toxicosis. It is like pouring gasoline on a fire in order to extinguish it. You are just making matters worse and aggravating an already toxic condition.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 9. Your Choice

## **9. Your Choice**

Persons with heart disease believe that they do not have any choice but to take drugs to palliate their symptoms. But they do have a choice. Drugs will not heal and they do not produce health. However, given the proper conditions, the body will heal. The most important requirement for all heart patients is rest. That is, to rest in bed and abstain from all food until healing of the heart has taken place. During this physiological rest, toxins will be eliminated from the body; cholesterol accumulations along the arteries will break up and will be eliminated; and the heart will begin to repair itself. During the fast, vital energy is not being expended for digestion and therefore, more energy is available for repair.

### **9.1 The Fast**

Dr. Hereward Carrington, author of *Vitality, Fasting and Nutrition*, recognized the fact that fasting resulted in strengthening of the heart. He attributed this improvement to the following three factors:

1. The added rest the fast provides the heart.
2. The resulting improvement of the bloodstream.
3. The absence of the "stimulants" that patients in general and heart patients in particular are accustomed to take.

Dr. Shelton Says, "If we consider angina pectoris, a disease of the heart that grows out of constant stimulation with tobacco, coffee, tea, wrong food combinations and excesses of carbohydrates, and observe the effects of the fast in these patients, we are amazed at the speed with which the heart recovers from its difficulties."

It is not claimed that fasting actually "cures" anything. We know that fasting takes a load off the heart so that it may restore its own normal condition in a more certain and speedy manner. Fasting results in the

quieting down of a rapid heart. This takes a heavy load off the heart and results in a speedy reduction of blood pressure.

With a reduction of tension and the number of repetitions of the heart's pulsation, a rest is secured. With less work to do, the heart repairs itself.

In the hundreds of cases of heart disease that Dr. Shelton has witnessed through fasts of various lengths, all but a few have developed stronger and better hearts. Many of them, even so-called "incurable" ones, have become entirely normal. Rapid hearts have slowed down, abnormally slow hearts have speeded up, weak hearts have greatly improved in vigor, hearts that were irregular have become regular in time and frequency, hearts that were missing pulsations (even as often as one pulsation out of four) have resumed regular pulsation, and many other improvements in heart function have been observed.

The rest provided for the heart is accounted for in several ways. There is a marked lessening of the number of pulsations of the heart; there is a fall of blood pressure; and there is a reduction in weight. Weight reduction is most marked in fat individuals whose size is such that the heart has to labor to keep the blood circulating through so much bulk. The loss of pounds relieves the long-suffering heart of a burden. Every pound that is lost relieves the heart of work it has been forced to do.

Edema is often observed in the weakened heart of the heart patient. This edema is a major consequence from taking common table salt (sodium chloride). This salt is nonusable and poisonous. It is excreted with difficulty, and tends to accumulate in the body of the salt eater. It is stored in the surface tissues just under the skin and in cavities, along with water that is needed to dilute it. This salt-occasioned edema, often sufficiently marked to be easily detected, places an added burden upon the heart and kidneys. The body of the fasting patient is able to bring the salt and water back into the circulation, from where it is excreted.

The principle of lightening the work of the circulatory system and particularly that of the heart by decreasing the food intake and by eliminating salt from the diet is carried to its ultimate stage when the heart patient fasts.

The fast seems to result in an instantaneous improvement in the function of the kidneys, so that there is an immediate increase of elimination. With the increased excretion through the kidneys of water and sodium chloride so that the edema is reduced or obliterated, the heart is greatly relieved. It has also been suggested that fasting may favorably affect certain vasomotor centers, (the nerve centers that control circulation), thus causing improvement in the condition of the heart and arteries.

It should be understood, however, that no sufferer from heart disease should ever attempt to fast on his own but should consult with a practitioner who has experience with the fast.

After the fast, it is imperative that a more healthful diet is strictly adhered to. That is a diet low in fats and proteins and high in natural carbohydrates. A diet of raw fruits, vegetables, and raw, unsalted nuts and seeds will provide the perfect nutritional requirements.

In addition to this, a regular vigorous exercise program should be gradually assumed. Accompany this with plenty of fresh air, sunshine, and emotional poise, and improved health will follow.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > 10. Questions & Answers

## **10. Questions & Answers**

**What is rheumatic fever and why does it affect the heart?**

The disease that physicians have labeled "rheumatic fever" is considered by them as the most common heart disease of childhood and youth. Most commonly, it begins by a minor sore throat and cold. This is an indication that the body is initiating a "housecleaning" and ridding itself of some of its toxic debris. It is a sign of vitality and should not be suppressed but instead you should cooperate with the body in this effort and health will be restored quickly. Most often, it is not understood that this "disease" is a healing process and drugs are given. Drugs suppress healing and add more toxins that are enervating. Now the joints become inflamed and heat and pain are felt in the knees, wrists or elbows. More drugs are given in the form of antibiotics or hormone drugs and the healing process is again suppressed, the body becomes even more enervated and toxic and the heart becomes inflamed. Instead of securing rest and allowing the body to eliminate its toxic overload and recover from its enervation, additional drugs are given. The end result from this series of abuses is extreme enervation and toxicosis and eventual damage to the heart itself. Physicians often blame this "disease" on a strep infection but it is not germs that produced the heart damage. If the body had been allowed to rest and fast when the minor sore throat first appeared, health would have been restored immediately.

### **Is vitamin E a good preventative for heart disease?**

Disease is not a normal occurrence and therefore does not need to be prevented.. If we live healthfully, we do not have to worry about heart impairment. The body does need vitamin E but cannot utilize it in a synthetic or inorganic form. Further, we do not require very much of this vitamin since a great deal is stored in our tissues and can be used over and over again. All of the vitamin E that we require is found in the fresh fruits and vegetables, nuts and seeds of our daily diet.

### **What is Raynaud's phenomenon and how should it be treated?**

Raynaud's phenomenon is a condition where the smallest arteries supplying the fingers or toes constrict on exposure to cold or following any stressful situation. Because the small veins are usually open, the blood drains out of the capillaries and the fingers or toes become pale, cold and numb. If there is a spasm in the small veins and the blood becomes trapped in the capillaries, the fingers or toes become blue as the blood loses its oxygen. The condition clears when the spasm is released by rubbing the parts affected or by returning to a warm environment

This condition should not be treated at all. Instead examine your lifestyle to see if all the proper conditions for health are present including a regular exercise program. A healthy individual possesses a purity of the bloodstream and circulatory system and abnormal conditions such as Raynaud's phenomenon do not occur.

### **Have researchers established a definite correlation between hypertension and high levels of salt use?**

In countries such as Japan, where there is an extraordinarily high level of salt in the common diet, there is also a significantly high rate of hypertension. Salt stresses the mechanism that controls the fluid and blood levels, and high blood pressure comes about as a response to the additional salt load

Dr. Lewis K. Dahl of the Brookhave National Laboratories conducted research on salt and hypertension. Dr. Dahl wishing to explore why hypertension is so rare among primitive peoples with low-sodium diets, investigated the correlation between salt consumption and hypertension. Dr. Dahl conducted a pilot study at Brookhave where 1,346 adults were

classified according to their intake of salt. There were three categories: low intake (never adds salt to food); average intake (adds salt after tasting if insufficiently salty); and high intake (customarily adds salt before tasting)

Of the adults in the study, 105 were found to be hypertensive. Of all the subjects who had a low intake of salt, one was hypertensive. The high-intake group had 61 cases of hypertension.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > Article #1: Coronary Thrombosis by Dr. Robert R. Gross, D.C., Ph.D.

### **Article #1: Coronary Thrombosis by Dr. Robert R. Gross, D.C., Ph.D.**

The leading fatal affliction killing people in the prime of life is coronary thrombosis. This is a blood clot occurring in the arteries of the heart and occluding it (coronary occlusion). The area supplied with blood by blocked arteries loses its source of nutrition and oxygen and degenerates. This area weakens and nonfunctioning scar tissue forms. A "myocardial infarction" with consequent heart disturbance and degeneration has occurred. If the block is severe, death comes very quickly. If it is a milder condition, the patient may recover in a few weeks through complete bed rest.

A blood clot in a blood vessel is a "thrombus." When it becomes detached from vessel walls and floats in the blood it is called an "embolus." The resultant condition is known as "thrombosis." Thrombi may lodge in a heart artery (coronary artery), plug it, and block blood supply to a wedge-shaped heart muscle section. Floating clots may reach the brain, obstruct blood to important motor areas and result in partial or complete paralysis: "a stroke." Clots may travel to the lungs and occlude an artery causing "pulmonary embolism."

### **Blood Coagulation**

Circulating blood in the cardiovascular (heart and blood vessel) system does not normally clot. When it is shed and exposed to air, it coagulates to form clots. The clotting mechanism consists of: *thromboplastin*, released from injured blood vessel walls, white blood corpuscles and blood platelets in the blood; *prothrombin*, a protein manufactured in the liver and converted into thrombin by thromboplastin; *thrombin*; *fibrinogen*, a protein manufactured in the liver and converted into fibrin by thrombin; fibrin, which forms lace networks, entrapping platelets (thrombocytes). A clot is produced.

Clotting is activated by the presence in the blood of calcium and substances known as "serum accelerators." Prevention of clots in normal blood is due to the presence of such substances as anti-thrombin, fibrinolysin, and heparin. Shed blood clots because these substances are oxidized and inactivated. Clots normally plug wounds in vessels, preventing hemorrhage. Calcium is the key factor in normal clotting; if inactivated or removed, blood will not, clot.

Coronary thrombosis occurs, usually, without warning. Many victims "had never been sick a day in their lives" or "just had a heart check-up and it was fine." Truthfully, the subject had been eating and living incorrectly most of his life. He or she was certainly sick with toxemia (general poisoning). Resultant chemical changes in the blood causes disequilibrium in the clotting mechanism. Clots formed adhering to the blood vessel's internal walls. Heavy work, eating an unusually large meal, excessive sex indulgence, over-exercise and emotional and temperamental outbursts cause dislodgement of clots leading to thrombosis.

The patient is prostrated and falls to the ground with ashen-faced pallor; pain in the heart region is severe, constricting and lancinating; pulse is thready—rapid, irregular and feeble; breathing becomes shallow and rapid; he has clammy, cold perspiration.

Tendency toward intravascular (within blood vessels) clotting is a serious hazard to life. Clots of coronary (heart) and cerebral (brain) arteries and the lungs often prove fatal. If such an episode occurs once, likely, others will form for causation still remains. The leg veins and heart are usual sites of clotting. Clots won't produce dangerous consequences unless they break off and float in the circulation to obstruct arteries, depriving a vital tissue of blood supply. Clots can consist of coagulated blood or fat droplets, air pockets, clumps of bacteria, tumor tissue, or inflamed heart vascular tissue.

## **Causes of Intravascular Clotting**

Intravascular clotting is often a complication following surgery. Coagulation of shed blood inside (internal bleeding) the body plays a role in postoperative adhesions. Clotting occurs when the blood slows up (stasis) as in varicose veins, some heart difficulties (auricular fibrillation) and in injuries to blood vessel walls from bruises, cuts, or hypodermic needle injections. Clotting results from inflammation of vessel walls in phlebitis (vein inflammation) and certain diseases of the heart valves.

The basic and fundamental blood clotting cause is change in chemical composition of blood due to incorrect feeding habits. Acid tendency of the blood results from eating devitalized, demineralized, and devitaminized foods as: white sugar, white bread, pasteurized milk, sweet rolls, crackers, cakes, cookies, biscuits, sweet desserts, ice cream, soft drinks, pie, potato chips, candies, jellies, jams, buns, syrups, thickened gravies, hot cakes, waffles, dry cereals, alcohol, meats, chicken, fish and spaghetti. Arteries degenerate or deteriorate. Walls of vessels thicken (atheroma) and retard blood; it sludges easily and clots, obstructing narrow diseased arteries. In obstructions affecting large sections of the heart, resulting myocardial infarcts can deteriorate so badly that insufficient power remains to effect adequate circulation. The heart wall becomes so weakened that it ruptures fatally.

The majority of "coronary" patients, however, have a good chance to live. Sufficient compensation and enlargement occur, permitting the heart to function effectively. Other blood vessels are formed by nature and assume the circulatory duties of the occluded one. This is called "collateral circulation."

## **Medical Treatment**

Physicians use "anti-coagulants" to dissolve formed, clots and prevent further clot formation. They are rutin, hirudin, heparin and dicoumarol. Like other drugs they are devastating, give a false sense of security to the patient, and produce chronic disease. They weaken walls (intercellular substance) of blood vessels and fatal hemorrhages can occur, internally and externally. Causes of internal clotting persist and danger of recurrences remains. Furthermore, the vital energy of the body is depleted by all drugs and other serious derangements occur in addition to clotting.

## **Natural Hygienic Care**

Annual physical fitness examinations which the President received from army physicians failed to protect him from, a coronary thrombosis. Increasing medical examinations failed to reduce incidence of deaths from this "heart disease." To overcome this abnormal tendency no medical examinations or drugs, shots or pills are required.

The real "treatment" is rest and quietude which permits the heart to function normally again. Time, perseverance and inactivity are required.

Complete fasting (drinking only distilled water) several days under competent supervision should be undertaken immediately. This physiological rest reconstitutes vitality of the body and accelerates internal purification processes. It enables the innate healing powers of the body to manifest themselves

unobstructedly and efficiently.

Hygienic feeding is essential. Raw fruits, nuts and vegetables, whole grain products and natural sweets like raisins, figs and dates should form the dietary. These vital foods keep the blood stream clean and help heal degenerated arteries by producing general improved health.

Habitual living in tension with its destructive emotions—anxiety, depression, worry, fear, apprehension—is one of the chief causes of coronary thrombosis. This mental tension, incorrectly "nervous tension," makes the individual sick and miserable and exerts destructive forces (through the nervous and hormonal systems).

It is a sheer impossibility for man to disregard the laws of nature and remain healthy. To the extent that he deviates, to that degree will he suffer. Disease is a warning by nature that our bodies are poisoned; if signs are unheeded, deterioration will follow. Each disease is a crisis in life. Crisis means decision. We must strive to recapture our health by adhering to Natural Hygienic principles. We must make leisure hours to meditate and reflect errors committed in living physically, emotionally, morally and spiritually. Recognition of these mistakes helps to discontinue them, preventing future disease.

Nature or God provided us at birth with sanctified temples occupied by our souls, minds and thoughts. We must not defile these temples. It is our inherent responsibility to provide the proper brick, mortar and wood (blood, bones, tissues) to maintain the integrity and indissolubility of the temple. To ignore and refute the laws of nature is to disregard God. Adhering to Natural Hygiene tenets will bring rewards of health in body, soul and mind.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > Article #2: Heart Attack by Dr. Geo. E. Crandall

## **Article #2: Heart Attack by Dr. Geo. E. Crandall**

In the past year, hundreds of people in middle life, especially men, have been killed by a heart attack. At least this is the statement appearing in our daily press. It could not appear on the death certificate as the cause of death for the simple reason that there is no such thing as a heart attack. How they conjured up such a misnomer is beyond comprehension. It comes from the same imagination as the nonsensical terms: FIGHT CANCER; FIGHT SYPHILIS; FIGHT PNEUMONIA and FIGHT TUBERCULOSIS! These false slogans impress the uninformed and misinformed and they are scary enough to make Congress shell out the almighty lucre without a dissenting vote.

You can't FIGHT cancer for the simple reason that the cause is not known, yea, not even suspected. The same holds true for syphilis, pneumonia and tuberculosis, the victims of these afflictions can only wrestle or fight with themselves to gain self-mastery. The battle is inherent and, if won, intelligent self-control will eradicate every so-called disease! This battle doesn't cost a dime, so what becomes of all the enormous sums of money allotted by the federal, state and municipal governments for the "FIGHT" racket? If the truth were known you would be surprised.

The heart of a man receives great protection from attack by the encasement formed by the thoracic wall. Except for the very small intercostal spaces or interstices between the ribs, it is securely protected by an armour of bone. From external sources it is nearly immune from attack except from a bullet or stab wound. However, in the so-called heart attacks, these two remote possibilities are not the cause; the attack, if there is one, must come from within. Can the individual attack his own heart? The answer is YES. Not directly in what is commonly spoken of as an attack or assault, but indirectly by a thousand and one subtle forms of over-stimulation.

The toxic effect of indigestion from overeating is the first great case, and this is ably aided and abetted by tobacco and alcohol, this is a trinity, friends, that is a constant attack upon the heart. In time it will ruin any heart, no matter how strong. No heart can withstand its onslaught much beyond 63 years, and many are taken by the Lord much younger. Everyone could postpone his or her death 30 years by overcoming all bad habits through self-mastery.

A normal life is the only protection one has from these so-called heart attacks. An individual must ruin his heart by years of abuse from bad habits before the attack is turned on that ends the career.

Inasmuch as there is no satisfactory treatment for a heart attack known to medical science, and often not enough time to apply even an unsatisfactory effort, it behooves all of us to play the game of life safely by giving up our bad habits and getting in tune with natural law and the universe. You can't be a "natural outlaw" for many years until the heart gives out; and then comes the inevitable newspaper recital ... heart attack and the mortician!

About 50% of the people do not know how to reform and live normally, and the other 50% prefer to cling tenaciously to their so-called "pleasures of life."

A normal heart beats 103,680 times a day. Think of the enormous amount of vital energy needed to carry on this work alone. Why should anyone wish to squander this vital energy in foolish, nonsensical, overstimulating habits? Why whip the heart that is willing and ready to beat 103,680 times daily, without rest, for 100 years? If you treat this magnificent organ decently, there will never be a so-called "attack." You are the only one to blame, and the attack, if there is one, is from within, never from without!

Should one drug this organ with digitalis, strychnine and other heart stimulants, or paralyze it with morphine or other narcotics? Should a physician jeopardize your life by suggesting or advising it? That heart of yours will pump 3,784,320,000 times without a miss if you will, by correct living, give it a chance.

The greatest enemy to a normal heart is perverted nutrition, or what is commonly referred to as indigestion. The cause of indigestion primarily is overeating of staple and chemically incompatible foods. This is further augmented by the use of tobacco, alcohol, tea and coffee. Correct the perverted nutrition by following the rules. Overcome all bad habits just mentioned and you have removed from your life the cause of a heart attack. If you don't have a good heart in this world, what chance do you have in the next? If you want to inherit the kingdom, play fair. It cannot be accomplished by fooling yourself with overstimulation ... the advice of the clergy to the contrary notwithstanding.

Of all animals, man is the only one endowed with intelligence. The others all have to depend on instinct. However, no other animal but man suffers from so-called heart attacks and dies in middle life.

Why should intelligence be inferior to instinct? To the question, there is but one answer, namely, that whoever is guiding us along the lines of health is giving us erroneous advice and false statements. Do doctors want us to have knowledge that will insure grand health, thereby making their ministrations unnecessary? Isn't it to their distinct advantage to give us wrong advice so we will need their services for ailments built from incorrect living?

You can overcome all your bad habits if they interfere with health, but from whom can you learn about the laws of nutrition? Man's physical salvation depends on demanding this knowledge and receiving it. Drugs, serums and surgery are now masquerading as a substitute, but they are a false prophet and fail to bring us rational health knowledge. To overcome disease and prevent sudden heart attacks, we must learn how to get back to the normal and live correctly. You should become a "natural Methodist" and live a century; three score and ten are not sufficient. They lived that long two thousand years ago when the mind of man was in incubation. Why haven't we made any improvement or progress since? Because man has believed in demonology—that disease is a dispensation of divine origin and "men of medicine" have fooled away 2000 years trying to outwit the deity with pills, potions and palaver instead of recognizing that disease, heart attacks, and premature senility, are merely states of perverted nutrition caused by an incorrect method of living. A thorough understanding of human nutrition and the laws that

govern it will allow man to live six more score years and carry out the promise of the scripture as found in Genesis 6:3.

[Home](#) > [Lesson 74 - Diseases Relating To The Heart And Circulatory System](#) > Article #3: Exercise and the Heart

### **Article #3: Exercise and the Heart**

Every one of man's organs is supplied with a reserve of functional power and ability, in excess of the needs of ordinary life, to be used in meeting emergencies or unusual demands. A considerable portion of the liver may be removed without its possessor appreciably missing it; about two-fifths of it may be removed, but if three-fifths are removed, he begins to feel it. We have much more liver than we really need for the preservation of life. This same is true of all the other organs of man's body, the heart included.

The capacity of the heart muscle for work is thirteen times as great as the amount of work it is ordinarily called upon to do. This most wonderful organ is one of the strongest and most resistant in the body. It is capable of outlasting any other organ of the body except the brain. Instead of work or heavy exercise injuring the heart, the muscles of the body become too tired to go on before the normal heart feels any strain.

The heart is a muscular organ—it is almost all muscle—and like all other muscles of the body, is strengthened by use. A heart that is never called upon to do vigorous work does not grow vigorous and strong. If it always does light work, it tends to become soft and flabby. If needs periods of vigorous work to build up and maintain its maximum strength and ability.

Running is the best exercise known for the heart. Running is the one universal exercise among the higher animals. Whether running merely for play, as one may observe dogs, cats and horses doing, or running away from an enemy or after prey, as one often observes in the wilds, running is frequently indulged in by life all around us.

Children run in play as naturally as do young kittens and calves, puppies and cubs. Running is the most natural form of exercise and has long been known to be the finest "conditioner" that athletes can employ in their training. "Road work" (running) is employed by the boxer to build up that condition of the heart and lungs that spells staying power when he comes into the ring for the fight.

Stop being afraid of your heart. What does it matter that some nit-wit has advised you not to attempt to climb even three steps? They have been killing those who take this advice for a long time. The best way to weaken your heart—to let it grow flabby like the muscles of your arms—is to never give it any vigorous work to do.

Stair climbing, started moderately and increased prudently, will result in recovery in many cases of supposed bad heart weakness. The late President Harding restored his heart to soundness by stair climbing after years of petting and pampering under the directions of his favorite pill roller who failed to help.

Any form of exercise—running, dumb-bell exercise, Indian club swinging, swimming, etc.—started moderately and increased prudently, will produce heart and lung development and lead to the establishment of robust health. Of all forms of exercise, running, as pointed out above, is perhaps best for the heart.

Although "regular medicine" never tires of telling us how many heart defects and other defects are susceptible of prompt eradication by proper measures, they seem never to be able to find the proper

measures. Their program of inactivity and drugging certainly does not remedy heart defects *d* and every day we see heart cases grow from bad to worse under this program of care.

The most difficult task in heart cases is that of ridding the patient of fear implanted by physicians. Yet the elimination of fear is one of our most important tasks. Fear paralyzes action and prevents the patient from carrying out the necessary exercise program. Fear cripples the heart itself. It impairs digestion and checks elimination and tends to prevent recovery.

In 1911 Clarence DeMar entered his name for a 26-mile Boston Marathon. His heart was examined by a doctor who told him to drop out if he got tired and advised him to give up running thereafter. DeMar won the race in record time. Since then, DeMar's record in 66 marathons, including three at the Olympic Games in 1912, 1924, and 1928, is 20 firsts, 12 seconds, 9 thirds, and he is still a keen marathon runner. Had he allowed the advice of the physician to frighten him and had he ceased running as advised, the name of DeMar would not stand so high in the athletic world.

Fear is man's greatest enemy. Fear is the greatest nerve annihilator known. It not only paralyzes action, it deranges digestion, impairs glandular action and checks elimination. Enervation, perverted metabolism, and toxemia are the results. Cases have come under my observation in which fear of activity (both conscious and subconscious) was so great, that the victims of fear were weak and always tired. Slight exertion exhausted them and made them feel bad. Those patients had been frightened by doctors and parents about their hearts and thus their hearts being denied the one thing that could make and keep them vigorous, had grown weaker and weaker.

Only exercise can strengthen and rebuild such hearts and peoples' fear of exercise prevents them from employing it. Fear paralyzes effort and denies their hearts the one thing essential to its recovery of vigor.

There are times and conditions in which the heart needs rest and nothing else will take the place of rest; but perpetual rest becomes rust. After rest has done its work, exercise is needed and nothing will take the place of exercise. After a period of preliminary preparation, vigorous exercise should be indulged. There are still many physicians who warn us of the grave dangers to the heart and other parts of our body that exist in athletics. Nobody ever warns the dog running after the hare, or the wolf chasing a deer, that running is bad for the heart. Only man seems to be built so poorly that he cannot indulge in the strenuous activities of life.

Physicians like to tell their heart cases that their heart troubles have been brought on by strenuous play like tennis, football, handball, swimming, running, jumping, etc., because any trouble so caused is supposed to be hard to cure and physicians find that patients have more patience with them when they fail to cure in a reasonable time, if they believe their troubles were caused by athletics.

Actually, this is one of the chief reasons why these patients are never restored to health. So long as physicians are mistaken about cause, so long as they fail to find the real cause, they cannot care for the patient in a manner that will restore health. Wrong care must always flow from an erroneous cause.

### 1. Introduction

There are many factors involved that may contribute to the development of cancer. There are

carcinogens in the environment, tobacco, alcohol, and in processed foods. There are cancer-causing toxins in drugs, X rays, and even in the cancer therapies themselves.

You also may develop cancer in the absence of these extraneous factors. This condition begins when you first become enervated and your body cannot cope with endogenous and exogenous toxins. These toxins accumulate, and if no corrections are made, eventually progress through the seven stages of disease terminating in the seventh stage—cancer.

Since all of these factors are equally important, we will examine them all in this lesson. It is important for you to be aware of the harmful results from all of these toxic substances. When you know the truth, you will be able to make rational decisions that will result in health.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 2. The History Of Cancer

## 2. The History Of Cancer

Cancer is a disease of civilization. And yet it is a very old disease. Several million years ago a dinosaur could be found with bone cancer, as fossilized remains discovered in Wyoming have shown. Perhaps other forms of cancer existed in those remote times, but bones are the only remains of extinct animals and therefore give a record of bone cancer alone.

Cancer in the ancestral species of man is more than a million years old. Some traces of it have been found in an anthropoid unearthed in Java in 1891. In antiquity the oldest evidences of cancer are Egyptian and Indian. Bone cancer is identifiable in some mummies discovered in the Great Pyramid of Gizeh. The Edwin Papyrus (2500 B.C.), the Leyde Papyrus (1500 B.C.), and the Ebers Papyrus (1500 B.C.) describe symptoms of cancer and primitive forms of treatment, such as the use of the knife. From the Hindu epic, the *Ramayana*, we learn that arsenic pastes were administered as long ago as 500 B.C. as a treatment for cancerous growth. Writings attributed to Hippocrates (about 400 B.C.) describe many forms of the disease, among them cancer of the breast, uterus, stomach, skin, and rectum. From him we have inherited the term carcinoma (Greek *karkinos*, crab—the great veins sometimes surrounding the malady were compared to the claws of a crab). But treatment in those days were crude, employing caustic pastes and cautery, although Hippocrates had the wisdom to advocate *no* treatment for what he called accult cancer and which would nowadays be called deep-seated cancer.

Hippocrates set forth the humoral theory of disease, which was to form an integral part of medical history for centuries. According to him there were four humors—blood (from the heart), phlegm (from the head), yellow bile (from the liver), and black bile (from the spleen). If the four elements were not properly balanced, bodily health would be impaired and illness would appear. Hippocrates believed that the black bile was mainly responsible for cancer. His theory of humors, although erroneous, demonstrated clearly his certainty that illness originated within the body, in contrast to beliefs in the magical, diabolical, or divine interference with human health.

In the first century A.D., the Roman physician, Aurelius Cornelius Celsus, was the first to operate on cancer, and, during the operation, to ligate blood vessels. He knew about the invasion of distant sites by original cancer cells. He described the appearance of secondary tumors after the primary one had been removed, and he was aware that certain tumors were painless and silent until they grew large enough to ulcerate.

Galen advocated the black bile theory of cancer, and his considerable influence blocked discoveries about the nature of the disease until after the Renaissance. Nevertheless he was the first to correlate psychosomatic problems and emotions with an understanding of cancer. In his treatise on tumors he

wrote that melancholic women are more prone to breast cancer than sanguine women.

Arabian physicians of the twelfth century, Avenzoar and Averrhoes, used esophageal sounds to diagnose cancer of the throat and to improve bleeding of patients whose esophagus was obstructed by cancer. Their clinical description of stomach and esophageal cancer is accurate. Another surgeon of the Renaissance, Fallopius (1523-1562), used caustic pastes instead of surgery in the treatment of cancer. It is perhaps worthy of note that there has been a return to this crude use of caustic pastes, as in the method of chemosurgery advocated by Dr. Frederic Edward Mohs in certain cases of face, head, and neck cancer.

The difference between benign and malignant tumors was clarified shortly after Hildanaus's time by Marcus Aurelius Severinus. In the eighteenth century the first cancer hospital was founded in Reims, France. At that time cancer was considered to be contagious and persons sick with various forms of the disease were avoided like lepers.

Discoveries were made in many directions during the latter part of the eighteenth century. The first experiments in animals were begun. Occupational cancer, in the form of scrotal cancer of chimney sweeps, was described (1775) by Percivall Potts.

Advanced knowledge in pathology came through the work of John Hunter, Rene Laennec, and Marie Francois Bichat, who espoused a concept of cells as basic units of tumors. The French gynecologist, Joseph Recamier, who spoke of generalized cancer, described invasion of the bloodstream by cancer cells. It was he who coined the term metastasis to describe the establishment of secondary cancer centers in the body as a result of the transportation of cancer cells by lymph and blood.

Toward the end of the nineteenth century in Germany, Christian Billroth, Alexander von Winiwater, Wilhelm Freund, Themistokles Gluck and others began to perform cancer operations on a larger scale than ever before. Hysterectomy and laryngectomy became common.

Early in the twentieth century the American surgeon, William Halsted, set forth his surgical principle in the treatment of cancer, namely, that the lesion, together with the regional lymph nodes, should be removed in an attempt to prevent metastases. This principle is best illustrated in his radical mastectomy operation for cancer of the breast. His method is still widely practiced today and is responsible for the unnecessary mutilation of many women.

In 1895, Roentgen discovered some unknown rays which were to become very widely used in the diagnosis and treatment of cancer. As he was working in his laboratory, experimenting with a vacuum tube through which an electric current passed, he noticed that a nearby piece of paper coated with barium platino-cyanide was giving out an unexpected glow. He placed different materials between the vacuum tube and the treated paper and found that some substances stopped the glow while others did not. He had the proof that certain rays emanated from the vacuum tube, and that denser materials interrupted them but lighter ones did not. The rays are sometimes known as roentgen rays, but more often by the name he gave them, X rays.

Three years later, the two French scientists, Pierre and Marie Curie, made another discovery when they found a new element in the ore pitchblende, which had already yielded uranium. This element they named radium. They found that the radiations emitted by radium are much more intense than those which uranium was already known to discharge. Marie Curie was also the first victim of the study of radium, which kills but never heals. She developed anemia from protracted exposure incident to her long years of research with this radioactive element.

Both X rays and radium are dangerous. Shortly after the discovery of X rays, a man employed in a factory making roentgen tubes developed an ulcer in an arm, the arm had to be amputated, and he finally died after a recurrence of the ulceration in the axilla. One of the pioneers in radium therapy fell victim to his work: the surgeon, Robert Abbe, died of anemia like Marie Curie after long exposure to radiations.

The French physician, Jean Bergonie, along with L. Tribondeau, gave us the Law of Radiosensitivity.

Bergonie died in 1925 from cancer caused by X rays. First his fingers, then one of his arms, had to be amputated. He finally developed pulmonary metastase, which ultimately caused his death.

To surgery and irradiation, the current mainstay in the treatment of cancer, has been added a third type of therapy, chemotherapy. Whole families of drugs have been created which are claimed to have remarkable influences on the growth of cancer cells and on the mechanisms whereby cells replicate, transmit, and translate genetic information. These new drugs not only kill the cancer cells themselves, but have many adverse effects on bodily processes in the individual harboring cancer.

We shall have to note the physician's inability, despite surgery, irradiation, or chemotherapy, to "cure" cancer. Healing can only occur endogenously through the organism's faculties when causes are removed and the conditions for health are provided.

Every time a woman sees her gynecologist for a Pap Test; every time she reports a lump in her breast to her doctor; every time a man or woman tells his physician about a sore which refuses to heal, a persistent bleeding, a change in an ordinary mole or wart, reports constant indigestion, or a change in bowel habits, physicians employ scare tactics. They advocate caution and promote reporting any such symptoms immediately to their physician so prompt treatment may commence to ensure a "cure." The sick individual does not understand that the physician holds no "cures" and only the body has the ability to heal. Any treatment applied at this time or any time will only hinder the body's own efforts to heal.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 3. What Cancer Is

### **3. What Cancer Is**

Cancer is the end point (the seventh stage) of a disease process. It is a group of "diseases" found in all races and ages of man and in all animal species. It is often considered a single disease only in the sense that all cancer is characterized by unrestrained growth of unintegrated cells.

Most body structures are composed of tissues made up of many different types of cells, any of which may become cancerous if any unhealthful lifestyle is carried on. A specific type of cancer draws its name from the type of cell affected:

Cancers in connective tissue, including bones, are called sarcomas.

Cancers in cells which line the body's internal and external surfaces (lungs, breast, skin) are called carcinomas.

Cancers in cells that compose the blood-forming system are called leukemias or lymphomas.

In most cases of cancer, unrestrained cell growth leads to the buildup of tumors which compress, invade, and/or destroy normal tissues. The specific type of tumor may (but not always) indicate a probable causative agent: for example, mesothelioma, a diffuse cancer of the chest or stomach lining, is associated almost exclusively with exposure to asbestos.

Malignant tumors generally share some characteristics: higher rate of cell growth than in the normal, surrounding tissues; failure to maintain the boundaries of normal tissue and organs; a microscopic appearance which suggests immature rather than mature tissues, and a tendency to spread to parts of the body distant from the original site of the cancer. Not all these features accompany every malignant tumor, but they characterize most forms of cancer.

## 4. Cancer Incidence

Cancer affects people of all ages but is predominantly a disease of middle and old age as it takes time for a disease to progress to this point. Persons around age 70 account for a higher number of cases than any other age group.

Cancer is also a significant factor in the death of children. For children between the ages of 5 and 14, it ranks second only to accidents. Projections from available data show that about 7,000 new cases of cancer occur annually in children under the age of 15 years. This can be attributed to the teratogenic effect of tobacco, alcohol, caffeine, drugs, etc. Another contributing factor is the unhealthful diet of our youth including the large amounts of junk foods and meat that is consumed by them.

Recorded deaths from cancer in the United States have more than doubled since 1935. Similarly, current death rates indicate a real increase in mortality from cancer.

The most dramatic changes are the nearly twenty-fold increase in lung cancer for males, and a two-thirds increase of stomach cancer in both males and females. The increase in lung cancer for males is primarily attributed to heavier smoking, coupled with impacts from other environmental pollutants; the stomach cancer is linked to diet.

There were 358,400 cancer deaths in 1974. About one million are under treatment for the disease, and each year 900,000 new cases are diagnosed. The American Cancer Society estimates that 25% of the 213 million people now living in the United States will ultimately develop some form of cancer.

An estimated \$1.8 billion per year is spent solely for hospital care of cancer patients. Additional costs, doctor bill, outpatient therapy, and other treatment-related fees, raise the direct expenditure for cancer well into the tens of billions of dollars, to these direct expenditures must be added indirect costs, such as the estimated 1.8 million work years lost in the national economy and to family income by unemployed or underemployed cancer sufferers.

Fasting and a raw food diet is an effective means to restore health; it is the only effective means. None of the cancer therapies now in use by orthodox practitioners ever result in health. Instead, they progressively destroy health.

## 5. Normal Cells To Cancer Cells

Cancer is a fundamental derangement of the normal mechanisms controlling the division, placement and function of cells. Whereas normal cells divide and stop dividing after a certain fixed time, cancer cells do not. They do not "know" when their division is to be stopped and they proliferate in a disorderly fashion.

As soon as cells become cancerous they are no longer controlled by body mechanisms. Cancer cells proliferate and form a mass of cells. Cancer cells have different degrees of affinity for each other, which accounts partly for their propensity to metastasize. An invasive cancer cell is a cancer cell that has a great predilection for spreading rapidly and uncontrollably.

Even though our knowledge about the division of normal cells is limited, we do know that they stop growing when they touch each other if placed on a solid surface such as that of a glass slide. This mechanism of growth control is called contact inhibition. Cancer cells, however, growing in the same

conditions, do not stop proliferating; they have lost contact inhibition. While normal cells grow on solid surfaces in single layers, cancer cells show less affinity for the solid surface and grow in irregular masses several layers deep.

Normal cells reside with one another and have a "home" of their own. A kidney cell stays in the kidney and lung cell in the lung. Cancer cells may be said to belong nowhere, to have no proper residence, no "home." We may compare the chemical composition of both normal and cancer cells, for they have the same components, although in slightly different amounts and relationships.

Cancer can be induced experimentally in animals by external agents called carcinogens. Once a cell has changed from normal to cancerous, its succeeding generations are cancerous too; this is true at the cellular level only. A cancer cell is a normal cell deranged by toxic substances and loses contact with the organism. It has been rendered "crazy" by poisoning.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 6. A "Cure" For Cancer

## 6. A "Cure" For Cancer

Regarding the search for "cures" for our illnesses, Dr. Shelton says, "Removing cause is the last thing the medical mind ever thinks of. They think always of 'cures.' They search always for 'cures.' They make their money out of the 'discovery,' manufacture, distribution, sale and administration of 'cures.' One of the largest industries in the world, one that pays rich dividends to a vast worldwide army of men and women, is built around this delusion that diseases can be 'cured'."

The search for a "cure" for cancer will be a never-ending one because there is no "cure" for our wrongdoing other than correcting our errors in living. Cancer is an end point in a pathological evolution that had its beginning long before any clinical signs of cancer manifested itself.

Dr. Shelton said, "Cancer does not attack. Cancer evolves. Cancer cells and cancer tissues are modifications of the patient's own cells and tissues. They are not foreign entities that pounce upon their unwary victims from out of the dark." So we must look to ourselves to reverse this process. When the pathological conditions which resulted in this abnormal cell growth are removed, health will begin to be restored as long as this condition has not advanced too far.

Medical pathologists recognize pre-cancer, early cancer and cancer, but they do not consider the sequences that precede pre-cancer. There are seven stages of disease which will be reviewed later. If the causes of our illness are corrected during any of the first six stages, health will be restored and cancer will never develop. Again quoting Shelton, "Searching for a cancer-causing chemical at this stage in the pathological evolution in the 'sawdust Caesar,' and ignoring all the antecedent stages of the evolution and the causes of the first and subsequent stages, is approved medical practice, but it is not at all scientific."

Destroying a growth does not remove the cause of that growth. The medical profession resorts to surgery, X rays, drugs, etc., to destroy growths but health is never restored because causes are not taken into consideration. If, for example, one lung is diagnosed as cancerous and removed, health cannot be restored if that person continues to smoke. If a woman undergoes a mastectomy for a cancerous lump and then goes home and continues to consume additive-laden junk food, her cancerous condition will continue to worsen.

Physicians do not recognize that cancer is an end point in a pathological process that has gone on for years and has had many causes. They refuse to see it as merely the last link in a chain of causes and effects that reaches back to the very childhood of the patient. Cancer begins with the first poisons

ingested. When a child eats a hot dog with coal-tar dyes and nitrite, he is initiating the first steps toward a slow poisoning of his body which, if persisted in, may result in cancer many years down the road.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 7. The Seven Stages Of Disease

## 7. The Seven Stages Of Disease

The seven stages of disease were explained in detail in Lesson 2, but I will review them here as they are important in our discussion on cancer

1. **ENERVATION** - This is the first step in disease. Our fund of nerve energy becomes overdrawn to the point that the body is unable to eliminate the toxic by-products of metabolism. Enervation is a state in which the body is either not generating sufficient nerve energy for the tasks the body must perform, or the tasks the body must perform may be greater than the normal nerve energy supply can cope with. The body thus becomes impaired and generates less nerve energy. All the body's functions become impaired and this includes the processes of elimination of both endogenous metabolic wastes and the exogenous poisons introduced into the body (such as in our chemicalized foods). This impairment results in further diminishing the body's ability to restore depletion of nerve energy. This situation results in a condition called toxemia or toxicosis—the second stage of disease.
2. **TOXICOSIS** - The blood and tissues become loaded with the uneliminated toxic materials from body metabolism and/or from toxins taken in from processed foods, drinks, drugs, etc. Intoxication occurs when we overload the body with toxic materials from the outside, or we fail to observe our capacities and overwork, get insufficient sleep, or are subjected to great stress, or when any number of other factors deplete the body of nerve energy or prevent its sufficient regeneration. For instance, stresses, emotional shocks, or traumatic experiences can drain our bodies of nerve energy very quickly.
3. **IRRITATION** - This is the third stage of disease. The body unloads its toxicity at various points in the body. Irritation takes the form of itchiness, edginess, uncomfortable feelings, etc. Any toxic material, be it salt, caffeine, or condiments will irritate or stimulate. This is a condition wherein the body sets in force its defensive mechanisms and accelerates its internal activities. A burst of activity will result in an effort to rid the body of these unwanted irritants  
If the causes of enervation/intoxication/irritation remain, inflammation results.
4. **INFLAMMATION** - This is the stage of disease that is usually first noticed and is recognized by physicians as pathology, for it involves pain. Energy that would normally be available for activity there is pre-empted and redirected to the massive effort to cope with a severe condition of intoxication  
In inflammation, the toxicants have usually been concentrated in an organ or area for a massive expulsive effort. It is an evidence or symptom of increased and intense body activity directed at cleansing and repair. It is a healing activity. If this eliminative effort is suppressed by drugs, the toxicity increases until other organs become saturated—not only with this toxicity but with the drugs administered as well. This fourth stage of disease is the body's most intense effort to cleanse and restore itself. The following degenerative stages of disease will result if the causes of general body intoxication are continued.
5. **ULCERATION** - During this stage, poisonous matters have begun destroying cells and cellular organizations (tissues). This condition is often very painful as there are exposed nerves. The body may use an ulcer as an outlet for extraordinary toxic buildup thereby relieving itself. It will heal the ulcer if causes are discontinued, or if the toxicity level is lowered significantly.

6. **INDURATION** - This is a hardening where the body creates tumorous tissue (a kind of scar tissue) to bridge the lost tissue and to encapsulate the poisonous materials that are destroying it. The ulcer and the toxic materials are scaled off by the hardening of the tissue around them. This is the way of quarantining the toxic materials, often called tumor formation. It is this condition that is often falsely diagnosed as cancer. If the Life Science health regimen is followed at this point, the condition can largely be repaired or reversed. Should the pathogenic practices, which brought matters to this stage be continued, cells and tissues go wild and live in a parasitic manner. This condition is called cancer.
7. **CANCER** - This is the seventh and final stage of disease. Body vitality is at a very low ebb; cells are no longer under the control of the body's master control system, the brain. They multiply wildly in an unorganized manner without purpose. They may be giants or dwarfs and they draw their needs from the bloodstream without contributing to body functions. Cancer cells are parasitic cells. Once this condition is reached, there is little hope except to arrest and control the process. Only the healthiest of regimens can do this.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 8. Can Cancer Be Prevented?

## **8. Can Cancer Be Prevented?**

You must keep in mind that health is natural and illness is not. Your body always strives to maintain homeostasis and a healthy state. If illness manifests itself, it means that the body has not been provided the best circumstances for maintaining this balance and has been overwhelmed with toxins. It therefore initiates a healing crisis in order to rid itself of its toxic burden in order to preserve a state of health that it is always striving for. This "healing crisis" may be in the form of a cold, flu, eczema, fever, tonsilitis, etc. At this point, if the causes of ill health are corrected and all the requirements for health are provided, illness will progress no further and health will again be reinstated. On the other hand, if these symptoms are suppressed, the toxic overload will not be discharged. More serious illnesses will ensue with the final end point being cancer.

It soon becomes clear that cancer cannot be prevented, neither is it an inevitable fate.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 9. How Not To Develop Cancer

## **9. How Not To Develop Cancer**

In spite of our polluted environment, the wide use of poisonous sprays on the crops (chemical farming), use of poisonous additives to our foods, and other environmental carcinogens, we do not have to develop cancer if we know how to live. What must we do to ensure ourselves of this health? Simply obey the "Laws of Life." If you provide the conditions for health, cancer cannot develop. Eat only those foods that we are biologically adapted to eat in their raw state. Exercise daily in the fresh air and sunshine. Drink only pure water when thirst demands it.

It is during the first stage of disease (enervation) where cancer begins and it is at this stage where it is most easily corrected. Simply fast for a day or two and look at your practices to determine what you are doing wrong. You may have to get more sleep or eat more healthfully. If you take these simple steps, you can rest assured that you will not develop, cancer or any other degenerative disease.

## **10. The Requirements For Health Will Fullfill The Needs Of The Sick**

Even if your illness has progressed as far as the sixth stage of disease, health may still be restored. Keep in mind that the needs of the sick individual are the same as for those in health. You cannot treat the sick individual with poisonous drugs or other enervating treatments and expect him to regain health any more than you could expect to administer these drugs to a healthy person and expect him to remain healthy.

The sick individual differs in that he needs more rest. His body is in a state of extreme enervation and in order to heal, all bodily energies must be directed solely to this task. Therefore, fasting is the most effective means for providing this requirement. During the fast, energy is conserved for this task and healing will immediately commence. Cysts and tumors will be autolyzed and general bodily cleansing and detoxification will take place. This must be followed by a correct dietary regime along with proper rest with the introduction of a moderate exercise program when strength returns.

If the cancerous condition has advanced well into the seventh stage of disease, it may not be possible to reverse this process through fasting. However, fasting at this time will result in a slowing down or halting of the advance of cancer and the individual will feel more comfortable with little or no pain. It is far better than the suffering experienced by those cancer patients who are treated with chemotherapy or any of the other orthodox cancer treatments.

## **11. Habits**

When it comes down to the bottom line, probably the greatest cancer-causing agent in our environment is we, ourselves. How we live and what we do affect, to a large extent, whether or not we will get cancer. Lung cancer is—80% of the time—the direct result of smoking. Cancer of the esophagus, throat and bladder has been linked to drinking alcohol and hot drinks such as coffee and teas. Early sex has been correlated with cancer of the cervix. Habits are hard to break. The first reports linking tobacco to cancer date back to the 1700s. Yet, even today, despite overwhelming evidence, people still smoke and rationalize about its dangers.

Diet has also been linked to cancer. But would Mexicans give up highly-spiced food or Japanese forgo talc-treated rice in an effort to avoid stomach cancer so prevalent among them? Would Americans forgo high-fat diets and highly-processed food to reduce chances of breast cancer and cancer of the colon? Would young girls and middle-aged women stop basking in the midday sun for hours at a time? No, because they equate a suntan with beauty. They choose to ignore the definite risk link between skin cancer and overexposure to ultraviolet rays.

However, if the truth were presented to these people in a rational manner, I am sure that they would see that it is much easier to give up their small habits than to suffer the immense discomfort and pain of cancer.

## 12. Cancer Treatment

It is a well-known paradox that many of the chemical agents currently used in the treatment of cancer are themselves carcinogenic. Virtually all the commonly-used alkylating agents, including the nitrogen mustards, HN2 and HN3, treatamine (TFM), chlorambucil, sacrolysin and melphalan, and busulphan (byleran) can induce cancer fairly readily in experimental animals.

Studies have proven conclusively that untreated cancer sufferers actually live up to four times longer than treated individuals.

For a type of cancer, people who refuse treatment lived for an average of 12 1/2 years. Those who accepted surgery and other kinds of treatment lived an average of only three years! Beyond a shadow of doubt, radical surgery on cancer patients does more harm than good.

According to Ivan Illich (*Medical Nemesis*), "There is little evidence of effective treatment of most cancers. The five-year survival rate in breast-cancer cases is 50 percent, regardless of the frequency of medical check-ups and regardless of the treatment used. Nor is there evidence that the rate differs from that among untreated women. Although practicing doctors and the publicists of the medical establishment stress the importance of early detection and treatment of this and several other types of cancer, epidemiologists have begun to doubt that early intervention can alter the rate of survival."

## 13. Chemical Contaminants

In the past 10 years, the production of synthetic organic chemicals has expanded by 255 percent; relatively few of the new compounds have been studied for their cancer-causing potential. Because of the typical development period of 15 to 40 years for cancer, we must assume that much of the cancer from recent industrial development is not yet observable.

The majority of known environmental carcinogens are encountered at the workplace. In fact, the link between cancer and chemicals was first detected among workers; in 1775, soot was singled out as a causative agent in chimney sweeps cancer, cancer of the scrotum. Above-normal incidences of cancer are found in workers having contact with known or suspected carcinogenic substances such as asbestos, arsenic, benzopyrene, benzidine, bis-chloromethyl-ether, coal tar, carbon black, and vinyl chloride.

One such agent is benzidine, of which many million pounds are produced annually in the United States for use in making dyes. An excess of bladder tumors among workers in the industry was first reported in the early 1930s. But because benzidine was just one of a number of compounds to which these workers were exposed, a specific causative agent could not be identified at that time.

Later studies of populations of workers exposed only to benzidine firmly established a cause-and-effect relationship. One retrospective study of a coal-tar dye plant conducted in 1965 showed that 17 of 76 (21%) of workmen, exposed only to benzidine developed bladder tumors. This incidence rate greatly exceeds that of bladder cancer in general U.S. population—13.2 cases per 100,000 population.

Association of occupational exposure to asbestos with increased lung cancer was first reported in the 1950s. The, diagnosis of mesothelioma, an otherwise rare type of cancer, in some asbestos workers provided conclusive evidence that asbestos is a cancer hazard. In the past decade, mesothelioma has suddenly become more common: where environmental data exist, most cancer sufferers may be traced to

potential or actual asbestos exposure. This exposure often occurred in the workplace, but not infrequently it was associated only with residence in the vicinity of an asbestos processor or in the household of an asbestos worker. Asbestos products—fabrics, housing insulation, ceiling tile, brake lining—are an additional source of exposure.

Until recently, vinyl chloride, a gas used primarily in the manufacture of polyvinyl chloride plastic, was also used as a propellant for aerosol sprays. In 1974, the discovery of four cases of angiosarcoma of the liver among vinyl chloride workers in a plant in Louisville suggested that vinyl chloride is a carcinogen. Workers exposed to vinyl chloride were later discovered to have a significant excess not only of angiosarcoma but also of more common cancers of the respiratory system, brain and the lymphatic system.

Chlorinated hydrocarbons and arsenical pesticides that have been used in homes and gardens are known carcinogens. Commercially-processed foods have also been found to contain residues of pesticides known to be carcinogenic and other chemicals suspected of being so. Foods may also contain naturally-occurring carcinogens such as aflatoxins produced by particular mold contaminants. Drugs and cosmetics have been reported as carcinogenic. Estrogen as well as synthetic drugs developed for treating chronic conditions such as diabetes, arthritis and anemia have been implicated in helping to produce a variety of malignant tumors.

Combustion products released from industrial smokestacks as well as from chimneys of office buildings, apartment buildings, hospitals, and government and municipal buildings may contain a variety of carcinogenic materials. In 1975, the Environmental Protection Agency found cancer-producing agents in low concentrations in the drinking water of all 80 cities whose water supplies it investigated.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 14. Geographical Factors

## **14. Geographical Factors**

Cancer rates vary significantly throughout the United States. In general, states with high rates are the industrial states. Analysis county by county reveals that a majority of the areas of high mortality from cancer are located in large cities. For example, the high mortality in Illinois reflects rates in the Chicago area.

It has long been known that densely-populated and industrialized areas have higher death rates from many causes than nearby rural areas. Urbanization and mortality have been associated for heart disease, cancer of the respiratory and digestive systems, and many other diseases. This excess health risk is related to lifestyle (urban dwellers use more tobacco), to occupation (working with industrial pollutants), to the environment of cities (air and water pollution), and to other factors.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 15. Cocarcinogens

## **15. Cocarcinogens**

Whether found in polluted urban air, in cigarette smoke, or in some products derived from coal tar and petroleum, environmental carcinogens usually occur in a complex mixture. The mixture of chemicals can multiply the risk of cancer that would be encountered with one carcinogen alone. For example,

although 75 to 85 percent of lung cancers are related to smoking, particularly cigarettes, atmospheric pollution and some occupational exposures appear to exacerbate the risk. According to one calculation, asbestos workers who are nonsmokers contract lung cancer at normal rates, but a cigarette smoker who works with asbestos has eight times the risk of dying of lung cancer as similar smokers of the same age who do not work with asbestos and 92 times the risk of laborers who neither work with asbestos nor smoke.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 1. Carcinogens In Food

## **1. Carcinogens In Food**

There are many carcinogens in food that is consumed by most Americans today. It is important that the general public be aware of these poisons so that they can make rational decisions when choosing food.

### **1.1 Fish**

Fish are extremely sensitive to pesticides. They sicken or die at very low concentrations, much lower than for most living organisms. Concentrations as low as two parts per trillion of DDT were found to cause problems in the Great Lakes. The consumer can be harmed by eating fish that has been poisoned but not killed outright. Fish have been known to concentrate these poisons 2,000-fold over the amounts in the water where they were found.

#### **1.1.1 Shellfish**

In recent years, state and federal agencies that control oyster beds and their care have been pouring materials into the sandbanks to protect oysters from their enemies, such as starfish and other sea creatures. These materials are made of insecticide, and a chemical (orthodichlorobenzene) combined with sand. Sea animals, venturing into the treated sandbank, perish from the poisons in different ways.

A starfish, for example, goes into a spasm and disintegrates. An oyster drill, a member of the snail family, swells up to such an extent that it is forced out of its shell and either dies or is devoured by fish. A crab loses its sense of balance and goes into convulsions. You may well wonder whether the chemicals ultimately make the oyster poisonous to eat. Oysters are far away from our natural food and these chemical toxins give us double reason to eschew them.

#### **1.1.2 Hatchery-Raised Trout**

The feeds developed for trout were similar to those previously used for poultry. When the pellets were fed to baby chicks, the birds developed cancer. Later rainbow trout, raised in hatcheries, were given this feed in hopes of achieving maximum weight gains in the shortest period of time before being released into streams.

In the early 1960s, hatchery-raised rainbow trout that were fed this pelleted feed developed liver cancer in what leading cancer specialists considered epidemic proportions. In some hatcheries, 100% of the trout were affected. The outbreak seemed related to a cancer-inducing ingredient, still not completely identified, but present in the fat fraction of the feed. Upon investigation, moldy cottonseed meal in the dry feed was suspected as the most likely cause of the cancer. Dr. Hueper, one of the investigators, says, "The fact that at times carcinomatous involvement affects not only the liver and other internal organs not ordinarily used for human foods, but at times also the muscle tissue, provides an additional reason for caution against any laxity in the application and enforcement of existing laws." The likelihood of strict

reinforcement of these laws is very low. The best advice is to not eat any fish.

### **1.1.3 Fresh Fish**

Fresh fish may be refrigerated in crushed ice containing preservatives such as sodium benzoate, sodium nitrite, hydrogen peroxide, ozone, or chlorine to inhibit spoilage. In recent years, cases of illness and deaths were traced to excessive amounts of sodium nitrite added to fish by sellers' who hoped to prolong even further the shelf life of their products.

## **1.2 Eggs**

Eggs are vehicles for residues of a wide range of chemicals present in the diet and environment of laying hens. Antibiotics in feed may more than double the egg laying in low-producing hens. There is also pressure to include antibiotics in the drinking water of layers as well. Feed medicated with antibiotics must be withheld from birds when they are laying. But even when this recommendation has been followed, antibiotics have been detected.

Although the FDA has set "zero" or "negligible residue" tolerance levels for pesticides in eggs, there is no assurance that this food is uncontaminated. Poultry management and poultry feed may both contribute to pesticide residues in eggs.

### **1.2.1 Drugs**

Drugs may be used with laying hens. A tranquilizer, used in conjunction with antibiotics in layer feed, was advertised as boosting egg production since it "calms birds, reduces blood pressure and heart rate, increases respiratory rate." Experimentally, hens fed aspirin laid more eggs. Another drug has been found to be effective in reducing "laying slump"; at the same time it cuts feeding costs.

## **1.3 Poultry**

### **1.3.1 Arsenic**

Since 1950, small amounts of arsenic as arsanilic acid have been incorporated into poultry feed to stimulate early maturation, increase efficiency of feed utilization, produce more eggs, "improve" skin coloring and feathering, and yield more profits.

Currently 90% of all commercial chickens are raised with arsenic in their feed. The arsenic-containing feed must be discontinued long enough before slaughter for the birds to eliminate most—but not all—of it from their meat. Even though arsenic is listed as a carcinogen for man, the FDA allows tolerance residues of 0.5 ppm for it in chicken and turkey tissues, and twice that amount in the byproducts of these birds.

The liver is the detoxifying organ of animal and man. Dr. Manuel Schreiber, FDA toxicologist, stated that dangerous accumulations of arsenic have been found in chicken livers.

### **1.3.2 Drugs**

Another group of "anti-infective" agents, the bacteriostats, are incorporated routinely in poultry feed to control the growth of "undesirable" bacteria. These include drugs which can result in dermatitis in man when applied to the skin, and others which are toxic. Little is known about the general effects of these materials, when eaten frequently in small amounts.

### **1.3.3 Caponettes**

Hormones in poultry production have been used even longer than with livestock. The estrogenic female sex hormones, especially stilbestrol, were first used to caponize birds chemically. The use of stilbestrol was extended to include the treatment of all types of table poultry of both sexes, being highly profitable to the poultrymen. It put weight on birds quickly, and could even give old birds the appearance of youth, with plumper, more attractive flesh.

Since the cancer-inciting nature of stilbestrol was established, the FDA was forced to take action. The agency chose a course least upsetting to the economics of poultrymen, by persuading the industry to "voluntarily" discontinue the use of stilbestrol implants.

Despite this agreement, hormonized birds continued to be shipped by individual poultrymen. In New York City, 25,000 pounds were seized by the Department of Markets. The shippers complained that New York City is "the only city in the country where the FDA ban is being rigidly enforced."

Although the stilbestrol pellet implants were banned, the use of stilbestrol was, and still is permitted in poultry and livestock feed. In addition, a U.S. patent was granted to allow stilbestrol as an additive to the drinking water of poultry, to increase "meat-producing efficiency."

### **1.3.4 Pesticides**

In 1965, the USDA tested 2,600 poultry samples in every federally-inspected plant throughout the nation, and found all birds contaminated with pesticide residues. No one section of the country was better than another. Primary sources of infection were traced to sprayed grain and animal tallows in the feed and to poor husbandry practices. No seizures were made, nor did the USDA divulge specific results, such as the most common contaminant or levels of pesticides found.

### **1.3.5 Cancerous Chickens**

Until 1970, the USDA's policy had been to condemn the entire carcass of the chicken if any organs or sections of the bird showed signs of leukosis. The poultry industry considered this to be an economic hardship and it pressured for lowering the standards for condemning birds. The USDA appointed a panel of veterinarians and animal-disease specialists to review the problem. Although the panel recommended continuing the policy, of condemning birds whose internal organs show active signs of leukosis, it suggested that chickens bearing cancer be allowed on the market if they "do not look too repugnant." The USDA endorsed the proposals. Officials from the agency said that if tumors were detected on the wing of a bird, the wing could be cut off and used in products such as hot dogs, while the rest of the bird could be cut up as chicken—all without posing a threat to human health.

If one portion of the animal shows signs of disease, the entire bird is in a diseased condition. Hiding the worst sections in such products as hot dogs does not make the meat acceptable for consumption. Just because people do not die immediately from ingesting these products does not mean that they are not being harmed by them.

## **1.4 Hamburger**

Toxins are prevalent in ground beef. This popular food item offers many opportunities for economic frauds, such as additives and illegal extenders. It may be adulterated with coal-tar colors, cochineal, and sodium nitrite or benzoate of soda. Dr. Freese at the National Institute of Health has strongly recommended that sodium nitrite be banned from use in foods. In the human stomach, sodium nitrite is converted to nitrous acid, which is mutagenic in a variety of lower organisms. Sodium sulfur is another additive, can mask the smell of deteriorating meat, and give it a fresh-meat redness. Such meat is injurious, especially if eaten rare. Sodium sulfite is a poison that destroys vitamin B, and is capable of causing considerable damage to the digestive system and other organs. Yet tested samples of ground beef

purchased as ready-chopped hamburger, or sold at hot dog stands, cafeterias, and restaurants, frequently shows adulteration with this chemical. Hamburger meat served in restaurants often contains sodium nicotinate to preserve its bright red color. Although this chemical is illegal in some municipalities, 37 states permit its use. Several outbreaks of poisoning have been traced to this additive.

Eating grilled or pan-fried hamburgers may result in cancer. Chopped meat cooked on a metal surface at temperatures higher than 300 degrees Fahrenheit produces mutagens (substances that cause genetic change). The particular mutagens in fried hamburgers have not yet been identified, but 90% of all mutagens ever tested cause cancer in laboratory animals. These hamburger mutagens represent a risk of cancer in people. The longer the cooking, the more mutagenic the hamburger. Further analysis revealed the new mutagen is distinct from two other carcinogens previously identified in cooked meat—benzopyrene, similarly mutagenic and produced by cooking meat over a high heat, and pyrolyzed amino acids from the charred surface of meat cooked directly over a flame.

So besides the toxins already present in meat, plus those added to the hamburger, there are additional risks when the meat is fried or charcoal broiled, which is the usual method of preparation. The traditional summer picnic including charcoal broiled hamburger is best left in the past. Substitute fruit picnics and your health will improve rather than decline.

## **1.5 Hot Dogs**

Preservatives similar to those in ground beef may also be used in frankfurters. Other, additives may also be present, such as antioxidants to retard rancidity, or tenderizers. A coal-tar color (Red No. 1) was commonly used in the casings of frankfurters until banned by the FDA after this material produced liver damage in experimental animals. Casings are still dyed with artificial colors, and proof of their safety is not conclusive. Although regulations prohibit the use of coloring if it penetrates the produce, on occasion dyes on frankfurters have been found to penetrate as much as one fourth of an inch into the meat.

## **1.6 Pork**

Results of a nationwide survey revealed that "whether the sausage came from a federally-inspected packing plant or from the meat grinder of a local butcher, it was often sour or rancid and frequently contaminated with an overabundance of bacteria. Some of it was contaminated with filth. Not one sample, out of the packages tested for quality and flavor, could be judged really outstanding."

Pigs raised commercially are diseased. Many die before the farmer gets a chance to market them. Those that do survive are sick and toxic. These toxins are transferred to the people who eat the pork.

## **1.7 Other Toxins in Meat**

### **1.7.1 Federal Label**

Labels for federally-inspected, canned, packaged, or frozen meat must list all the ingredients, common name of the produce, name and address of the processor or distributor, mark of approval and accurate weight. However, meat can be processed legally with sodium nitrate, sodium nitrite, sodium ascorbate, and many other chemicals sanctioned by the FDA.

Presently in the United States, up to 500 ppm of sodium nitrate, and up to 200 ppm of sodium nitrite are permitted in certain meats and meat products (and in certain fish and fish products, poultry, and wild game). Far lower limits are set in Europe.

"Nitrites should be immediately reduced or eliminated as food preservatives, especially on meat and fish." This recommendation was made jointly in February of 1970, by Dr. Samuel S. Epstein of the

Children's Cancer Research Foundation of Boston and Dr. William Lijinsky of the college of medicine at the University of Nebraska. Noting that nitrosamines—which include nitrites—can produce mutagenic changes, the researchers suspect that by similar pathogenic processes, these agents are carcinogenic and teratogenic as well.

### **1.7.2 Stilbestrol**

Medications in feed are used to increase weight rapidly. The most sensational gains are achieved by adding hormones and hormone-like substances to the feed. Stilbestrol is used extensively. Currently, it is estimated that 80 to 85% of all beef cattle are being fed on feed containing stilbestrol. It is also used in the feed for sheep and lambs.

Stilbestrol has been acknowledged by scientists as a potent carcinogen, and has been labeled "biological dynamite." Quantities of stilbestrol as small as 2 ppb are toxic in diets of experimental mice. Cancers in these test animals have been induced by daily doses as low as 7/100,000,000 of a gram (one fourth of a hundred-millionth of an ounce). It can also cause leukemia and cysts in animal organs. In human beings, it has resulted in breast cancer, fibroid tumors, and excessive menstrual bleeding in women, sterility and impotence in men, and arrested growth in children. *The Medical Officer*, an English journal for government health officers, reported that hormone traces in the meat of chemically-fattened livestock are causing British school girls to mature at least three years earlier than in the past.

More important than an occasional large dose of stilbestrol is the danger of repeated small amounts. Since consumers may be ingesting small amounts repeatedly in food consumed over a period of years, this is a factor of prime importance.

The use of stilbestrol for livestock is permitted by the FDA as long as no "detectable" residue of it is found in the edible portions. Stilbestrol fed to experimental rats broke down into four or five products, and they were found in areas of the animals' bodies not previously known to contain such residues. Using a radioactive tracing technique, the breakdown products were found in the muscles, livers, kidneys, lungs, and skeletons. Such materials also may be present in treated livestock.

Despite the hazards of this hormone, the FDA doubled the amount of stilbestrol permitted in the feed of beef cattle in late 1970.

Besides hormones, antibiotics, tranquilizers and pesticides are fed to meat animals. Injections are also given to animals on the hoof before they are slaughtered to tenderize the meat.

### **1.7.3 Unhealthy Animals**

An average of 10 to 30% of beef livers at slaughterhouses are condemned because of abscesses. USDA records showed that during a one-year period, Americans ate millions of pounds of beef from cattle that had "cancer eye" or similar tumorous disorders. The diseased parts were merely cut out and the remainder of the carcass was permitted to be marketed. Agriculture officials claim that such localized tumors pose no threat to human beings eating meat from other portions of such animals. A government report showed that more than 10% of the 30.1 million cattle carcasses approved by federal inspection underwent some post-mortem cutting for removal of diseased parts.

Another report showed that 2,400,000 cattle whose cancerous or tubercular livers were discarded had the rest of their carcasses sent on to be processed for food.

You can see now, why cancer is so prevalent among meat eaters.

## **1.8 Sugar**

The refined-carbohydrate diet is blamed by Dr. Denis F. Burkitt as the single most important cause of large-bowel cancers, occurring on a worldwide scale when people forsake their traditional dietary habits

and consume large amounts of refined carbohydrates.

Avoid sugar, advises a famous English nutritionist, and you are less likely to become fat, run into nutritional deficiencies, have a heart attack, develop diabetes or dental decay or a duodenal, ulcer, and possibly reduce your chances of getting gout, dermatitis, some forms of cancer, and in general increase your life span. It is important to realize that by the mere omission of a single common food, and beverage ingredient such as sugar, so many benefits may result, and that its excessive use can contribute, at least in part, to so many desperate conditions and diseases.

### **1.8.1 Brown Sugar**

The commercial brown sugar color isn't from molasses residue. Virgin sugar is rinsed to remove molasses residue, then put into a centrifuge where it is separated from the crystals. This is melted, filtered and boiled repeatedly with animal-bone charcoal to concentrate and form crystals. Molasses is added back to sugar to achieve its brown color.

Dr. W. C. Heuper, M.D. in an experimental study for Cancer Research warns that sugar manufactured with this animal-bone charcoal process may be carcinogenic (cancerous).

## **1.9 Fats and Oils**

### **1.9.1 Hydrogenation**

How is the liquid oil or soft fat hardened? It is exposed to a high temperature and placed under pressure. Hydrogen is then bubbled through the oil in the presence of nickel, platinum, or some other catalyst.

The hydrogen atoms combine with the carbon atoms, and the produce becomes saturated or hardened.

There is no assurance that nickel, if used as the catalyst, leaves no residue in the product. This element, even in minute quantities in the diet, is suspected of being a carcinogen.

As evidence has mounted revealing the menace of hydrogenation, some shortening processors have attempted to change their methods to avoid economic losses. They proclaim their products "high in unsaturates" but adding that they "stay freshly sweet at room temperature." These products may contain antioxidants, in addition to emulsifiers, defoamers, and artificial colors and flavors. Artificial antioxidants in fats are considered possible carcinogens.

### **1.9.2 Heated Oils**

Prolonged heating and reheating at high temperatures produce harmful substances suspected as cancer-inciting or oils. Deep-fat frying is favored in many short-order diners and also in "good" restaurants for economy, speed, and convenience. It is a method also used extensively in processed foods like potato chips, doughnuts, baked goods, serve-and-heat dishes, as well as in many homes. Consumers Research recommends that deep-fat frying should be avoided. Also be shunned are all burned fatty foods and charcoal-broiled meats. All charred, blackened, or burned portions of meats or other fatty foods are carcinogenic.

## **1.10 Caffeine**

Caffeine has been shown to result in genetic and chromosomal changes in animals, bacteria, and higher plants. A retrospective study showed that men who drank cola beverages containing caffeine have a significant increase in bladder cancer compared to noncola drinkers. Other studies' which implicate coffee and caffeine as mutagenic include discussion of genetic effects and effects on chromosomes of human lymphocytes.

## 1.11 Alcoholic Beverages

Consumption of alcoholic beverages entails an increased risk of developing cancer of the mouth, larynx, pharynx, and esophagus according to the International Agency for Research on Cancer of the World Health Organization. The evidence is that the increase in cancer of the esophagus is proportional to the amount of ethanol consumed. In all four cancer sites, the role of tobacco is also important, and the ill effects of these two factors—drinking alcoholic beverages and smoking tobacco—tend to multiply when they act together. Ethanol may act as a cocarcinogen by enhancing the role of other cancer-causing agents. Ethanol is an excellent solvent for chemicals that are themselves cancer-causing agents, such as polycyclic hydrocarbons and nitrosamines. The presence of these chemicals has been detected in some commonly-consumed alcoholic beverages drunk in areas where esophageal cancer is common.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 2. Some Specific Carcinogens In Food

## 2. Some Specific Carcinogens In Food

### 2.1 Coal-Tar Dyes

Coal, when heated in the absence of air, is converted to coke (impure carbon), coal gas, and coal tar. The coal tar, a viscous black liquid, is a mixture of many organic compounds. In the 1800s, English and German chemists learned that they could produce intensely-colored substances when they purified some of these compounds and reacted them with other chemicals. These synthetic substances are known as coal-tar dyes and are used in great quantity by the food, fabric and cosmetic industries.

Americans are consuming coal-tar dyes in their food at an increasingly rapid rate. In 1970, slightly over 3,735,000 pounds were certified by government inspectors. These dyes are used in beverages, candy, ice cream, dessert powder, baked goods and sausages. Levels used ranged from approximately ten parts to five hundred parts per million, the lower levels being used in liquid foods (beverages, gelatin desserts) and the higher levels in solid foods (pet food, breakfast cereal, etc.).

People have been concerned about the possible toxicity of coal-tar dyes ever since they were introduced in the second half of the nineteenth century.

In view of the repeated dangers associated with coal-tar dyes, one might assume that the dyes now in use have been thoroughly tested. That is not the case. Adequate lifetime feeding studies (two rodent species, forty or more animals per dosage level), which must be done to reveal carcinogenic and cumulative effects, have been conducted for only five dyes (Yellow 6, Red 4, Green 3, Orange B, and Citrus Red 2). Lifetime studies on dogs have been performed only with Orange B, Red 2, Red 4, and Yellow 6. Not one of the coal-tar dyes used in food has been adequately studied for causation of mutations.

If these tests were to be correctly conducted, there is no doubt that they would find that all coal-tar dyes are indeed carcinogenic. They are all extremely poisonous substances and everyone should exclude these products from their diet if they wish to maintain health.

The safety of Violet 1 was a question mark for many years. The dye was used to stamp the Department of Agriculture's inspection symbol on meat and also to color candy, beverages and pet food. The FDA certified almost 67,000 pounds of this dye in 1972. Consumers may ingest a small amount of the dye when they eat a steak or roast. Workers in packinghouses may be exposed to much greater amounts. The men who imprint USDA's mark on carcasses frequently get the dye on their hands; occasionally large amounts drip down their hands and arms. One Department of Agriculture meat inspector in North Carolina observed that "the dye is pretty hard to get off. Once you get it on your skin, you almost have

to wear it off."

A study published in 1962 by Dr. W. A. Mannell and his colleagues at Canada's Department of National Health and Welfare, involved rats. This study indicated that the dye (Violet 1) caused cancer. Of thirty rats fed 3 percent dye in their food for seventy-five weeks, five developed malignant tumors. Three of the tumors were skin tumors. Four of the five tumors occurred in females. Only one out of thirty untreated rats developed a tumor.

In early 1971, nine years after Violet 1 was first suspected of being carcinogenic, the FDA asked the National Academy of Sciences to convene a group of nongovernment scientists to evaluate all available studies. The committee met in Washington on September 1, 1971, and filed its final report in November. The committee's conclusion and recommendations were finally made public in March 1972, more than a year after the committee was first announced.

The NAS committee dismissed out of hand the Canadian study that indicated that Violet 1 caused cancer. The committee declared the dye safe, but did recommend that a lifetime feeding study be conducted on dogs. The net effect of their report will be to postpone the permanent acceptance or banning of this coloring for at least eight years or more.

Citrus Red 2 is another coal-tar dye under investigation. Florida orange growers use the dye, mainly from October through December, to cover up the mottled green color on oranges, tangelos, and temple oranges.

Four lines of evidence suggest that the dye might be a carcinogen:

1. When the dye was mixed with cholesterol and implanted in the urinary Bladders of mice, 14.5% of the animals developed tumors; cholesterol without dye caused tumors in 4.5% of the mice.
2. When the dye was injected under the skin of mice, malignant tumors developed in the lungs.
3. The liver converts the dye to less noxious substances, which then pass into the urine; one of the intermediates in the conversion process is 1-amino-2-naphthol; there is evidence that this chemical causes cancer.
4. The walls of the urinary bladders were markedly thickened in animals whose diet contained the dye.

On the basis of this array of evidence the FAO/WHO Committee issued the following warning at its annual meeting:

Citrus Red 2 has been shown to have carcinogenic activity and the toxicological data available were inadequate to allow the determination of a safe limit. The Committee therefore recommends that it should not be used as a food color.

American consumers are endangered if they eat or suck the peel of treated oranges or use the peel in marmalade. Unfortunately, oranges are no longer individually stamped "color added" so it is difficult to identify treated oranges. When oranges are not stamped, supermarkets are supposed to post signs saying "artificially-colored oranges." FDA administrators in Washington admit that grocers from one end of the country to the other are ignoring FDA's regulations, but plead that they have too little manpower to stop this "minor" infraction. Workers who produce Citrus Red 2 and who dye the oranges may ingest or inhale relatively large amounts of the chemical. They would be exposed to a proportionately-greater hazard than the average consumer.

The identification of coal-tar dyes on food labels is as inadequate as the testing the chemicals have undergone. The presence of coloring in butter, cheese, and ice cream need not be specified at all. In other foods, colorings are never identified specifically as Violet 1, Green 2, etc., but only say "artificial coloring."

Name of Dye	Effects on Test Animals	Permitted In
Amaranth (U.S. Red Dye No. 2)	Tumor production	jams and jellies, fruit drinks, bread, ice cream, flavored milk, pickles, ketchup
Brilliant Blue	FCF Tumor production	as above
Citrus Red, No. 2	Tumor production	orange skins
Carbon Black	Tumor production	jams and jellies, fruit drinks, dried eggs

## 2.2 Tannins and Tannic Acid

Tannic acid occurs in the bark and fruit of many plants notably in the bark of the oak species, in sumac, cherry wild bark, and in coffee and tea. It is used to clarify beer and wine and as a refining agent for rendering fats. Tannins are used as a flavoring in butter, caramel, fruit brandy, maple and nut flavorings for beverages, ice creams, ices, candy, baked goods and liquors. They are used medically as a mild astringent. When applied, they may turn the skin brown. Tannic acid has a low toxicity when taken orally, but large doses may result in gastric distress. During World War II, liver damage was observed in humans treated with tannic acids for burns. Subsequently, experiments with rats showed repeated subcutaneous injections of a water solution of tannin led to liver toxicity, cirrhosis and tumors.

## 2.3 Nitrate

Potassium nitrate, also known as saltpeter and nitre, is used in gunpowder and fireworks and as a color fixative in cured meats. Sodium nitrate, also called Chile saltpeter, is used as a color fixative in cured meats. Both nitrates are used in matches and improve the burning properties of tobacco. They combine with natural stomach saliva and food substances (secondary amines) to create nitrosamines, powerful cancer-causing agents. Nitrosamines have also been found in fish treated with nitrates. Nitrates have caused deaths from methemoglobinemia (it cuts off oxygen from the brain). Because nitrates are difficult to control in processing, they are being used less often. However, they are still employed in long-curing processes, such as country hams, as well as dried, cured, and fermented sausages.

## 2.4 Nitrite

Potassium nitrite is used as a color fixative in the \$125 billion a year cured meats business. It is used as a color fixative in cured meats, bacon, bologna, frankfurters, deviled ham, meat spread, potted meats, spiced ham, Vienna sausages, smoked-cured tuna fish products, and in smoked-cured shad and salmon. Nitrite combines with natural stomach and food chemicals (secondary amines) to create nitrosamines, a powerful cancer-causing agent!

## 2.5 Fish Tumors

Populations of catfish, croakers, calamanders, and other marine animals found in polluted areas often have tumors, while the same species living in a clean environment do not. Scientists have already proven that pollution may be passed along the food chain to people when aquatic organisms accumulate cancer-causing chemicals. Mollusks living in areas polluted with domestic sewage can be reservoirs for disease,

and eating mollusks from such areas may result in thyroid disorders and hepatitis.

Pollution certainly seems to play a part in fish tumors. Fish caught in the Fox River on the outskirts of Chicago have almost 16 times as much cancer as do fish caught in Lake of the Woods, Ontario, Canada.

## **2.6 Ethyl Alcohol**

Ethyl alcohol contains ethanol, grain alcohol, and neutral spirits. It is used as a solvent in beverages, ices, ice cream, candy, baked goods, liquors, and gelatin desserts. It was approved in 1976 for use in pizza crusts to extend handling and storage life. It causes cancer when inserted in the rectum of mice in doses of 548 milligrams per kilogram of body weight, and it causes tumors when given orally to mice in 2,770 milligram doses per kilogram of body weight.

## **2.7 Aflatoxins**

Aflatoxins are the best-studied members of a class of compounds called "mycotoxins" (toxins formed by molds). An outbreak in 1960 in England of "Turkey X disease," an acute liver condition, was traced to peanut meal contaminated with the mold, which occurred after improper harvesting and storage.

A single dose of 5 milligrams per kilogram of body weight has induced tumors in rats. The marked differences in, geographical distribution of liver cancer in humans has long suggested the presence of some common factor. In areas of Africa where there is a high incidence of liver cancer, aflatoxin contamination is common. Aflatoxin B1 is one of the most potent cancer-causing agents known in animal testing. Levels as low as one part per billion produced liver cancer in rats. Previous experiments showed a 100% incidence in rats on a lifetime diet containing 15 times that amount of aflatoxin B1.

In addition to liver cancer, aflatoxins have been implicated in the formation of tumors of the stomach, kidney, and some other tissues.

Make sure that the nuts you eat are fresh. Dr. William Wardell, director of the Center for the Study of Drug Development, University of Rochester School of Medicine, speaking at a symposium on Public Issues and Private Medicine, December 6, 1978, in Philadelphia, pointed out that "when a batch of peanuts is imported containing aflatoxin levels that are too high for us to eat, the current method of control is to dilute the contaminated batch with a clean batch to bring the level down to acceptable proportions."

## **2.8 Charcoal Broiling**

Cancer-causing agents can be formed in charcoal-broiled food according to the NCI. It is safer to boil or poach food than to charcoal broil it. It is believed that at least two kinds of substances are formed in broiling; one is related to the tar in cigarette-smoke condensate and is produced when the surface of the food is charred; the other factor involves the breakdown of some amino acids in protein.

## **2.9 Carrageenan**

An Irish moss derivative, carrageenan absorbs water easily, has a seaweed-like odor and a gluey, salty taste. It is used as a stabilizer and emulsifier in chocolate products, chocolate-flavored drinks, chocolate milk, gassed cream (pressure-dispensed whipped), syrup for frozen products, confections, evaporated milk, cheese spreads, cheese foods, ice cream, frozen custard, sherbets, ices, French dressing, artificially-sweetened jellies and jams.

Carrageenan results in the stimulation of the formation of fibrous tissue when subcutaneously injected into guinea pigs. When a single dose of it dissolved in saline was injected into the subcutaneous tissues of rats, it resulted in sarcomas after approximately two years. Its cancer-causing qualities may be that of

a foreign body irritant, because upon administration to rats and mice at high levels in their diet it did not appear to induce tumors, although survival of the animals for this period was not good. Its use as a food additive and as a treatment for gastric ulcers is being further tested.

## **2.10 Azo Dyes**

A large category of colorings used in both food and cosmetics, azo dyes are characterized by the way they combine with nitrogen. They are made from diazonium compounds and phenol and usually contain a mild acid such as citric or tartaric acid. Among the foods in which they are used are "penny" candies, caramels and chews, Life Savers, fruit drops, filled chocolates (but not pure chocolates); soft drinks, fruit drinks and ades; jellies, jams, marmalades; stewed-fruit sauces; fruit gelatins; fruit yogurts; ice cream; pie fillings, puddings (vanilla, butterscotch, and chocolate puddings), caramel custard, whips, dessert sauces (such as vanilla and cream in powdered form); bakery goods (except plain rolls); crackers, cheese puffs, chips; cake and cookie mixes, waffle/pancake mixes; macaroni and spaghetti (certain brands); mayonnaise, salad dressings, catsup (Vermin brands); mustard, ready-made salads with dressings; remoulade, bearnaise and holladaise sauces, as well as sauces such as curry, fish, onion, tomato, and white cream; mashed rutabagas, purees; packaged soups, and some canned soups; canned anchovies, herring, sardines, fish balls, caviar and cleaned shell fish.

As far back as 1906 an azo dye, scarlet red, was found to cause tumors in rabbits in Germany. In 1924 it was reported to cause liver tumors in mice. In 1934 Tomizu Yoshida, professor of pathology at Tokyo University, Japan, reported liver cancer in rats that ingested azo compounds in their diet. Azo dyes have since been found carcinogenic in a wide variety of experiments worldwide, but they are still used in our food and cosmetics.

## **2.11 Sugar**

Dr. Hieper has said: "In themselves, sugars may not be carcinogenic—but carcinogenic impurities may be introduced into sugars when concentrated. Sugar solutions are filtered for decolorizing purposes through improperly prepared charcoal containing polycyclic hydrocarbons. Chemicals of the dibenzanthracene type are eluted (washed out) from charcoal by concentrated sugar solutions. Traces may be introduced in this manner and may remain in apparently chemically pure sugars."

## **2.12 Saccharin**

"Saccharin is a noxious drug, and even in comparatively small doses it is harmful to the human system," wrote Dr. Wiley in 1913. He tried to keep this nonnutritive adulterant out of food and drink.

As early as 1951, three FDA scientists reported that saccharin at certain levels showed a high incidence of unusual combinations of cancers. The FDA chose to ignore the report. In November 1969 Dr. George T. Bryan, a tumor expert and cancer researcher at the medical school of the University of Wisconsin, reported to the FDA that using saccharin, he had produced bladder cancer in 47% of the mice in one group, and in 52% of another group. In a press interview, Dr. Bryan admitted that although direct cancer hazard to man from saccharin has not yet been established, he was "very suspicious." He added, "It may take many years before it is known exactly how dangerous the substance is ..."

## 1. Pesticides

Most pesticides are poisonous and can be dangerous to the user, the environment, and the food consumer. Pesticides that reach the consumer generally do so by the oral route. Thus, stomach and bowel cancers are of particular interest to agronomic and agricultural scientists.

Pesticides may promote or induce cancer. Insecticides all are readily absorbed through the skin and may also be inhaled or ingested. Acute symptoms following massive exposure including vomiting; dizziness, tremors, and convulsions. Such exposure can be fatal. Other insecticides result in skin and lung irritation. Dithiocarbonates, a group of chemicals commonly used as fungicides, are highly irritating to the skin, eyes, and respiratory tract.

Tests for pesticides frequently establish the ability of the compounds to promote and induce cancer. A further complication is that of multiple carcinogens, a multiplier effect when one is added to another. The sale and use of some 2,000 pesticide products containing 23 potentially hazardous ingredients has been restricted by the EPA to farmers and commercial users.

### 1.1 Pronamide

This pesticide, used mainly on lettuce, alfalfa, and to a lesser extent, on berries, turf and sugar-beet seed, caused cancer in mice. On January 15, 1979 the FPA proposed that the continued use of pronamide be allowed, but with additional precautions to reduce potential risks to humans. FPA Assistant Administrator Steven Jellinek said: "In general, EPA concluded that for all uses the economic benefits of pronamide outweigh its risks. Most pronamide is used on lettuce in California and Arizona, which produce most of this country's lettuce. Without pronamide, the estimated loss to lettuce and alfalfa growers would be approximately \$17.3 million annually. Pronamide is used primarily as an herbicide to control weeds, which compete with lettuce and alfalfa. Other herbicides available for weed control of these crops are not always as effective, and for lettuce these uses would result in additional labor costs for growers who would have to control the weeds by hand or mechanically."

Organic gardeners will attest to the fact that highly poisonous sprays are not necessary to have a bumper crop of lettuce. A few weeds among the lettuce will do no harm but may distract or repel certain pests. There can never be any legitimate excuse for using sprays that are known to be harmful to the consumer. When weeds are controlled by hand or mechanically on a regular basis, they will not harm the crops and may in addition eliminate some unemployment.

### 1.2 Parathion

An organophosphorus pesticide, parathion was given in feed to rats and mice for 80 weeks. It was carcinogenic to the adrenal glands of male and female rats.

### 1.3 Nitrofen

Nitrofen is an agricultural pesticide used as a selective contact herbicide for pre- and post-emergent control of annual grasses and broad-leaf weeds on a variety of food crops. Agricultural workers and manufacturers are exposed through skin absorption and by inhalation. The general public is exposed through ingestion due to possible persistent residual quantities of nitrofen on food crops. Adverse effects on agricultural workers following excessive exposure over prolonged periods included a reduction of hemoglobin and white blood cell counts, inhibition of cholinesterase (an enzyme in the heart muscle) and abnormalities in red-blood and serum-enzyme levels. The chemical was given to rats and mice for 78 weeks. It proved to be a liver carcinogen in mice of both sexes and in female rats.

## 1.4 Maleic Hydrazide

Maleic hydrazide regulates the growth of unwanted "suckers" on about 90% of the United States tobacco crop and is also applied to 10 to 15% of domestic potatoes and onions to prevent sprouting after harvest. It is highly toxic to humans and has produced central nervous system disturbances and liver damage in experimental animals. It has led to liver and other tumors in some mice. It has resulted in genetic damage in plant and animal systems, a fact that often signals a cancer-causing effect.

## 1.5 ETU2-Imidazolidinethione

Cancer-causing ETU, a contaminant and breakdown product of some widely-used fungicides, can contaminate plants, whether sprayed onto leaves or mixed in the soil. Readily transmitted from roots to leaves, ETU persists for as long as two weeks. For this reason it is recommended that the fungicides called ethylenebisdithiocarbamates (EBDC), in use for 30 years, should not be applied to crops two weeks before harvest.

When ETU is given in large doses, it has been shown to be carcinogenic in rats, tumorigenic in mice, and teratogenic (fetus-deforming) in rats and mice. Reports have shown that cooked spinach contained more of the cancer-causing chemical than the corresponding raw spinach; an inadvertent addition to food of a carcinogen caused by the breakdown of remaining fungicide when heated. A heat-caused degradation product of widely-used EBDC fungicide, ETU is found 10 to 90 times higher in cooked tomatoes than in raw tomatoes. During cooking, the ETU presumably is formed from residues of the parent fungicides that are present on the food. The amount of ETU formed in the cooked produce varies with the parent fungicide and ultimately depends upon the amount of fungicide residue that remains on the harvested crops. Although the amount of ETU may drop to very low levels in 14 days, that is no reflection of the amount of this carcinogen that may be found in the cooked produce.

In addition, degradation products of unknown toxicity, for instance ethylene thiuram monosulfide, are formed from the EBDC fungicides in the field. Several toxicological studies have shown that ETU was carcinogenic in the thyroid of rats, tumorigenic in the liver of mice, and teratogenic in pregnant rats. Studies have also suggested an effect of ETU on the liver.

## 1.6 Dieldrin

Dieldrin is a neurotoxin (a toxin that destroys nerve tissue). First introduced by cotton growers in the 1950s, when the chemical was found to be more effective than aldrin, dieldrin has also been used as an insecticide on crops, for public health pest control, and for mothproofing woolen goods. The tests showed that there was a significant increase in the incidence of liver cancers in high-dose male rats and in cancer of the adrenal glands in low-dose female rats. Tumors occurred in the pituitary and thyroid glands in tests.

## 1.7 Chlorinated Hydrocarbons

Hydrocarbons in which one or more of the hydrogen atoms have been replaced by chlorine are called chlorinated hydrocarbons. Many members of the group have been shown to cause cancer in animals and some of them to cause cancer in humans. Among the designated carcinogens, chloroform, vinyl chlorides bis chloromethyl ether, trichlorethylene, aldrin, chlordane, dieldrin, heptachlor, lindane, methoxychlor, toxaphene, terpene polychlorinates, and carbon tetrachloride. Concern about the potential hazard of certain chlorinated hydrocarbons is based on their ubiquity; their persistence in the environment; their capacity to accumulate in living organisms, including humans and the human fetus; and the experimental evidence of a potential carcinogenic effect.

## 1.8 Chlordane

An organochlorine pesticide, chlordane was introduced in 1945 and was among the first to be developed for insect control. Because of its persistence in the environment, most of its uses were suspended by order of the EPA in 1975. Several specified uses are still permitted including pest control on pineapple, strawberries, and Florida citrus crops; it is also used for a number of other pest control problems.

Chlordane and heptachlor were once used at the rate of 14 to 16 million pounds per year. Current legal usage accounts for 6 to 8 million pounds per year. Chlordane causes cancer of the liver in mice. It is less toxic than other similar pesticides, but acute exposure has the effect of stimulating the central nervous system. It has also been implicated in acute blood abnormalities, such as aplastic anemia. It is said to be absorbed through the skin. It has been found to be mutagenic. Eventually, it will probably be banned entirely.

## 1.9 Atrazine

One of the most widely-used pesticides in the United States, atrazine reacts under acidic conditions such as those found in the stomach, to form a potential carcinogen. It is used as a weed-control agent for corn and for noncrop and industrial sites. Found in drinking water supplies in Iowa and Louisiana, atrazine reacts with nitrite to form N-nitrosoatrazine, a suspected carcinogen. Sodium nitrite is used as a meat preservative and may also be present in acid soils because of the large amounts of nitrite fertilizers used.

## 1.10 Amitraz

Amitraz is a pesticide used on pears in Washington, Utah, Oregon, Michigan, New York, and Pennsylvania since 1975 on an emergency basis to control an aphid-like insect called pear psylla. It is claimed that there is no effective alternative pesticide available to control the pear psylla, which is capable of damaging both the fruit and the trees. The EPA claims that without amitraz the economic losses to growers could be as high as \$33 million for three years. On January 15, 1979, the EPA proposed to approve the pesticide on the condition that certain restrictions be imposed "to reduce potential risks to human health." They said that amitraz could be used on pears for four years, pending completion of additional laboratory tests by the manufacturer. The proposal follows a full-scale review of the risk versus benefits of using the pesticide on pears. There is some evidence that it may cause tumors in laboratory animals and therefore might present "a small risk of cancer to humans." As a result, EPA would require application only by trained users wearing protective clothing. To reduce residue levels on the fruit before it is marketed, EPA would require longer time periods from the time a crop is sprayed to the time it is harvested. Amitraz is distributed in this country by Upjohn of Kalamazoo, Michigan. It is estimated that about 120,000 pounds of it might be used on pears each year.

The facts still remain that this pesticide is extremely toxic and even in small doses are definitely harmful.

[Home](#) > [Lesson 75 - Cancers, Tumors](#) > 1. Environmental Carcinogens

## 1. Environmental Carcinogens

Over the past 100 years, there has been a significant rise in life expectancy, particularly in the developed portions of the world. Since 1950, there have been no appreciable changes in life expectancy in the United States. The two leading causes of death in the United States, heart disease and cancer, have increased since 1900 at a rate much higher than may be accounted for by population growth and by

aging of the population. Environmental influences may already be factors in life expectancy and health in the United States.

Cancer has more than doubled since the turn of the century. Much of the increase may be attributed to cigarette smoking, but overall cancer rates exclusive of lung cancers are also rising.

Cancer has a long latency period. In humans there is usually a 15- to 40-year period through the progressive stages that eventually terminates in cancer. Increased levels of exposure to a carcinogen carry with them an increased risk of developing cancer, a single exposure to a chemical may also result in a cancer.

About two million chemical compounds are known, and each year thousands more are discovered by the U.S. chemical industry and hundreds are introduced commercially. We know very little about the possible health consequences of these new compounds. The sheer number of chemical compounds, the diversity of their use, and the adverse effects already encountered from some make it increasingly probable that chemical contaminants in our environment have become a significant determinant of human health and life expectancy.

It must be remembered that cancer is a disease of the whole organism. It possesses attributes ranging from unrestricted growth to invasiveness.

It is true that many agents that are mutagenic, that is, responsible for cellular mutation, are also carcinogenic, capable of inducing cancer, but a direct correlation between mutagenic and carcinogenic occurs within the cell and may initiate cancer. First, for a mutation to happen, an agent foreign to the cell constituents is needed. A number of agents are capable of resulting in cellular mutations and sometimes ultimately cancer.

We can thus distinguish three steps in the development of cancer:

1. Initiation (or the first change).
2. Promotion (from the dormant to the visible stage).
3. Progression (leading to the irreversible state).

All normal cells have a finite life span. The normal cell divides in two at a constant rate, then the two daughter cells into four, and so on, but along the road of reproduction some of the cells die at a constant rate equal to the rate of reproduction. Balance is therefore maintained. But not so for cancer cells. They do not have a finite life span. Nor do they die in the same proportion as those that reproduce.

Uncontrolled growth, or geometric, not linear, reproduction occurs, the outstanding characteristic of cancer cells. The volume of the growing tissue continuously increases, and balance in number and volume is not maintained. In this first step toward cancer the transformed cells have escaped the controls and balances which govern normal cells.

Once a neoplastic cell has reached the stage of progression, the third, stage in carcinogenic growth, it is a cancer cell forever. But, before that stage, the neoplastic transformation may be reversible. The first step, initiation, or mutagenesis, does not necessarily lead to cancer; if the second stage (promotion) fails to take place, the third and definitive stage will not be attained. In other words, the initial change in the DNA of the cell may not be permanent or irreversible. In this case, if the cause of the cell irritation is removed, the cell will repair and resume normal function.

If we think of the process of neoplastic transformation in terms of the interaction in the cell of DNA, RNA, and protein, we could say that the primary change, or initiation, occurs in the base sequences of DNA; the second step, promotion, and the third step, progression, would be expressed in the perpetuation of the change as DNA replicates itself.

## **1.1 Chemical Carcinogenesis**

It is probable that a high proportion of human cancer, perhaps 60 to 90% is due to environmental causes.

Cigarette smoke, atmospheric pollution, and various other materials in our environment contain certain hydrocarbons which can produce cancer. For centuries some meats have been conserved in salt and it has been found that the nitrates present in meat cured in this way can also be carcinogenic.

Chemical carcinogenesis is generally a two-stage process as mentioned above consisting of, first, initiation and second, promotion. An example of this double process is to be found in the relationship of croton oil and polycyclic hydrocarbons to skin cancer. Croton oil alone rarely produces skin cancer but if a single dose of a polycyclic hydrocarbon is applied to the skin of an experimental animal and if this is then followed by an application of croton oil, skin cancer frequently occurs: the polycyclic hydrocarbon acts as an initiator and the croton oil as a promoter of the cancer process. Observations of this type are pertinent to human cancer since we know that our natural environment contains a number of chemical carcinogens. It is logical to assume that even a low level of these chemicals might serve as initiating agents, and that association with promoting agents could result in cancer.

### **1.1.1 Asbestos**

The naturally-occurring fibrous silicates classified as "asbestos" now are believed to be the most deadly cancer-causing agents in the workplace. There has been a thousandfold increase in output of asbestos during the past 50 years, and although it has been known for more than half a century that persons who inhaled large amounts of it in the course of their work sometimes developed disabling or fatal fibrosis of the lungs, it has only been within the last 30 years that it has been found to cause cancer. It is estimated that as many as 3,000 different products in daily use throughout the world contain some asbestos

The first suggestion that it could cause cancer was raised in 1935 by two physicians who noticed a correlation between asbestosis, a condition caused by fibers remaining in the lungs, and lung cancer. The link was definitely established around 1960 when Mt. Sinai School of Medicine researchers found that asbestos was the cause of mesothelioma, a rare and always fatal cancer of the membranes surrounding the lungs and lining of the abdominal cavity. Cancer of the stomach has also been found among American insulation workers and among the Japanese who like to eat rice coated with talc, a substance usually contaminated with asbestos. Asbestos has also been linked with cancer of the larynx, and a study by the American Cancer Society showed that asbestos workers who smoke may be 92 times more likely than the average nonsmoker to develop lung cancer. Even relatively brief exposure can increase the risk of cancer 20 to 40 years later.

Asbestos has been found in the air we breathe. An estimated 158,000 pounds of this mineral is released from automobile brake linings every year, and thousands of schools and other buildings have been constructed with asbestos insulation and flame proofing.

Dr. Irving Selikoff of Mt. Sinai School of Medicine, one of the world's leading experts on asbestos, says that a worker could be exposed heavily to asbestos for one day and develop cancer much later in life as a result, because his lungs continue to be exposed to the asbestos fibers deposited there.

Altogether, 2.5 million Americans are now working in trades involving asbestos, including asbestos mining and processing, insulation work, building demolition, and brake-clutch repair.

The modern home has asbestos from roof to basement—asbestos roofing or roof tiles, gutters, rainwater pipes, ceiling and floor tiles. The tiles, even if polished, are subject to wear and tear and presumably the liberation of asbestos. The instances of plural disease, one of them mesothelioma, have been found in workers who sanded asbestos floor tiles. Central-heating furnaces and pipes insulated by asbestos are common. Insulation of electrical equipment in the home, such as electric irons and stoves, is almost always compounded with asbestos. Ironing-board covers are made from the substance.

The latency period for asbestos-caused cancer is from four to fifty years. It primarily appears in the lungs, pleural cavity, gastrointestinal tract, ovary, skin, liver, and larynx.

### **1.1.2 Air Pollution**

Polluted air affects the health of human beings and of animal and plants. Emitted pollutants are diluted in the atmosphere and swept away by winds, except during an inversion (when surface air cannot rise). Then, for a period that varies from a few hours to a week or more, pollutants are trapped and the dilution process is impeded. When an inversion persists for a week or more, pollution intensifies substantially, and there is an accompanying increase in the death rate. Scientists are convinced that air pollution is very definitely a factor contributing to the three major types of diseases that result in sickness and death in our country—heart disease, lung and respiratory diseases, and cancer. Studies have shown that air pollution can actually be hazardous to people who live 50 to 100 miles away from the pollution source. This is because some common pollutants while moving through the atmosphere are transformed by chemical reactions with sunlight into more hazardous pollutants, such as photochemical oxidants that poison the lungs and respiratory system. Sulfur oxides aggravate asthma, lung and heart diseases, and lung functions of children. The amount of suspended particles in the air is related to injury to the surfaces of the respiratory system, that is, to the linings of the lungs and throat. Chemicals carried into the lungs by particulates may cause cancer to develop on the lung lining. Carbon monoxide is harmful to persons who have lung disease, anemia, or cerebral-vascular disease. Photochemical oxidants may cause respiratory irritation and even changes in lung function. Nitrogen oxides in high concentrations can be fatal, and in lower concentrations they can cause acute bronchitis and pneumonia.
